- Although the presentation of baseline health conditions may be based on data of varying levels of completeness and quality, the evaluation of health impacts is generally more qualitative; and some potential health consequences, by their very nature, are complex, and not easily quantifiable. The evaluation of social determinants of health is particularly subject to uncertainty, because many of the choices that affect social and mental health and behavioral risk factors are actually made at the level of the individual, and many of the choices may have both beneficial and negative aspects associated with them. Two individuals exposed to the same

AMERICAN OVERSIGHT

situation may make very different behavioral choices; therefore, there is uncertainty in trying to predict the aggregate of individual choices at a community level in terms of overall severity, likelihood, and impact rating. The evaluation uses published literature, where feasible, to provide context for this type of uncertainty. In addition, effects related to communicable and non-communicable diseases typically cannot be quantified, because their prevalence depends on numerous environmental, behavioral, and genetic factors. The potential for these indirect health effects to occur is included in the assessment, based on reports of their occurrence at other projects and sites, but the severity and likelihood of their occurrence in relation to the project cannot be precisely estimated.

Where quantifiable evaluations are not possible, qualitative evaluations strive for transparency in professional judgement. To this end, the components of the severity ranking system and the likelihood ranking system follow the gradations described in the ADHSS guidance, and the final impact ratings are based on a combination of severity and likelihood considerations. This allows the reader to clearly understand the basis of the ratings for project-related health consequences.

- Another source of uncertainty is the rating system for "likelihood" of impacts that is employed by the ADHSS guidance. Uncertainties regarding the reliability of impact ratings and the methodology have been pointed out by several authors (Thomson 2008; Petticrew et al. 2007). Uncertainty in estimating likelihood is easier to describe and quantify for certain types of health impacts such as exposure to potentially hazardous materials, and more difficult for other kinds of impacts such as social determinants of health, or diseases (both infectious and non-communicable). For this health assessment, estimation of likelihood is based on a general understanding of baseline health status and trends; project description, including proposed programs and measures to avoid or minimize health impacts; the detailed evaluation of certain types of impacts in other sections of the EIS (e.g., air quality, water quality, socio-economics, subsistence, transportation); and publicly available literature regarding these impacts on other, similar projects. The actual likelihood of the impacts may vary from the estimated level.

For each alternative, the consequences of the project activities are described with regard to relevant issues and concerns associated with the eight HECs described in the HIA guidance (ADHSS 2015). Although all components were considered, the project was primarily analyzed as a whole because effects could not be attributed to a single component (i.e., there was overlap of affected communities for multiple components). Finally, the health consequences are summarized by HEC and for the alternative as a whole; and expressed as Category 1, 2, 3, or 4. ADHSS does not provide narrative descriptions for these numeric impact category rankings, and only suggests that they be used to propose recommendations for actions.

K4.10.1 No Action Alternative

It is difficult to project the No Action Alternative health status 24 years into the future due to the many factors and variables that could impact the health of communities in the EIS area in the future; therefore, current baseline condition is assumed as a reasonable proxy to qualitatively evaluate the future in the No Action Alternative. As a result, no quantitative discussion (i.e., rating) is presented for the No Action Alternative.

As discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics, the No Action Alternative would have direct impacts related to the PLP exploration activities; PLP exploration-related employment and income—which were realized in the Bristol Bay region over the previous decade—would cease. Human health impacts associated with the loss of jobs and

AMERICAN OVERSIGHT

decrease in household income for communities closest to the mine site (Nondalton, Iliamna, and Newhalen) would be expected to be minor in magnitude, with changes relative to baseline; with potential increases or decreases in SDH, such as income, psychosocial stress, substance abuse, and family stability. There would be no impact to communities in the lower Bristol Bay watershed, such as Dillingham, other than removing uncertainty about the fate of this project. Other health factors would likely be similar to current conditions (baseline), such as potential rates of accidents and injuries, communicable and non-communicable diseases, exposure to hazardous constituents, and access to healthcare services.

Health impacts from the No Action Alternative would not be perceptible, or those impacted would be able to adapt to the impact with ease, and not require medical intervention. Direct effects would be largely similar to baseline levels of health. There would be no contribution to cumulative effects on human health. Current health conditions and trends, as described in Section 3.10, Health & Safety, would continue in the EIS analysis area.

K4.10.2 Action Alternative 1 – Applicant's Proposed Alternative

This section presents the environmental consequences to community health for Alternative 1. This evaluates potential impacts (both positive and negative) to the affected communities from the Pebble Project during all three phases. The HIA does not evaluate human health impacts from potential spills or failures. The potential health impacts from exposure to chemicals due to a spill or failure are unanticipated and are typically short-term, acute exposures. Section 4.27, Spill Risk, evaluates impacts from potential spills or failures, as well as rates, volume, and likelihood of occurrence. Project design measures, standard permit conditions, and best management practices would be implemented for preventing and reducing impacts from potential spills (see Section 5, Mitigation and Monitoring). For example, the design of ferry reduces the risk of grounding or sinking, thereby reducing the risk of a spill, and reduces the potential for concentrate dust.

As discussed in Section 3.10, Health and Safety, the communities potentially affected by the project range from small, remote, and rural communities to larger regional and urban centers. The eight communities identified in that section in the Lake and Peninsula Borough would be most closely affected by multiple project components. In addition, three Nushagak/Bristol Bay communities in the Dillingham Census Area were also identified as potentially affected by project components. The Kenai Peninsula Borough and Anchorage would also be potentially affected economically by all components of the project, in a relatively small way. In addition, more communities have been identified as using the EIS analysis area for subsistence; therefore, these communities could also be potentially affected by all of the components of the project (see Section 3.9, Subsistence).

The consequences (described below per HEC) for all project components would be expected to be more noticeable in smaller, rural communities, and less perceptible in the Municipality of Anchorage. The following HECs were evaluated for potential negative (adverse) and positive impacts from the project.

K4.10.2.1 HEC 1: Social Determinants of Health

The following subsections present the evaluation of potential health impacts, both beneficial and adverse, that are often correlated with SDH. Table K4.10-3 summarizes the potential impact levels and categories for the SDH, including the health effect consequences, magnitude, duration, and geographic extent of the impact, and likelihood of the impact occurring.

AMERICAN OVERSIGHT

Table K4.10-3: Summary of HEC 1 Impacts: Social Determinants of Health

Potential Impact	Project Phase	Negative/ Positive	Health Effect	Magnitude	Duration	Geographic Extent	Severity Ranking	Likelihood Rating	Impact Rating	Impact Category
Increase in household incomes, employment, and education attainment	Construction	+	1	2, beneficial impacts to health for specific population	2, medium-term	2, limited to regional households that benefit from regional economic opportunities	**7**	66-90%	♦♦♦	**3**
	Operations				3, long-term		**8**	66-90%	♦♦♦	**3**

AMERICAN OVERSIGHT

Household Incomes, Employment, and Education Attainment

Increases in household incomes, employment rates, and education attainment would likely result in an improvement to the overall health and well-being of residents living in the communities from which the workforce for the project would be employed, and where ancillary municipal tax revenue might be spent. Section 4.3, Needs and Welfare of the People—Socioeconomics, discusses the economic impacts of household incomes, employment rates, and education attainment. The following summarizes the findings:

- The project would result in 2,000 jobs during the construction phase, and 850 jobs during the operations phase, and some jobs would continue during closure.
- The benefits would be more apparent in the small, rural communities closest to the mine site (e.g., Lake and Peninsula Borough communities) where even small changes in their economies could have a measureable impact on their overall health and well-being.
- The benefits of these employment opportunities would be felt most in the households of those employees, but the ancillary sales and taxes would benefit the communities, regions, and state as a whole. However, it cannot be assumed that the economic benefits to the communities and region would directly correspond to increased healthcare spending or enhancement or development of community healthcare facilities, because these decisions may require involvement from multiple levels of government.
- Under the summer-only ferry operations variant, communities may wish to stockpile food, fuel, and other supplies, or receive shipments via air when the ferry is not operating. In addition, more mine site employees (e.g., truck drivers, ferry/terminal workers) would be needed seasonally during summer operations, but less year-round employees would be needed (PLP 2018-RFI 065). This variant would likely lower the income earned by community members in the core EIS analysis. Overall, the high cost of living for the communities near the transportation corridor would still be lowered under this variant, but not to the extent of the proposed year-round ferry operations.

The summary impact to human health due to increased household incomes, employment rates, and education attainment for the potentially affected communities would be Category 3 (beneficial) for all three phases (see Table K4.10-3), because health benefits are expected to result in perceptible minor benefits, and more apparent benefits in the small rural communities, although they may extend to a state-wide level. The duration ratings for this potential impact, as well as all potential impacts/HECs, would correlate with the expected duration of the three phases of the project. The likelihood of this benefit occurring is considered good, because PLP has committed to filling as many positions as possible within the region.

Psychosocial Stress

As defined by ADHSS (2015), the term psychosocial refers "to social situations that produce psychological distress or psychological relief." Adverse health behaviors may be adopted by people to cope with psychological stress; and likewise, beneficial health behaviors may be fostered during times of perceived optimism and hopefulness (e.g., change in economic and education status; increased food security, improved infrastructure, and access to healthcare services). Poverty, lack of employment, rural and urban isolation, impacts to subsistence practices, cultural change, family instability, and outward and inward migration are some of the social factors that may impact psychological stress. An example would be a community's fear that a proposed project could impact their environment and subsistence resources. Increased

AMERICAN OVERSIGHT

stress could also occur from increased exposure to physical stressors such as noise, vibration, and light.

As discussed in Section 4.19, Noise, and Section 4.5, Recreation, mine site activities during all phases would increase noise levels above existing outdoor ambient concentrations in proximity of the mine, which could lead to sleep disturbance for recreational or subsistence hunters sleeping outdoors; however, beyond 10 miles from the mine site, noise impacts would be well below the existing outdoor sound level. Similarly, the transportation corridor, Amakdedori port, and natural gas pipeline could result in noise impacts that may result in sleep disturbance for overnight recreational and subsistence receptors, depending on their location and proximity to these features, particularly during construction and operations. The noise generated by these activities would also likely displace wildlife from the vicinity of the noise-impacted area, thereby reducing the likelihood of hunting success close to project components. Therefore, subsistence and recreational users would likely stop using these noise-impacted areas. It would result in minimal displacement to other areas with similar habitats during construction, operation, and closure activities. In addition, noise impacts may also be realized for inhabited structures near the Kokhanok spur road, depending on their potential location. Vibration and light could be increased at the mine site, particularly during construction and closure, but the nearest communities (Nondalton, Iliamna, and Newhalen) would be approximately 17 miles away. Overall, noise impacts to communities would be expected to be minimal. Therefore, physical stressors could increase psychosocial stress for individuals on overnight recreational or subsistence trips. However, it is also possible that recreational and subsistence receptors would adapt and sleep outside the noise-impacted areas, and therefore not experience an increase in psychosocial stress.

Although it is difficult to predict changes in the direction and magnitude of psychosocial stresses and indicators, it is considered that both positive and negative impacts may occur in the area of psychosocial stress; but that changes are not readily predictable or quantifiable and are relatively unlikely, because they are influenced by complex, multi-dimensional contributing factors. Because the same household and/or individual may be impacted by both positive and negative factors resulting from the project, the nature of the impacts would vary among different populations; and as a result, the likelihood of the different impacts would also be expected to be variable for the project phases.

Some potential health outcomes of psychosocial stress (i.e., indicators) may include substance abuse, suicide (overlaps with HEC 2), and mental health issues. The potential for decreases in psychosocial stress could occur from improved economic opportunities and employment (see Section 3.10, Health and Safety). The project would likely have a drug- and alcohol-free workplace, with a zero tolerance policy and targeted and random drug testing. Potential decreases in rates of psychosocial stress could also occur, due to the increase in jobs available in the region. New jobs and increased income could contribute to increased family stability, and subsequently lead to decreased rates of poor mental health and lower rates of substance abuse.

There is also the potential for increases in psychosocial stress in the potentially affected communities, related to fear of changes in lifestyle and cultural practices, land encroachment, impact to the environment, and food security and quality associated with both commercial and recreational fishing, and with subsistence. The addition of new stressors to the populations in the EIS analysis area could potentially worsen existing mental health conditions, primarily for those individuals that are susceptible and who are not benefiting from increased economic security related to the project or accessory economic development. As noted in Section 3.10, Health and Safety, in the area of the affected communities, there are currently shortages of mental health professionals as a contributing factor to its Medically Underserved

AMERICAN OVERSIGHT

Area/Population and Health Professional Shortage Area designations. Any substantial increases in mental health disorders would further strain an already underserved system.

The summary impact to human health due to changes in psychosocial stress for the potentially affected communities is rated as Category 2 (beneficial and adverse) for construction, operations, and closure (see Table K4.10-3). The health effect is expected to result in moderate benefits and risks. However, the likelihood of this impact occurring is considered unlikely for all phases, because it is a multi-dimensional aspect that is influenced by many factors, and the probability of a significant contribution from any one factor would be low.

Family Stress and Stability

As with psychosocial stress, there may be both decreases and increases in family stress and instability, with different potential causes and effects in different segments of the community. Increases in family stress and instability could occur due to long-term work rotations (i.e., living at the mine site while working and going home during off periods). Rotational work schedules can increase stress and instability in families, put a strain on relationships and child care, and may increase feelings of fatigue, anxiety, worry, and jealousy, contributing to domestic violence, extra-marital affairs, and unwanted sexual harassment—particularly of women (UBC 2014; Diavik 1999). However, potential decreases in family stress and increases in family stability could also occur due to the increase in jobs available in the region, and increase in household income. Proportions of adverse and beneficial effects cannot be predicted, because the causes and effects would vary among different portions of the population.

The summary impact on human health due to increased family stress for the potentially affected communities is rated as Category 1 (beneficial and adverse) for construction; and Category 2 (beneficial and adverse) for the operations and closure (see Table K4.10-3). The health effect is expected to result in minor benefits and risks. Similar to psychosocial stress, the nature and likelihood of project effects on family stress and stability may be highly variable and unpredictable. Construction and operation are assigned a slightly higher likelihood than closure because it would be expected that individuals in the potentially affected communities would be more directly and extensively affected during the initial phases of the project.

K4.10.2.2 HEC 2: Accidents and Injuries

Accidents (e.g., motor vehicle crashes, falls, and fires) can result in unintentional injuries. Unintentional injury (e.g., falls, poisoning, drowning, motor vehicle crashes) is the third leading cause of death in the state and most regions (ADHSS 2017a, ANTHC 2017i). Intentional injuries include homicide and suicide (note: suicide overlaps with HEC 1, psychosocial stress). Non-fatal and fatal intentional and unintentional injuries can place a substantial burden on available healthcare resources (such as hospitals, clinics, and ambulances).

Transportation Accidents

Transportation-related unintentional accidents and injuries account for approximately 44 percent of hospitalizations in the state (Section 3.10, Health and Safety). Section 4.12, Transportation and Navigation, presents the evaluation of potential impacts from transportation (air, surface, and water) and navigation (water) activities. Road and ferry terminals would be sited to avoid environmentally sensitive areas, archaeological resources, and areas of known high subsistence use. During project construction, operations, and closure, public access to or through the mine site would be restricted for safety. Along the transportation corridor, spur roads would be gated to prevent traffic on the mine access road and south access road. Known trail crossings would be marked, and traffic controls would be implemented for safety (PLP 2018-RFI

AMERICAN OVERSIGHT

027). Additional access would be coordinated between the State of Alaska, the Lake and Peninsula Borough, PLP, and landowners. Potential surface transportation impacts to the public from the project could occur related to taking alternate routes, crossing the access roads at marked crossing points, or other potential community uses. It should be noted that state and local authorizations may affect final road alignment and uses.

When Iliamna Lake is frozen, it is used as a travel way for the public on snowmachines. Open water created by the ice-breaking ferry would disrupt some cross-lake snowmachine routes, and could potentially create a safety hazard. The project would work with communities (and supply funding) to provide for the marking and maintenance of snowmachine trails between communities across Iliamna Lake, when lake ice is thick enough to support such traffic. Alternate, marked safe routes would avoid the ferry path, but would have the potential to add to travel time and distance. The construction of the natural gas pipeline corridor would impact a high-traffic area of Cook Inlet, and could cause navigational hazards for vessels passing nearby on Cook Inlet and Iliamna Lake.

If the Kokhanok east ferry terminal variant were to be built, differences in impacts would occur; however, because impacts would be mitigated by the creation of an alternate route to Sid Larson Bay that would not cross ferry traffic (Section 4.12, Transportation and Navigation). Navigation on Iliamna Lake at the east Kokhanok terminal would be more sheltered from wind and waves, but would contain more navigational hazards such as shallow water and a longer ferry route (PLP 2018-RFI 078).

If the ferry were to only operate in the summer, the concentrate would be stockpiled in the winter, and truck and ferry trips would double in the summer. This would mean that winter snowmachine traffic across the lake would not be interrupted by an ice-breaking ferry, but vessels on the lake in the summer would experience double the ferry traffic.

Based on Section 4.12, Transportation and Navigation, evaluation, accidents, and injuries (mortality and morbidity rates) could occur for mine site workers and for the public at surface access road crossings (at a minimum), if alternate safe routes or mitigation measures were not taken across Iliamna Lake; and from navigation hazards during the pipeline corridor construction phase. For transportation-related accidents and injury, the summary impact to human health due to air, surface, and water transportation are rated Category 2 for all phases (Table K4.10-4). The health effect is assigned a score of 3 (“severe”) due to the potential for serious health injury and loss of life for all modes of transportation. The magnitude of the effect is assigned a score of 2 for surface and water accidents, because those affected may require medical intervention to maintain pre-impact level of health, while air accidents are assigned a score of 3, because air accidents have a higher likelihood of death, and those affected may be unable to maintain pre-impact level of health. The geographic extent of potential transportation and navigation impacts is assigned a score of 0, because impacts would be limited to individual cases, although the individuals may come from any of the communities in the EIS analysis area. The likelihood of these accidents occurring range from extremely unlikely for air transport (they generally occur rarely), to very unlikely for surface transportation (given the potential for limited public access except at designated crossings, and that service capacity of roadways are expected to be below capacity even if final use designation of certain transportation corridor segments also become available to the public), to unlikely for water navigation (given low nautical speeds, but shared waterbodies).

Other Unintentional Injuries

As shown in Section 3.10, Health and Safety, unintentional injuries from falls accounts for 44 percent of hospitalizations in the state (equal to transportation-related injuries), followed by

AMERICAN OVERSIGHT

cuts (3.6 percent), poisoning (3.4 percent), and all other injuries/accidents combined (17.6 percent). It is difficult to predict changes in direction and magnitude of these types of unintentional injuries due to their unintentional nature. The project would provide safety training (as required by OSHA and MSHA) for all employees; health and safety plans would be developed and implemented; and public access would be prohibited in industrial facilities. Therefore, it is assumed that the project workforce would adhere to the project's safety procedures when travelling or operating in the public domain, and promote the safety culture outside of standard work operations as well (i.e., outside the fence). Based on this, the summary impact to human health due to increases in non-transportation unintentional injury rates would be Category 2 for all project phases (Table K4.10-4). The health effect would be considered severe due to the potential for serious health injury and loss of life. The likelihood of this impact occurring is considered very low, because of the potential for promotion of safety awareness and culture, and its likely limited scale.

Intentional Injury: Suicide Rate

As discussed in Section 3.10, Health and Safety, suicide mortality rates vary by region, but was the fourth leading cause of death among Alaska Native people during the period 2012 to 2015 (ANTHC 2017f). Similar to psychosocial stress and family stability (HEC 1), it is difficult to predict changes in the direction and magnitude of impacts to suicide rates because it is influenced by complex, multi-dimensional contributing factors. Increases in suicide rates could potentially occur due to increases in psychosocial stress and decreases in family stability. Conversely, decreases in psychosocial stress and increases in family stability may also occur, and could potentially result in decreased suicide rates. Note that baseline suicide rates for the Bristol Bay region and the Kenai region may not be statistically significant due to the low number of reported cases, and any interpretations should be viewed with caution.

The summary impact to human health due to increases in suicide rates would be Category 2 for all project phases (Table K4.10-4). The health effect would be considered severe due to the potential for loss of life. The magnitude of the effect is assigned a score of 3, because those affected would not maintain pre-impact level of health. The geographic extent of this potential impact is assigned a score of 0, because impacts would be limited to individual cases. The likelihood of this impact occurring is considered very low on a large scale (1 to 10 percent), because both beneficial and adverse effects could occur due to the project.

AMERICAN OVERSIGHT

Table K4.10-4: Summary of HEC 2 Impacts: Accidents and Injuries

Potential Impact	Project Phase	Negative/ Positive	Health Effect	Magnitude	Duration	Geographic Extent	Severity Ranking	Likelihood Rating	Impact Rating	Impact Category
Increase in unintentional accidents and injuries, morbidity, and mortality rates due to air, surface, and water transportation (same rating unless otherwise noted)	Construction	-	3	air = 3, unable to maintain pre-impact level of health surface and water = 2, able to maintain pre-impact level of health with medical intervention	2, medium-term	0, individual cases	8 (air) 7 (water/ surface)	<1 % (air) 1-10% (surface)	♦♦	2

AMERICAN OVERSIGHT

K4.10.2.3 HEC 3: Exposure to Potentially Hazardous Materials

This section evaluates the health determinants and outcomes from potential exposure to project-related hazardous materials consistent with ADHSS (2015) and NEPA practice. As noted above, this section does not evaluate human health impacts from potential spills or failures. The key health outcomes considered are the potential for increases and decreases in illnesses or exacerbation of illnesses commonly associated with exposure to chemicals of potential concern (COPCs) through inhalation, physical (dermal) contact, and direct or indirect ingestion (e.g., direct exposure through incidental soil ingestion, indirect exposure through ingestion of subsistence foods that have the potential to bioaccumulate COPCs).

The first step in the HIA evaluation is the exposure pathway analysis. This step includes the identification of the primary potential project-related sources of contamination, COPCs, determination of exposure pathway completeness, and an assessment of the likelihood of exposure (e.g., complete but insignificant). The presence of a complete exposure pathway is established when there is an unbroken chain from a project-related COPC source to exposure point. If a pathway is incomplete, then there is no exposure and no associated risk. One way to show the exposure pathway analysis is through the use of a conceptual site model (CSM) that illustrates the potential project COPC source(s), release mechanism(s), secondary source(s), exposure media, and exposure routes, as well as the likelihood of exposure. Likelihood of exposure may be deemed insignificant based on multiple factors, including but not limited to expected project mitigation measures or geographical distance from the source. Two Pebble Project CSMs were developed and are presented in Figure K4.10-1 (mine site) and Figure K4.10-2 (transportation corridor, Amakdedori port, and natural gas pipeline).

For those pathways that are deemed potentially complete and significant, the concentration of any COPCs at the expected exposure points is determined when possible (i.e., the geographical locations where an individual comes in contact with the source material, such as air, soil, groundwater, sediment, surface water, or subsistence foods). Future media-specific exposure point concentrations are estimated, when possible, by modeling expected project-related increases from baseline concentrations. Then, baseline conditions and estimated future concentrations (when available) can be compared to health-protective criteria to determine if project impacts from exposure to hazardous chemicals is unlikely to or could potentially result in human health concerns. In the absence of available estimated future exposure point concentrations, a more qualitative evaluation may be performed to assess potential future exposure and effects. These quantitative and qualitative evaluations are then used to inform risk-management decisions (e.g., impact avoidance, monitoring, and mitigation measures).

The following subsections present the anticipated project sources and COPCs, and the media-specific exposure pathway analysis and exposure concentrations evaluation when relevant.

AMERICAN OVERSIGHT

Figure K4.10-1: Mine Site Conceptual Site Model

AMERICAN OVERSIGHT

Figure K4.10-2: Transportation Corridor, Amakdedori Port, and Natural Gas Pipeline Conceptual Site Model

AMERICAN OVERSIGHT

Anticipated Project Sources and Chemicals of Potential Concern

The primary anticipated project sources of potential contamination are from hazardous chemicals used, released, or present during construction, operations, and closure. Specific project sources are summarized below, along with their project-associated COPCs:

- Mine site, transportation corridor, Amakdedori port, and the natural gas compressor station on the Kenai Peninsula air emissions during construction, operations, and closure from stationary sources (e.g., turbines, generators, boilers), mobile sources (e.g., vehicle and mobile equipment exhaust), and fugitive sources (e.g., air particulates from blasting, drilling, vehicle road dust, road wind erosion). The associated COPCs include criteria air pollutants: carbon monoxide, nitrogen oxides (NOX), particulate matter (PM), sulfur dioxide, volatile organic compounds (VOCs) and lead. The project air emissions would also release hazardous air pollutants (HAPs), including VOCs (e.g., benzene, formaldehyde, and toluene) and several heavy metals (e.g., lead, mercury, and arsenic). Although lead emissions from all project components would be negligible, they are included as COPCs for consistency with air quality regulations (see Section 4.20, Air Quality).
- Mine site fugitive emissions from material and handling activities (mined ore, quarry rock, overburden, and waste rock) would result in fugitive air emissions and could result in dust deposition onto soils, waterbodies, and vegetation (e.g., berries). This could result in elevating concentrations of metals above baseline in and outside the mine site due to the concentration of heavy metals found in orebody materials (see Section 4.14, Soils). The transportation corridor, Amakdedori port, and natural gas pipeline fugitive emissions also have the potential to result in dust deposition. However, since baseline soils would be disturbed during construction and local rock sources would be used for construction of the roadway, dust deposition would not be expected to increase metal concentrations above baseline conditions (see Section 4.14, Soils). Mine site fugitive emission COPCs would include metals.
- Mine site use of non-potentially acid generating (PAG) waste rock for infrastructure construction at the mine (e.g., tailings storage facility [TSF] embankments, water management pond embankments, and roads) would result in negligible metals releases compared to other mine sources such as material and handling fugitive emissions (see Section 4.14, Soils). Non-PAG waste rock is considered to have a low susceptibility to hydraulic and wind erosion. Therefore, the use of non-PAG waste rock for infrastructure construction in the mine site is considered an insignificant source of COPCs (e.g., metals) “inside the fence” at the mine site and an incomplete source “outside the fence.”
- Mine site surplus water (e.g., non-contact stormwater runoff and contact water) would be collected separately on site and discharged to downstream drainages during operations and closure after treatment. Contact water influent COPCs would include metals and general water quality parameters such as weak acid dissociable cyanide. Weak acid dissociable cyanide would be negligible in the surplus water influent, but are included for consistency with water quality regulations (see Section 4.18, Water and Sediment Quality).
- Mine site operations and facilities (e.g., tailings, waste rock, and contact water storage) would directly impact groundwater quality in the mine site. During the life of the mine, groundwater impacts would likely be limited to local groundwater in the vicinity of mine facilities, expected to remain in mine site boundaries, and would not be expected to impact the mine drinking water wells located north of the core facility and estimated cone of depression around the open pit (see Section 4.18, Water and

AMERICAN OVERSIGHT

Sediment Quality, and Chapter 2, Alternatives). Post-closure, once groundwater seepage collection system monitoring indicates that the water quality meets the approved criteria for discharge without treatment, direct discharge would occur. Similar to mine site effluent, post-closure groundwater COPCs would include metals and general water quality parameters.

- Mine site dust deposition could result in increased concentrations of metals in soil (see discussion above) and subsequently leach to groundwater. Groundwater COPCs would include metals.
- Mine site activities would create new areas of standing water (e.g., main water management pond, tailings pond, open pit water management pond, sediment ponds, and seepage collection and recycling ponds). A variety of birds could potentially be affected by environmental contamination by contact with water and foraging in these locations (see Section 4.23, Wildlife Values). These birds may then be harvested and ingested by human recreational and subsistence receptors (see Section 4.9, Subsistence). COPCs would include metals and general water quality parameters.
- Transportation corridor operations could result in the release of small amounts of vehicle- or ferry-related pollutants such as fuel, oil, and lubricants during the normal course of operations. COPCs would include petroleum hydrocarbons.

An evaluation of the potentially complete media-specific exposure pathways are presented below for those project sources identified above that could be sources of COPCs to the affected communities. Those project components that were identified as being an incomplete source of COPCs are not evaluated further below.

Air Exposure Pathways

Project air emissions could potentially be inhaled by the affected communities, including subsistence and recreational users in the vicinity of these project components and phases (e.g., inhalation of particulate matter (PM) from vehicle traffic along the transportation corridor). As noted in ADHSS (2015), air emissions that are in compliance with permits are presumed to be protective of human health; however, unregulated emissions (e.g., particulate deposition from fugitive dust that may contain heavy metals or other potentially toxic substances) may impact wild foods (e.g., berries and other wild plants consumed) and may require evaluation prior to human consumption.

This section describes air quality impacts to health in the context of three types of sources:

- Stationary point sources (air permits required)
- Mobile sources (permits not required)
- Fugitive sources (permits not required)

As detailed in Section 4.20, Air Quality, project air emissions were modeled to evaluate permit applicability and to evaluate compliance with potentially applicable ambient air quality standards (AAQS), which are protective of human health and the environment. The following summarizes the air quality assessment presented in Section 4.20, Air Quality:

- Mine site construction emissions (from point and fugitive sources) were modeled under a near-field impact assessment and demonstrated to be in compliance with permitting requirements and AAQS.
- Mine site operations would be subject to a minor permit and the power generation facility is assumed to be subject to Prevention of Significant Deterioration (PSD) and

AMERICAN OVERSIGHT

Title V permitting. The power generation facility would therefore be subject to Best Available Control Technology (BACT). In the future, the mine site would undergo a complete permitting analysis and would be expected to operate in compliance with these permits. Mine site operation emissions (from point and fugitive sources) were modeled under near-field and far-field impact assessment. The near-field impact assessment demonstrated that air emissions would be in compliance with permitting requirements and AAQS. The far-field impact assessment demonstrated that impacts to Air Quality Related Values (AQRVs) would not be anticipated at any nearby PSD Class I areas.

- The transportation corridor ferry terminals would be considered stationary emission sources and subject to permitting requirements. The ferry terminals operational emissions' were modeled and demonstrated to be in compliance with permitting requirements (i.e., minor permit not required). Although near-field modeling was not conducted for the transportation corridor, it would be anticipated that near-field impacts would be similar or less than the mine site.
- Amakdedori port operational emissions were modeled and demonstrated to be in compliance with permit requirements (i.e., minor permit not required) and the near-field impact assessment for NO_2 demonstrated compliance with AAQS. Because fugitive PM emissions from unloading the concentrate into the hold of the bulk carrier would be negligible, estimates of dry and wet deposition for HAPs were not calculated. The far-field impact assessment concluded that AQRVs would not likely be affected at any of the PSD Class I or federal PSD Class II areas.
- The compressor station on the Kenai Peninsula operational emissions demonstrated that a minor permit would be required due to NO_x. The near-field impact assessment modeled annual NO_2 concentrations and demonstrated that NO_2 would be in compliance with AAQS.

Other Sources Evaluated for Air Quality

In addition to the project component air emissions evaluated above, the project would also release mobile and fugitive emissions that would not be subject to permitting requirements and were not quantitatively evaluated in Section 4.20, Air Quality. These project components and phases include mine site closure, all phases relating to the transportation corridor (except ferry terminal operations), all phases relating to the Amakdedori port (except port operation NO_x emissions), and all phases relating the natural gas pipeline (except compressor station operation NO_x emissions). To evaluate human health and safety in this HIA, these mobile and fugitive emissions were semi-quantitatively evaluated by estimating annual emissions and conservatively comparing them to the stationary source permit thresholds as an initial step.

As shown in Table K4.10-5, the annual HAP emissions from all the evaluated project components and phases are less than the stationary source Title V HAP permit thresholds, which are set at limits protective of human health and the environment. The annual PM emissions for mine site closure and transportation corridor construction, operations, and closure, which do not take into account mitigation measures, were greater than the stationary source permit thresholds (Table K4.10-5); therefore, they were further evaluated semi-quantitatively, as described below.

AMERICAN OVERSIGHT

Table K4.10-5: Annual HAP and PM Comparison for Components not Modeled

Project Component	Phase	Total HAPs[1] (tons)	Total PM[1] (tons)	Duration (years)	Annual HAPs[2] (tpy)	Annual PM[2] (tpy)	Annual HAP Threshold[3] (tpy)	Annual PM Threshold[4] (tpy)
Mine Site	Construction	5.5	--	4	1.38	--	10 / 25	25 / 100/ 250
	Operations	9.1	--	20	0.46	--		
	Closure	94.5	48,447	20	4.73	2,422		
Transportation Corridor	Construction	7.35	5,762	4	1.84	1,441		
	Operations	2.6	1568	20	0.13	78.4		
	Closure	ND	ND	20	ND	ND		
Amakdedori Port	Construction	3.6	35.8	4	0.90	8.95		
	Operations	8.9	19.4	20	0.45	0.97		
	Closure	ND	ND	20	ND	ND		
Natural Gas Pipeline Corridor	Construction	0.02	2.53	4	0.0050	0.63		
	Operations	0.22	1.40	20	0.011	0.07		
	Closure	ND	ND	20	ND	ND		

-- = Evaluated for permit applicability, and compared to AAQS in Section 4.20, Air Quality; see Sources Evaluated for Permitting and Air Quality above. Near-field modelling indicates that these parameters would meet AAQS.

ND = no data

tpy = tons per year

(1) For total HAPs and PM, see Section 4.20, Air Quality.

(2) Annual emissions were estimated by dividing the total emissions by duration.

(3) Title V Permit Thresholds for individual (10 tpy) and combined (25 tpy) HAPs, see Section 4.20, Air Quality.

(4) PSD Significant Emission Rate (25 tpy), Title V Permit Threshold (100 tpy), and Major Source (250 tpy), see Section 4.20, Air Quality.

As noted in Section 4.20, Air Quality, it would be anticipated that near-field impacts for the components that did not have modeling performed, would be similar or less than the mine site. Given this, near-field results for PM were estimated for those components and phases that had total annual PM exceeding the stationary source permit thresholds based on mine site operations near-field results. Since mine site operations near-field PM_{10} had the highest ratio of estimated maximum cumulative concentration to AAQS (25 percent) (see Section 4.20, Air Quality), it was used as a relative representation for the other projects and components in this semi-quantitative and semi-qualitative ratio evaluation. Mine site operations annual PM_{10} estimates were compared to the evaluated project/phase annual PM_{10} to generate an annual PM ratio. Next, the mine site operations PM_{10} near-field results were multiplied by the annual PM_{10} ratio to estimate the evaluated project phases' likely ratio of PM_{10} cumulative maximum concentration to AAQS. As shown in Table K4.10-6, the ratio of cumulative PM_{10} for each of the evaluated project phase was estimated at less than the AAQS (i.e., ratio less than 100 percent), with the exception of mine site closure. Since the near-field models are more complex than a straight ratio approach (i.e., not linear), this evaluation provides a high-level approximate estimate (rough estimate) with a high margin of error (higher level of uncertainty) and is intended only to provide a general perspective regarding potential health concerns. In addition,

AMERICAN OVERSIGHT

given that these estimates of PM do not account for dust suppression or other mitigation measures, PM was further qualitatively evaluated below.

Table K4.10-6: Near-Field Ratio Estimates for Components not Modeled

Project Component	Phase	Total PM_{10} (tons)[1]	Duration (years)	Annual PM_{10}[2] (tpy)	Annual PM_{10} Ratio to Mine Site Operation[3]	Estimated Ratio of PM_{10} Conc. to AAQS[4,5]
Near-field Modeled						
Mine Site	Operation	3,009	20	151	--	25%
Not Near-field Modeled						
Mine Site	Closure	22,478	20	1,124	7.4	185%
Transportation Corridor	Construction	1,866	4	467	3.1	77%
	Operation	407.4	20	20.4	0.14	3.4%
	Closure	ND	ND	ND	ND	ND

Notes:

ND = no data

tpy = tons per year

(1) For total PM10, see Section 4.20, Air Quality.

(2) Annual PM10 emissions were estimated by dividing the total PM10 emissions by duration.

(3) Modeling for mine site operations PM10 resulted in the highest ratio to AAQS of 24 percent. The relationship was used to estimate proportion of AAQS to the other evaluated project and phase. PM10 for each of the evaluated projects and phases was divided by mine site operations PM10.

(4) Ratio of cumulative impact to AAQS for mine site operations found in Section 4.20, Air Quality.

(5) For each of the other evaluated projects and phases, the ratio of PM10 to AAQS was estimated by multiplying the mine site operations PM10 ratio to AAQS (25 percent) by the annual PM10 ratio to mine site operation (e.g., mine site closure ratio of 7.4 multiplied by 25 percent = 185 percent).

The following presents a qualitative evaluation of PM emission impacts. With implementation of the mitigation measures for idling and dust suppression, dust/PM would not be expected to exceed the annual PM thresholds and further reduce the ratio of the estimated near-field concentrations for all project components to below AAQS.

- PM emission impacts would be expected to be fairly localized in the vicinity of the project activity and linearly along the roadways. PLP expects a 35-foot wide buffer zone on either side of the transportation corridor to be impacted by snow plow spray, gravel spray, and road dust (PLP 2018-RFI 082). Since the affected communities are not located in close proximity to these project features or in the roadway buffer zone, residents in the affected communities would not be expected to be directly impacted. In addition, subsistence and recreational users would likely adjust the resource use areas to target resources that would be less affected by dust/PM (see Section 4.9, Subsistence).
- PLP would follow an idling policy, such as not allowing haul trucks to idle for more than a set amount of time if the vehicle or equipment is not in motion, which would reduce fuel consumption and reduce vehicle exhaust emissions, including PM (see Section 4.20, Air Quality).
- Mitigation measures would be used to control dust generation at the mine site and along the transportation during operations activities, as well during construction and

AMERICAN OVERSIGHT

closure activities for all components (see Section 4.20, Air Quality). A fugitive dust control plan (FDCP) would be developed by PLP for mitigation and control of project activity related fugitive dust and wind erosion. The anticipated FDCP would use best management practices and BACTs (PLP 2018-RFI 071a). As discussed in Section 5, Mitigation, mitigation measures would include the use of dust palliatives and chip seal on transportation surfaces, dust suppression watering, and posting/enforcing lower speed limits on project roads. Non-contact water from local, un-impacted water sources would be used for dust suppression outside the mine site boundaries (PLP 2018-RFI 021). These mitigation measures would be expected to result in lower total PM emissions than those calculated in Section 4.20, Air Quality that do not account for these mitigation measures. In addition, precipitation would naturally reduce fugitive dust (e.g., long winters with more than 50-inches of precipitation a year).

Summary of Air Exposure Pathway

In summary, the air inhalation exposure pathway from all Pebble Project components would not be expected to substantively impact the health of the affected communities, including subsistence receptors and recreational users, as long as effective dust control measures were implemented in accordance with the FDCP. With effective dust mitigation measures, the potential air exposure pathways for the project would be insignificant. Potential impacts from mine site potential dust deposition onto soil, waterbodies, and wild foods "outside the fence" are discussed below.

Soil Exposure Pathways

Mine site material and handling activities (mined ore, quarry rock, overburden, and waste rock) would result in fugitive emissions that could result in dust deposition in the mine site and "outside the fence," resulting in increased metals in soil. The predominant wind directions are from the southeast and northwest (PLP 2018 RFI-009).

In the mine site, the employee camp would be located northeast of the core mine facility (Chapter 2, Alternatives), away from the predominant wind directions. In addition, the mine camps would implement dust deposition mitigation measures and follow PLP's health and safety plans, which would be protective of the health of mine employees while on-duty and while off-duty at the on-site camp. Therefore, mine site fugitive emissions would not be expected be a substantive source of metals from dust deposition to off-duty employees at the mine site camp.

Outside the mine site, members of the affected communities, such as human subsistence receptors and recreational users, could come into direct contact with soil potentially impacted from mine site dust deposition. As discussed in Section 4.14, Soils, potential increases of metal concentrations in soils at the mine site from fugitive dust deposition were estimated using the AERMOD modeling data, dust deposition rates (PLP 2018-RFI 009), and baseline soil data. Dust deposition rates were estimated at the maximum point along the ambient air boundary of the mine site (i.e., "at the fence"). Section 4.20, Air Quality, presents the predicted change in soil quality from mine site dust deposition. These results indicate a small expected increase in metals concentration in soil due to dust deposition. Expected total concentration increases for all metals ranged from 0.11 percent to 0.72 percent, with the exception of antimony, which would be expected to increase by 3.04 percent.

The three metals (arsenic, chromium, and copper) that have baseline concentrations above the selected human health comparative action levels (CALs) (i.e., the ADEC Soil Method 2 values), would remain above the human health CALs with negligible increased cancer risk and hazard (i.e., increased concentration indistinguishable from baseline risk/hazard). In the remaining

AMERICAN OVERSIGHT

metals, the increases from dust deposition would not cause exceedances of the human health CALs. For cobalt and manganese, which lack human health CALs, the baseline and increased concentrations were compared to the Environmental Protection Agency (EPA) residential soil Regional Screening Levels (RSLs) of 2.3 milligrams per kilogram (mg/kg) and 180 mg/kg, respectively (EPA 2018a). Both baseline and estimated future concentrations of cobalt and manganese were above the EPA residential RSLs (at target hazard quotients of 0.1); however, the estimated future hazards would be indistinguishable from baseline hazards given the negligible increases estimated for future concentrations. Therefore, dust deposition impacts to soil would not be expected to substantively impact the health of the affected communities, including subsistence receptors and recreational users.

Water Exposure Pathways

Mine Site Discharges to Surface Waterbodies – As discussed in Section 4.18 and Appendix K4.18, Water and Sediment Quality, the stormwater runoff from mine site facilities that does not come in direct contact with mining infrastructure would be treated for sediment and discharged under general APDES stormwater permits (Knight Piésold 2018a). Mine site contact water would be treated to ensure compliance with the most stringent applicable water quality standards (Appendix K3.18) before being discharged to the environment. As with air, water discharges that are in compliance with permits would be presumed to be protective of human health (ADHSS 2015). Since mine site effluent would meet permitting requirements prior to discharge, the mine site effluent would not be expected to result in impacts to surface water quality and would be presumed to be protective of human health. Therefore, the treated mine site effluents (non-contact stormwater and WTP discharges) would not be considered a significant source of COPCs to human receptors "outside the fence." This potential exposure pathway would be complete but insignificant.

Once groundwater seepage collection systems post-closure monitoring indicates that water quality meets the approved criteria for discharge without treatment, direct discharge would occur. This would occur at approximately year 50 post-closure (Section 4.18, Water and Sediment Quality). Similar to mine site treated effluents, direct discharge of post-closure mine site groundwater would only occur once water quality criteria are met; therefore, it would be considered a complete but insignificant exposure pathway.

Transportation Corridor Minor Releases to Surface Waterbodies – Transportation corridor operations could result in the release of small amounts of vehicle- or ferry-related pollutants such as fuel, oil, and lubricants during the normal course of operations. These releases could occur onto the roadbed and runoff into stream or pond substrates, or be released into Iliamna Lake and incorporated into lakebed substrate. As discussed in Section 4.18, Water and Sediment Quality, these potential impacts on freshwater sediment contamination would likely be of low intensity, and would extend throughout the life of the mine and into post-closure. Similarly, marine vessel operations could result in small amounts of pollutants during normal operations to Kamishak Bay and Cook Inlet waters, and become incorporated into seafloor sediment. However, sediment contamination at the port from regular vessel activity would likely be negligible. These impacts would be expected to be indistinguishable from other minor contributions from non-project watercraft. Therefore, this potential exposure pathway would be considered insignificant.

Mine Site Fugitive Dust Deposition to Surface Waterbodies – Mine site material and handling activities (mined ore, quarry rock, overburden, and waste rock) would result in fugitive emissions that could result in dust deposition "outside the fence" and result in increased metals in waterbodies. As discussed in Section 4.18 and Appendix K4.18, Water and Sediment Quality, potential increases of metal concentrations in sediments at the mine site from fugitive dust

AMERICAN OVERSIGHT

deposition was estimated using the AERMOD modeling data, dust deposition rates (PLP 2018-RFI 009), and baseline sediment data. Dust deposition rates were estimated at the maximum point along the ambient air boundary of the mine site (i.e., "at the fence"). Appendix K4.18 presents the predicted change in sediment quality from mine site dust deposition. These results indicate a small expected increase in metals concentration in sediment due to dust deposition. Expected total concentration increases for all metals ranged from 0.11 percent to 0.66 percent, with the exception of antimony, which would increase by 3.17 percent.

The three metals (arsenic, chromium, and copper) that have baseline concentrations above the selected human health CALs (i.e., the ADEC Soil Method 2 values), would remain above the human health CALs with insignificant increased cancer risk and hazard (i.e., increased concentration indistinguishable from baseline risk/hazard). In the remaining metals, the increases from dust deposition would not cause exceedances of the human health CALs. For cobalt and manganese, which lack human health CALs, the baseline and increased concentrations were compared to the EPA residential soil RSLs of 2.3 mg/kg and 180 mg/kg, respectively (EPA 2018a). Both baseline and estimated future concentrations of cobalt and manganese were above the EPA residential RSLs (at target hazard quotients of 0.1); however, the estimated future hazards would be indistinguishable from baseline hazards given the negligible increases estimated for future concentrations. Therefore, mine site dust deposition impacts to sediment would not be expected to substantively impact the health of the affected communities, including subsistence receptors and recreational users.

Next, the potential increases of metal concentrations in surface water at the mine site from fugitive dust deposition were estimated as detailed in Appendix K4.18, Water and Sediment Quality, which presents the predicted change in surface water quality from dust deposition at the North Fork Koktuli watershed, South Fork Koktuli watershed, Upper Talarik Creek, and Frying Pan Lake. These results indicate a small expected increase in metals concentration in surface water at each of these watersheds/waterbodies due to dust deposition. Expected total concentration increases ranged from 0.11 percent to 0.66 percent and caused no exceedances of the most stringent water quality criteria, which are presumed to be protective of human health.

In addition, as discussed above under air exposure, a FDCP would be developed by PLP for mitigation and control of project activity related fugitive dust and wind erosion. The anticipated FDCP would use best management practices and BACTs (PLP 2018-RFI 071a). Appropriate dust suppression water would be used at the mine site and along the transportation corridor (PLP 2018-RFI 021).

Mine Site Fugitive Dust Deposition To Groundwater – As discussed above, mine site dust deposition impacts were estimated at the boundary of the mine site (i.e., "at the fence") and would result in slight increases of metal concentrations in soil. Metals in soil may subsequently leach to groundwater, representing a potential source of increased metals to groundwater in the EIS analysis area, which could be used as drinking water by the affected communities. Appendix 4.18, Water and Sediment Quality, presents baseline and estimated soil concentrations of potentially hazardous metals due to dust and compares them to the ADEC migration to groundwater CALs. The migration to groundwater CAL represents the soil concentration level at which there would be potential for substances to leach to groundwater and pose a human health risk or hazard (ADEC 2017b).

As shown in Appendix K4.18, Water and Sediment Quality, with the exception of arsenic, baseline and predicted future soil concentrations would be below the migration to groundwater CALs, below which human health is presumed to be protected. Both the baseline and estimated future arsenic concentrations exceed the migration to groundwater CALs. However, given the

AMERICAN OVERSIGHT

slight estimated future soil increase (0.57 percent), the potential increases in future groundwater would similarly be negligible. For cobalt, lead, and manganese, which lack migration to groundwater CALs, the baseline and increased concentrations were compared to the EPA residential soil to groundwater RSLs of 0.027 mg/kg, 14 mg/kg, and 2.8 mg/kg, respectively (EPA 2018a). Lead baseline and future estimated concentrations were below the EPA residential RSL. Both baseline and estimated future concentrations of cobalt and manganese were above the EPA residential RSLs (at target hazard quotients of 0.1); however, the estimated future hazards would be indistinguishable from baseline hazards given the negligible increases estimated for future concentrations. Therefore, the incremental arsenic risk/hazard from exposure to future groundwater would be expected to be indistinguishable from baseline risk/hazard in groundwater.

Subsistence Foods Exposure Pathways

Affected communities, particularly rural residents, consuming a subsistence diet may be exposed to higher levels of bioaccumulative compounds because subsistence foods may comprise a very large portion of their daily dietary intake. Section 4.21, Subsistence, notes that subsistence users may avoid harvesting resources near the mine site and transportation corridor due to air/dust deposition concerns and may avoid harvesting waterfowl because of concerns about birds becoming contaminated from landing on and using open water at mine site facilities. However, this HIA evaluates the potential exposure of project-related chemicals that may be released to primary media (e.g., soil, surface water, sediment) and may be bioaccumulated in biota (e.g., subsistence foods), which in turn could be ingested by subsistence receptors. The subsistence receptor evaluation is protective of residential exposure to harvested biota shared by subsistence receptors and of residential recreational exposure. Since the subsistence receptor evaluation captures and is protective of these potential exposure pathways (i.e., residential exposure to subsistence foods and residential recreational exposure), they are not evaluated separately.

Mine Site Dust Deposition to Wild Foods – As previously discussed, mine site fugitive emissions would result in dust deposition to soil, surface waterbodies, and vegetation (e.g., berries). Mine site dust deposition from fugitive emissions would result in small increases in metal concentrations in abiotic media. Potential impacts from dust deposition would decrease as distance from the mine site increases. In soil, sediment, and surface water, all metal concentrations, except antimony, were estimated to increase by less than 1 percent at the mine site boundary (i.e., "at the fence") at the end of operations (after 20 years). Estimated increases of antimony were likewise low, at less than 3.2 percent in all abiotic media. Estimated future surface water metal concentrations would remain below water quality criteria, and most metals in soil and sediment would remain below their criteria. For arsenic, chromium, and copper, which had baseline soil and sediment concentrations greater than their CALs, the future estimated concentrations would be indistinguishable from baseline risks/hazards. Although ADEC considers several of these metals to be potentially bioaccumulative (e.g., arsenic, cadmium, hexavalent chromium, copper, lead, methyl mercury, nickel, selenium, and zinc) (ADEC 2017b), future increases in wild foods (e.g., berries, upland game, fish) would be expected to negligible to slight given the predicted negligible increases in future abiotic media. Therefore, risks and hazards to the affected communities from harvesting and ingesting wild foods in the future would be expected to be indistinguishable from baseline; this potential exposure pathway is considered complete but insignificant.

Waterfowl Exposure to Mine Site Standing Waterbodies – Mine site activities would create new areas of standing water (e.g., main water management pond, tailings pond, open pit water management pond, sediment ponds, and seepage collection and recycling ponds). A variety of

AMERICAN OVERSIGHT

birds could potentially be affected by environmental contamination by contact with water and foraging in these locations (see Section 4.23, Wildlife Values). These birds may then be harvested and ingested by human subsistence receptors (see Section 4.9, Subsistence). Appendix K4.18, Water and Sediment Quality, presents the predicted concentrations of metals and water quality parameters in mine site standing water bodies during operations and at closure. Multiple metals (e.g., aluminum, antimony, arsenic, beryllium, cadmium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, and zinc) would be predicted to exceed their water quality criteria. Several of these metals are considered bioaccumualtive, as noted above.

The TSF would be characterized by ongoing mining activity during operations, and would be unlikely to support growth of vegetation or waterfowl food resources. Without vegetated cover and food resources, birds are not likely to be attracted to the TSF. The open pit lake would be deep, contain no shallow water habitats, and lack freshwater vegetation, but some waterfowl may use it during open water months (Section 4.23, Wildlife Values). Based on this, migratory waterfowl would not be expected to have substantive exposure to the mine site water storage features. PLP would develop a Wildlife Management Plan to minimize the potential for wildlife interaction with project activities; therefore, this potential exposure pathway is considered potentially complete but insignificant.

Summary of HEC 3 Impacts

The mine site CSM (Figure K4.10-1) and transportation corridor, Amakdedori port, and natural gas pipeline CSM (Figure K4.10-2) present an illustrated summary of the exposure pathway analysis. Table K4.10-7 summarizes the potential impact levels for the potentially complete hazardous chemical exposure pathways, including the potential health effect consequence, magnitude, duration, and geographic extent of the impact, and likelihood of the impact occurring based on the evaluations presented above. The summary impact to human health is rated Category 1 for potential increased risk of exposure to potentially hazardous chemicals in air, soil, surface water, sediment, groundwater, and wild foods. For the mine site during all phases, the health effect was assigned scores of 1 (i.e., “minor” risk/hazard increases compared to baseline). For the three other project components (transportation corridor, port, and pipeline) during all phases, health effects were assigned a score of 0 (i.e., “not perceptible” from baseline). The magnitude of these impacts are expected to be “minor” and assigned a score of 0 because the impacts would be below permit thresholds or result in impacts imperceptible or negligible compared to baseline. The geographic extents of these impacts are assigned score of 2 because the affected communities could be impacted. The likelihood of these impacts occurring is very unlikely (1-10 percent) for the transportation corridor, Amakdedori port, and the natural gas pipeline since impacts above baseline would not be expected, while the likelihood of impacts from the mine site would be unlikely (10-33 percent) since the potential incremental cancer risk and non-cancer hazards would be expected to be indistinguishable from baseline risks and hazards.

AMERICAN OVERSIGHT

K4.10.2.4 HEC 4: Food, Nutrition, and Subsistence Activity

As noted in ADHSS (2015), most of rural Alaska sustains a "mixed, subsistence-market" economy, wherein families invest money into small-scale, efficient technologies to harvest wild foods. In the non-urban areas of the state, many households depend on a mix of cash, subsistence (hunting, fishing and gathering), sharing, and non-cash trading; and many of the communities in the vicinity of project components have a high participation in subsistence harvest activities and consumption. Potential impacts, either positive or negative, on food security and subsistence resources, could have large and persistent impacts on community health. Section 4.3, Needs and Welfare of the People—Socioeconomics, evaluates the potential environmental consequences to socioeconomics from the project, including impacts to cost of living and price of food, which subsequently can impact community nutrition and food security. Section 4.9, Subsistence, evaluates the potential consequences to subsistence activity and associated community nutrition and food security. This section summarizes those findings, and incorporates them in the generation of this HEC ranking.

The evaluation presented in Section 4.3, Needs and Welfare of the People–Socioeconomics, concluded that the project could result in increases in economic opportunities that could result in steady income throughout the year, and help reduce seasonal fluctuations prevalent in the region. It also has the potential to lower the cost of living for nearby communities, which would likely decrease regional food costs and increase food security through reduced transportation costs. Additional impacts could include potentially stemming the current trend of out-migration, increasing or maintaining the number of schools in the region, and other indirect economic benefits (e.g., taxes, sales/revenue, and other fiscal effects to the regional and local communities). It could also result in replacement by store bought foods at greater expense.

The evaluation presented in Section 4.9, Subsistence, found that there could be both adverse and positive potential impacts. Potential negative impacts could be from actual or perceived decreases in access to, availability/quantity of, and/or quality of subsistence recourses, which could also adversely impact community health/well-being and cultural identity. Subsistence users would likely adjust the seasonal round, resource use areas, and species composition of harvest resources to target resources that would be less affected by project activities. Although these adaptive approaches would likely sustain harvest levels for affected communities, they may increase expenses and time needed to harvest subsistence resources. However, positive benefits may also occur, because increased incomes and employment can positively affect subsistence harvest levels and participation in a myriad of ways, including making procurement of hunting and fishing equipment more affordable. Once constructed, the transportation corridor roads and the natural gas pipeline right-of-way could have a positive effect on access to subsistence resources (depending on the level of access agreed to between the State, PLP, and the LPB); because these cleared routes could facilitate overland travel by all-terrain vehicles and snowmachines. The ferry could also facilitate access to subsistence resources by transporting local residents and their vehicles across the lake. PLP would work with local communities to find solutions for ferry transportation use (PLP 2018-RFI 027). Under the summer-only ferry operations variant, the ferry would not impact cross-lake local transport.

In addition, the HEC 3 evaluation on potential exposure to hazardous chemicals through subsistence wildfoods was taken into consideration. The HEC 3 evaluation concluded that project-related hazardous chemical increases to the environment from the mine site would be expected to be negligible compared to baseline concentrations, while the other project components would be insignificant. Any increased risks or hazards to human health from the project would be expected to be indistinguishable from baseline.

AMERICAN OVERSIGHT

Table K4.10-8: Summary of HEC 4 Impacts, summarizes the potential impact levels for food, nutrition, and subsistence activity, including the potential health effect consequence, magnitude, duration, and geographic extent of the impact, and likelihood of the impact occurring based on the evaluations presented in Section 4.3, Needs and Welfare of the People—Socioeconomics, Section 4.9, Subsistence, and HEC 3. The summary impact to human health is rated Category 2 for potential health benefits due to the potential for decreased cost of living, which would likely decrease regional food costs and increase food security. The summary impact to human health relative to access to, quantity of, and quality of subsistence resources is rated Category 2 for mine site construction, Category 1 for construction of the other project components, and Category 2 for operations and closure for components for both negative (adverse) and positive impacts (potential for decreased access to and/or quantity of subsistence resources and increased income for subsistence equipment).

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

K4.10.2.5 HEC 5: Infectious Diseases

The following subsections present the evaluation of the potential impacts on rates of infectious diseases, including sexually transmitted infections (STIs) (e.g., gonorrhea, chlamydia, Hepatitis C, and HIV); respiratory diseases (e.g., influenza and pneumonia); foodborne illness (e.g., salmonella and E. Coli); and zoonotic diseases (disease that is passed between animals and humans). Table K4.10-9 summarizes the potential impact levels for infectious diseases, including the potential health effect consequence, magnitude, duration, and geographic extent of the impact, and likelihood of the impact occurring.

The mine site personnel camp facilities would include a main construction camp to accommodate 1,700 workers. During construction and operation, the camp facilities would include a potable water supply from a series of groundwater wells north of the mine site, outside of the estimated cone of depression around the proposed open pit. The camp facilities would likely include common wash modules containing toilets, showers, and personnel laundry facilities. Temporary camps would be used during construction that would be moved as construction progresses. The Amakdedori port shore-based complex would include employee accommodations and common washrooms during operations. A groundwater well would be installed at the port to supply potable water for use by personnel. The well would be situated upland from the shoreline to avoid potential saltwater intrusion. PLP would likely conduct worker code of conduct training, and implement a closed work camp and workforce health education programs that would promote awareness of infectious diseases and preventive measures. The project would likely provide a place where workers who have infectious diseases (of any kind) could be diagnosed and treated, and measures would be taken to avoid transmittal of diseases to others. See Chapter 2, Alternatives, and Section 4.17, Hydrogeology, for more project details.

The following sections describe the potential project impacts on affected communities due to potential increases or decreases in rates of infectious disease.

Increases in Sexually Transmitted Infection Rates

Increases in STI rates could occur due to employment of workers from outside the region, and/or the rotation of the workforce during the various project phases; particularly construction. Residents living in the vicinity of the project workforce camps are the most vulnerable receptors to increases in STIs due to their proximity. Because the mine site and Amakdedori port would be located in remote areas, the probability of worker interactions with the residents living in local communities would be lower, relative to the construction workforce camps for the transportation corridor and natural gas pipeline.

Chlamydia and gonorrhea are reported as higher than national prevalence rates for the state, but particularly among Alaska Native populations (Section 3.10, Health and Safety). Chlamydia trachomatis was reported as 4 times more common than gonorrhea. In the Bristol Bay Region, rates of chlamydia are higher than state-wide Alaska Native populations, while chlamydia rates in the Kenai Peninsula Region are lower than state-wide Alaska Native populations, but still much higher than non-white Alaska Native state populations and nationally. Although Bristol Bay Region and Kenai Peninsula Region appear to have gonorrhea rates less than the state-wide Alaska Native rates, both had fewer than 20 cases of gonorrhea during the reporting period, and the rate may not be statistically reliable.

The potential impact of increases in STI rates for the potentially affected communities is rated Category 1 for all phases and components, except for during construction of the transportation corridor and natural gas pipeline, which are rated Category 2 (Table K4.10-9). For all components and phases, the health effect is considered to pose a minor risk of health injury.

AMERICAN OVERSIGHT

Because the project would use individuals primarily from the region for the workforce (i.e., there would not be a major influx of workers from outside the region), and statewide STI rates are lower than the local regional rates, it is expected that STI rates would not show a discernable change. Therefore, the likelihood of increased STI rates is considered as likely as not (33-66 percent) for the construction of the transportation corridor and pipeline due to the larger workforce (including those that already have STIs and may transmit to others) that would be housed in temporary camps near local communities; but unlikely (10-33 percent) for all phases at the mine site and Amakdedori port due to geographic remoteness.

Increases in Infectious Diseases

Increases in infectious disease rates could occur from employment of workers from outside the region and/or the rotation of the workforce during the project phases. Influenza and pneumonia was the tenth top cause of death statewide (ANTHC 2017i). Influenza and pneumonia rates of death are higher for Alaska Natives than those experienced by non-Alaska Natives and nationally. In addition, Alaska continues to have some of the highest tuberculosis rates in the nation (ADHSS 2017b), with Alaska Natives experiencing the greatest rates (Section 3.10, Health and Safety).

Impacts to human health from increases in infectious disease rates would be the same as discussed for sexually transmitted diseases. The potential impact of increases in infectious (respiratory) diseases rates for the potentially affected communities is rated Category 1 for all phases and components, except for during construction for the transportation corridor and natural gas pipeline, which are rated Category 2.

Increases in Rates of Foodborne Illnesses and Zoonotic Diseases

Increases in rates of foodborne illnesses and zoonotic diseases could occur due to improper food handling/catering services and food disposal at the project workforce camps during the project phases. Food-borne illnesses or zoonotic diseases from improper food disposal practices, such as harboring and feeding of wildlife near project camps, could occur at the project workforce camps, and be transmitted to the local communities via rotating staff. The potential for increased rates of foodborne illnesses and zoonotic diseases would be expected to impact primarily the local communities near the project components. This scenario is considered unlikely if the project adheres to and enforces regulations related to food services (such as 18 AAA 31) and wildlife interactions at the base camps or workforce housing.

The potential for increases in rates of foodborne illnesses and zoonotic diseases would be greatest in project workforce camps or workforce housing, with camps at all project components during construction, and at the mine site and Amakdedori port during operations and closure. The potential impact of increases in rates of foodborne illnesses and zoonotic diseases is rated Category 1 for all project phases (Table K4.10-9). For all project phases, the health effect is considered a minor risk of health injury. The magnitude of this impact is assigned a score of 1, because those affected would be expected to easily adapt to this impact with some intervention. The geographic extent of this impact is assigned a score of 0, because this impact would be limited to individual cases. The likelihood of this impact occurring would be very unlikely (1 to 10 percent), because the base camps would have safe food handling and disposal protocols in place to manage the food handling and catering services that would be provided for the project workforce.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

K4.10.2.6 HEC 6: Water and Sanitation

This section presents the evaluation of the potential impacts of increases in morbidity and mortality rates due to the availability and quality of water and sanitation services. Lack of in-home water and sewer service in some locations of rural Alaska causes severe skin infections and respiratory illnesses; residents of Southwest Alaska suffer rates of invasive pneumococcal disease that are among the highest in the world (ADEC 2018d). As discussed in Section 3.10, Health and Safety, as of 2016, 83.5 percent of rural Alaska Native communities were served by water and sewer services (a significant increase since 2004). In the Bristol Bay Region, 99 percent of households had water and sewer services; and in the Kenai Peninsula region, service was 100 percent (ANTHC 2017n). It is unlikely that the project would directly affect access to water and sanitation services in the local communities.

The potential impact of increases in mortality and morbidity rates due to change in the availability, and quality of water and sanitation services is rated Category 1 for the potentially affected communities for all project phases (Table K4.10-10). Because the majority of potentially affected communities have high baseline rates of water and sanitation service, it would be unlikely that there would be any perceptible changes from baseline to the affected communities due to the project. Therefore, the health effect and magnitude of impact are both assigned scores of 0 for all phases. The geographic extent of this impact is assigned a score of 0, because this impact would be limited to individual cases and households, if it does occur. The likelihood of increasing mortality and morbidity rates due to change in the availability and quality of water and sanitation services of communities near the project would be considered extremely unlikely (<1 percent).

AMERICAN OVERSIGHT

Table K4.10-10: Summary of HEC 6 Impacts: Water and Sanitation

Potential Impact	Project Phase	Negative/ Positive	Health Effect	Magnitude	Duration	Geographic Extent	Severity Ranking	Likelihood Rating	Impact Rating	Impact Category

	Operations				3, long-term		3		♦	1
	Closure				3, long-term		3		♦	1

AMERICAN OVERSIGHT

K4.10.2.7 HEC 7: Non-Communicable and Chronic Diseases

This section presents the evaluation of the potential impacts of increases in non-communicable and chronic morbidity and mortality rates in the potentially affected communities (such as cancer, cardiovascular, and respiratory). Although several factors (such as excess weight, physical activity, diet and nutrition, diabetes, and tobacco use) can contribute to increases in non-communicable and chronic morbidity and mortality rates, the evaluation of potential impacts focused on factors that could be directly attributed to the project. Potential exposure to project-related hazardous chemicals could result in increases in non-communicable and chronic (such as cancer, respiratory, and cardiovascular) morbidity and mortality rates in the potentially affected communities. For example, increased cancer rates in affected communities could occur from hazardous chemical exposure through ingestion of bioaccumulative and carcinogenic chemicals in subsistence foods. Changes in subsistence habits, diet, and nutrition, and changes in activity patterns could also affect the incidence of chronic diseases.

Chronic Disease Impacts from Diet, Nutrition, and Exercise

As discussed for HEC 4, the project would be expected to decrease food costs and increase food security, related to increased income levels for those who benefit economically from the project; while impacts to access to, quantity of, and quality of subsistence resources could be both negative and positive (see Table K4.10-4). Subsistence activities are a central feature of Alaska Native history and society, and support healthy diet and nutrition, physical activity needs, and are an important aspect of preserving cultural heritage and mental health (see Section 3.10, Health and Safety). All of the affected communities report higher baseline subsistence lifestyle compared to Alaska overall, while LPB and Bristol Bay Borough report higher percentages of adults who believe they get enough physical activity. With increased food security and decreased food costs (relative to income), it is possible that subsistence activities could be reduced in some community households and lead to lower rates of physical activity; but it is also possible that increased income would be used to supplement the subsistence lifestyle. In addition, subsistence users would likely adjust the resource use areas to target resources that would be less affected by actual or perceived impacts from the project (see Section 4.9, Subsistence) For community members employed by PLP, the project could increase rates of physical activity for some, while reducing physical activity rates for those in less physically active positions (i.e., vehicle drivers and equipment operators). In addition, individuals who may obtain full-time employment on the project may have reduced availability to engage in subsistence activities, thereby simultaneously experiencing increased incomes and reduced levels of fitness and subsistence activities, as reported in several other studies for Alaskan populations (Nobmann et al. 2005; Redwood et al. 2008).

The summary impact level for increased morbidity and mortality rates for cancer, respiratory, and cardiovascular diseases from changes in diet, nutrition, and physical activity for the potentially affected communities is rated Category 2 (Table K4.10-11). For the three components and project phases, the health effect was assigned a score of 1 (minor), given both the positive and negative potential impacts to diet, subsistence, and physical activity. The magnitude of impact was also assigned a score of 1, given the likely noticeable but limited/localized positive project impacts to diet and nutrition, and that those potentially negatively impacted are expected to be able to adapt and maintain pre-impact level of health. The geographic extent of this impact is assigned a score of 1, because impacts would be limited to a number of households. The likelihood of increased cancer, respiratory, and cardiovascular morbidity and mortality rates due to decreased diet/nutrition and decreased physical activity is considered as likely as not (33-66 percent).

AMERICAN OVERSIGHT

Chronic Disease Impacts from Exposure to Hazardous Chemicals

Based on the findings of the evaluation on potential exposure to hazardous chemicals, as presented for HEC 3, the project-related hazardous chemical increases to the environment from the mine site would be expected to be negligible compared to baseline concentrations, while the other components would be insignificant. Any increased risks or hazards to human health would be expected to be indistinguishable from baseline In addition, mitigation measures and best management practices would be implemented to further minimize potential exposures of hazardous chemicals to receptors in the potentially affected communities. The summary impact level for increased morbidity and mortality rates for cancer, respiratory, and cardiovascular diseases for the potentially affected communities is rated Category 1 (Table K4.10-11). For the mine site during all phases, the health effect and magnitude of impact are assigned scores of 1 and 0, respectively ("minor" increases compared to baseline). For the other components during all project phases, the health effect and magnitude of impact are both assigned a score of 0 (not perceptible and minor, respectively). The geographic extent of this impact is assigned a score of 2, because the communities in the vicinity of the EIS project area could be potentially affected. Based on the HEC 3 findings, the likelihood of increased cancer, respiratory, and cardiovascular morbidity and mortality rates due to increased exposure to potentially hazardous chemicals is considered unlikely (10-33 percent) for the mine site and very unlikely (1-10 percent) for the other three components.

AMERICAN OVERSIGHT

K4.10.2.8 HEC 8: Health Services Infrastructure and Capacity

Access to health services is important for achieving health equity and increasing the quality of life for all individuals. The level of access to health services can impact life expectancy, mortality, and morbidity rates; early detection and treatment of health conditions; and control of infectious diseases through increased access to vaccines. The following subsections present the evaluation of the potential impacts from decreased access to healthcare under routine conditions and emergency situations that could overwhelm local and regional healthcare capacities. Table K4.10-12 summarizes the potential impact levels for health services infrastructure and capacity, including the potential health effect consequence, magnitude, duration, and geographic extent of the impact, and likelihood of the impact occurring.

Access to Routine Healthcare

Several entities provide healthcare services in the EIS Analysis Area (Section 3.3, Needs and Welfare of the People—Socioeconomics). Every LPB community has a health clinic (Nondalton, Kokhanok, Newhalen, Iliamna, Levelock, Pedro Bay, and Igiugig), with the exception of two communities (Port Alsworth and Ugashik). The three Nushagak/Bristol Bay communities in the Dillingham Census Area in close proximity to the core EIS analysis area (New Stuyahok, Koliganek, and Ekwok) each have a health clinic. In addition, health clinics are in every community in the Dillingham Census Area, except Portage Creek and Ekek, which had a population of zero in 2009 (McDowell Group et al., 2011a; McDowell Group et al. 2018b).

The project has the potential to impact access to routine healthcare. On-site mine rescue and medical emergencies would likely be handled by a mine rescue team. Medical evacuation would be available by fixed-wing aircraft or helicopter to fly injured workers to medical facilities; likely in Anchorage. All project workforce camps would include first-aid provisions. Some project employees might obtain healthcare from healthcare facilities in nearby communities (e.g., Kokhanok, Iliamna, Newhalen, and Nondalton), although that would not be expected to occur often, because the mine site would have on-site medical facilities to support workers. Therefore, a noticeable effect on access to routine healthcare services would not be expected for residents living in the EIS analysis area, including the communities near the mine site.

In addition, positive impacts may also occur related to routine healthcare. Municipal tax revenues generated by the project may result in expansion or improvements to existing healthcare facilities and services, and therefore result in net benefits to all members of the community with regard to healthcare access and the quality of available services.

The summary impact level for access to routine healthcare for the potentially affected communities is rated Category 1 for all project components and phases (Table K4.10-12). For all project phases, the health effect is assigned a score of 1 (minor). The likelihood of this impact occurring would be unlikely, because mine site workers would be expected to typically use on-site medical facilities.

Access to Healthcare due to Large-Scale Emergency Situations and Overwhelming Local and Regional Healthcare Capacities

Although many of the workers would be trained in emergency response and first aid, the mine site medical resources may not be adequate to handle life-threating health conditions or multiple injured personnel in an emergency situation, depending on the situation. Due to the remote region and terrain, air travel is the primary mode of long-distance transportation, especially for major medical or medical emergency issues. However, while this scenario is possible, the probability of occurrence of emergency scenarios would be rare.

AMERICAN OVERSIGHT

As discussed in Section 3.10, Health and Safety, much of the region is classified as medically underserved, or has a shortage of health care professionals; however, the LPB (closest to the all project phases) is not listed as having a shortage of primary care health professionals. The LPB is serviced by a network of healthcare clinics, which are located in seven of nine communities (McDowell Group et al., 2011a). The three Nushagak/Bristol Bay communities (New Stuyahok, Koliganek, and Ekwok) are each serviced by a healthcare clinic (McDowell Group et al. 2018b). These clinics are staffed by medical and dental professionals with internet connections to specialists in Anchorage and around the country. However, the closest hospital is in Dillingham, approximately 125 miles southwest of the mine site, and is only a 16-bed facility. Because air/water transportation service to Anchorage (200 miles northeast of the mine site) is better equipped than to Dillingham, the affected communities in the LPB and the Kenai Peninsula Borough typically receive hospital care and other major medical services at the Alaska Native Medical Center in Anchorage (McDowell Group et al., 2011a). Mine site workers in need of medical emergency care that surpasses the capabilities of the on-site medical facility would be evacuated (via air, as described above) to appropriate medical facilities, likely in Anchorage.

The summary impact level for access to routine healthcare for the potentially affected communities is rated Category 2 for all project components and phases (Table K4.10-12). For all project phases, the health effect is assigned a score of 2 (moderate injury that may require intervention). Although possible, the probability of occurrence of emergency scenarios would be expected to be rare due to project safety protocols that would be employed. Therefore, this impact would be considered very unlikely (1-10 percent) to occur.

AMERICAN OVERSIGHT

Table K4.10-12: Summary of HEC 8 Impacts: Health Services Infrastructure and Capacity

Potential Impact	Project Phase	Negative/ Positive	Health Effect	Magnitude	Duration	Geographic Extent	Severity Ranking	Likelihood Rating	Impact Rating	Impact Category

AMERICAN OVERSIGHT

K4.10.3 Action Alternative 2 – North Road and Ferry

Impacts from the project would be the same as or similar to Alternative 1, with few exceptions. The area of Iliamna Lake used for the ferry would be different because it encompasses the areas at the north end of the lake around Pedro Bay (as opposed to the mid-lake region; i.e., Kokhanok). Under the summer-only ferry operations variant, transportation impacts on the lake would be eliminated during the winter, but double during the summer; and the air quality impacts from ferry and truck traffic would be the same as those for Alternative 1. Socioeconomic impacts under this variant would be similar to impacts under Alternative 1. This alternative's natural gas pipeline alignment would follow the north road alignment and not go across Iliamna Lake; there would be no hazards or impacts at Iliamna Lake during construction of the pipeline as would occur under Alternative 1. Impacts from the port at Diamond Point would be the same or similar to those as Amakdedori port.

Overall, the HEC for which Alternative 2 consequences may be most noticeably different from Alternative 1 is HEC 2: Accidents and Injuries due to transportation. However, even given the differences noted above, the transportation-related accidents and injury summary impact to human health would remain the same, and would remain at a Category 2 for all phases and transportation types (Table K4.10-13). The health effect, magnitude, duration, and geographic extent would all remain the same as Alternative 1. The likelihood for air and surface water would remain the same. Surface transportation likelihood would remain very unlikely (1 to 10 percent), but has the potential to increase to unlikely (10 to 33 percent) under the summer-only ferry variant if the road is not built to meet the increased summer capacity needs (i.e., traffic on Williamsport-Pile Bay Road would include doubled mine-related summer traffic and continuing or increasing levels of public boat portage). If mitigation measures include building the road to handle this increased summer capacity, then this potential likelihood increase could be mitigated, and likelihood would remain at very unlikely.

K4.10.4 Action Alternative 3 – North Road Only

Impacts from the project would be the same as or similar to Alternatives 1 and 2, with few exceptions. The use of Iliamna Lake for a ferry would be eliminated, shifting project-related transportation impacts to the area around Pedro Bay, rather than around Kokhanok. Impacts from the port at Diamond Point would be the same or similar to those as Amakdedori port. The concentrate pipeline variant would build a concentrate slurry pipeline from the mine to the port, and include a waste treatment plant at Diamond Point to treat the slurry, which would then be discharged to Iliamna Lake. Potential hazardous materials impacts would remain the same as under Alternative 1, because the effluent would be treated to meet the Alaska water quality criteria prior to discharge. This variant would likely decrease employment of truck operators, but increase employment at the water treatment plant (WTP)/dewatering facility, but with lower overall employment. Similar to the Alternatives 1 and 2 summer-only ferry operations variant, the overall impact would likely be to lower the high cost of living for the affected communities near the transportation corridor, but not to the extent of the non-variant alternative.

Similar to Alternative 2, the HEC for which Alternative 2 consequences may be most noticeable from other alternatives is HEC 2: Accidents and Injuries due to transportation. However, even given the differences noted above, the transportation-related accidents and injury summary impact to human health would remain the same—at a Category 2 for all phases and transportation types (Table K4.10-13). The health effect, magnitude, duration, and geographic extent would all remain the same as Alternative 1. The likelihood for air would remain the same, as would surface, because the Williamsport-Pile Bay road would be expected to handle year-round capacity needs. Even though the ferry operation on Iliamna Lake would be eliminated, the

AMERICAN OVERSIGHT

project would continue to use of Cook Inlet; therefore, the surface water likelihood would be remain unlikely.

AMERICAN OVERSIGHT

Table K4.10-13: Summary of HEC 2 Impacts: Accidents and Injuries for Alternatives 2 and 3

Table 4.10-14: Summary of Key Issues for Health and Safety

Impact-causing Project Component	Alternative 1 and variants	Alternative 2 and variants	Alternative 3 and variants
All Project Components	Increase in household incomes, employment, and education attainment. The summer-only ferry variant would lower the cost of living and increase employment opportunities, but not by as much as Alternative 1 because of seasonal vs. year-round employment (+ Category 3). Decrease in food cost relative to income and increased food security (+ Category 2).	Same as Alternative 1, including summer-only variant.	Same as Alternative 1. The concentrate pipeline variant would have similar impacts to the summer-only ferry variant under Alternative1.
	Increase and decrease psychosocial stress, family stress, and family stability (+/- Category 2). Increase and decrease in unintentional injury (e.g., falls, cuts, poisoning) and intentional injury (suicide) (+/- Category 2). Increase and decrease access to quantity and quality of subsistence resources (+/- Category 2). Increase in cancer, respiratory, and cardio-vascular morbidity and mortality rates due to change in diet, nutrition, and physical activity (+/- Category 2). Decreased access to healthcare due to emergency situations and overwhelming local and regional healthcare capacities (- Category 2).	Same as Alternative 1.	Same as Alternative 1.
Transportation Corridor	Increase in unintentional accidents and injuries morbidity and mortality rates due to air, surface, and water transportation, particularly regarding winter access across Iliamna Lake from the ice-breaking ferry. PLP would put some measures in place to minimize impacts, such as trail marking and crossings. The east Kokhanok ferry terminal variant would include access to Sid Larson Bay without crossing the ferry route. The summer-only ferry variant would eliminate the potential hazards to snowmachine winter lake crossings,	Impacts would be similar to Alternative 1, except that the routes and closest communities affected would be around Pedro Bay and the northern end of the lake instead of Kokhanok and the mid-lake region. The summer only ferry variant could increase the likelihood of surface transportation accidents and injuries along Williamsport-Pile Bay Road from an increase in truck	Same as Alternative 2, except that the elimination of the ferry on Iliamna Lake would reduce the likelihood of water transportation accidents and injuries, but could increase the likelihood of surface transportation accidents and injuries if mitigation measures are not taken to build the Williamsport-Pile Bay Road to meet mine-related and public summer capacity.

	but increase summer lake and road traffic (- Category 2).	traffic if mitigation measures are not taken to build to meet the increased mine-related and public summer capacity (- Category 2).	(- Category 2)
Transportation Corridor and Natural Gas Pipeline	Increase in sexually transmitted infection rates and in infectious (respiratory) disease morbidity and mortality rates (- Category 2, during construction phase only).	Same as Alternative 1.	Same as Alternative 1.

K4.10.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to impacts on health and safety. These potential future actions are similar to the proposed actions in that each may result in direct and indirect effects to the project-affected communities. To varying degrees, all the RFFAs identified in Section 4.1 have the potential to impact cumulative health and safety through impacts to transportation (e.g., increase in Cook Inlet vessel traffic), subsistence (e.g., impacts on cultural resources and disturbance of wildlife), socioeconomics (e.g., increased household income from other employment opportunities), and water quality and soil quality (e.g., sources of contamination).

RFFAs in the core EIS analysis area have the greatest potential to impact health and safety to the affected communities due to the more-direct nexus to the project. Of these, the following RFFAs have the greatest potential to impact cumulative health and safety:

- Pebble Project buildout – develop 55 percent of the resource over a 78-year period
- Lake and Peninsula Borough Transportation Projects
- Lake and Peninsula Borough Community Development and Capital Improvement Projects
- Rural Alaska Village Grant Program Projects
- Lake and Peninsula Borough and other regional Renewable Energy Initiatives
- Nushagak Electric Cooperative Village Intertie Project
- Industrial Pollutants and Contaminated Sites within Project Area Communities.

Of these, the Pebble Project buildout is the most notable, and would extend the operation of the project for an additional 78 years. This has the potential to result in increased health impacts, especially from increased impact durations, and possibly increased releases and affected community exposure to potentially hazardous materials. The buildout is not part of the proposed action, and would require additional permits and separate NEPA compliance. Project area communities with pre-existing industrial pollutants and contaminated sites have the potential to add to the cumulative health impacts from exposure to potentially hazardous materials in communities where PLP proposes construction and operations support activities. It would be expected that mitigation measures would be used to minimize or mitigate exposure (e.g., avoidance of ADEC-contaminated sites, protective clothing and equipment, dust

AMERICAN OVERSIGHT

suppression). The improvement-related RFFAs have the potential to add to positive impacts to the affected communities (e.g., road improvement and increased safety).

As discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics, several RFFAs could have socioeconomic impacts on the potentially affected communities. Transportation, infrastructure, and energy improvements could induce increased development, and these potential impacts would likely be greater if the proposed project is implemented. Other RFFAs were noted as likely having minimal socioeconomic cumulative impact on the potentially affected communities.

As discussed in Section 4.9., Subsistence, many of the RFFAs could contribute to increased potential for impacts on subsistence resources by environmentally disturbing activities, and cause an increased volume of people. Environmental impacts could include habitat fragmentation, increased noise and atmospheric pollution, and disturbances and impacts to fish and wildlife. The increased volume of people could lead to increased recreational hunting/fishing, and impact subsistence cycles for local communities. The cumulative impacts would be long term to permanent, and geographically broad in scope (regional level).

As discussed in Section 4.12, Transportation and Navigation, most of the RFFAs would contribute to the cumulative increase in vessel traffic in Cook Inlet; increased demand for regional and helicopter air transportation and logistical support (particularly if mining development projects were to overlap); and increased surface transportation impacts along roads leading to the communities of Iliamna, Newhalen, and Nondalton via the proposed Iliamna spur road from RFFAs related to subsistence and recreational uses. It would be likely that any increased demand for air transport could be met by adding supply, because the RFFA sites are distributed rather than clustered with different airstrips or staging sites.

Cumulative effects would be the same under all alternatives.

K4.25 THREATENED AND ENDANGERED SPECIES

K4.25.1 Overview of Underwater Acoustics

This appendix contains additional information on applicable underwater noise concepts and methodologies used in development of Section 3.25, Threatened and Endangered Species, and Section 4.25, Threatened and Endangered Species). This appendix summarizes the properties of underwater noise, which are relevant to understanding the effects of noise produced by construction and operations activities on the underwater marine environment in the analysis area. This document does not provide a detailed acoustical calculation of specific project components proposed under the action alternatives. This detailed information would be analyzed further in a Marine Mammal Protection Act (MMPA) authorization request to the regulatory agencies to meet Level A and B guidelines.

K4.25.1.1 Underwater Noise Descriptors

Noise received at and below the sea surface is relevant to marine mammals and some other marine animals at sea. The noise descriptors used in this report and for underwater acoustics in general, include the following:

- Sound pressure level (SPL) represents the sound pressure of a sound relative to a reference pressure; it is measured in decibels (dB)
- Sound exposure level (SEL) is the total energy of an event referenced to a period of 1 second; therefore, the SEL accounts for both the noise level and duration of an event. SEL can be used to represent a range of different types of noise sources and is expressed in dB with a reference pressure of 1 $\mu Pa^2 \cdot s$ (Pa = microascal). Variations of SEL include:
  - Single strike sound exposure level (SEL_{ss}), which is the total energy of a single occurrence of an impulsive noise source, and;
  - The cumulative sound exposure level 24-hour cumulative SEL (SEL_{24h}), which is the total energy of the entire period of exposure.
- Peak level, which is the maximum instantaneous noise level for an event. A peak level is typically used to represent impulsive noise sources and is expressed in dB with a reference pressure of 1 µPa.

Underwater sound propagation depends on several factors including sound speed gradients in water, depth, temperature, salinity, and seafloor composition. In addition, characteristics of the sound source like frequency, source level, type of sound, and depth of the source will also affect propagation. For ease in estimating distances to thresholds, simple transmission loss (TL) can be calculated using the logarithmic spreading loss with the formula:

$$TL = B * log10(R)$$

TL is transmission loss, B is logarithmic loss, and R is radius

The three common spreading models are cylindrical spreading for shallow water, or 10 log(R); spherical spreading for deeper water, or 20 log(R); and practical spreading, or 15 log(R).

K4.25.1.2 Applicable Noise Criteria

Under the MMPA, the National Marine Fisheries Service (NMFS) and US Fish and Wildlife Service (USFWS) have defined levels of harassment for marine mammals. Level A harassment is defined as, "…any act of pursuit, torment, or annoyance which has the potential to injure a

AMERICAN OVERSIGHT

marine mammal or marine mammal stock in the wild." Level B harassment is defined as, "…any act of pursuit, torment, or annoyance which has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering."

For Level A, NMFS 2018 provides guidelines for assessing the onset of permanent threshold shifts (PTS) from anthropogenic sound. Under these guidelines, marine mammals are separated into five functional hearing groups; source types are separated into impulsive (e.g., seismic) and non-impulsive; and require analyses of the distance to the peak received SPL; L_{pk}, and SEL_{24h}.

The current Level B (i.e., disturbance) threshold for assessing the onset of temporary threshold shifts for impulsive sound is 160 decibels referenced to one microPascal (dB re 1 µPa) root mean square (rms) for impulsive and 120 dB re 1 µPa rms for non-impulsive sound for all marine mammals.

Table K4.25-1 provides a summary of the disturbance guidelines. For purposes of this section, all underwater SPLs are reported as dB re 1 µPa.

Table K4.25-1: Summary of NMFS Acoustic Thresholds

Marine Mammals	Injury (Level A) Threshold		Disturbance (Level B) Threshold	
	Impulsive	Non-Impulsive	Impulsive	Non-Impulsive
Low Frequency Cetaceans	219 dB L_{pk} 183 dB SEL	199 dB SEL	160 dB rms	120 dB rms
Mid-Frequency Cetaceans	230 dB L_{pk} 185 dB SEL	198 dB SEL	160 dB rms	120 dB rms
High-Frequency Cetaceans	202 dB L_{pk} 155 dB SEL	173 dB SEL	160 dB rms	120 dB rms
Phocid Pinnipeds	218 dB L_{pk} 185 dB SEL	201 dB SEL	160 dB rms	120 dB rms
Otariid Pinnipeds	232 dB L_{pk} 203 dB SEL	219 dB SEL	160 dB rms	120 dB rms
Sea Otters	190 dB rms	180 dB rms	160 dB rms	160 dB rms

K4.25.1.3 Description of Sound Sources

The acoustic characteristics of each of the activities proposed under Alternative 1 are described in the following section and summarized in Table K4.25-2. Not all sources of noise will result in Level A or B acoustic harassment, but are presented for reference. The underwater noise sources associated with the construction will comprise:

- Vessels;
- Aircraft;
- Causeway construction; and
- Pile driving (impact and vibratory).

The majority of underwater vessel sound energy is restricted to frequencies below 100 to 200 Hertz (Hz), but broadband sounds may include acoustic energy at frequencies as high as 1 kiloHertz (kHz). The underwater SPLs of vessels depend on size and speed, but typically range from 145 to 175 decibels referenced to dB re 1 µPa-m (Richardson et al. 1995). Underwater sound levels from pile driving vary with the size and type of piles, as well as the size and type of

AMERICAN OVERSIGHT

hammer. Impact pile driving is generally below 4 kHz, with peak sound pressure levels ranging from 185 to 220 dB re 1 µPa at 10 m; vibratory pile driving generally has energy up to 10 kHz, but produces lower peak levels ranging 165 to 195 dB re 1 µPa at 10 m (Illingworth and Rodkin 2007). Underwater noise from aircraft (e.g., helicopter and fixed-wing) is greatest directly below the aircraft, with energy generally below 500 Hz, and ranging 100 to 124 dB re 1 µPa-m. Airborne sound levels associated with construction equipment generally range from 75 to 85 dB re 20 µPa at 15 m, with pile driving producing higher sound levels between 95 to 105 dB re 20 µPa at 15 m.

Table K4.25-2: Summary of Noise Sources for Each Activity

Activity	Sound Pressure Levels (dB re 1 µPa)	Frequency	Reference
General vessel operations	145-175 dB rms at 1 m	10 Hz – 1,500 Hz	Richardson et al. 1995; Blackwell and Greene 2003; Ireland and Bisson 2016
General aircraft operations	100-124 dB rms at 1 m	<500 Hz	Richardson et al. 1995
Rock laying for causeway	Less than dredging: 136-141 dB rms at 12-19 m	<500 Hz	Nedwell and Edwards 2004; URS 2007
Impact pile driving (12-60-inch pipe pile)	185-210 dB peak at 10 m 160-185 SEL at 10 m 170-195 rms at 10 m	<100-1,500 Hz	Illingworth & Rodkin 2007
Vibratory pile driving (12-72-inch pipe and sheet pile)	165-195 dB peak at 10 m 150-180 dB SEL at 10 m 150-180 dB rms at 10 m	<100-2,500 Hz	Illingworth & Rodkin 2007

Vessel Operations

Vessels are major contributors to the overall acoustic environment (Richardson et al. 1995), particularly in the Alaska (Huntington et al. 2015). In a 2012 Cook Inlet Vessel Traffic Study Report (Cape International, Inc. 2012), patterns of activities were described for vessels over 300 gross tons operating during 2010. Results showed that there were 480 port calls or transits through Cook Inlet, with 80 percent of the transits made by 15 ships for the purpose of crude oil and product transport, packaged commodity shipments, and passenger/vehicle carriage. This class of vessel is characterized with source levels of 160 to 200 dB re 1 µPa rms at 1 m in the 6 to 500 Hertz (Hz) range (Richardson et al. 1995).

Position keeping in Cook Inlet is a challenge due to strong currents; therefore, some vessels use dynamic positioning with bow thrusters when anchoring is not possible. Ireland and Bisson (2016) measured source levels from 148.5 dB re 1 µPa rms at 1 m at 2,000 Hz to 174.5 dB re 1 µPa rms at 1 m at 10 Hz with 100 percent of all four thrusters.

Blackwell and Greene (2003) recorded underwater noise produced by both large and small vessels near the Port of Anchorage. The Leo tugboat produced the highest broadband levels of 149 dB re 1 µPa at a distance of approximately 100 m, while the docked cargo freight ship, Northern Lights, produced the lowest broadband levels of 126 dB re 1 µPa at 100-400 m. Ship noise was generally below 1 kHz.

AMERICAN OVERSIGHT

Aircraft Operations

Helicopters and fixed-wing aircraft generate noise from their engines, airframe, and propellers. The dominant tones for both types of aircraft generally are less than 500 Hz (Richardson et al. 1995). Richardson et al. (1995) reported that received sound levels in water from aircraft flying at an altitude of 152 meters were 109 dB re 1 µPa for a Bell 212 helicopter, 101 dB re 1 µPa for a small fixed-wing aircraft, 107 dB re 1 µPa for a twin otter, and 124 dB re 1 µPa for a P-3 Orion.

Penetration of aircraft noise into the water is greatest directly below the aircraft; at angles greater than 13 degrees from vertical, much of the sound is reflected and does not penetrate (Richardson et al. 1995). Duration of underwater sound from passing aircraft is much shorter in water than air. For example, a helicopter passing at an altitude of 152 meters, audible in air for 4 minutes, may be detectable underwater for 38 seconds at 3 meters depth, and 11 seconds at 18 meters depth (Richardson et al. 1995).

Pile Driving

Impulsive underwater sound generated by construction activities has the potential to harass marine mammals where it exceeds 160 dB re 1 µPa (rms). Impulsive noise sources proposed for the construction phase of the project include pile driving using an impact hammer. Pile driving would be necessary for construction of the pile supported dock variants at the Amakdedori port site under Alternative 1 and the Diamond Point port site under Alternative 2. Illingworth and Rodkin (2007) compiled measured near-source (i.e., 10 meter) SPL data from impact pile driving for pile sizes ranging in diameter from 12 to 96 inches (Table K4.25-2). Non-impulsive underwater sound generated by construction activities has the potential to harass marine mammals where it exceeds 120 dB re µ1 Pa (rms) for NMFS-species and 160 dB re 1 µ Pa (rms) for sea otters. Vibratory pile driving generally results in lower source sound levels, but the harassment threshold is larger than for impulsive sounds. Illingworth and Rodkin (2007) also compiled measured near-source (i.e., 10 meter) SPL data from impact vibratory driving for pile sizes ranging in diameter from 12 to 72 inches. Because the in-water construction details are not fully developed, a range of sound is provided in Table K4.25-2.

Rock Laying

Measurements of underwater noise during rock placement have shown that the rock placement itself is not distinguishable from the vessel noise (Nedwell and Edwards 2004); rock placement vessels are similar to dredging vessels. URS (2007) measured underwater sound levels from clamshell dredging at the Port of Anchorage and reported broadband levels of 136 to 141 dB re 1 µPa rms at 12 to 19 meters.

K4.25.1.4 Acoustic Analysis

Per the MMPA and Endangered Species Act, applicants are required to evaluate the number of marine mammals potentially exposed to sound levels exceeding the thresholds from Table K4.25-2. This method requires an estimated density of marine mammals' (animals per square kilometer) area of ensonification (square kilometers), which is determined by calculating the distance from the source to the threshold, duration in a 24-hour period of the activity. Once project specific details are finalized, details such as pile type and size, size of hammer and number of strikes per pile to install, number of piles per day, and duration of the pile strike will be used to calculate the appropriate number of potential marine mammal exposures. Calculated distances to agency thresholds are also used to establish mitigation and monitoring zones.

AMERICAN OVERSIGHT

3.4 ENVIRONMENTAL JUSTICE

The affected environment for environmental justice includes definitions of minority and low-income populations; a discussion of race, ethnic origin, and a discussion of the relationship between environmental justice and subsistence resources, socioeconomics, cultural resources, and community health.

3.4.1 Definitions of Minority and Low-Income Populations

Executive Order 12898 (1994) requires federal agencies to identify and address disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority communities and low-income populations. Under Executive Order 12898, demographic information is used to determine whether minority populations or low-income populations are present in the areas potentially affected by the project. If so, a determination must be made as to whether implementation of the project may cause disproportionately high and adverse human health or environmental effects on those populations.

For the purposes of this analysis, a minority community is defined as a community with a majority (i.e., 50 percent or greater) minority population, and a low-income community is defined as having a greater percentage of the population living in households below the poverty threshold as defined by the US Census Bureau than the percentage of the population in the state living below that level. This is consistent with guidance by the Council on Environmental Quality (CEQ) (CEQ 1997). Historically, minority and low-income populations have suffered a greater share of adverse environmental and health impacts related to industry and development projects relative to the benefits. In addition, impacts to Alaska Native populations may be different from impacts on the general population due to a community's distinct cultural practices (CEQ 1997). Therefore, agencies would consider impacts to subsistence and sociocultural characteristics as a component of the environmental justice analysis.

3.4.2 Minority and Low-Income Populations

The project's potentially affected population includes those who live, work, or subsist in the EIS analysis area. Table 3.4-1 presents available community-level racial and ethnic characteristics as well as the percent living below the poverty level for the population in the EIS analysis area that would be affected during construction and operations of the mine site, transportation corridor, Amakdedori port, and natural gas pipeline. Figure 3.4-1 shows minority and low-income communities in the EIS analysis area.

Data in this section were obtained from the US Census Bureau 2012-2016 American Community Survey (ACS). Estimates from the ACS are all "period" estimates that represent data collected over a period of time (as opposed to "point-in-time" estimates, such as the decennial census, that approximate the characteristics of an area on a specific date). The primary advantage of using multi-year estimates in this analysis of low-income populations is the increased statistical reliability of the data for less populated areas and small population subgroups. Statistics for the state of Alaska are provided as a reference.

Note: Minority population = Total population – (White, non-Hispanic population + Some Other Race Alone, non-Hispanic population).

1. Alone, non-Hispanic.

2. Alone or in combination with one or more other races.

3. Of any race.

Source: USCB 2016a, 2016b

Most Alaskan communities tend to have a bi-modal racial structure. Most commonly, communities either have a substantial majority of the community that identify as White and other ethnic groups, or a majority that identify as Alaska Native or American Indian (Himes-Cornell et al. 2013). These trends are consistent with the EIS analysis area. As shown in Table 3.4-1, the majority of individuals in the Kenai Peninsula, Bristol Bay Borough, and Anchorage Municipality identify as White, whereas the majority of individuals in the Lake and Peninsula Borough and the Dillingham Census Area identify as Alaska Native or American Indian.

The Kenai Peninsula Borough, Bristol Bay Borough, Municipality of Anchorage, and Port Alsworth in the Lake and Peninsula Borough are not considered minority or low-income

AMERICAN OVERSIGHT

communities. Igiugig and Pedro Bay are considered minority communities but not low-income communities. Iliamna, Kokhanok, Levelock, Newhalen, Nondalton, and the Dillingham Census Area as a whole are considered both minority and low-income communities. Of these communities, Levelock, Kokhanok, and Iliamna have the largest percentage of minority individuals. Kokhanok, Newhalen, and Levelock have the highest percentage of persons below poverty level.

In addition, median incomes through communities in the region are less than half the statewide average of $74,444. High rates of the population living below the poverty level and low median income are partly based on economies being largely subsistence based, as wage employment is limited (Himes-Cornell et al. 2013). Many residents seek additional wage employment outside of their community. It should be noted that ACS data are based on wage earnings and do not take into account the value of subsistence in the local economy (see Section 3.3, Needs and Welfare of the People–Socioeconomics, for further discussion of employment and income in the EIS analysis area).

Table 3.4-2 evaluates if communities in the EIS analysis area meet the CEQ definitions of minority and low-income communities. Igiugig, Iliamna, Kokhanok, Levelock, Newhalen, Nondalton, and Pedro Bay in the Lake and Peninsula Borough; Ekwok, Koliganek, and New Stuyahok in the Dillingham Census Area; and the Dillingham Census Area as a whole meet CEQ definition of minority and/or low-income communities. Therefore, this environmental justice analysis will consider if the project results in disproportionately high and adverse human health or environmental effects on those populations.

Table 3.4-2: Determination of Minority and Low-Income Communities with Environmental Justice

Source: Data summarized from Table 3.4-1

As stated above, impacts to Alaska Native populations may be different from impacts on the general population due to a community's distinct cultural practices; impacts associated with subsistence are a component of the environmental justice analysis. Section 3.9, Subsistence, describes subsistence resources, harvest, and sharing patterns for subsistence-based communities in the EIS analysis area. These communities include Nilchik and Seldovia in the Kenai Peninsula Borough; Naknek, South Naknek, and King Salmon in the Bristol Bay Borough; and Aleknagik, Clark's Point, Dillingham, Manokotak, New Stuyahok and in the Dillingham Census Area. The proportion of minority and low-income populations in these communities are generally similar to those shown in Table 3.4-1 for the Kenai Peninsula Borough, Bristol Bay Borough, and Dillingham Census Area. Other communities in the Kenai Peninsula Borough and Bristol Bay Borough are not considered minority and low-income communities because there is a high proportion of White residents and the percentage of populations at income levels below the poverty level are generally low. The populations in the Dillingham Census Area are considered minority and low-income communities, with a high proportion of Alaska Native residents and a high percentage of populations at income levels below the poverty level (Himes-Cornell et al. 2013; State of Alaska 2017).

3.4.3 Relationship to Subsistence, Health, and Environment

Environmental justice analysis is an intersection between several resource topics. The relationship includes subsistence users, subsistence resources, cultural practices, socioeconomic characteristics, and community health, with a potential for both beneficial and adverse impacts. Socioeconomic impacts associated with population, housing, and employment are described in Section 3.3, Needs and Welfare of the People–Socioeconomics. Section 3.9, Subsistence, describes subsistence resources and harvest patterns for subsistence-based communities in the EIS analysis area. Project-related impacts to human health are described in Section 4.10, Health and Safety, including effects from changes in air quality and water quality, as well as concerns about contamination and subsistence food consumption. Each alternative is evaluated in Section 4.4, Environmental Justice, for possible disproportionate impacts to minority and low-income communities using the information provided in the socioeconomic, subsistence, and human health sections of this EIS; determinations are made on whether environmental justice effects would occur.

AMERICAN OVERSIGHT

3.10 HEALTH AND SAFETY

The evaluation of impacts on human health is a required component of the National Environmental Policy Act (NEPA) as it pertains to negative and beneficial consequences of a proposed project on potentially affected communities. There are laws and regulations, such as the Clean Air Act, Clean Water Act, and various Alaska statutes that have been enacted to ensure protection of human health. Compliance with health laws and regulations are taken into consideration in the evaluation of health impacts. This section presents a human health assessment for the Pebble Project EIS. This assessment is intended to document baseline health status in the EIS analysis area so that project-related positive and negative health consequences for the proposed action and alternatives may be identified and ranked in Section 4.10 as to their likelihood and degree, and mitigation measures may be recommended to minimize potential negative impacts that could occur as a result of the project. Human health data for the EIS analysis area are generally available at broad regional scales, but some data are available at the community level. When differences are able to be distinguished between the two, they are distinguished to the extent that is relevant for the purposes of the assessment.

For the purposes of this document and consistent with Alaska Department of Health and Social Services (ADHSS), health is defined not merely as the absence of disease, but as "the reduction in mortality, morbidity, and disability due to detectable disease or disorder, and an increase in the perceived level of health" (ADHSS 2015). Thus, it represents an integrated state of physical, social, and mental well-being. Health is affected by environmental, social, cultural, and genetic factors often called "determinants of health." Community health in Alaska, with its environmental and social setting and complex blend of health determinants, is in many ways different from national health trends in the US (ADHSS 2015). Large projects such as mining activities can often affect the health of nearby communities in complex ways; impacts may be both positive and negative.

Although this assessment describes the broad health effects categories (HECs) and several typical health metrics for each category included in the ADHSS guidelines, emphasis is focused on assessing key issues and potential impacts identified during scoping (as required by NEPA) and those expressed by stakeholders. In accordance with NEPA practice, the scope of the human health section is limited to "outside of the fence." Consistent with ADHSS (2015), this assessment does not include a direct evaluation of the anticipated workforce safety and health issues (i.e., "inside the fence") because the project is governed by the regulations of the Occupational Safety and Health Administration and the Mining Safety and Health Administration. However, the assessment does consider crossover issues where workforce behaviors result in interactions/overlap with the local communities.

The primary sources of baseline affected community and environmental information were obtained from the PLP, Environmental Baseline Documents (EBDs) (BEESC 2011a, McDowell Group et al. 2011a, McDowell Group, 2013b, Schlumberger et al., 2011a, Schlumberger, 2015b, SRB&A 2011b, TPP 2011a, TPP 2011b), Socioeconomics – Bristol Bay Drainages, Updated Detailed Cumulative Baseline Data (2000-2018) (McDowell Group 2018a) and Human Health Cumulative Baseline Data: Bristol Bay Drainages (2010-2018) (McDowell Group 2018b), and have been condensed and summarized for this EIS. When practicable, additional or updated data have also been incorporated from the Pebble Limited Partnership (PLP) and other publicly available sources (e.g., ADHSS' Alaska Health Analytics and Vital Records). This health evaluation focuses on the communities associated with proposed project components and phases (see Chapter 2, Alternatives, for a description).

AMERICAN OVERSIGHT

There is generally overlap between the affected communities in relation to the project components and phases; therefore, the functional classification of baseline information for the affected communities was at the EIS analysis area through the end of the closure phase. Specific affected community distinctions by component, area, or phase are only denoted when relevant.

3.10.1 Assumptions and Limitations

Focus on Most Relevant Human Health Effects Categories and Diseases. The assessment has been streamlined to focus on the HECs that could be directly impacted by the project and may be expressed as a primary stakeholder concern (HEC 3: Exposure to Hazardous Materials), as well as Infectious Disease (HEC 5) and Non-Communicable and Chronic Diseases (HEC 7). Infectious Disease and Non-Communicable and Chronic Diseases will focus on the top several diseases in each category based on their public health significance and frequency of occurrence. The sources of data cited also provide information on less prevalent diseases and conditions. The remaining five categories (i.e., Social Determinants of Health; Accidents and Injuries; Food, Nutrition, and Subsistence Activity, Water and Sanitation, and Health Services Infrastructure) will primarily rely on the data and conclusions from Section 4.3 (Needs and Welfare of the People–Socioeconomics), Section 4.12 (Transportation and Navigation), and Section 4.9 (Subsistence), and will supplement those sections as appropriate.

Age of Available Information. This EIS relies upon previously compiled baseline information for most of the HECs, which date from about 2008 to 2010. More current data was accessed, when available, with a focus on the effects categories and diseases most relevant to human health effects.

Identifying Potentially Affected Communities: The project covers a relatively large geographical distance (e.g., the transportation corridor would extend approximately 93 miles and the Pipeline Corridor would extend approximately 188 miles) and considers effects to broad rural areas. The potentially affected communities for most HECs (with the exception of HEC 4, Subsistence) are identified primarily based on proximity to the project components. They are identified first by those local communities in the vicinity of the core EIS analysis area (i.e., mine site, transportation corridor, and Amakdedori port project components) and then by regions (e.g., boroughs) (see Section 3.3, Needs and Welfare of the People–Socioeconomics, and Section 3.12, Transportation and Navigation).

The eight communities in the Lake and Peninsula Borough that were identified as those closest to the core of the EIS analysis area and evaluated for all HECs included: Nondalton, Newhalen, Kokhanok, Port Alsworth, Iliamna, Pedro Bay, Levelock, and Igiugig. These small rural communities have approximate population ranges of 48 to 128 people (McDowell Group et al. 2011a) and may be more directly impacted both positively and negatively, compared to communities farther away, due to their relative proximity to the project components. In addition, three Nushagak/Bristol Bay communities in the Dillingham Census Area were also identified as geographically close to the core EIS analysis area and were evaluated at the community-level when data permitted: New Stuyahok, Koliganek, and Ekwok. Health data are not always available at the community level for these potentially affected communities, due to privacy concerns and very small community sizes, and are not considered to be severe limitations for the purposes of the project. For the project, these limitations are addressed by using regional data sources within and near the EIS analysis area, including the Lake and Peninsula Borough, Bristol Bay Borough, Dillingham Census Area, Kenai Peninsula Borough, and city of Anchorage. Of these, only the city of Anchorage is considered an urbanized area, and while it lies outside the EIS analysis area, it is likely that some project workers will come from this population. The other boroughs are considered remote, rural areas. As mentioned above, the eight Lake and

AMERICAN OVERSIGHT

Peninsula Borough communities are within the core EIS analysis area, the three Nushagak/Bristol Bay communities are in close proximity to the core EIS analysis area, the Kenai Peninsula is the start of the natural gas pipeline corridor, and all the rural boroughs may use the area for subsistence (discussed below).

The limitation to evaluating health impacts to communities based on proximity to the project components is that some effects may not be directly related to the length of distance between the community and the project component, such as employment opportunities. Although the direct economic effects are discussed in Section 3.3, Needs and Welfare of the People–Socioeconomics, the relationship between income and health cannot be overstated. The rural location of the mine and the planned on-site housing camps make traditional commute times irrelevant, and therefore the communities that would contribute to the workforce may include more than those closest to the site. Also not directly related to distance would be changes in a community from project features, such as additional communities that might want to utilize project components like the Amakdedori port. These factors that are not dependent on distance also warrant consideration, along with the communities located relatively close to the project components.

For subsistence (HEC 4), the local communities evaluated include the eight affected communities in the Lake and Peninsula Borough and two of the three affected communities in the Nushagak/Bristol Bay area (data for Ekwok are insufficient to evaluate subsistence), as well as ten other communities that are known to use the area for subsistence, as discussed in detail in Section 3.9, Subsistence. These subsistence-related communities include six communities within the Dillingham Census Area (Dillingham, Clark's Point, Manokotak, Aleknagik, Koliganek, and New Stuyahok), three communities within the Bristol Bay Borough (Naknek, South Naknek, and King Salmon), and two communities within the Kenai Peninsula Borough (Ninilchik and Seldovia). Although it is possible that additional communities may occasionally utilize the EIS analysis area, these 19 communities capture those most likely to use the area and are adequate to assess potential project impacts in this EIS.

3.10.2 Demographic Summary of Potentially Affected Communities

Demographic and socioeconomic profiles of the affected communities are presented in McDowell Group et al. 2011a, McDowell Group 2018a, in Section 3.3, Needs and Welfare of the People–Socioeconomics, and Section 3.4, Environmental Justice; the information is not repeated here. The Alaska Native Health Status Report (ANTHC 2017a) presents recent state and regional overviews of sociodemographic highlights (e.g., demographics, education attainment, unemployment, poverty, and household income), as well as mortality highlights, morbidity highlights, and maternal, infant, and child health highlights. To provide context for the assessment, a brief summary of the demographic data is presented in Table 3.10-1.

Table 3.10-1: Demographic Summary

3.10.3 Baseline Community Health Conditions

Information for the 11 potentially affected communities is presented and compared to other local and regional data as warranted, and also compared to state or US data. Primary data sources include government, regional, community, and academic sources.[1]

[1] Primary data sources include the Alaska Department of Commerce, Community, and Economic Development, Alaska Department of Environmental Conservation, Alaska Department of Fish and Game, ADHSS, Alaska Department of Labor and Workforce Department, Alaska Native Tribal Health Consortium, Alaska State Troopers, Bristol Bay Area Health Corporation, Bristol Bay Native Association,

AMERICAN OVERSIGHT

Although statewide data offers some context, the HEC discussions in this section are limited to health endpoints that have relevant and recent regional and local data available. Current data are generally preferred, older data are presented as warranted or if current data were not available. In some cases, local community data are neither reported nor available due to small size or privacy concerns. When available, local community data are representative of very small populations. Comparisons of statewide rates with local small population community rates should be interpreted with caution due to the statistical uncertainty associated with small populations. For regional rates based on fewer than 20 cases, they should also be viewed with caution because they may not be statistically reliable.

3.10.4 Health Effects Categories

3.10.4.1 HEC 1: Social Determinants of Health

The ADHSS Technical Guide (ADHSS 2015) suggests a broad list of social determinants of health (SDH) for consideration. Many of these SDH for the affected communities evaluated in this EIS are presented in Section 3.3, Needs and Welfare of the People–Socioeconomics, including discussion and tables with information and statistics on demographics, age distribution, population size and trends, educational attainment, employment rates and categories, household income, and poverty rates. SDHs such as isolation and cultural change lack of meaningful available data at the level of community health but are addressed in larger context in Section 3.7, Cultural Resources, and Section 3.9, Subsistence.

Overall, the affected communities whose health may be most impacted by the project within EIS analysis area (or may use the area for residence, subsistence, or recreation) are the remote, rural communities within the Bristol Bay Region (includes the Lake and Peninsula Borough, Bristol Bay Borough, and Dillingham Census Area) and Kenai Peninsula Region. The remote communities generally have lower levels of employment, income, formal educational attainment, and access to amenities than the urbanized communities.

For those SDH not covered in Section 3.3, Needs and Welfare of the People–Socioeconomics, Table 3.10-2, below, summarizes the additional SDH that are relevant and important indicators for this HEC and may potentially be impacted by the project. The remote, rural communities have similar life expectancy with the urbanized communities. While the Kenai Peninsula region typically has SDH similar to Anchorage, the Bristol Bay region tends to have higher rates of inadequate prenatal care and teen pregnancy, but higher rates of adult dental care and lower rates of adult tooth loss, poor mental health, and adult binge drinking.

Cook Inlet Region, Inc. Foundation, Commercial Fisheries Entry Commission, US Department of Commerce, Bureau of Economic Analysis, US Census Bureau, US Centers for Disease Control and Prevention, US Department of Health and Human Services, World Health Organization, and other government, regional, community, and academic sources.

The Bristol Bay Region includes the Lake and Peninsula Borough, Dillingham Census Area, Bristol Bay Borough, and surrounding area. Kenai Region includes Kenai Borough and surrounding area.

AMERICAN OVERSIGHT

Adult mental health, suicide mortality, and substance abuse (e.g., alcohol abuse) can be indicators of psychosocial stress. Mental health is measured as self-reported stress, depression, and problems with emotions in the past 30 days; the average statewide number of poor mental health days was 20 percent higher for Alaska Natives than Alaska Whites (ANTHC 2017e). Suicide mortality rates varied by region, but was the fourth leading cause of death among Alaska Native people during the period from 2012 to 2015 (ANTHC 2017f). Binge drinking is measured as self-reported adults aged 18 years of older who had five or more drinks (men) or four or more drinks (women) on one or more occasions in the past 30 days (ANTHC 2017g).

3.10.4.2 HEC 2: Accidents and Injuries

Accidents and injuries include both fatal and non-fatal incidents that are primarily unintentional and affect the mortality and morbidity rates of a community. Unintentional injury (e.g., falls, poisoning, drowning, motor vehicle crashes) is the third leading cause of death in the state and most regions (ADHSS 2017a; ANTHC 2017i). Intentional incidents include suicide and homicide.

McDowell Group et al. 2011a presents regional baseline rates of hospitalization discharges by diagnosis (2001 through 2005) for the Lake and Peninsula Borough, Dillingham Census Area, and Bristol Bay Borough. It also presents the leading causes of non-fatal injuries requiring hospitalization (2000 through 2004) for the Bristol Bay Borough. McDowell Group 2018b presents inpatient and outpatient hospitalizations/admissions demographics and leading diagnoses for the Lake and Peninsula Borough, Dillingham Census Area, and the Bristol Bay Borough.

Table 3.10-3 presents the baseline accident and injury rates for the affected communities. The role of alcohol in accidents and injuries is well-known, and various Alaska Native villages have enacted policies that designate a community as dry (i.e., no sale or consumption of alcohol), damp (i.e., no sale, but possession allowed), and wet (i.e., sale, importation, and possession allowed).

AMERICAN OVERSIGHT

3.10.4.3 HEC 3: Exposure to Potentially Hazardous Materials

Environmental exposure to chemical or physical hazards through the air, land, or water is also considered a health determinant. Baseline data may be qualitative in terms of proximity to known contamination sources, or quantitative through analytical data collection (e.g., water quality data, soil analytical data).

Physical Hazards. There are no specific baseline data on physical hazards, but it should be recognized that the rural and remote regions in Alaska carry exposure risk from the terrain, elements, and wildlife.

Air Quality. The role of poor air quality on community health, particularly with regard to respiratory disorders, has been well-documented (WHO 2016). The available regional baseline air quality data for criteria pollutants is sufficient for establishing baseline EIS analysis area conditions for NEPA purposes and is provided in Section 3.20, Air Quality. As discussed in Section 3.20, Air Quality, hazardous air pollutants (HAPs) are not measured in the region due to lack of large regional anthropogenic sources of HAPs in the area (e.g., factories, refineries, or power plants); therefore, no baseline data is available. Given the absence of large sources of HAPs in the region, there is no reason to expect measurable concentrations in the project study area except what is biogenic in nature. Local practices of burning trash, generating power using diesel generators, and heating some homes using wood stoves could contribute to poor air quality indoors and outdoors. Unpaved roads are a major source of dust, and may circulate pollutants in dust, which affects air quality and may also settle on food sources. There are also indoor air quality issues with the use of old wood and fuel oil burning stoves, which may be made worse by spending a lot of time indoors in winter.

Water Quality. The baseline water quality data is provided in Section 3.18, Water and Sediment Quality. Baseline surface water resources in the vicinity of the mine site had numerous detections of naturally occurring trace elements/metals, which occasionally exceeded their maximum criteria, and while cyanide was only occasionally present in detectable concentrations, some detections were above maximum criteria.

Community drinking water wells are located within the transportation corridor; arsenic and pH were noted as above maximum drinking water standards in one or more of the community wells (Schlumberger et al., 2011a, Schlumberger, 2015b). Arsenic is a naturally occurring element in rock and soil, and often present in trace amounts in groundwater. Concentrations of arsenic in groundwater are generally associated with volcanic deposits and gold-mining areas, and high concentrations of arsenic in groundwater are largely the result of arsenic-containing minerals (e.g., iron-sulfide and copper-sulfide minerals) dissolving naturally over time from weathered rock and soils (Schlumberger et al., 2011a, Schlumberger, 2015b).

Potentially Hazardous Materials. There are numerous known contaminated sites within the EIS analysis area. The following summarizes the number of open Alaska Department of Environmental Conservation (ADEC) regulated contaminated sites listed for each of the boroughs within and in the vicinity of the EIS analysis area on ADEC's Contaminated Sites database, as of March 2018 (ADEC 2018d):

- Lake and Peninsula Borough – 30 open sites
- Bristol Bay Borough – 60 open sites
- Dillingham Census Area – 25 open sites
- Kenai Peninsula – 130 open sites

AMERICAN OVERSIGHT

In addition, there are four US Environmental Protection Agency Comprehensive Environmental Response, Compensation, and Liability Act sites in Anchorage (EPA 2018), as well as several USACE formerly used defense sites in the Lake and Peninsula Borough (4 sites) and the Kenai Peninsula Borough (10 sites). Contaminants of concern from these sites include, but are not limited to: metals, asbestos, polychlorinated biphenyls (PCBs), petroleum hydrocarbons (e.g., fuel, lubricants), pesticides, and solvents. All these sites are under active oversight by government agencies, and agency directives are expected to control or prevent exposure to the general public. Therefore, the proximity of these sites is not expected to contribute to the baseline exposure to hazardous materials.

In the core EIS analysis area, baseline trace element (metal) data (2004 to 2008) were collected for soil, vegetation, fish tissue, as well as sediment and surface water (BEESC 2011, Schlumberger et al., 2011a, Schlumberger, 2015b, TPP 2011a, TPP 2011b). These baseline data are provided and discussed in Section 3.14, Soils, Section 3.26, Vegetation, Section 3.24, Fish Values, and Section 3.18, Water and Sediment Quality. Exposure to these trace elements may have the potential to impact human health from direct exposure or through subsistence (i.e., some of these trace metals are considered bioaccumulative) and represents baseline hazardous exposure potential.

3.10.4.4 HEC 4: Food, Nutrition, and Subsistence Activity

As discussed in Section 3.3, Needs and Welfare of the People–Socioeconomics, the cost of living in Alaska is higher than the national average, while the price of food is comparatively high in small rural communities that are not connected to the Alaska main road system and instead rely on air and water transportation. For example, on an August 2018 visit to Iliamna, the price of a half-gallon of whole milk was $13.49, which is equivalent to $27 a gallon and is nearly nine times the 2017 national average price of $3.16 (Statistica 2018). Subsistence activities are a central feature of Alaska Native history and society, and support healthy diet and nutrition. Subsistence foods are vital in small rural communities, often the basis of many local economies. These foods are important for food security due to high cost of living/food in the region, and are widely recognized as healthier than market food options. Subsistence foods include fish (primarily sockeye and Chinook salmon), shellfish, game and wildlife (primarily moose and caribou), and plants and berries. Subsistence activities are also an important aspect of preserving cultural heritage and mental health. Subsistence activity is discussed in detail in Section 3.9, Subsistence.

McDowell Group 2018b presents nutrition and lifestyle baseline information for Lake and Peninsula Borough, Dillingham Census Area, and Bristol Bay Borough compared to Alaska's population overall. Percentages of physical activity and nutritional intake are similar between these communities and Alaska, with some noted differences. These communities report a higher subsistence lifestyle (74.1 to 79.5 percent) compared to Alaska's population overall (30.5 percent). Lake and Peninsula Borough and Bristol Bay Borough believe they have higher percentages of getting enough physical activity (74.3 and 73.2 percent, respectively) compared to Alaska overall (52 percent). Bristol Bay Borough is more likely to be overweight/obese according to body mass index (84.7 percent) and eat less than five daily servings of fruits and vegetables (90.8 percent) compared to Alaska overall (66.1 percent and 78.6 percent, respectively); while Dillingham Census Area reports higher servings of sugar drinks (48.6 percent) compared to Alaska overall (30.5 percent). See (HEC 7) for further baseline details on weight and physical activity (chronic disease contributing factors).

AMERICAN OVERSIGHT

3.10.4.5 HEC 5: Infectious Diseases

The role of infectious diseases in the mortality and morbidity rates of a population is well known. Reportable infectious diseases (i.e., influenza and pneumonia) were the tenth leading cause of death to all races in Alaska (ADHSS 2017a). Noteworthy are the conditions that promote the spread of infectious disease, such as unsafe water, poor personal hygiene, and unsanitary conditions. Other infectious diseases impact human health quality and mortality, including sexually transmitted infections, HIV, tuberculosis, septicemia, and viral hepatitis. Immunizations play an important role in decreasing the rates of infectious diseases. Table 3.10-4 presents the leading infectious disease rates for Alaska and regions, when available, as well as childhood immunization rates.

Table 3.10-4: Infectious Diseases

Infectious Disease Indicators (Period)	Bristol Bay Region	Kenai Region	Anchorage/ Mat-Su Region	Alaska	National
Influenza and Pneumonia (mortality age-adjusted rate per 100,000 population) (2012-2015)	--	--	--	21.3 (AN) 9.9 (non-AN)	15 (White)
Laboratory Confirmed Influenza (count) (2016-2017 Season)	165 (Southwest Alaska)		1309	3276	--
Tuberculosis (rate per 100,000 population) (2016)	--	--	--	37 (AN) 7.7 (all races)	2.9 (all races)
Chlamydia Cases (age-adjusted rate per 100,000 population) (2015)	1,728.3 (AN)	873.8 (AN)	2504.4 (AN)	1,653.8 (AN) 452.3 (non-AN)	187.2 (White)

The Bristol Bay Region includes the Lake and Peninsula Borough, Dillingham Census Area, Bristol Bay Borough, and surrounding area. Kenai Region includes Kenai Peninsula Borough and surrounding area.

Sources: ANTHC 2017a, 2017k; 2017l; 2017m; ADHSS 2017b, 2018; McDowell Group 2018b

AMERICAN OVERSIGHT

Some regional rates (i.e., mortality from influenza and pneumonia, tuberculosis rate, and immunization rates) are not readily available. This might be due to the low state rates (i.e., influenza/pneumonia mortality), privacy concerns, and/or tracking or reporting methodology.

3.10.4.6 HEC 6: Water and Sanitation

The lack of safe water supply (i.e., running water) and suitable sewage disposal can represent a major public health and community development problem. Lack of in-home water and sewer service in rural Alaska causes severe skin infections and respiratory illnesses. Residents of Southwest Alaska suffer rates of invasive pneumococcal disease that are among the highest in the world (ADEC 2018d). That would include areas in the Yukon-Kuskokwim Delta that are not near the project area. Prior to 2004, a large portion of rural Alaska communities were classified as "unserved Rural Alaska Communities," which is defined as a community having 45 percent or more homes that are not served by central wells, and have a mix of central sewage plumbing, septic systems, honey buckets, and outhouses.

In 2016, 83.5 percent of rural Alaska Native communities were served by water and sewer services (a significant increase since 2004). In the Bristol Bay Region (includes Bristol Bay Borough, Dillingham Census Area, and Lake and Peninsula Borough), 99 percent of households had water and sewer services. In the Kenai Peninsula, service was 100 percent (ANTHC 2017n).

3.10.4.7 HEC 7: Non-Communicable and Chronic Diseases

Non-communicable and chronic diseases consume a large part of healthcare resources and affect the overall health status of a population. McDowell Group et al. 2011a presents regional baseline rates for the leading causes of death for the Lake and Peninsula Borough and Dillingham Census Area for the period from 2006 to 2008.

The three recent leading causes of death due to non-communicable and chronic diseases were cancer, heart disease, and chronic obstructive pulmonary disease (COPD), including chronic lower respiratory disease (ADHSS 2017a; ANTHC 2017a). Cancer was one of the top two causes of death in the Lake and Peninsula Borough, while cancer and heart disease were the top two causes of death in the Dillingham Census Area. The three types of cancer with the highest incidence were colon/rectum (17.9 percent), lung (17.2 percent), and breast (15.1 percent) (ANTHC 2017a, o).

McDowell Group 2018b reports that the highest rate (per 100,000 individuals) of cancer incidence is colorectal cancer in the Lake and Peninsula Borough (107.7) and Dillingham Census Area (107.7), while the highest rate of cancer incidence is breast cancer in Bristol Bay Borough (213.7). Colorectal cancer and lung and bronchus cancer had the highest cancer mortality rates per 100,000 individuals in the Lake and Peninsula Borough (107.7 and 48.5, respectively), and the Dillingham Census Area (73.9 and 38.2, respectively). Most of these cancer incidence and mortality rates appear higher than those reported for Alaska overall: colorectal cancer incidence rate of 43.1, female breast cancer incidence rate of 125.6, and colorectal cancer mortality rate of 43.1; while Alaska's lung and bronchus cancer mortality rate (59.9) is higher.

Table 3.10-5 presents the recent average age-adjusted non-communicable and chronic disease mortality (death) rates for the three leading regional causes, as well as several chronic disease contributing factors.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

3.10.4.8 HEC 8: Health Services Infrastructure and Capacity

An important measure of the health-related resilience and support structure of a community is the quality and quantity of healthcare that is available to the residents.

Health Services. The baseline health services infrastructure and capacity information for the eight affected communities in the Lake and Peninsula Borough and at the regional level are presented in McDowell Group et al. 2011a. Baseline health services infrastructure for the eight Iliamna Lake/Lake Clark communities in the Lake and Peninsula Borough and the three Nushagak/Bristol Bay communities in the Dillingham Census Area were updated and presented in McDowell Group 2018b. McDowell Group 2018b also summarizes health access for Lake and Peninsula Borough, Dillingham Census Area, and Bristol Bay Borough. The Lake and Peninsula Borough and Bristol Bay Borough report lower or similar access to health plans, medical care, and a personal doctor compared to Alaska overall, but higher medical costs. The Dillingham Census Area reports lower or similar access to medical care, access to a doctor, and medical cost, but reports higher access to health plans than seen in Alaska overall.

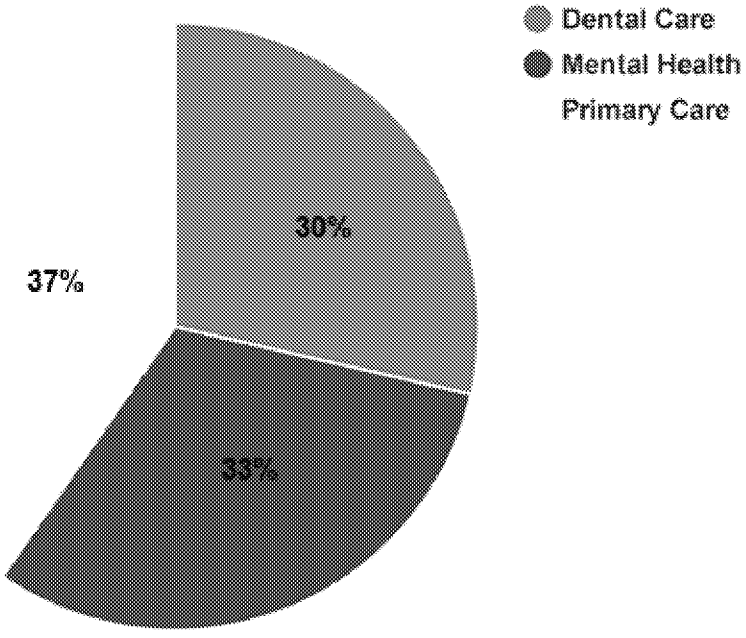
These health services findings are summarized on a more regional basis in Section 3.3, Needs and Welfare of the People–Socioeconomics. Healthcare services generally include small local clinics operated by regional providers. Access to the region and most of its communities is limited to small aircraft and boat.

Hospitalizations. The top three leading hospital discharges in the Lake and Peninsula Borough, Bristol Bay Borough, and Dillingham Census Area by diagnosis (2001 to 2005) were circulatory system, injury or poisoning, and digestive system (McDowell Group et al. 2011a). In 2015, the statewide leading causes of diagnosed hospitalizations were pregnancy/childbirth, respiratory diseases, and digestive system diseases (ANTHC 2016d). The following summarizes the leading causes of hospitalizations in 2016 (ADHSS 2017c) and 2017 (McDowell Group 2018b):

- Statewide – Pregnancy/childbirth, newborn/neonate conditions, musculoskeletal/ connective tissue diseases in 2016. Childbirth, septicemia (except in labor), and osteoarthritis in 2017.
- Southwest Region (includes Lake and Peninsula Borough, Dillingham Census Area, and Bristol Bay Borough) – Pregnancy/childbirth, newborn/neonate conditions, and respiratory diseases in 2016.
    - Lake and Peninsula Borough – Childbirth and other complications of birth, including postpartum care of mother in 2017.
    - Dillingham Census Area – Childbirth, septicemia (except in labor), pneumonia (except that caused by tuberculosis or sexually transmitted diseases), and alcohol-related disorders in 2017.
    - Bristol Bay Borough – Childbirth and alcohol-related disorders in 2017.
- Gulf Coast Region (includes Kenai Peninsula) – Musculoskeletal/connective tissue diseases/disorders, pregnancy/childbirth, and newborn/neonate conditions in 2016.
- Anchorage – Pregnancy/childbirth, newborn/neonate conditions, and musculoskeletal/ connective tissue diseases/disorders in 2016.

Although there are some variations in the top three leading causes of hospitalizations by year and region, pregnancy/childbirth and newborn/neonate complications of pregnancy and childbirth or newborn/neonate conditions are consistently leading causes.

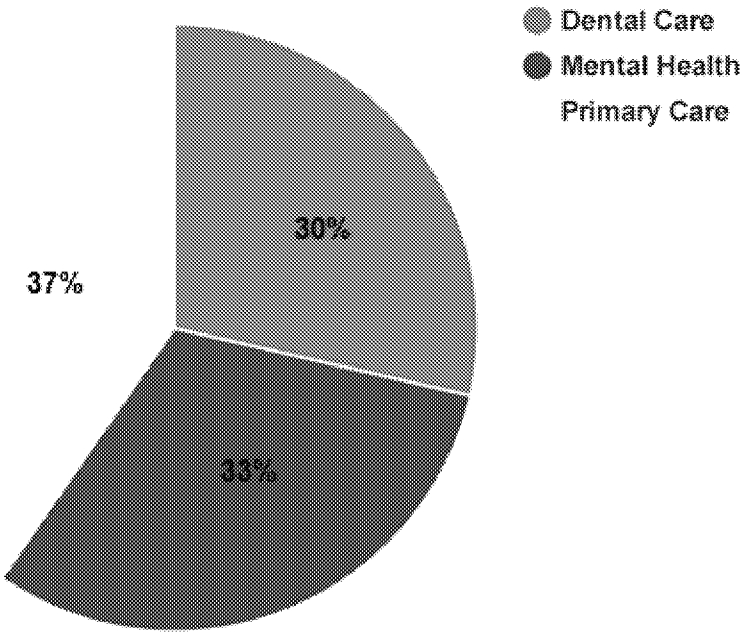
AMERICAN OVERSIGHT



Adequacy of Health Services. Areas may be designated as having health impact issues for the adequacy of the health services, designated as Health Professional Shortage Area (HPSA) and/or a Medically Underserved Area/Population (MUA/P). HPSA designation may be due to a shortage of primary medical care, dental, or mental health providers, while MUA/P designation may include groups of persons who face economic, cultural, or linguistic barriers to healthcare (HRSA 2018). The Lake and Peninsula Borough (with the eight communities closest to the core EIS analysis area), Dillingham Census Area, Bristol Bay Borough, Kenai Peninsula, and Anchorage are all designated as MUA/P (Dillingham Census Area and Kenai Peninsula Borough are designated MUA/P – governor's exception). Table 3.10-6 presents the HPSA ratings (out of 26) for these regions. The rating is used to establish the communities with the greater needs per shortage area, indicated by those communities with higher HPSA ratings.

Table 3.10-6: Health Professional Shortage Area Ratings

Shortage Area	Lake and Peninsula Borough	Bristol Bay Borough	Dillingham Cenus Area	Kenai Peninsula Borough	Anchorage Borough
Primary Care	--	15-17	13-17	8-18	3-21
Dental Care	16	0-16	16-20	6-23	6-20
Mental Health	14	14-16	14-20	15-21	6-20



Notes: -- = Not listed.

Figure 3.10-1: Health Professional Shortage Areas by Discipline in Alaska

It should be noted that these designations are most directly comparable when the populations are similar; otherwise, a relatively low population area such as the Lake and Peninsula Borough may appear to have less "need" than a densely populated area when the difference may be more due to the population disparity than the actual "need." Furthermore, comparing a community to a larger region or state would not be meaningful since the region or state value represents a sum total that includes the communities.Figure 3.10-1: Health Professional Shortage Areas by Discipline in Alaska

3.11 AESTHETICS RESOURCES

This section describes the existing conditions against which the potential effects of a project will be assessed, pertinent regulatory and management framework, and information about the regional and project landscape. Aesthetic attributes addressed in the assessment focused on perceptual elements of visual environment, including night sky and soundscape. Aesthetics can refer to the perception of beauty by one or a combination of the senses, and can apply to the quality of life enjoyed by the general public and property owners (40 Code of Federal Regulation [CFR] 230.53).

3.11.1 Environmental Impact Statement Analysis Area

The aesthetic resources analysis area extends westward from Happy Valley on the Kenai Peninsula and the Bristol Bay and Cook Inlet drainages to the eastern side of the Iniskin Peninsula, encompassing Iliamna Lake and the surrounding communities. The analysis area includes a 50-mile radius from the mine site; 15-mile radius from the ferry terminals, 20-mile buffer from the transportation corridor and natural gas pipeline, and 25-mile radius around Amakdedori port.

3.11.2 Methods for Establishing Baseline Conditions

Baseline visual resource conditions were established by: 1) implementing a viewshed analysis to determine locations where the project could be visible (i.e., seen areas); 2) completing a regulatory and management review; 3) assessing landscape character attributes, viewer groups and related visual sensitivity, and visual distance zones (visibility) in the analysis area; and 4) assessing baseline soundscape.

3.11.2.1 Regulatory and Management Framework

The regulatory and management framework review included federal, state, and local planning documents for planning areas with geographic nexus to the project area. The review focused on identifying specific regulations or planning objectives pertaining to visual resources or scenery management.

3.11.2.2 Viewshed Analysis

Locations from which the project could be seen in the analysis area were determined by implementing a viewshed analysis using geographic information system (GIS). This analysis determines project visibility based on the relationship between topography, height of project components, average eye height of the viewer, and height of vegetation. The resulting "seen area" represents an area that may contain views of proposed project features. However, it does not represent any measure of detectability of these features.

Viewshed analyses were performed for the following project components: mine site (including the tailings storage facility [TSF] main embankment, the TSF south embankment, and the course or stockpile), north ferry terminal, south ferry terminal, Amakdedori port, Kenai compressor station, north road corridor, and south road corridor. Models were developed using assumptions of bare earth (i.e., not considering the potential screening effects of vegetation) and vegetation for Alternative 1, and bare earth only for Alternatives 2 and 3, at a viewer height of 5 feet 5 inches. The completed viewshed analyses are in Appendix K4.11.

AMERICAN OVERSIGHT

3.11.2.3 Landscape Character

Landscape Character: Landscape character attributes were assessed by first dividing the analysis area into geographic units defined by prevailing physiography (Wahrhaftig 1965), then assessing landscape character in each geographic unit. Landscape character attributes were described in terms of landscape character typology; the basic elements of form, line, color, and texture of prevailing landform, water, vegetation, and cultural modification. This approach was applied across the analysis area to ensure that baseline data in visual resources were collected consistently across all jurisdictions.

Viewer Groups and Visual Sensitivity: Viewer groups were identified through coordination with recreation, cultural, and subsistence resources, as well as review of scoping comments. These sources were used to understand how specific locations in the analysis area are used, and the types of viewer groups that may be associated with those uses. Characteristics of identified viewer groups, such as seasonality, amount of use, and predominant viewer activity were included in this inventory.

Distance Zone: Project visibility, or distance zones, was assessed by subdividing into three zones based on relative distance from travel routes or observation points. Common travel routes included common commercial flight paths and common local flight paths. Distance zones were classified as: foreground (0 to 0.5 mile from view point), middleground (0.5 mile to 5 miles), and background (over 5 miles). Visual clarity applies to all distance zones.

3.11.2.4 Key Observation Points

Key Observation Points (KOPs) representing common and/or sensitive viewer locations were established in the analysis area. These locations represent point-based (vistas), linear (roadways), and area-based viewer locations characterized by residential, subsistence or recreational uses discussed above. The KOPs were used as standard locations from which to describe existing visual resources at a localized scale, and to assess potential effects that may result from the proposed project. KOPs are listed in Table 3.11-1 and shown in Figure 3.11-1.

3.11.2.5 Soundscape

Soundscape was evaluated using a noise receptor analysis from 10 miles around the mine site infrastructure, and from 0.5 miles around the pipeline work area at Happy Valley, the transportation corridor (proposed new access roads), the north and south ferry terminals, and Amakdedori port infrastructure (See Section 3.19, Noise).

3.11.3 Regulatory and Management Framework

3.11.3.1 Federal

Clean Water Act 404(b)(1), Section 230.53 Aesthetics

(a) Aesthetics associated with the aquatic ecosystem consist of the perception of beauty by one or a combination of the senses of sight, hearing, touch, and smell. Aesthetics of aquatic ecosystems apply to the quality of life enjoyed by the general public and property owners.

3.11.3.2 State

The project area is located in the Alaska Department of Natural Resources Bristol Bay and Kenai planning units. These areas are managed per the Bristol Bay Area Plan (ADNR 2013a) and the Kenai Area Plan (ADNR 2001), respectively, to “maintain the quality and diversity of the

AMERICAN OVERSIGHT

natural environment and protect heritage resources and the character and lifestyle of the community."

The project area also takes into account lands owned by seven Alaska Native Claims Settlement Act (ANSCA) corporations. ANSCA does not provide provisions for the protection or management of visual resources; however, individual landowners may implement such management policies.

3.11.4 Landscape Character

The landscape setting in the visual resources analysis area includes mountain ranges surrounded by river valleys, rivers, shrub tundra, marshy lowlands, wetlands, coastal shoreline, estuaries, and ocean inlet environments. Primary river drainages intersecting the analysis area include the Mulchatna, the Nushagak, and Koktuli rivers. The waterways provide access to remote recreation and subsistence use areas. Human development in the analysis area is generally limited to areas in and around geographically isolated communities and small fishing and hunting lodges. Development includes roads, airstrips, and docks.

3.11.4.1 Regional

The visual resources analysis area falls within portions of four different physiographic units: Nushagak–Big Hills, Nushagak–Bristol Bay Lowland, Aleutian Range, and Alaska Range (Wahrhaftig 1965). The landscape character of each physiographic unit is influenced by the fluvial geomorphologic, hydrologic, vegetation cover, elevation, and landforms.

The **Nushagak—Big River Hills** are characterized by flat-topped ridges ranging in elevation from 1,500 feet to the west, 2,500 feet to the east, and 4,200 feet to the north. The Big River Hills unit drains to the Kuskokwim River from primary tributaries. The southern section of the physiographic unit drains to the Mulchatna and Nushagak rivers. Vegetation communities consist of spruce, birch, and cottonwoods along riparian corridors (Shacklette et al. 1969, ADNR 2005).

The **Nushagak—Bristol Bay Lowland** is dotted with moraine lakes rising from sea-level to an altitude of 300 to 500 feet at its high point. Linear narrow belts of elevated topography enclose large glacial lakes fed by upland hydrology. The lowland is drained by the Nushagak River and other rivers flowing to the estuaries of Bristol Bay. This physiographic unit is of the marine phase of the tundra climate with mild winters and short, cool summers. Dominant vegetation includes moist wet tundra plant communities. Standing water, mosses, sedges, and low-growing shrubs cover the landscape with clumping stands of alder, willow, and patches of stunted spruce and birch growing along the riparian edges of major streams and rivers (Shacklette et al. 1969, Bailey 1995).

The **Aleutian Range** consists of heavily glaciated U-shaped valleys, rugged ridges, and mountain peaks anchored between the Pacific Ocean and the Bering Sea. It runs west to Aleutian Island with an elevation ranging from 1,000 to 4,000 feet. The Aleutian Range is flanked by large volcanic peaks elevating upward to 8,500 feet. Steep rivers drain south to the Pacific Ocean, while braided meandering rivers run slowly to the Bering Sea. The west end of the Aleutian Range drains into the Bristol Bay Lowland, feeding hundreds of small lakes and ponds. Vegetation is sparse and consists of spruce, birch, and cottonwoods along riparian corridors and a spattering of open low-shrub tundra as the elevation increases (Shacklette et al. 1969, Kevin Waring & Associates 2015a).

To the east, the **Alaska Range** connects with the Aleutian Range between Iliamna Lake and Mount Spurr. The mountain range extends over 600 miles to the Canadian border. The heavily

AMERICAN OVERSIGHT

glaciated mountain ranges average between 7,000 and 10,000 feet in elevation with a number of peaks exceeding 10,000 feet. The Alaska Mountain range is the divide for rivers flowing from the Yukon Territory south to the Gulf of Alaska. The southern section drains through glacial streams to the Kuskokwim River and to the Nushagak or Kvichak rivers, eventually flowing into Bristol Bay (Shacklette et al. 1969, Kevin Waring & Associates 2015a).

3.11.4.2 Analysis Area

Mine Site

The proposed mine site would be located in the southern section of the Nushagak–Big River Hills physiographic unit. The landscape is large in scale, characterized by the rugged Sharp, Pig, Kaskanak, and Groundhog Mountains that appear prominent and distinct from the surrounding lowlands and Iliamna Lake.

Views from ridgetops are largely panoramic; however, there is more enclosure in drainages and low elevation areas. Topography is dominated by numerous rounded hills that appear as consistent and well-defined by the converging lines of drainages. As elevation increases, trees become stunted and vegetation becomes intermixed with short alpine tundra and exposed rock outcrops.

The upper sections of Talarik Creek and the Koktuli rivers meander through eroded, braided wetlands and tundra flowing into Iliamna Lake to the Kvichak River, before draining into Bristol Bay. The Talarik Creek floodplain is characterized by exposed flat grasslands and low sand dunes created from strong winds with little diversity of vegetation. These river systems not only provide habitat for salmon, but also provide important travel routes to remote areas for subsistence use in the summer and winter.

Viewer groups in this area are limited to individuals engaged in subsistence or recreation activities. These individuals experience the landscape from fixed points while fishing or viewing wildlife and can be transient as they move through the landscape on foot, snowmachine, or aircraft. Small aircraft are used to provide access for fishing and hunting areas, and to a lesser extent, provide tours for nature viewing. Areas on the flight paths provide an expansive view of the landscape settings. During winter months, overland travel (via snowmachine) is common as the ground is frozen.

Amakdedori Port

The proposed Amakdedori port site is located on state lands designated for habitat use in the Kenai Peninsula Borough area boundary. The area located to the northern end of the Aleutian Range is considered wet shrub tundra, collecting runoff forming wet meadows, bogs, and hundreds of small lakes.

This area is noteworthy because of its close proximity to Katmai National Park and Preserve, the McNeil River State Game Sanctuary, Kamishak Bay, and the steep mountain peaks of Katmai National Park and Preserve.

As described in Section 3.5, Recreation, the McNeil State Game Refuge and Sanctuary is a premier destination for bear viewing and is home to one of the largest bear populations in Alaska. McNeil River Falls, which is located about a mile from the mouth of the McNeil River, slows the movement of salmon. Large numbers of brown bears can be seen at McNeil State Game Refuge and Sanctuary in early July through mid-August (ADF&G 2018b).

Viewer positons take into account the elevation and whether the viewer is in a fixed or a moving status. Private outfitters run single and multi-day commercial tours to Katmai National Park and

AMERICAN OVERSIGHT

Preserve from May through September. Single day adventure tours are offered from as far away as Anchorage, and as close as Dillingham.

Single day tours are almost exclusively accessed via aircraft. Visitors are flown into the park over the proposed project area to access bear viewing locations along the coastline, in the estuaries and up the stream corridors and over the glaciers of Four Peaks Mountain. Multi-day commercial tours either stage outside the park on large boats in Kamishak Bay, or at lodges in the park.

Transportation Corridor

The proposed transportation corridor is a linear system that cuts through the Nushagak-Big River Hills, and Nushagak-Bristol Bay Lowland physiographic units.

Iliamna Lake sits in the Bristol Bay Lowlands, southwest of Lake Clark National Park and Preserve and the northwestern edge of the Alaska Range. Iliamna Lake is approximately 100 miles long by 30 miles wide and is the largest fresh water lake in Alaska. The shallow shoreline is made up of long, fine edges, meandering inlets, and checkered islands. The low topographic relief provides extensive panoramic views extending across the tundra to Iliamna Lake. In the immediate foreground, the wet shrub tundra presents limited obstruction to vast views of the surrounding landscape. To the west is the Bristol Bay lowlands made of wet shrub tundra, marsh lands and hundreds of small lakes. Northern views feature the rounded mountains of the Nushagak–Big River Hills.

From Iliamna Lake the viewing position is either from the shoreline or from a boat on the water. Access to the surrounding landscape for commercial, subsistence, and recreation uses are through the main airport and community of Iliamna. Air transportation is a prominent form of travel in the area. From the elevated position in an aircraft, the viewer can relate to the expansive, undisturbed landscape setting. There is minimal lighting visible from the existing communities, which primarily seen in the winter months when there is limited daylight.

Flowing into Iliamna Lake from the north is the Lower Talarik Creek. The State of Alaska established the Lower Talarik Creek Special Use Area in 1999 as a high value resource for fish and wildlife habitat and subsistence harvest, as well as local and commercial recreation.

Lake Clark National Park and Preserve is located to the north and east of the transportation corridor access roads, at the northwestern edge of the Alaska Range. The park is the start of the long string of mountains tied together through glaciers and snow covered peaks. The features are viewed by aircraft while traveling in and out of the park, and local communities.

Roadhouse Mountain is a popular summer all-terrain vehicle (ATV) route that is located to the southwest of the mine site along the border of Lake Clark National Park and Preserve and the north end of Iliamna Lake. Expansive 360 degree panoramic views dominate the viewer experience from the top of Roadhouse Mountain. Significant visual features include Iliamna Lake and its distinct shoreline. The marshy wet lowlands and the river valleys of the Nushagak–Big River Hills dominate the foreground view while Sharp, Groundhog, and Kaskanak mountains frame the background views.

As shown in Figure 3.2-1A, the Alagnak River is designated as a Wild River in the Wild and Scenic River System. The Alagnak River is located about 30 miles west of the proposed mine site and 10 miles from Iliamna Lake. The Alagnak River provides opportunities for exemplary Alaska recreation due to remoteness, scenery, and sport fisheries. The Alagnak River is accessed by aircraft and from the west side of Katmai National Park and Preserve. The river has a reputation of being a world-class fishery and is considered to be one of the most popular fly-in fishing destinations in southwest Alaska.

AMERICAN OVERSIGHT

Natural Gas Pipeline

The pipeline would interface with the entire physiographic unit system tying the Cook Inlet–Susitna Lowlands to the Nushagak–Big River Hills. The Sterling Highway winds its way along the steep shoreline of Susitna Lowlands, terminating in the town of Homer. Vast panoramic views of the Cook Inlet and the rocky beaches are consistent along this linear corridor. The area is populated with residents, recreationists, and tourists and commercial operators using the Cook Inlet and Kenai Peninsula as base to access the natural and remote setting of Bristol Bay, Iliamna Lake, and the national parks and preserves.

3.11.5 Viewer Groups and Visual Sensitivity

There is seasonal variation in the number and type of viewers in the analysis area. According to Section 3.5, Recreation, a majority of visitors come to experience the "naturalness" and "abundance of resources" from May through October. This seasonal access corresponds with fishing and hunting activities and is the high season for recreation, tourism, and subsistence activities. Access to fishing and hunting grounds for recreation and subsistence use is from air travel, boat, and ATVs.

Although the majority of recreation and tourism occurs in the summer, ongoing subsistence activity and inter-village travel occur in the winter. As the wet grounds freeze, travel via snowmachine provides access to areas not available in the warmer seasons. Commercial activities consist of fisheries, recreation, and tourism.

Commercial recreation fishing lodges and camps are located on the Kvichak and Alagnak rivers. Several lodges on the main stem of the Alagnak, at the outlet of Nonvianuk Lake, and one on the Kulik River, provide guided fishing services. Together these lodges support the majority of the visitation for fishing in the area. Access to the fishing lodges and camps is through aircraft or motorized boat transportation. The elevated position provides a contextual experience, allowing the viewer to see broad expanses of the landscape.

Viewer groups in the analysis area include local residents and communities, as well as those engaging in subsistence activities, recreationists, and travellers.

Local Communities. Local communities are located throughout the analysis area. Communities along the shoreline of Iliamna Lake consist of Iliamna, Newhalen, Pedro Bay, Kokhanok, and Igiugig. To the north, at the edge of Lake Clark National Park and Preserve, is the community of Nondalton. The landscape is dominated by vast panoramic views of Iliamna Lake, with a backdrop of the mountains of the Big River Hills.

Subsistence Areas. See Section 3.9, Subsistence, for subsistence activity locations. Summer access to these areas is primarily by boat, aircraft, and ATV, while in winter travel predominantly follows the frozen rivers and tundra by snowmachine. Air travel is also prevalent in the throughout the year.

Recreation Areas. Recreation extends from the fishing camps along Iliamna Lake into Lake Clark National Park and Preserve, Katmai National Park and Preserve, and up the Koktuli River Watershed and into the tundra of the Big River Hills. Outfitters provide guide service from fishing and hunting camps to remote locations in the Big River Hills and fishing areas on Iliamna Lake and Kamishak Bay in the Cook Inlet.

Transportation Routes. Several transportation routes used by industry, local communities, and subsistence and recreation users are limited to air travel, boat, ATV, and snowmachine. Short unimproved roads connect the communities of Newhalen and Iliamna to Nondalton in the winter,

AMERICAN OVERSIGHT

although in the summer that route involves an impassable river crossing. In the winter, there are transportation routes across Iliamna Lake or along its shores between the lake communities.

Air Travel. Low-altitude local aircraft may fly over the project area during scheduled air service or in route to remote communities or hunting/fishing destinations.

3.11.6 Key Observation Points

A total of 12 KOPs were identified for use in the analysis as described in Table 3.11-1 and shown in Figure 3.11-1.

3.11.7 Soundscape

There is no known residential land use or other type of noise-sensitive receptor within 10 miles of the mine site and its facilities. However, subsistence users and recreationists may be temporarily present in any of the management areas in the analysis area. The existing ambient noise level is estimated to be comparable to "wilderness ambient" (see Section 3.19, Noise), and thus, 35 decibel day-night average noise level (L_{dn}).

AMERICAN OVERSIGHT

3.25 THREATENED AND ENDANGERED SPECIES

Note: This section will be updated with 2018 environmental baseline field survey results for the Draft EIS.

This section covers threatened and endangered species listed under the federal Endangered Species Act (ESA)(16 United States Code [USC] Section 1531 et seq.) of 1973 that occur, or are likely to occur, in the project area. The ESA provides for conservation of fish, wildlife, and plant species considered to be at risk of extinction (threatened or endangered) in all or a substantial portion of their ranges, and to conserve the ecosystems and habitats upon which they depend. The US Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) share regulatory authority for implementing the ESA for threatened and endangered species potentially affected by the project and alternatives. The federally listed species known or with a potential to occur in the project area are described herein based on a review of scientific literature and wildlife surveys conducted as part of the environmental baseline survey program. Marine mammal species with NMFS oversight are discussed first, followed by the marine mammal and avian species managed by the USFWS.

Additionally, to comply with the ESA, the US Army Corps of Engineers (USACE) is in the process of preparing biological assessments to assess the potential impacts that a federal action may have on federally listed species or critical habitat. Note: The biological assessments and any resulting consultation documentation will provide a greater level of detail and will be referenced in this Environmental Impact Statement once complete.

3.25.1 Action Alternative 1 – Applicant's Proposed Alternative

3.25.1.1 Cook Inlet Beluga Whale

Stock Identification and Abundance

The Cook Inlet beluga whale stock (CIBS) occurs in the project area and is the most isolated of the five recognized beluga whale stocks (Laidre et al. 2000). The Cook Inlet beluga whale population was designated as depleted under the Marine Mammal Protection Act (MMPA) in 2000 (NMFS 2000a). In 2006, NMFS announced initiation of another Cook Inlet beluga whale status review under the ESA (NMFS 2006). NMFS issued a decision on the status review on April 20, 2007, concluding that the Cook Inlet beluga whale is a distinct population segment (DPS), in danger of extinction throughout its range; NMFS issued a proposed rule to list the Cook Inlet beluga whale as an endangered species (NMFS 2007a). The Cook Inlet beluga whale population was listed by NMFS as endangered under the ESA on October 17, 2008 (NMFS 2008b). NMFS published the Cook Inlet Beluga Whale Recovery Plan in 2016 (NMFS 2016b), as required by ESA, as well as the Final Conservation Plan (NMFS 2008a) as required by the MMPA. According to the annual abundance surveys conducted every June and August since 1999, the Cook Inlet beluga whale population has continued to decline at a rate of approximately 0.4 percent per year (Shelden et al. 2017).

Critical Habitat

NMFS announced the designation of critical habitat for the CIBS on April 8, 2011 (NMFS 2011, Figure 3.25-1). Critical habitat includes two areas: Critical Habitat Area 1 and Critical Habitat Area 2, which encompass approximately 7,804 square kilometers, collectively, of marine and estuarine habitat in Cook Inlet (NMFS 2011).

AMERICAN OVERSIGHT

Critical Habitat Area 1 consists of approximately 1,911 square kilometers and encompasses all marine waters of Cook Inlet north of a line connecting Point Possession and the mouth of Three Mile Creek, including waters of the Susitna, Little Susitna, and Chickaloon rivers below mean higher high water. Critical Habitat Area 1 does not overlap with the project area.

Critical Habitat Area 2 consists of approximately 5,892 square kilometers south of Critical Habitat Area 1, includes nearshore areas along western Cook Inlet and Kachemak Bay, and does overlap with the project area (Figure 3.25-1). Critical Habitat Area 2 includes fall and winter foraging and transit habitat for beluga whales, as well as spring and summer habitat for smaller concentrations of beluga whales (NMFS 2011). This area consists of less concentrated spring and summer beluga use; however, it includes known fall and winter feeding and transit areas.

Habitat Use and Distribution

The CIBS remains in Cook Inlet throughout the year (Goetz et al. 2012), although Rugh et al. (2010) documented a significant northward contraction in the early summer range of Cook Inlet beluga whales since the 1970s (Shelden et al. 2016; NMFS 2016b). During ice-free months, Cook Inlet beluga whales are typically concentrated near river mouths (Rugh et al. 2010). NMFS has conducted aerial surveys to estimate abundance of the beluga population in Cook Inlet every June, July, or both from 1993 to 2012. Biennial surveys began in 2014, which have included the project area. Results of these surveys indicate that the majority of Cook Inlet beluga whales have been concentrated in shallow areas near river mouths north of the project area, not occurring as frequently in the central or southern portions of Cook Inlet (Shelden et al. 2017). The concentration of beluga whales in the northernmost portion of Cook Inlet appears to be consistent from June to October (Rugh et al. 2000, 2004, 2005, 2006, 2007).

The primary foraging locations of the CIBS include the Susitna River Delta (the Big and Little Susitna rivers), Eagle Bay, Eklutna River, Ivan Slough, Theodore River, Lewis River, and Chickaloon Bay and River (NMFS 2008a; NMFS 2016b). All of these locations are considerably north of the project area. The CIBS feeds on a wide variety of prey species including eulachon (*Thaleichthys pacificus*) and gadids (e.g., Pacific cod [*Gadus macrocephalus*], Saffron cod [*Eleginus gracilis*], and walleye pollock [*Theragra chalcogrammal*]).

The fall/winter/spring distribution of this stock is not fully determined; however, there is evidence that most whales in this population inhabit upper Cook Inlet year-round (Muto et al. 2017). Satellite location data found 70 to 100 percent of 20 tagged whales were in the lower to middle inlet (i.e., south of Point Possession and the North Forelands) from January through March; these tagged whales rarely traveled south of the Forelands (Ezer et al. 2013), indicating that winter distribution is north of the project area. However, this small sample size may not be indicative of the population as a whole. The satellite telemetry used by NMFS to track the movements of belugas from September 2000 through March 2003 provided detail on seasonal movements and habitat use. None of the 14 belugas tagged in that study moved south of Chinitna Bay (Hobbs et al. 2005), which is notably north of the project area; however, this small sample size may not be indicative of the population as a whole. NMFS aerial surveys have not reported beluga whale sightings south of Tuxedni Bay (Shelden et al. 2015). In the fall, as anadromous fish runs begin to decline, belugas return to consume resident fish species (e.g., cod and groundfish) found in nearshore bays and estuaries. Groundfish include Pacific staghorn sculpin (*Leptocottus armatus*), starry flounder (*Platichthys stellatus*), and yellowfin sole (*Pleuronectes asper*).

AMERICAN OVERSIGHT

Figure 3.25-1: Federally Listed Wildlife Species Habitat in Cook Inlet

AMERICAN OVERSIGHT

3.25.1.2 Humpback Whale

Stock Identification and Abundance

Humpback whales were designated as endangered under the ESA in 1973 (35 Federal Register [FR] 18319). No critical habitat has been designated for the humpback whale. In 2013, NMFS published a 90-day finding to identify the Central North Pacific population of humpback whales as a DPS under the ESA, and recommended that this DPS be delisted from the ESA based on population abundance (NMFS 2013c). On September 8, 2016, NMFS revised the listing status of the humpback whale. NMFS divided the globally listed species into 14 DPSs, removing the current species listing and replacing it with four endangered DPSs (Cape Verde Islands/Northwest Africa, Western North Pacific, Central America, and Arabian Sea), and one threatened DPS (Mexico). The remaining nine DPSs did not warrant listing. Critical habitat for the three DPSs found in US waters (Western North Pacific, Central America, and Mexico) has not been determined (NMFS 2016c). Only the Central North and Western North Pacific stocks could be present in the project area.

Habitat Use and Distribution

North Pacific humpbacks spend the winter mating and calving in the subtropical and tropical waters of the Northern Hemisphere and the Southern Hemisphere. In the spring, humpback whales migrate north and feed in the prey-rich, sub-polar waters of southern Alaska, British Columbia, and the southern Chukchi Sea. Individuals from the Western North Pacific (endangered), Hawaii (not listed under the ESA), and Mexico (threatened) DPSs migrate to areas near and potentially in the project area; however, most of the individuals that migrate to the Gulf of Alaska, Cook Inlet area are likely from the Hawaii DPS and not the Western North Pacific or Mexico DPSs (NMFS 2017c). The Mexican DPS breeds along the Pacific coast of Mexico, the Baja California Peninsula, and the Revillagigedos Islands, and feeds across a broad range from California to the Aleutian Islands (Muto et al. 2017). The Hawaii DPS breeds in the main Hawaiian Islands and feeds in most of the known feeding grounds in the North Pacific, particularly Southeast Alaska and northern British Columbia (Muto et al. 2017). The western North Pacific DPS breeds in the areas of Okinawa, Japan and the Philippines, and feeds in the northern Pacific, primarily off the Russian coast (Muto et al. 2017).

Humpback whales have been observed during the NMFS beluga whale aerial surveys conducted in Cook Inlet from 2000 to 2016. These surveys occurred in or adjacent to the project area, but most sightings occurred outside of the project area near Augustine, Barren, and Elizabeth islands (Shelden et al. 2013, 2015, 2017).

Primary foraging areas for humpback whales in the Gulf of Alaska region are south of the project area including the waters east of Kodiak Island (the Albatross and Portlock), waters along the southeastern side of Shelikof Strait, and in the bays along the northwestern shore of Kodiak Island (Ferguson et al. 2015).

3.25.1.3 Fin Whale

Stock Identification and Abundance

Fin whales were listed as endangered under the ESA in 1973 (35 FR 18319; July 30, 1970). No critical habitat has been designated for the fin whale. For management purposes, NMFS divided fin whales in United States waters into several management units or "stocks." One of these stocks, the Alaska (Northeast Pacific), occurs in Alaskan waters. The Northeast Pacific stock is seasonally found off the coast of the Chukchi and Bering seas and the Gulf of Alaska during the

AMERICAN OVERSIGHT

summer (Muto et al. 2017). The closest dedicated surveys aimed at estimating the abundance of fin whales occurred in the Gulf of Alaska in 2013 and 2015, with an abundance estimate of 3,168 fin whales (Rone et al. 2017). There are no abundance estimates for fin whales in Cook Inlet or the project area.

Habitat Use and Distribution

Fin whales range across the entire North Pacific Ocean from April to October in both pelagic and shelf waters, and especially use shelf edge upwelling and mixing zones. Fin whales have been acoustically detected in the Gulf of Alaska year-round, with highest acoustic detections rates from August through December, and lowest call occurrence rates from February through July (Moore et al. 2006; Stafford et al. 2007). In July and August, they concentrate in the Bering Sea / eastern Aleutian area (Mizroch et al. 2009) and are regularly seen in the Gulf of Alaska (Muto et al. 2017). Results from a study off the Kenai Peninsula and the central Aleutian Islands indicate that fin whales occurred primarily from the Kenai Peninsula to the Shumagin Islands, but were abundant near the Semidi Islands and Kodiak (Zerbini et al. 2006).

Fin whale sightings in Cook Inlet are rare (NMFS 2017b). The NMFS beluga whale aerial surveys from 1993 through 2016 report only 10 fin whales scattered offshore between Anchor Point and Cape Douglas, mostly near the mouth of Cook Inlet and south of the proposed natural gas pipeline corridor. Panigada et al. (2006) found water depth to be the most significant variable in describing fin whale distribution, with more than 90 percent of sightings occurring in waters deeper than 2,000 meters. As fin whales are very rare in Cook Inlet and specifically in the project area, they are not expected to be encountered during project operations.

In January and February, fin whales have been sighted in the Aleutian area and Bering Sea. In March, concentrations of fin whales have been seen around Kodiak Island and in the Bering Sea. In April, sightings are generally concentrated around Kodiak Island. In May through July, sightings indicate high use of the Gulf of Alaska, and in June and July the Bering Sea; August data show fewer sightings in the Gulf of Alaska. In September and October, sightings indicate that fin whales are in the Bering Sea and the Gulf of Alaska. In November, fin whales are still observed in the Kodiak region, while in December, sightings in Alaska have not been documented (Uhen and Kwon 2007).

3.25.1.4 Steller Sea Lion

Stock Identification and Abundance

Steller sea lions inhabit waters of Alaska year-round; however, large numbers of individuals may widely disperse from concentrated breeding areas and rookeries after the breeding season (late May through early July), likely to access seasonally important prey resources (Muto et al. 2017). NMFS listed the Steller sea lion as a threatened species under the ESA in 1990 (NMFS 2013b). In 1997, NMFS designated the Western DPS as endangered (NMFS 1997a). The 2016 Stock Assessment Report lists a minimum population estimate of 50,983 for the Western DPS (Muto et al. 2017). NMFS reclassified Steller sea lions as two DPSs under the ESA based on genetic studies and phylogeographical analyses from across the sea lions' range (NOAA 1997a). The Eastern DPS consists of sea lions breeding to the east of Cape Suckling (144°W longitude), and the Western DPS consists those animals breeding to the west of Cape Suckling (144°W longitude; NMFS 2013a). This document only discusses the Western DPS Steller sea lions, as the range includes the project area in the lower Cook Inlet. Animals in this region are further classified for purposes of population analysis into regions; those animals that typically use the waters surrounding the project area are part of the central Gulf of Alaska region.

AMERICAN OVERSIGHT

Habitat Use and Distribution

Steller sea lions occur in lower Cook Inlet, south of Anchor Point around the offshore islands, and rarely north of Nikiski (NMFS 2008c; Shelden et al. 2017). Steller sea lions have been observed during NMFS beluga aerial surveys conducted in Cook Inlet from 2000 to 2016; sightings of Steller sea lions occurred outside of the project area on land in the mouth of Cook Inlet (i.e., Elizabeth and Shaw Islands to the south of the project area) (Shelden et al. 2013, 2015, 2017).

NMFS designated Steller sea lion critical habitat on August 27, 1993 (NMFS 1993). Steller sea lion critical habitat does not overlap with the project area.

The Western DPS of Steller sea lion habitat extends along Alaska's southern coast (NMFS 2008c) including the coastline adjacent to the Amakdedori port site; therefore, individuals from the Western DPS are expected to occur in the project area, as the center of abundance for the Western DPS is considered to extend from Kenai to Kiska Island (NMFS 2008c). The range of the Western DPS includes 38 rookeries and hundreds of haul-out sites.

Steller sea lions feed on a variety of demersal, semi-demersal, and pelagic prey indicative of a broad spectrum of foraging behaviors likely based primarily on prey availability (NMFS 2010). Greg and Trites (2008) determined that juvenile and female Steller sea lions particularly forage relatively close to rookeries and haul-outs, all south of the project area.

The few surveys of Steller sea lions from 2004 to 2008 show little pronounced spatial patterns other than consistent occurrence in the Iniskin Islands. Steller sea lions were observed hauling-out on islands near and off the mouths of Iliamna and Iniskin bays (ABR 2011d), north of the project area. Historical data from aerial herring surveys conducted by the Alaska Department of Fish and Game (ADF&G) in the spring suggest a long-standing preference of the Iniskin Islands by sea lions, with smaller numbers of animals scattered elsewhere throughout the study area. In offshore waters, Steller sea lions occurred along the open coastline between Iliamna and Iniskin bays, north of the proposed project port location at Amakdedori Point.

3.25.1.5 Northern Sea Otter

Stock Identification and Abundance

Three sea otter populations are recognized in Alaska: Southcentral, Southwest, and Southeast. Two stocks occur in Cook Inlet, the Southwest and the Southcentral; the dividing line between the two stocks is an arbitrary line in a north-south direction in the middle of Cook Inlet. Only the Southwest stock occurs in the proposed Amakdedori port area. The Southwest DPS was listed as threatened under the ESA on August 5, 2005 (NMFS 2005) and is classified as a strategic stock under the MMPA (USFWS 2014a). The Southwest DPS range extends along the western shore of lower Cook Inlet (USFWS 2014a). Critical habitat management Unit 5, Kamishak Bay, is the only unit that includes the project area (Figure 3.25-1). The estimated size of Unit 5 is approximately 6,752 square kilometers (USFWS 2009). The greatest proportion of the critical habitat area within the project area is comprised of waters within the 20 meter isobath.

USFWS conducted aerial surveys in May 2017 in two density units, which apply to the proposed Amakdedori port site, Kachemak Bay, and western Cook Inlet (which includes the upper west Cook Inlet and Kamishak Bay) (K. Klein, personal communication 2018). In Kamishak Bay, USFWS counted 364 sea otters, and estimated a density of 2.3 otters per square kilometer. The western Cook Inlet survey yielded a total western lower Cook Inlet abundance estimate of 10,737 sea otters.

AMERICAN OVERSIGHT

Critical Habitat

In 2009, USWFS designated five management units as critical habitat (Figure 3.25-1). Critical habitat includes approximately 15,164 square kilometers, all of which is located in Alaska. For management purposes, USWFS designated five units as critical habitat. Critical habitat defined in Unit 5 includes the entire nearshore marine environment ranging from the mean high tide line to the 20 meter depth contour as well as waters occurring within 100 meters of the mean high tide line (USFWS 2009). The proposed Amakdedori port site's location is in sea otter critical habitat Unit 5.

USFWS's determination of the primary constituent elements (PCEs) for the Southwest DPS of northern sea otters and the status of each PCE in the action area are summarized below.

Habitat Use and Distribution

Northern sea otters occur year-round throughout lower Cook Inlet (Garshelis 1987), which spans southwest from the North Forelands to the inlet mouth between English Bay and Cape Douglas. The Southwest DPS range is along the western shore of lower Cook Inlet (USFWS 2014d). Critical Habitat Unit 5, Kamishak Bay, Alaska Peninsula, contains all of the PCEs essential for the conservation of the Southwest Alaska DPS of sea otters (USFWS 2009). The greatest proportion of the critical habitat area within the project area is comprised of waters within the 20 meter isobath.

1. PCE 1: Shallow, rocky areas where marine predators are less likely to forage, which are waters less than 2 meters in depth.
2. PCE 2: Nearshore waters that may provide protection or escape from marine predators, which are those up to 100 meters from the mean high tide line.
3. PCE 3: Kelp forests that provide protection from marine predators, which occur in waters less than 20 meters in depth.
4. PCE 4: Prey resources within the areas identified by PCEs 1, 2, and 3 that are present in sufficient quantity to support the energetic requirements of the species

Sea otters forage in nearshore waters at depths of around 40 meters in the nearshore benthos of rocky and soft-sediment communities (Marshall 2014), which includes all of Kamishak Bay and therefore the proposed Amakdedori port site. Approximately 40 percent of sea otters' daily activity is spent foraging, and they primarily feed on benthic invertebrates, including mussels, crabs, urchins, sea cucumbers, and clams.

NMFS beluga whale aerial surveys have documented the presence of sea otters in the project area, especially in Kamishak Bay (including Augustine Island) where the proposed project port at Amakdedori Point is located. In the greater Kamishak Bay area, groups of over 30 animals were observed in multiple survey years (Shelden et al. 2013, 2015, 2017).

AMERICAN OVERSIGHT

3.25.1.6 Steller's Eider

The Alaska population of Steller's eider (*Polysticta stelleri*), federally listed as threatened, is the only federally listed avian species known to occur in the project area. This section focuses on known locations of Steller's eiders in relation to project components and includes the Amakdedori port (in the larger area known as Kamishak Bay), Iliamna Bay, and the eastern side of Cook Inlet near Anchor Point. The species is only present in these areas of Cook Inlet during the late fall, winter, and early spring. The project is located outside of the geographic breeding range for Steller's eider and does not support the coastal tundra habitats where the species breeds. The mine site, transportation corridor, and natural gas pipeline corridor (excluding the portion in the Cook Inlet) lack suitable breeding, wintering, staging, molting, or foraging habitat for Steller's eider. Steller's eiders may occasionally fly through the mine site and terrestrial portions of the transportation corridor and natural gas pipeline corridor while moving between Cook Inlet, the Alaska Peninsula, and the western coast of Alaska. No Steller's eiders were documented during any biological surveys in the mine site, therefore the species is considered absent from the mine site.

There are three main Steller's eiders breeding populations, with the majority breeding in Russia (30,000 to 50,000 of the Russian Atlantic population, and 50,000 to 100,000 of the Russian Pacific population), and a much smaller Alaska-based breeding population (around 500 individuals) (USFWS 2011, 2012). The Alaska-based breeding population was listed as federally threatened on June 11, 1997 (USFWS 2011). The Alaska-based breeding population nests primarily along the Arctic Coastal Plains around Utqiaġvik with a small sub-population nesting in the Yukon-Kuskokwim Delta (Y-K Delta). There is no USFWS designated critical habitat for Steller's eider anywhere in the project area; therefore, critical habitat for this species will not be discussed.

Steller's eiders do not breed within several hundred kilometers of the project area, and therefore a discussion of the species' reproductive ecology is not included herein. In addition to areas in Russia and the Alaska Peninsula, Steller's eiders molt and spend the winter in nearshore waters in lower Cook Inlet, which includes the project area. As such, this section is focused on Steller's eiders' fall molt, winter distribution, and migration as it relates to those areas in lower Cook Inlet that may be impacted by the project.

Fall Molt and Winter Distribution

Of the Steller's eiders that winter and molt in the Cook Inlet, the USFWS assumes that less than one percent is from the listed Alaska-based breeding population (USFWS 2008b). After breeding in the Arctic Coastal Plains and Y-K Delta, Steller's eiders move to marine waters where they mix with birds from the Russian-based breeding population and undergo a three week flightless molt. Adult birds undergo a flightless molt in fall with most birds molting in a few lagoons on the north side of the Alaska Peninsula and along the western Alaska coast (USFWS 2011). During the fall molt (from late July until late October; USFWS 2002), eiders undergo a complete molt including all flight feathers, which renders them flightless. In a study conducted along the north side of the Alaska Peninsula, sub-adult birds were flightless first, followed by adult males, and then adult females, with eiders maintaining spatial and temporal sex and age class separation during the flightless period (Petersen 1981). While some Steller's eiders remain in their molting areas throughout winter, other birds disperse to coastal waters that include southern Cook Inlet. Molting and wintering Steller's eiders occur in the western part of Cook Inlet and the adjacent nearshore coastal waters, including the project area (Figure 3.25-1).

The preferred marine habitat for Steller's eiders includes marine waters up to 9 meters deep, the associated invertebrate communities, and where present, eelgrass beds along with their

AMERICAN OVERSIGHT

associated flora and fauna (USFWS 2000). Molting areas tend to be characterized by extensive shallow areas with eelgrass beds and intertidal sand flats and mudflats. Since Steller's eiders prefer to winter in shallow waters, they are usually found within 400 yards of shore, except where shallows extend farther offshore in bays and lagoons or near reefs (USFWS 2002). The coastal/nearshore areas of Kamishak Bay have been designated a global Important Bird Area by the Alaska Audubon Society, due in part to the presence of Steller's eiders (National Audubon Society 2013).

During a historical aerial and boat survey conducted in Cook Inlet during February of 1994, 1,363 Steller's eiders were reported in nearshore areas of Kamishak Bay from McNeil Cove to Iniskin Bay (Agler et al 1995). During a more recent survey from 2004 to 2006, 24 satellite transmitter-tagged Steller's eiders captured during winter at Kodiak Island documented molting and wintering in Kamishak Bay. Approximately 20 percent of the birds used Kamishak Bay as a molting area and at least two birds molted on two consecutive years, suggesting some site fidelity. In both 2005 and 2006, an estimated minimum of 2,500 birds were counted molting in Kamishak Bay based on aerial photography. Most birds were associated with a large reef (Douglas River Shoals) near the southern end of Kamishak Bay, approximately 27 kilometers south of Amakdedori port (Rosenberg et al 2016). During aerial transect surveys in 2005, approximately 2,000 molting Steller's eiders were observed in the Douglas River Shoals in late August and September. During winter surveys in 2005, 3,921 Steller's eiders were recorded in southern Kamishak Bay (Larned 2006). Data from 2004 and 2005 indicate that the number of Steller's eiders in Cook Inlet increases in early winter, peaks in January and February, and then declines from early March through mid- to late April as birds depart on spring migration for their breeding grounds (Larned 2006).

Based on data from Larned (2006), Steller's eiders appear to be concentrated both north and south of Amakdedulia Cove, with low numbers of Steller's eiders around Amakdedulia Cove. Specific surveys of Kamishak Bay (Larned 2006), including Amakdedulia Cove, indicated that low numbers of Steller's eiders may occasionally be found in the area during winter months. Two groups of between one and 37 Steller's eiders were observed during aerial surveys from February 11 to 16, 2004 in the area around Amakdedulia Cove (Larned 2006). Several more groups between one and 30 Steller's eiders were observed in the same area from March 11 to 17, 2004. Only one group between eight and 30 birds were detected during April 12 and 13, 2004, indicating that most wintering Steller's eiders had left the area by mid-April in 2004. Surveys conducted that following December (December 4 through 8, 2004), detected several small flocks of Steller's eiders between one and 60 birds. Surveys were repeated again from January through April 2005, with similar results of small flocks of Steller's eiders using the nearshore waters of Amakdedulia Cove (Larned 2006). Most eider flocks were located closer to Bruin Bay, near the northern part of Amakdedulia Cove.

Steller's eiders are known to occur on the east side of Cook Inlet around Anchor Point, where the natural gas pipeline would extend from Cook Inlet and connect to an existing pipeline north of Anchor Point. Historical survey data from Larned (2006) indicate that several small flocks of less than 100 birds each winter around Anchor Point. The actual number of birds and location varies throughout the winter, often depending upon the extent of the sea ice cover, but most small flocks congregate around an extensive shoal south of Anchor Point. Clusters of flocks of Steller's eiders were observed in locations ranging from Anchor Point, to north of Ninilchik, with numbers of birds ranging from 1,141 in January 2005, to 2,370 in March 2001 (Larned 2006). During surveys in winter 2004 and 2005, the average monthly mean was 463 Steller's eiders in the area located north of Anchor Point to Ninilchik, and 1,713 Steller's eiders in Kamishak Bay (Larned 2006). The number of eiders peaked in January and drastically decreased by early April. Groups of eiders were consistently observed around an extensive shoal south of Anchor

AMERICAN OVERSIGHT

Point. Therefore, Steller's eiders are present in both western and eastern parts of Cook Inlet during the winter months. By mid- to late April, most Steller's eiders have left Cook Inlet for their northern breeding grounds.

Migration

The path of migration for Steller's eiders to and from Cook Inlet during the fall molt and throughout the winter and early spring is not known. However, Steller's eiders' bird strikes on towers and power lines at Togiak, Naknek, and King Salmon (including inland sites) indicate that there may be some overland pathway that includes Iliamna Lake (USFWS 2008b). Satellite transmitter data from 2004 to 2006 documented Steller's eiders molting in Kamishak Bay from mid- to late August, until mid- to the end of November, and through the end of January (Rosenberg et al 2016). Prior to departure for the breeding grounds and migrating north, Steller's eiders stage in several locations along the Alaska Peninsula. In 2005, Rosenberg et al (2016) documented two satellite transmitter-tagged birds that staged in Kamishak Bay from March 25 to May 8. These data indicate that Kamishak Bay is used by the same individual eiders during consecutive years and that the species use the bay for molting, wintering, and staging. The birds then fly to the north side of the Alaska Peninsula (exact route is unknown) and up the west coast of Alaska before heading to Russia, the Y-K Delta, and the Arctic Coastal Plains.

3.25.2 Action Alternative 2 – North Road and Ferry

Action Alternative 2 is described in Chapter 2. The species discussed in this section have broad distributions and are expected to occur in similar densities throughout the marine environment as described above. Where there are anticipated differences between species' distribution and habitat use across the preferred alternative and the other alternatives, further discussion is provided.

3.25.2.1 Cook Inlet Beluga Whale

During NMFS beluga whale aerial surveys in Cook Inlet, a small group of two belugas was seen in Iniskin Bay on June 4, 1994 (Rugh et al. 2000). ADF&G biologists have occasionally recorded belugas in the area of Iliamna and Iniskin bays during herring surveys from 1978 to 2002; in 1997, an ADF&G biologist recorded a group of 12 to 15 belugas off the mouth of Iniskin Bay, with only a few individuals seen in Iliamna Bay (ABR 2011d). In September 2007, ADF&G biologists recorded 25 to 30 beluga whales in inner Chinitna Bay (ABR 2011d), and 12 beluga whales were seen in upper Iniskin Bay (ABR 2011d).

Several studies have been conducted in the marine environment that would potentially be affected by Alternative 2, where beluga observations were recorded. Twelve beluga whales were seen in Iliamna, Iniskin, and Chinitna bays, as well as near the Iniskin Islands. Beluga whales were also recorded along the eastern shore of Iliamna Bay in October 2008 (ABR 2011d). Cook Inlet beluga whales are expected to occur in similar densities throughout the marine environment across the proposed alternatives.

3.25.2.2 Humpback Whale

Humpback whales have been observed during NMFS Cook Inlet beluga whale aerial surveys from 2000 to 2016. Although a number of humpback whale sightings occurred mid-inlet between the Iniskin Peninsula and Kachemak Bay, most sightings occurred in the area near the Augustine, Barren, and Elizabeth Islands (Shelden et al. 2013, 2015, 2016), which are to the

AMERICAN OVERSIGHT

south of Alternative 2 suggesting less habitat use in the marine environment that would be potentially affected by Alternative 2.

3.25.2.3 Fin Whale

Fin whales are rarely observed in Cook Inlet, with most sightings near the mouth of Cook Inlet. They have not been observed in the Alternative 2 marine environment, and are not expected to occur in the area.

3.25.2.4 Steller Sea Lion

Sightings of large congregations of Steller sea lions during NMFS beluga whale aerial surveys occurred outside of the project area, on land in the mouth of Cook Inlet (e.g., Elizabeth and Shaw Islands)(NMFS 2008b). During studies conducted in Iliamna and Iniskin bays, Steller sea lions were rarely observed, with only a few animals being recorded. The majority of the observations occurred in April (ABR 2011d). The few records of Steller sea lions show little pronounced spatial patterns other than consistent occurrence in the Iniskin Islands. Historical data from aerial herring surveys conducted by the ADF&G in the spring suggest a long-standing preference of the Iniskin Islands by sea lions, with smaller numbers of animals scattered elsewhere throughout the study area. In the offshore waters, Steller sea lions occurred in the open coastline between Iliamna and Iniskin bays (ABR 2011d). Steller sea lions are expected to occur in similar densities throughout the marine environment across the proposed alternatives. Alternative 2 is farther away than the closest known Steller sea lion rookery location on Shaw Island, located at the southwest entrance of Kamishak Bay.

3.25.2.5 Northern Sea Otter

Sea otters were commonly observed during studies in Iliamna and Iniskin bays and were recorded in the project area primarily during winter, with only scattered individuals recorded during the spring and summer. Sea otters occurred broadly throughout the study area, but most otters were found outside Iniskin and Iliamna bays in offshore habitats and among islands at the mouths of the bays (ABR 2011d). Sea otters were observed moving into the sheltered bays when the sea ice lessened starting in March, and were seen in higher densities offshore in the winter. Otters were scarce in Iniskin Bay, although a few were recorded in Iliamna Bay during winter months (ABR 2011d); this trend is speculated to continue for all bays on the west side of Cook Inlet. The number of sea otters observed in Iliamna and Iniskin bays increased from fall to mid-winter, presumably as the weather in the exposed Kamishak Bay deteriorated. Numbers dropped in the spring as otters began moving into Kamishak Bay to summer. This data suggest that the use of the marine environment associated with Alternative 2 varies seasonally, but that the total number of otters using this environment does not vary. Sea otters are expected to occur in similar densities throughout the marine environment across the proposed alternatives.

3.25.2.6 Steller's Eider

Historical surveys during winter 1994 in lower Cook Inlet by Agler et al (1995) documented 435 Steller's eiders ranging among Oil, Iniskin, and Iliamna bays. Larned (2006) consistently observed Steller's eiders at the mouth of Iniskin Bay (between 160 and 435 individuals) between December 2004 and early spring 2005. Surveys conducted by ABR regularly recorded Steller's eiders in Iniskin and Iliamna bays during winter and early spring based on helicopter surveys conducted from 2006 through 2008 (ABR 2011d). Additional helicopter-based surveys were conducted from 2009 to 2012, with the focus on nearshore marine waters from Iniskin Bay south to Bruin Bay (ABR 2015c). These additional surveys confirmed results from previous surveys, but also documented two flocks totalling 2,462 eiders between Ursus Cove and Bruin

AMERICAN OVERSIGHT

Bay along Fortification Bluff (west of Augustine Island) in December 2012 (ABR 2015c). Steller's eiders were found primarily in offshore waters in the middle portions of Iniskin and Iliamna bays, and occasionally in nearshore waters. Most birds occurred around a shallow shoal in the lower part of Iniskin Bay and in the middle of the channel between Cottonwood and Iliamna bays. Generally, several hundred Steller's eiders were present from late November to early December, through the end of March to early April. In 2006, the highest count was 300 Steller's eiders in early December; numbers increased to 676 Steller's eiders during the surveys in early March 2007. In 2008, the highest number recorded was in early March with 275 eiders. Between 2006 and 2008, the total number of Steller's eiders observations (which may represent some of the same individuals) ranged from 790 in 2006, 1,636 in 2007, and 808 in 2008 (ABR 2011d). Surveys from 2009 through 2012 documented between 1,231 to 265 eiders, respectively. The fluctuation in Steller's eider numbers during winter is likely related to the location and presence of sea and shorefast ice, in addition to severity and timing of fall storms (which push eiders from southerly locations into more northerly protected bays). Therefore, surveys conducted by Agler et al (1995), Larned (2006), and ABR (2011d, 2015c) indicate that Iniskin and Iliamna bays provide overwintering habitat for several hundred Steller's eiders.

3.25.3 Action Alternative 3 – North Road Only

There are no new geographical areas covered by this alternative, thus no new information for any of the federally listed species. All information for this alternative is previously covered by Alternatives 1 and 2, above.

AMERICAN OVERSIGHT

4.4 ENVIRONMENTAL JUSTICE

As described in Section 3.4, Environmental Justice (EJ), Executive Order 12898 requires federal agencies to identify and address "disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations," including Alaska Native communities. Furthermore, Executive Order 12898 also requires the protection of populations with differential patterns of consumption of fish and wildlife. The Council on Environmental Quality (CEQ) defines this as differences in rates or patterns of subsistence consumption by minority, low-income, and Indian tribes, as compared with rates and patterns of consumption by the general population (CEQ 1997).

The CEQ's "Environmental Justice: Guidance Under the National Environmental Policy Act" (1997) and the Environmental Protection Agency's (EPA's) *Promising Practices for EJ Methodologies in NEPA Reviews* (2016) were developed to provide agencies with a process for identifying environmental justice communities and addressing potential impacts on those communities. According to these guidance documents, the basic components of an environmental justice assessment should include:

- A demographic assessment of the affected communities to identify minority and low-income populations that may be present.
- An integrated assessment to determine whether any adverse impacts would disproportionately affect minority or low-income populations.
- An opportunity for the public to participate in the process, including community, minority, low income, and tribal participation.

CEQ guidance indicates that when determining whether natural and physical effects on the environment are "high and adverse," agencies are to consider if environmental effects are significant (as that term is defined by the National Environmental Policy Act [NEPA] lead agency), and if those significant effects are or may have an adverse impact on minority populations, low-income populations, or Indian tribes that appreciably exceeds or is likely to appreciably exceed those on the general population or other appropriate comparison group (CEQ 1997).

CEQ guidance also indicates that when determining whether human health effects, which may be measured in risks and rates, are high and adverse, agencies are to consider if those risks and rates are significant or above generally accepted norms (CEQ 1997).

In addition, the EPA recommends considering the following factors in the determination of disproportionately high and adverse human health effects (EPA 2007, 2016):

- Proximity and exposure to chemical and other adverse stressors, including impacts commonly experienced by "fence-line" communities.
- Unique exposure pathways, including subsistence fishing, hunting, or gathering in minority and low-income populations.
- Multiple or cumulative impacts, including exposure to several sources of pollutions or pollutants from single or multiple sources.
- Physical infrastructure, including inadequate housing, roads, or water supplies in communities.
- Non-chemical stressors, including chronic stress related to environmental or socioeconomic impacts.

AMERICAN OVERSIGHT

The project's potentially affected population includes those who live, work, subsist, visit, or recreate in the environmental impact statement (EIS) analysis area. Section 3.4, Environmental Justice, presents racial and ethnic characteristics and poverty status for the population in the EIS analysis area that would be affected during construction and operations of the project. In the EIS analysis area, Igiugig, Iliamna, Kokhanok, Newhalen, Nondalton, and Pedro Bay, all of which are communities in the Lake and Peninsula Borough, meet the CEQ definition of minority and/or low-income communities (see Section 3.4, Environmental Justice). Many of the potential physical, environmental, and social effects would be experienced more frequently and intensely by residents of those communities, given their proximity to multiple project components and their use of the area and nearby areas for subsistence harvests.

Section 4.3, Needs and Welfare of the People—Socioeconomics, Section 4.9, Subsistence, and Section 4.10, Health and Safety, describe impacts to affected communities and the population in the EIS analysis areas for these resources. This environmental justice analysis considers information presented in those sections, considers the distribution of adverse and beneficial impacts throughout the EIS analysis area, and concludes whether there may be disproportionately high and adverse effects to minority or low-income communities. Potential impacts include:

- Changes in job opportunities, employment, income, and the cost of living;
- Changes in access to subsistence resources and resource availability;
- Changes in sociocultural conditions; and
- Changes in health and well-being, including the risk of exposure to hazardous chemicals and bioaccumulative compounds, and non-chemical stressors.

4.4.1 No Action Alternative

The No Action Alternative assumes that the mining operations at the Pebble deposit are not undertaken. The Pebble Limited Partnership (PLP) would not move forward with the project. Under the No Action Alternative, PLP would have the same options for exploration activities that currently exist (PLP 2018-RFI-073). Therefore, it is anticipated that PLP would continue current activities in an effort to identify future opportunities.

PLP has employed local community members at the site during the exploratory phase of the project. In particular, the communities closest to the exploration area in the Lake and Peninsula Borough, likely including Nondalton, Iliamna, and Newhalen, provide the greatest proportion of the local workforce. These communities are identified as minority and/or low-income communities. Similarly, these communities and others harvest caribou, large land mammals and other subsistence resources in the vicinity of project components. Scoping comments suggested that exploration activities have affected wildlife populations (caribou) used for subsistence.

4.4.1.1 Needs and Welfare of the People – Socioeconomics

Under the No Action Alternative, it is anticipated that PLP would continue current activities in an effort to identify future opportunities. As a result, the current number of direct and indirect jobs would remain the same and there would be no impact on income, economic stability, or social integrity in minority and low-income communities.

AMERICAN OVERSIGHT

4.4.1.2 Subsistence

The extent of effects on subsistence would be localized impacts near the exploration area. PLP would still be permitted to perform exploratory activities and research at the site and would be expected to do so.

Resource availability would not change from the conditions present during exploration activity and environmental studies at the mine site. Minority and low-income communities in the vicinity of the exploration area would bear a disproportionate share of effects associated with subsistence. It is likely that existing trends in subsistence resources and uses would continue, and that these communities would continue to harvest subsistence resources; the effects of the No Action Alternative would not be high or adverse.

4.4.1.3 Health and Safety

As discussed in Section 4.10, Health and Safety, human health impacts associated with the potential loss of some jobs and decrease in household income could result in potential increases or decreases in social determinants of health, such as income, psychosocial stress, substance abuse, and family stability. These impacts would mainly affect those workers in minority and low-income communities in the Lake and Peninsula Borough in the communities closest to the exploration area. Therefore, the human health effects of the No Action Alternative would potentially be disproportionately "high and adverse." In addition, a decision not to permit the project may relieve some stress in affected communities associated with concerns regarding project development and perceived impacts on salmon.

4.4.2 Action Alternative 1 – Applicant's Proposed Alternative

Alternative 1 assumes that construction and operations at Pebble Mine would occur as described in Chapter 2, Alternatives. This section presents the potential for Alternative 1 to result in high and adverse effects on minority and low-income populations. Both adverse and beneficial effects are summarized below.

4.4.2.1 Needs and Welfare of the People

As discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics, Alternative 1 would provide economic benefits to individuals, families, and communities in the form of increased incomes, year-round employment, and steady income, and would reduce the impacts of the seasonal fluctuations in employment. Under Alternative 1, the number of employees would increase to about 2,000 during the 4-year construction phase, and 850 during the 20-year operation of the mine. For the operations phase, PLP has estimated that 250 employees would come from the surrounding communities, with 50 of these employees coming from communities connected to the project site by road (PLP 2018-RFI 027).

The communities closest to the mine site include Nondalton, Iliamna, and Newhalen, and Kokhanok on the southern shore of Iliamna Lake; these communities are also proximal to the proposed transportation corridor. These communities are minority and low-income communities and have a lower median household income and a higher unemployment rate than Anchorage, as well as Alaska as a whole. Although PLP has generated exploration-related employment for residents of villages throughout the Lake and Peninsula Borough and broader Bristol Bay region over the past decade, the communities surrounding Iliamna Lake and connected by road, have provided the greatest proportion of the local workforce. It is anticipated that residents of the communities surrounding Iliamna Lake would continue to provide the majority of the local workforce for construction and operations of the project. Therefore, employment through the project would have beneficial economic effects on minority and low-income communities.

AMERICAN OVERSIGHT

The Lake and Peninsula Borough is not connected by road to the rest of the state and has few roads, contributing to an extremely high cost of living. As described in Section 4.12, Transportation and Navigation, Alternative 1 would result in the construction of roads and ports. Although the road and port would have limited access, PLP has stated that they would work with all local communities to identify the best solutions for controlled-access use of the road and ferry for community transportation (PLP 2018-RFI 027). Additional access would be coordinated between the State of Alaska, the Lake and Peninsula Borough, PLP, and landowners. Because the higher cost of living in rural areas is primarily associated with high transportation cost of food, fuel, and other supplies (ADOL 2008, 2017a), Alternative 1 has the potential to reduce transportation costs of materials and goods to the transportation corridor area's potentially affected communities (Kokhanok, Iliamna, Newhalen, and potentially Nondalton). Reduced transportation costs would lower the cost of living for these communities, many of which are minority and low income.

Communities adjacent to the natural gas pipeline would have the opportunity to connect to the pipeline. Natural gas would likely be less expensive than diesel heating oil, which could lower the cost of living once equipment (e.g., furnace, water heater) is converted to natural gas.

The summer-only ferry variant would likely shift some of the positions held by community members from year-round to seasonal, which would also lower the overall income earned by community members that stays in the region compared to year-round ferry operations (see Section 4.3, Needs and Welfare of the People—Socioeconomics for additional information).

The increase in job opportunities, year-round or seasonal employment, steady income, and lower cost of living described above would have beneficial impacts on the EIS analysis area, especially for communities in the Lake and Peninsula Borough, during construction and operations of the project. Therefore, the effects of Alternative 1 on the needs and welfare of the people would not be "high or adverse."

4.4.2.2 Subsistence

As discussed in Section 4.9, Subsistence, communities closest to project infrastructure would be the most affected by changes in resource availability. These include the minority and/or low-income communities of Iliamna, Newhalen, Pedro Bay, Igiugig, Nondalton, and Kokhanok. Communities in the Nushagak River drainage and the Kvichak River drainage below Iliamna Lake would experience little to no impact on resource availability or access to resources during routine operations.

Project construction—and to a lesser extent, operations—would impact the availability and abundance of traditional and subsistence resources through habitat loss; behavioral disturbance to resources from increased noise and human activity; fugitive dust deposits on vegetation; concerns about contamination of resources; avoidance of traditional use areas; and increased costs and times for traveling to more distant areas. The communities closest to project infrastructure and transportation activities, including the mine site, transportation corridor, the ferry and terminals, port, and airports, would be the most affected by changes in resource availability. These communities include the minority and low-income communities of Iliamna, Newhalen, Pedro Bay, Igiugig, Nondalton and Kokhanok. There is a potential for a small population increase in communities closest to the mine site, which could introduce a slight amount of resource competition to the area. Adaptive strategies for the harvest of resources would likely maintain harvest levels for affected communities, but potentially at the cost of additional time and money. In general, the impacts of subsistence resource availability on minority and low-income communities would potentially be adverse.

AMERICAN OVERSIGHT

Construction and operations of the project would result in changes in access to subsistence resources. During the construction period, access to the area around project components would be inhibited or restricted. This would impact a number of communities located near project infrastructure that use this land for subsistence fishing, hunting, gathering, education of youth on subsistence traditions, and other cultural and customary practices. Construction of linear features, such as the roads, pipeline, and ice-breaking ferry corridor, could interrupt travel to resources or communities on the other side of the linear features, and create some unease with hunting in the vicinity of these construction activities and facilities, resulting in adverse effects on those minority and low-income communities.

Once constructed, the natural gas pipeline corridor right-of-way and the transportation corridor roads would likely have a positive impact on minority and low-income communities by providing access to subsistence resources, because these cleared routes would facilitate overland all-terrain vehicle and snowmachine travel under approved conditions. During operations, PLP would work with local communities to identify safe, practicable ways for residents to use the access roads, such as scheduled, escorted convoys for private vehicle transport. However, the Iliamna Lake ice-breaking ferry could disrupt winter travel over the frozen lake by potentially adding to travel time and increasing fuel expenditures. This could potentially result in adverse effects on minority and low-income communities that rely on winter travel over the lake. In addition, the open water in the ferry's wake would present a safety hazard for subsistence users. PLP would work with communities (and supply funding) to provide for the marking and maintenance of snowmachine trails between communities across Iliamna Lake when lake ice is thick enough to support such traffic (see Chapter 5, Mitigation). The ferry could also facilitate access to subsistence resources by transporting local residents and their vehicles across the lake. The summer-only ferry operations variant would not have impacts to lake travel in the winter.

Impacts on access to subsistence resource harvest areas would occur for the minority and/or low-income communities located closest to the project components: Nondalton, Iliamna, Newhalen, Pedro Bay, Igiugig, and Kokhanok. Impacts associated with access around the mine site for subsistence use and harvest would be most concentrated near the mine site area and would diminish with distance. Impacts of the transportation corridor and associated uses to use areas would vary depending on the activity of the user and the location of the use area in relation to the transportation corridor. The effects would be localized in geographic extent; as there is availability of alternate areas in traditional and currently used subsistence areas for activities for these communities and mitigation for access to areas near or around project components is planned (PLP 2018-RFI 078). Therefore, the impacts of access to subsistence resource harvest areas for minority and low-income communities would not be high and adverse (see Section 4.9, Subsistence, for a detailed discussion of impacts related to changes in access of subsistence resource harvest areas for the communities of Nondalton, Iliamna, Newhalen, Pedro Bay, Igiugig, and Kokhanok).

Project construction and operations would be expected to increase employment opportunities for local residents, particularly for those living in communities surrounding Iliamna Lake. Many subsistence activities depend on cash income to pay for the tools, ammunition, equipment, maintenance, and fuel used to harvest, process, and store subsistence resources. When cash incomes increase, subsistence production often increases as a result. Therefore, new employment opportunities would benefit minority and low-income communities.

Changes in harvest participation are a leading indicator of cultural changes. The level of participation may be affected by changes in resource abundance and quality, season and bag limits, changes in physical access, changes in cultural perceptions of resources (e.g., fish and animals are seen as tainted/contaminated, or water is seen as polluted) and the times and funds

AMERICAN OVERSIGHT

available for subsistence activity change. Year-round and rotational employment could reduce the opportunity for subsistence users to harvest and process resources, as well as reduce their ability to pass on skills and knowledge to the next generation. Households and communities would need to adjust to new roles of subsistence labor, changes in sharing networks, and to possible changes in harvest levels. Project employment or related regional out-migration (see Section 4.3, Needs and Welfare of the People—Socioeconomics for additional information) could cause the reduction or loss of subsistence production from high-harvesting households. In typical communities, 30 percent of households harvest 70 percent of the resources and there is a high level of sharing that occurs among households (Wolfe et al. 2009). If high-harvesting households leave the community or reduce their production, it could have an impact on the rest of the community and nearby communities from sharing. The loss of high-harvesting households and a reduction in sharing could result in adverse impacts on minority and low-income communities. However, the effects could be reduced with planned periods of leave options during subsistence harvest periods.

4.4.2.3 Health and Safety

Section 4.10, Health and Safety, describes impact ratings for the health effects category under Alternative 1. These effects determinations take into account impact-reducing design features proposed for the Pebble Project.

The Pebble Project would increase household incomes, employment rates, and education attainment, and those economic benefits would likely result in an improvement to the overall health and well-being of residents living in the communities from which the workforce for the project would be employed. Many of the communities that would experience these beneficial effects are minority and low-income communities. Economic benefits to these communities would also likely result in increased diet options and lower regional food costs, and therefore food security; positive effects on affordability of healthcare services; and improvements to mental health, including lowering suicide rates. The benefits would be more apparent in the small, rural Lake and Peninsula Borough communities where even minor changes in their economies could have a measureable impact on their overall health and well-being.

Impacts on psychosocial health, family stress, other unintentional injuries (e.g., falls, poisoning), and intentional injuries (e.g., suicide) would be both beneficial and adverse. Beneficial effects could include increased funding from the borough to maintain or improve community health services, and additional disposable income for project employees. Adverse health consequences may be related to decreased access to healthcare due to emergency situations, and increased stress and infectious (communicable) disease rates during the construction phase. For those individuals that harvest fish as part of subsistence, commercial fishing, and commercial recreation activities, there may be additional stress over perceived impacts to fish and the quality of the fish resource, associated with construction and operation of the project. This would constitute an adverse impact.

Impacts on access to and quantity of subsistence resources could be both adverse and positive to health and safety, and many of these effects would be most noticeable to minority and low-income communities in close proximity to the mine site and transportation corridor. Potential negative impacts could be from actual or perceived decreases in access to, availability, and/or quality of subsistence recourses, which could also adversely impact community health/well-being and cultural identity. Subsistence users would likely adjust the seasonal round, resource use areas, and species composition of harvest resources to target resources that would be less affected by project activities. Although these adaptive approaches would likely sustain harvest levels for affected communities, they may increase expenses and time needed to harvest subsistence resources. However, positive benefits may also occur since increased incomes and

AMERICAN OVERSIGHT

employment can positively affect subsistence harvest levels and participation including making procurement of hunting and fishing equipment more affordable. These would positively impact communities' health for reasons discussed above.

Other key health outcomes considered are the potential for increased risk of exposure to hazardous chemicals in air, soil, groundwater, surface water, and sediment. Exposure to hazardous chemicals could occur through inhalation, physical (i.e., dermal) contact, and direct or indirect ingestion (e.g., direct exposure through incidental soil ingestion). See Section 4.10, Health and Safety, for information on risk of exposure.

4.4.3 Action Alternative 2 – North Road and Ferry Alternative

4.4.3.1 Needs and Welfare of the People

The impacts of Alternative 2 on employment and income would likely be the same as the impacts of Alternative 1. It is anticipated that residents of the communities surrounding Iliamna Lake would continue to provide the majority of the local workforce for construction and operations of the project under Alternative 2. The increase in job opportunities, year-round employment, and steady income under Alternative 2 would have the same beneficial impacts on minority and low-income communities as Alternative 1. However, there would be impacts to Pedro Bay instead of Kokhanok.

The impacts on the cost of living of Alternative 2 would likely be the same as the impacts of Alternative 1 for the communities of Nondalton, Iliamna, and Newhalen. However, because the north access road and ferry would be located at the north end of the lake around Pedro Bay as opposed to the mid-lake region, the cost of living benefits provided to Kokhanok under Alternative 1 would not be provided under Alternative 2; however, Pedro Bay, which is considered a minority community, would benefit from reduced transportation costs that would lower the high cost of living.

4.4.3.2 Subsistence

Impacts from the changes in resource availability, access to subsistence resources, and the sociocultural dimension of subsistence under Alternative 2 would be the same as Alternative 1, except for the differences described below. As described above for Alternative 1, impacts could result in both beneficial and adverse effects on minority and low-income communities.

Changes in resource availability along the transportation corridor and the natural gas pipeline for Alternative 2 would be similar to Alternative 1. Disturbance to and displacement of subsistence resources would occur at approximately the same levels. The primary difference is that there are fewer communities using the area in between Pile Bay and Williamsport for subsistence, and so the magnitude of the impact would be much less than Alternative 1.

Under Alternative 2, there would be an overland pipeline right-of-way from Pile Bay to the mine site. This could introduce some competition to subsistence users from recreational sport hunting and fishing, although because of the relatively low recreational use of the area, the magnitude of the effects would be expected to be small. Therefore, there would be no adverse effects on minority and low-income communities from competition for subsistence resources.

Under Alternative 2, the north access road and ferry terminal would be located at the north end of the lake as opposed to the mid-lake region. The transportation corridor and ferry would cause more disruption of access to subsistence resource areas for residents of Nondalton, Iliamna, Newhalen, and Pedro Bay and less disruption of access for residents in Igiugig and Kokhanok. In addition, there would be a higher number of overlapping use areas along the road corridor of

AMERICAN OVERSIGHT

Alternative 2 from Pedro Bay to the mine site, and so the magnitude of the impact would be slightly greater than Alternative 1. However, similar to Alternative 1, there is availability of alternate areas within traditional subsistence areas for activities for these communities. Therefore, the impacts of access to subsistence resource harvest areas for minority and low-income communities would not be high and adverse.

4.4.3.3 Health and Safety

Alternative 2 would have the same health and safety impacts on minority and low-income communities as Alternative 1. Alternative 2 would provide the same economic benefits and improvements to the overall health and well-being of residents, would have the same beneficial and adverse impacts on psychosocial health, family stress, and unintentional and intentional injuries, and would have the same beneficial and adverse impacts on access to and quantity of subsistence resources as described above for Alternative 1.

Alternative 2 would have the same potential for increased risk of exposure to hazardous chemicals in air, soil, groundwater, surface water, sediment, and bioaccumulative compounds as Alternative 1. However, this alternative includes a natural gas pipeline variant along the north road, which eliminates any potential hazards and impacts at the Iliamna Lake segment during the construction phase under Alternative 1. See Section 4.10, Health and Safety, for information on risk of exposure.

4.4.4 Action Alternative 3 – North Road Only

4.4.4.1 Needs and Welfare of the People

The impacts of Alternative 3 on employment and income would likely be the same as the impacts of Alternative 1. It is anticipated that residents of the communities surrounding Iliamna Lake would continue to provide the majority of the local workforce for construction and operations of the project under Alternative 3. The increase in job opportunities, year-round employment, and steady income under Alternative 3 would have the same beneficial impacts on minority and low-income communities as Alternative 1. There would be less potential for interference with winter access across Iliamna Lake, as there are no ferry operations under Alternative 3.

The impacts on the cost of living of Alternative 3 would likely be the same as the impacts of Alternative 1 for the communities of Nondalton, Iliamna, and Newhalen. However, because the north access road would be located at the north end of the lake around Pedro Bay as opposed to the mid-lake region, the cost of living benefits provided to Kokhanok under Alternative 1 would not be provided under Alternative 3; however, Pedro Bay, which is considered a minority community, would benefit from reduced transportation costs that would lower the high cost of living.

Alternative 3 includes a variant for a concentrate pipeline. The impacts of the variant would likely be a decrease in employment of truck operators and increased employment at the dewatering facility. Overall, the total number of employees needed during operations would likely decrease, which would decrease the overall income and employment in the potentially affected communities. However, the variant would still provide some economic benefits to minority and low-income communities by providing job opportunities, year-round employment, and steady income to a lesser extent than Alternative 1.

AMERICAN OVERSIGHT

4.4.4.2 Subsistence

Impacts from the changes in resource availability, access to subsistence resources, and the sociocultural dimension of subsistence under Alternative 3 would be the same as Alternative 1, except for differences described below. As described above for Alternative 1, these impacts could result in both beneficial and adverse effects on minority and low-income communities.

Changes in resource availability along the transportation corridor and the natural gas pipeline for Alternative 3 would be similar to Alternative 1. Disturbance to and displacement of subsistence resources would occur at approximately the same levels. The primary difference is that there are fewer communities using the area between Pile Bay and Williamsport for subsistence, and so the magnitude of the impact would be much less than Alternative 1.

Under Alternative 3, there would be a road from Pile Bay to the mine site. This could introduce some competition to subsistence uses of resources from recreational sport hunting and fishing, although the road beyond Pile Bay would have similar controlled access as described under Alternative 1, therefore the magnitude of the effects would be expected to be small.

Access to subsistence resource use areas would be similar to Alternative 2 for residents of Nondalton, Iliamna, Newhalen, and Pedro Bay. Igiugig and Kokhanok have not reported using the areas inland of the east end of Iliamna Lake along the transportation corridor for subsistence harvest. Similar to Alternative 1, there is availability of alternate areas in traditional subsistence areas for activities for these communities. Therefore, the impacts of access to subsistence resource harvest areas for minority and low-income communities would not be high and adverse.

4.4.4.3 Health and Safety

Alternative 3 would have the same health and safety impacts on minority and low-income communities as Alternative 1. Alternative 3 would provide the same economic benefits and improvements to the overall health and well-being of residents, would have the same beneficial and adverse impacts on psychosocial health, family stress, and unintentional and intentional injuries, and would have the same positive and adverse impacts on access to and quantity of subsistence resources as described above for Alternative 1.

Alternative 3 would have the same potential for increased risk of exposure to hazardous chemicals in air, soil, groundwater, surface water, sediment, and bioaccumulative compounds as Alternative 1. This alternative includes a natural gas pipeline variant along the north road, which eliminates any potential hazards and impacts at the Iliamna Lake segment during the construction phase under Alternative 1. See Section 4.10, Health and Safety, for information on risk of exposure.

Alternative 3 includes a variant for a concentrate pipeline. This variant would likely decrease employment of truck operators and increase employment at the dewatering facility. Overall, the total number of employees needed during operations would likely decrease. However, this variant would still provide some economic benefits and improvements to the overall health and well-being of residents as described for Alternative 1, but to a lesser extent.

Because Alternative 3 does not involve operation of a ferry across Iliamna Lake, there would be no potential safety hazards to winter transportation by local residents across Iliamna Lake compared to Alternatives 1 and 2.

4.4.5 Summary of Key Issues:

See Table 4.4-1 for a summary of key issues.

AMERICAN OVERSIGHT

Table 4.4-1: Summary of Key Issues for Environmental Justice

Impact	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Socioeconomics	Economic benefits to minority and low-income communities. Alternative 1 would increase job opportunities, create year-round employment, and provide steady income. Minority and low-income communities nearest the project components (i.e., Newhalen, Iliamna, Nondalton, and Kokhanok) would likely see the greatest impacts in employment and income. Reduced transportation costs would likely lower the high cost of living for the communities near the transportation corridor (i.e., Newhalen, Iliamna, Nondalton, and Kokhanok). The natural gas pipeline could also provide opportunities for adjacent communities to lower their cost of living.	Same as Alternative 1 except that the cost of living benefits would not be provided to Kokhanok, but would be provided to Pedro Bay instead.	Same as Alternative 2 except that the impacts of the concentrate pipeline variant would likely be less to employment and income. There would still be economic benefits to minority and low-income communities from job opportunities, year-round employment, and steady income, but to a lesser extent.
Subsistence	Changes in resource availability would be adverse for minority and low-income communities. Impacts to access of subsistence resource harvest areas for minority and low-income communities would not be high or adverse. Employment opportunities could provide additional revenue to support subsistence activities.	Same as Alternative 1, except that the transportation corridor and ferry would cause more disruption of access to subsistence resource areas for residents of Iliamna, Newhalen, and Pedro Bay, and less disruption of access for residents in Igiugig and Kokhanok.	Same as Alternative 1 for resource availability, access to subsistence resources. Access to subsistence resource use areas would be the similar to Alternative 2 for residents of Iliamna, Newhalen, Pedro Bay and, Nondalton.
Health and Safety	Alternative 1 would provide economic benefits and improvements to the overall health and well-being of residents, especially those in the Lake and Peninsula Borough. Beneficial and adverse impacts on minority and low-income communities from psychosocial and family stress, injuries.	Same as Alternative 1.	Same as Alternative 1, except that the impacts of the concentrate pipeline variant. This variant would provide the same economic benefits and improvements to the overall health and well-being of residents as described for Alternative 1, but to a lesser extent.

AMERICAN OVERSIGHT

Table 4.4-1: Summary of Key Issues for Environmental Justice

Impact	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
	Beneficial and adverse impacts on minority and low-income communities related to access to and quantity of subsistence resources. Increased risk of exposure to hazardous chemicals in air, soil, groundwater, surface water, sediment, and bioaccumulative compounds would not be high or adverse. Perceived impacts could cause additional stress for local residents harvesting salmon for subsistence, commercial fishing, and recreational fishing purposes.		

4.4.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to cumulatively contribute to disproportionately high and adverse effects on minority and low-income communities. The geographic area for the cumulative effects consideration consists of those who live, work, subsist, or recreate in the EIS analysis area and the broader region that would be affected by the RFFAs. These areas include the Kenai Peninsula Borough, Bristol Bay Borough, and Municipality of Anchorage, which are not considered minority or low-income communities as a whole, as well as the Lake and Peninsula Borough and Dillingham Census Area, which are considered minority and low-income communities (see Section 3.4, Environmental Justice).

This cumulative analysis considers information presented in Section 4.3, Needs and Welfare of the People—Socioeconomics, Section 4.9, Subsistence, and Section 4.10, Health and Safety. These sections took into consideration RFFAs as identified Section 4.1 and Appendix K4.1. The specific RFFAs with the greatest potential to cumulatively impact socioeconomic, subsistence, and health and safety conditions are identified in those respective sections.

4.4.6.1 Needs and Welfare of the People

RFFAs identified in Section 4.3, Needs and Welfare of the People—Socioeconomics, would provide economic benefits to individuals, families, and communities in the form of increased incomes, year-round employment, and steady income.

The RFFAs related to transportation and infrastructure improvements could have a cumulative impact on potentially affected communities in the EIS analysis area. For example, the Lake and Peninsula Borough transportation projects, such as the Williamsport-Pile Bay Road upgrade and the Nondalton-Iliamna River Road corridor and bridge, would reduce high transportation costs and lower the cost of living for minority and low-income communities in the Lake and

AMERICAN OVERSIGHT

Peninsula Borough. These benefits would be anticipated to be greater if the project is implemented.

The proposed Donlin Gold Project would contribute to regional economic benefits similar to those of the Pebble project. Employees would likely come from the city of Bethel as well as other parts of the Bethel Census Area, the Kusilvak Census Area, and the Yukon-Koyukuk Census Area. Therefore, these benefits would not directly contribute to economic benefits for minority and low-income communities in the EIS analysis area. From a statewide perspective, both the Donlin Gold Project and the Pebble Mine Project could create a need for support services and secondary/indirect jobs associated with such services in the region.

The proposed Diamond Point rock quarry would be located near the convergence of Cottonwood and Iliamna bays. This project could increase job opportunities and provide steady income to minority and low-income communities in the Lake and Peninsula Borough and the Kenai Peninsula Borough.

Since community members of the potentially affected communities participate in commercial fishing activities, any changes in regulations under the RFFA could result in impacts. However, there would be less of an impact to the potentially affected communities around Iliamna Lake than to the coastal communities where commercial fishing is a much larger part of the economy.

4.4.6.2 Subsistence

Cumulative subsistence impacts could result from changes in availability and abundance of subsistence resources and access to harvest areas. Each of the RFFAs identified in Section 4.9, Subsistence, contribute to the increased potential for impacts on subsistence resources, as each involves some aspect of activity that can lead to the disturbance and displacement of subsistence resources at those locations. Actions that expand mineral development near the Pebble deposit and around Iliamna Lake contribute to landscape-level effects where there is increased noise and atmospheric pollution, along with an increased volume of people. This can lead to an invasion of privacy and solace during subsistence activities and adverse impacts on subsistence resources and practices that are central to cultural belief systems and the life way of local people and could have far reaching social and physical health impacts. Effects such as habitat fragmentation, noise, and increased access for recreational hunting and fishing could also disrupt subsistence cycles, and may result in direct impacts on resource gathering areas. Local residents have observed that there has already been a loss to subsistence opportunities and the way of life due to planning and exploration activities that are associated with the Pebble Project can cause changes in distribution to local wildlife and disturbance from helicopter traffic. Subsistence users in Nondalton noted in Fall (2006) that their community uses traditional trapping and hunting areas near Groundhog Mountain that could see development. Many of the communities in the region that would experience these adverse effects are minority and low-income communities.

These types of effects are also applicable to an increase in resource development actions along the coast of Cook Inlet, which may impact the associated subsistence resources and access to sites that are important for harvest, as well as religious and spiritual practices central to the health and relationship of people to the land they inhabit. The cumulative impacts would be long term to permanent and geographically broad in scope (at a regional level).

4.4.6.3 Health and Safety

The RFFAs considered in Section 4.10, Health and Safety, have the potential to increase household incomes, employment rates, and education attainment; those economic benefits would likely result in an improvement to the overall health and well-being of residents living in

AMERICAN OVERSIGHT

the communities from which the workforce would be employed. Many of the communities in the region that would experience these beneficial effects are minority and low-income communities. The benefits would be more apparent in the small, rural communities, where even small economic changes could have a measureable impact on their overall health and well-being.

The Pebble Project has the potential to result in increased health impacts, especially from increased impact durations from RFFAs, possible increased releases into the environment, and affected community exposure to potentially hazardous materials. The Pebble Project buildout would extend the operations of the project for an additional 78 years; however, this project is not part of the proposed action and would require additional permits and separate NEPA compliance. Project area communities with pre-existing industrial pollutants and contaminated sites have the potential to add to the cumulative health impacts from exposure to potentially hazardous materials in communities where PLP proposes construction and operations activities. It would be expected that mitigation measures would be used to minimize or mitigate exposure (e.g., avoidance of ADEC contaminated sites, protective clothing and equipment, dust suppression).

The capital improvement-related RFFAs and rural development projects have the potential to add to positive impacts to any affected minority and low-income communities (e.g., road improvement and increased safety) in the EIS analysis area.

AMERICAN OVERSIGHT

4.10 HEALTH AND SAFETY

As discussed in Section 3.10, Health and Safety, and Appendix K4.10, the Alaska Department of Health and Social Services (ADHSS 2015) defines health as "the reduction in mortality, morbidity and disability due to detectable disease or disorder and an increase in the perceived level of health." Because health is a multi-dimensional concept with physical, mental, and social aspects, the proposed project may affect aspects of health at a localized or individual level, a community level, a regional level, or a statewide level, depending on the nature and extent of the effect. Potential impacts include:

- Potential for increases and/or decreases in household incomes, employment rates, education attainment, stress and family stability, food costs, food security, and access and quantity of subsistence resources.
- Potential for increases and/or decreases of unintentional accidents and injuries, intentional injury (suicide rate), infectious diseases, and non-communicable and chronic diseases, as well as access to healthcare.
- Potential for increases and/or decreases in illnesses or exacerbation of illnesses due to potential direct or indirect exposure to hazardous materials associated with the project.

Human health impacts were evaluated in accordance with National Environmental Policy Act (NEPA) practice, and generally followed the ADHSS methodology. The terminology used for descriptions and rankings of health impacts in this section generally correspond to the terms and ratings used in the ADHSS Health Impact Assessment (HIA) guidance. A characteristic of this guidance is that the individual dimensions of health impacts (i.e., nature of health effect, duration, magnitude, extent, and likelihood) are each given their own descriptive terms for the estimated relative degree of occurrence; and a final consolidated health impact rating for each health metric or health effects category (HEC) is numerical (Category 1 through 4). The guidance suggests that impact ratings of 2 or higher may markedly increase or decrease illness and injury rates, and may warrant interventions, if negative (ADHSS 2015).

In accordance with NEPA practice and ADHSS (2015), the scope of this assessment is limited to affected communities "outside of the fence," (outside the mine site and other mine-related components). Accordingly, this assessment does not include a direct evaluation of the anticipated workforce safety and health issues ("inside the fence") because the project would be governed by the Occupational Safety and Health Administration and the Mine Safety and Health Administration regulations in the areas where project activities would occur. However, this assessment does consider "crossover issues," such as health impacts where workers may be housed in work camps, or where workforce behaviors result in interactions/overlap with the affected communities.

The analysis of potential consequences to human health for the affected communities using ADHSS (2015) criteria is consistent with the principles of analysis required by NEPA. The first step is to determine the impact score, which takes into consideration four impact dimensions: severity of potential health effects (which can be positive or negative, and considers the need for intervention if the impact is negative), duration, magnitude, and extent of the impact (Table 4.10 1). Each component of the impact dimension is assigned a score of 0, 1, 2, or 3 to derive the overall impact rating score.

AMERICAN OVERSIGHT

Table 4.10-1: Step 1 – Impact Dimensions

Step 1				
Impact Rating Score	**A – Health Effect (+/-)**	**B – Duration**	**C – Magnitude**	**D – Extent**
0	Effect is not perceptible	Less than 1 month	Minor	Individual cases
1	(+/-) minor benefits or risks to injury or illness patterns (no intervention needed)	Short-term: 1 to 12 months	Those impacted will: 1) be able to adapt to the impact with ease and maintain pre-impact level of health; and 2) see noticeable but limited and localized improvements to health conditions.	Local: small limited impact to households
2	(+/-) moderate benefits or risks to illness or injury patterns (intervention needed, if negative)	Medium-term: 1 to 6 years	Those impacted will: 1) be able to adapt to the health impact with some difficulty and will maintain pre- impact level of health with support; or 2) experience beneficial impacts to health for specific populations; some maintenance may still be required.	Entire Potentially Affected Communities; village level
3	(+/-) severe benefits or risks: marked change in mortality and morbidity patterns (intervention needed, if negative)	Long-term: more than 6 years/life of project and beyond	Those impacted will: 1) not be able to adapt to the health impact or to maintain pre-impact level of health; or 2) see noticeable major improvements in health and overall quality of life.	Extends beyond Potentially Affected Communities; regional and statewide levels

Source: ADHSS 2015

Next, the severity and likelihood of each type of impact is evaluated, and those ratings are used to develop an overall significance impact rating category of 1, 2, 3, or 4 (Table 4.10-2). Recommended actions for negative impacts are listed by category below:

- Category 1: Actions to reduce negative impacts are not needed.
- Category 2: Recommend that decision-makers assess whether actions to reduce negative impacts would be helpful for negative impacts.
- Category 3: Recommend that decision-makers develop and implement actions to reduce negative impacts.
- Category 4: Strongly recommend that decision-makers develop and implement actions to reduce negative impacts.

Source: ADHSS 2015

For each alternative, the consequences of the project activities are described with regard to relevant issues and concerns associated with the eight HECs described in the HIA guidance (ADHSS 2015). Although all components were considered, the project was primarily analyzed as a whole because effects could not be attributed to a single component (i.e., there was overlap of affected communities for multiple components). Finally, the health consequences are summarized by HEC and for the alternative as a whole and expressed as Category 1, 2, 3, or 4. ADHSS does not provide narrative descriptions for these numeric impact category rankings, and only suggests that they be used to propose recommendations for actions. The detailed analysis for the below conclusions can be found in Appendix K4.10.

4.10.1 No Action Alternative

It is difficult to project the No Action Alternative health status 24 years into the future due to the many factors and variables that could impact the health of communities in the Environmental Impact Statement (EIS) analysis area in the future; therefore, current baseline condition is assumed as a reasonable proxy to qualitatively evaluate the future in the No Action Alternative. As a result, no quantitative discussion (i.e., rating) is presented for the No Action Alternative.

As discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics, the No Action Alternative would have direct impacts related to the current PLP exploration activities; PLP exploration-related employment and income, which were realized in the Bristol Bay region over the previous decade, would decrease or continue at the same rate. Human health impacts associated with the loss of jobs and decrease in household income for communities closest to the mine site (Nondalton, Iliamna, and Newhalen) would be expected to be minor in magnitude, with changes relative to baseline; and potential increases or decreases in social determinants of health, such as income, psychosocial stress, substance abuse, and family stability. There would be no impact to communities in the lower Bristol Bay watershed, such as Dillingham, other than removing uncertainty about the fate of this project. Other health factors would likely be similar to current conditions (baseline), such as potential rates of accidents and injuries, communicable and non-communicable diseases, exposure to hazardous constituents, and access to healthcare services.

Health impacts from the No Action Alternative would be imperceptible, or those impacted would be able to adapt to the impact with ease and not require medical intervention. Direct effects would be largely similar to baseline levels of health. There would be no contribution to

AMERICAN OVERSIGHT

cumulative effects on human health. Current health conditions and trends, as described in Section 3.10, Health & Safety, would continue in the EIS analysis area.

4.10.2 Action Alternative 1 – Applicant's Proposed Alternative

This section presents the environmental consequences to community health for Alternative 1. This evaluates potential impacts (both positive and negative) to the affected communities from the Pebble Project during all three phases. The HIA does not evaluate human health impacts from potential spills or failures. The potential health impacts from exposure to chemicals due to a spill or failure are unanticipated, and are typically short-term, acute exposures. Section 4.27, Spill Risk, evaluates impacts from potential spills or failures, as well as rates, volume, and likelihood of occurrence. Project design features, Standard Permit Conditions, and best management practices would be implemented for preventing and reducing impacts from potential spills (see Chapter 5, Mitigation and Monitoring). The detailed analysis for conclusions can be found in Appendix K4.10.

As discussed in Section 3.10, Health and Safety, the communities potentially affected by the project range from small, remote rural communities, to larger regional and urban centers. The eight communities in the Lake and Peninsula Borough identified would be most closely affected by multiple project components. In addition, three Nushagak/Bristol Bay communities in the Dillingham Census Area were also identified as potentially affected by project components. The Kenai Peninsula Borough and Anchorage would also be potentially affected economically by all components of the project in a relatively small way. In addition, more communities have been identified as using the EIS analysis area for subsistence; therefore, these communities could also be potentially affected by all of the components of the project (see Section 3.9, Subsistence).

Appendix K4.10 presents the detailed discussion of consequences per HEC, as well as associated uncertainties with the HIA. The consequences for all project components would be expected to be more noticeable in smaller, rural communities, and less perceptible in Anchorage. The following HECs were evaluated for potential negative (adverse) and positive impacts from the project in Appendix K4.10:

- **HEC 1: Social Determinants of Health**, which evaluated potential impacts to household incomes, employment and education attainment, as well as potential impacts to psychosocial stress of individuals and to family stress and stability.
- **HEC 2: Accidents and Unintentional Injuries**, which covered potential impacts to rates of accidents and unintentional injuries (e.g., transportation accidents, falls, fires, drownings, food poisoning).
- **HEC 3: Exposure to Potentially Hazardous Materials**, which evaluated the potential for increases and decreases in illness, or exacerbation of illnesses commonly associated with exposure to site-related chemicals of potential concern (COPCs) through inhalation, physical (dermal) contact, and direct or indirect ingestion (e.g., incidental soil ingestion or ingestion of impacted subsistence foods).
- **HEC 4: Food, Nutrition, and Subsistence Activity**, which evaluated the potential impacts on food costs, food security, and access to and quantity of subsistence resources.
- **HEC 5: Infectious Diseases**, which covered the potential impacts on rates of infectious diseases, including sexually transmitted infections, to the affected communities, as well as workers living at the on-site camp.

AMERICAN OVERSIGHT

- **HEC 6: Water and Sanitation**, which evaluated the potential impacts of increases in morbidity and mortality rates due to the availability and quality of water and sanitation services.
- **HEC 7: Non-Communicable and Chronic Diseases**, which covered the potential impacts of increases in non-communicable and chronic morbidity, as well as mortality rates (e.g., cancer, cardiovascular, and respiratory).
- **HEC 8: Health Services and Infrastructure and Capacity**, which evaluated the potential impacts on access to routine healthcare, as well as potential impacts to healthcare due to large-scale emergency situations and overwhelming local and regional healthcare capacities.

Table 4.10-3 presents a summary of the impact ratings for these HECs under Alternative 1. Human health impacts resulting from Alternative 1 would affect primarily low income and minority communities, as discussed in Section 3.3, Needs and Welfare of the People—Socioeconomics, and Section 4.4, Environmental Justice.

Table 4.10-3: Summary of Alternative 2 Impact Levels by HEC

Health Effects Categories[1]	Summary Impact Category	Beneficial (+)or Adverse (-)Rating
HEC 1: Social Determinants of Health		
Household incomes, employment, and education attainment	3	+
Psychosocial stress (substance abuse and suicide as indicators)	2	+/-
Family stress and instability	1-2	+/-
HEC 2: Accidents and Injuries		
Unintentional accidents and injuries morbidity and mortality rates due to transportation/navigation	2	-
Other unintentional injury (falls, poisoning, etc.)	2	+/-
Increase in Intentional Injury (suicide rate)	2	+/-
HEC 3: Exposure to Potentially Hazardous Materials		
Air quality impacts	1	-
Surface water and sediment impacts	1	-
Groundwater impacts	1	-
Soil impacts	1	-
Bioaccumulated chemicals in subsistence foods	1	-
HEC 4: Food, Nutrition, and Subsistence Activity		
Regional food costs and food security	2	+
Access to and quantity of subsistence resources	1-2	+/-
HEC 5: Infectious Disease		
Rates of sexually transmitted infections such as gonorrhea and chlamydia	1-2	-
Rates of respiratory diseases such as influenza and pneumonia	1-2	-
Foodborne illness and zoonotic disease	1	-
HEC 6: Water and Sanitation		

AMERICAN OVERSIGHT

Table 4.10-3: Summary of Alternative 2 Impact Levels by HEC

Health Effects Categories[1]	Summary Impact Category	Beneficial (+)or Adverse (-)Rating
Access to potable water and sanitation facilities	1	-
HEC 7: Non-communicable and Chronic Disease		
Cancer, respiratory, and cardiovascular morbidity rates due to changes in diet, nutrition, and physical activity	2	+/-
Cancer, respiratory, and cardiovascular morbidity and mortality rates due to exposure from hazardous chemicals	1	-
HEC 8: Healthcare Services Infrastructure and Capacity		
Access to routine healthcare	1	+/-
Access to healthcare due to large-scale emergency situations	2	-

Overall, the economic and health benefits of improvements in economic status would be considered substantial for the residents of the affected communities. Project-related economic benefits are rated Category 3, and would be expected to result in benefits to many supplementary aspects of human health, including increased income, employment, and educational opportunities. Economic benefits would also likely have positive effects on affordability of healthcare services and improving mental health, including the possibility of lowering suicide rates. In addition, municipal revenue likely generated by the project would lead to the maintenance and improvement of community health services and facilities. No negative impacts at a rating of Category 3 were identified.

Benefits that are rated as Category 2 include reduced food costs relative to income and increased food security for those members of the community who would realize economic benefits from the project. Negative health consequences rated as Category 2 may be related to potential transportation-related accidents and injuries for all phases (due to accidents by air, water, and surface transportation), decreased access to healthcare due to emergency situations, and increased infectious (communicable) diseases rates during construction. Impacts on psychosocial stress; other unintentional injuries (e.g., falls, poisoning); intentional injuries (i.e., suicide); and impacts on rates of non-communicable diseases due to changes in diet, nutrition, and activity are also rated Category 2 for both positive and negative effects. Intentional injuries are rated as Category 2 primarily because of the severity of the consequence, although it is considered very unlikely to occur, relative to baseline conditions. Impacts to access to and quantity of subsistence resources are rated as Category 1 (construction) to 2 (operations and closure) for both positive (increased income for hunting and fishing equipment) and negative (perceived or actual decreases in access to and quantity of resources) effects. Other potential impacts were rated Category 1.

Alternative 1, as a whole, is rated as a Category 2 for both negative (adverse) and positive potential impacts. These effects determinations take into account the implementation of impact-reducing design features proposed by PLP, and also the Standard Permit Conditions and best management practices that would be implemented.

4.10.3 Action Alternative 2 – North Road and Ferry

Impacts from the project would be the same as or similar to Alternative 1, with few exceptions. The area of Iliamna Lake used for the ferry would be different, because it encompasses the areas at the northern end of the lake around Pedro Bay (as opposed the mid-lake region; i.e.,

AMERICAN OVERSIGHT

Kokhanok). Under the summer-only ferry operations variant, transportation impacts on the lake would be eliminated during the winter, but double during the summer; and the air quality impacts from ferry and truck traffic would be the same as those for Alternative 1. Socioeconomic impacts under this variant would be similar to impacts under Alternative 1. This alternative's natural gas pipeline alignment would follow the north road alignment, and not go across Iliamna Lake; there would be no hazards or impacts at Iliamna Lake during construction of the pipeline, as would occur under Alternative 1. Impacts from the port at Diamond Port would be the same or similar to those as Amakdedori port.

Overall, the HEC for which Alternative 2 consequences may be most noticeably different from Alternative 1 is HEC 2: Accidents and Injuries due to transportation. However, even given the differences noted above, the transportation-related accidents and injury summary impact to human health would remain the same and would be Category 2 (see Appendix K4.10).

4.10.4 Action Alternative 3 – North Road Only

Impacts from the project would be the same as or similar to Alternatives 1 and 2, with few exceptions. The use of Iliamna Lake for a ferry would be eliminated, shifting project-related transportation impacts to the area around Pedro Bay, rather than around Kokhanok. Impacts from the port at Diamond Point would be the same or similar to those as Amakdedori port, with the exception that there is existing port-related activity at both Williamsport and Diamond Point. The concentrate pipeline variant would build a concentrate slurry pipeline from the mine to the port, eliminating concentrate truck traffic, and include a waste treatment plant at Diamond Point to treat the water after slutty has been removed, which would then be piped to and discharged in Iliamna Lake. Potential hazardous materials impacts would remain the same as under Alternative 1, because the slurry pipeline effluent would be treated to meet the Alaska water quality criteria prior to discharge. This variant would likely decrease employment of truck operators, but increase employment at the water treatment plant (WTP) / dewatering facility, but with lower overall employment. Similar to Alternatives 1 and 2 summer-only ferry operations variant, the overall impact would increase seasonal employment but lower year-round employment and likely be to lower the high cost of living for the affected communities near the transportation corridor, but not to the extent of the non-variant alternative.

Similar to Alternative 2, the HEC for which Alternative 3 consequences may be most noticeable from other alternatives is HEC 2: Accidents and Injuries due to transportation. However, even given the differences noted above, the transportation-related accidents and injury summary impact to human health would remain the same; at a Category 2 (see Appendix K4.10).

AMERICAN OVERSIGHT

4.10.5 Summary of Key Impacts

See Table 4.10-4 for a summary of key issues.

Table 4.10-4: Summary of Key Issues for Health and Safety

Impact-causing Project Component	Alternative 1 and variants	Alternative 2 and variants	Alternative 3 and variants
All Project Components	Increase in affected community household incomes, employment, and education attainment. The summer-only ferry variant would lower the cost of living and increase employment opportunities, but not by as much as Alternative 1 because of seasonal vs. year-round employment (+ Category 3). Decrease in food cost relative to income and increased food security (+ Category 2).	Same as Alternative 1, including summer-only variant, although cost of living would be lowered and employment increased in Pedro Bay and not Kokhanok.	Same as Alternative 1. The concentrate pipeline variant would have similar impacts to the summer-only ferry variant under Alternative1.
	Increase and decrease in psychosocial stress, family stress, and family stability (+/- Category 2). Increase and decrease in unintentional injury (falls, cuts, poisoning, etc.) and intentional injury (suicide) (+/- Category 2). Increase and decrease access to quantity and quality of subsistence resources (+/- Category 2). Increase in cancer, respiratory, and cardio-vascular morbidity and mortality rates due to change in diet, nutrition, and physical activity (+/- Category 2). Decreased access to healthcare due to emergency situations and overwhelming local and regional healthcare capacities (- Category 2).	Same as Alternative 1.	Same as Alternative 1.
Transportation Corridor	Increase in unintentional accidents and injuries morbidity and mortality rates due to air, surface, and water transportation, particularly regarding winter access across Iliamna Lake from the ice-breaking ferry. PLP would put some measures in place to minimize impacts, such as trail marking and crossings. The east Kokhanok ferry terminal variant would include access to Sid Larson Bay without crossing the ferry route. The summer-only ferry variant would eliminate the potential hazards to snowmachine winter lake crossings, but increase summer lake and road	Impacts would be similar to Alternative 1, except that the routes and closest communities affected would be around Pedro Bay and the northern end of the lake, instead of Kokhanok and the mid-lake region. The summer-only ferry variant could increase the likelihood of surface transportation accidents and injuries along Williamsport-Pile Bay Road from an increase in truck traffic if mitigation	Same as Alternative 2, except that the elimination of the ferry on Iliamna Lake would reduce the likelihood of water transportation accidents and injuries, but could increase the likelihood of surface transportation accidents and injuries if mitigation measures are not taken to build the Williamsport-Pile Bay Road to meet mine-related and public summer capacity. (- Category 2)

AMERICAN OVERSIGHT

Table 4.10-4: Summary of Key Issues for Health and Safety

Impact-causing Project Component	Alternative 1 and variants	Alternative 2 and variants	Alternative 3 and variants
	traffic (- Category 2).	measures are not taken to build to meet the increased mine-related and public summer capacity (- Category 2).	
Transportation Corridor and Natural Gas Pipeline	Increase in sexually transmitted infection rates and in infectious (respiratory) disease morbidity and mortality rates (- Category 2, during construction phase only).	Same as Alternative 1.	Same as Alternative 1.

4.10.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to impacts on health and safety. These potential future actions are similar to the proposed actions in that each may result in direct and indirect effects to the project-affected communities. To varying degrees, all the RFFAs identified in Section 4.1 have the potential to impact cumulative health and safety through impacts to transportation (e.g., increase in Cook Inlet vessel traffic), subsistence (e.g., impacts on cultural resources and disturbance of wildlife), socioeconomics (e.g., increased household income from other employment opportunities), and water quality and soil quality (e.g., sources of contamination).

RFFAs in the core EIS analysis area have the greatest potential to impact health and safety to the affected communities due to the more-direct nexus to the project. Of these, the following RFFAs have the greatest potential to impact cumulative health and safety:

- Pebble Project buildout – develop 55 percent of the resource over a 78-year period
- Lake and Peninsula Borough Transportation Projects
- Lake and Peninsula Borough Community Development and Capital Improvement Projects
- Rural Alaska Village Grant Program Projects
- Lake and Peninsula Borough and other regional Renewable Energy Initiatives
- Nushagak Electric Cooperative Village Intertie Project
- Industrial Pollutants and Contaminated Sites within Project Area Communities.

Of these, the Pebble Project buildout is the most notable, and would extend the operation of the project for an additional 78 years because it would use the Alternative 1 transportation corridor for the first 20 years, and then add some infrastructure from Alternatives 2 and 3 for the next 53 years and expands the mine site facilities. This has the potential to result in increased health impacts, especially from increased impact durations and possibly increased releases and affected community exposure to potentially hazardous materials. The buildout is not part of the proposed action, and would require additional permits and separate NEPA compliance. Project area communities with pre-existing industrial pollutants and contaminated sites have the potential to add to the cumulative health impacts from exposure to potentially hazardous materials in communities where PLP proposes construction and operations support activities. It

AMERICAN OVERSIGHT

would be expected that mitigation measures would be used to minimize or mitigate exposure (e.g., avoidance of Alaska Department of Environmental Conservation-contaminated sites, protective clothing and equipment, dust suppression, etc.). The improvement-related RFFAs have the potential to add to positive impacts to the affected communities (e.g., road improvement and increased safety).

As discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics, several RFFAs could have socioeconomic impacts on the potentially affected communities. Transportation, infrastructure, and energy improvements could induce increased development, and these potential impacts would likely be greater if the proposed project is implemented. Other RFFAs were noted as likely having minimal socioeconomic cumulative impact on the potentially affected communities.

As discussed in Section 4.9, Subsistence, many of the RFFAs could contribute to increased potential for impacts on subsistence resources by environmentally disturbing activities and increased human activity. Environmental impacts could include habitat fragmentation, increased noise and atmospheric pollution, and disturbances and impacts to fish and wildlife. The increased volume of people could lead to increased recreational hunting/fishing, and impact subsistence cycles for local communities. The cumulative impacts would be long term to permanent, and geographically broad in scope (regional level).

As discussed in Section 4.12, Transportation and Navigation, most of the RFFAs would contribute to the cumulative increase in vessel traffic in Cook Inlet; increased demand for regional and helicopter air transportation and logistical support (particularly if mining development projects were to overlap); and increased surface transportation impacts along roads leading to the communities of Iliamna, Newhalen, and Nondalton via the proposed Iliamna spur road from RFFAs related to subsistence and recreational uses. It would be likely that any increased demand for air transport could be met by adding supply, because the RFFA sites are distributed rather than clustered with different airstrips or staging sites.

Cumulative effects would be the same under all alternatives.

AMERICAN OVERSIGHT

4.11 AESTHETICS

Aesthetic impacts include in those that could result from changes in the visual landscape (including night sky) and/or soundscape. For this analysis, visual impacts are defined as changes to the scenic attributes of the landscape resulting from the introduction of visual contrasts (e.g., development) and the associated changes in the human visual experience of the landscape (NPS 2014b). Impacts to soundscape are defined by changes in decibels (dBA) levels that altered soundscape from a "wilderness ambient" character.

4.11.1 Visual Impacts

Visual impacts were assessed by determining 1) the magnitude and geographic extent of visual contrast caused by the proposed project, and 2) the potential effects of visual contrasts on the viewer experience based on the context of the impact and how it is perceived.

4.11.1.1 Magnitude and Geographic Extent of Impacts

The magnitude of impacts on aesthetics and visual resources were assessed by determining the overall change in landscape character based on an assessment of visual contrast and scale dominance. The geographic extent of the effects was measured by the extent of moderate to strong visual contrast, and was summarized as localized, extended, or regional.

- **Visual Contrast:** The Bureau of Land Management (BLM) Contrast Rating Procedure was used to determine visual contrast that could result from construction and operation of the project (BLM 1986). The project would not directly affect federal land; however, the BLM Contrast Rating Procedure is an established and developed methodology commonly used to assess visual impacts. This method assumes that the extent to which a project results in adverse effects on visual resources is a function of the visual contrast between the project components and the existing landscape character. Levels of contrast are defined as follows:
  - None – The element contrast is not visible or perceived.
  - Weak – The element contrast can be seen but does not attract attention.
  - Moderate – The element contrast begins to attract attention and to dominate the characteristic landscape.
  - Strong – The element contrast demands attention, would not be overlooked, and is dominant in the landscape.
- **Scale Dominance:** The contrast created by a project is directly related to its size and scale as compared to the surroundings in which it is placed. Scale dominance refers to the scale of an object relative to the visible expanse of the landscape that forms its setting (BLM 1986). A dominant feature of a landscape tends to attract attention and becomes the focal point of the view. Where two or more features both attract attention and have generally equal visual influence over the landscape, they are considered co-dominant. An object or feature that is easily overlooked or absorbed by the surrounding landscape is considered subordinate. Scale dominance was classified using the following metrics:
  - Not Visually Evident (NVE)
  - Visually Subordinate (VS)
  - Visually Evident (VE)
  - Dominant (D)

AMERICAN OVERSIGHT

Visual Impacts: Potential visual impacts perceived by viewers was assessed at each Key Observation Point (KOP) based on the level of exposure to moderate or high magnitude impacts, viewer sensitivity to change, the potential for those effects to alter the human experience of the landscape, and the context of the impact. Exposure was measured based on viewer duration, viewer geometry, and distance from the project component. These metrics were assessed as follows:

- **Viewer Duration:** Viewer duration or exposure refers to the length of time project features may be in view. This description discloses whether expected viewer exposure would be limited to a short duration and/or small number of viewpoints, or would be of a prolonged duration and/or experienced from multiple viewpoints.
- **Viewer Geometry:** Viewer geometry refers to the spatial relationship of the observer to the viewed object (i.e., the project), including both the vertical and horizontal angles of view (BLM 2013). The vertical angle of view refers to the observer's elevation relative to the viewed object. The horizontal angle of view refers to the compass direction of the view from the observer to the object. Visibility is typically greater for observers whose viewing angle is directed toward a project feature than for those with a lateral view.
- **Distance:** The degree of perceived visual contrast and scale dominance of an object is influenced by the object's distance from the viewer. As viewing distance increases, the project appears smaller and less dominant. Likewise, as distance increases, the apparent contrast of color decreases (BLM 1986). Distance from project components is classified as follows:
  - Immediate foreground (less than 3 miles)
  - Foreground–middleground (3 to 5 miles)
  - Background (5 to 15 miles)
  - Seldom seen (beyond 15 miles).

Soundscape: The soundscape was analyzed using the information and methods described in Section 3.19, Noise, and Section 4.19, Noise.

4.11.2 No Action Alternative

Under the No Action alternative, the project would not be constructed, and therefore would not have any new or additional effects on aesthetics.

4.11.3 Action Alternative 1 – Applicant's Proposed Alternative

Due to the scale of the project, many of the components are geographically isolated, and as such, visual impacts of the project may be limited to that caused by one component. However, some viewers' locations may be characterized by broader or expansive views, and as such have the potential for exposure to more than one project component (e.g., mine site and transportation corridor). To address this, potential visual and aesthetic impacts are provided below by project component and collectively for all project components.

4.11.3.1 Mine Site

Visual Impacts: Specific mine site components would result in variable levels of visual contrast and scale dominance. For example, the open pit mine, tailings storage facility overburden stockpiles, material sites, and quarries would create strong visual contrast in form, line, color, and texture due to alterations in the existing natural contours of the landscape and removal of vegetation. Smooth texture and reflective surface of water management ponds would result in

AMERICAN OVERSIGHT

strong contrast against the coarse textures and natural matte colors of the landscape. Milling and processing facilities, along with supporting infrastructure such as the power plant, water treatment plants, camp facilities, and storage facilities, would appear industrial. These industrial straight lines and geometric forms would contrast against the softer, less angular lines of the landscape. These features would also include lighting that would have a strong contrast level against the existing dark sky nightscape. Lighting could be visible at distances from high elevation locations beyond 15 miles due to the lack of night lighting and intactness of night sky. During periods of snow cover, lighting at the mine site would reflect against the snow, thereby creating a halo effect that could extend outward to background distance zones.

Collectively, and where visible from locations within 15 miles, the mine site would appear dominant in the landscape and would alter scenic quality and night sky. Viewshed models indicate that visibility of mine components from ground-based locations would be limited by topography and vegetation screening (refer to Appendix K4.11 for figures of the viewshed). Visibility would generally be limited to high-elevation areas on Sharp Mountain and Groundhog Mountain, and the upper Stuyahok River Valley. The mine site could also be visible from higher elevations located west of Lake Clark (but outside of Lake Clark National Park and Preserve); however, visual contrast is expected to attenuate to a weak level at this distance (approximately 20 miles away). Refer to Appendix K4.11 for visual simulations of the project at defined KOPs. At Iliamna Lake, views of the mine site would largely be screened by vegetation and topography; however, night lighting would be evident as haloing during winter months.

Impacts of the mine site perceived from residents, recreationists, or subsistence users in the analysis area for the mine site would be of medium-high magnitude and localized geographic extent due the remoteness of the site and the existing topographic and vegetation screening. Viewer duration would be intermittent to prolonged, depending on the activity of the viewer. If remote recreation or subsistence use should occur within 15 miles of the mine site and in the seen area, impacts could be high magnitude due to the increased visual contrast perceived from this distance. The duration of impacts would be long term, extending beyond the life of the project. Visual impacts would not impact viewers located in areas identified by special designations. The likelihood of impacts is high.

Soundscape: Operations at the mine site would involve noise-producing activities and processes that include extracting rock at the pit and transporting rock material to milling facilities or the pyritic tailings storage facility/potentially acid generating storage facility. Section 4.19, Noise, describes anticipated noise-related impacts that could result from construction, operation, and closure of the mine. Based on the results of the noise analysis, it was determined that the existing "wilderness ambient" soundscape would be maintained beyond a distance of 10 miles from the mine site. Within approximately 18,450 feet, the estimated operational noise level would be at least 30 dBA equivalent continuous sound level (L_{eq}), and thus, would risk causing sleep disturbance for recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient". Within approximately 12,900 feet, the estimated operational noise level would be at least 45 times day-night sound level (dBA L_{dn}) at a building exterior. These impacts to soundscape would last for the duration of project operations.

4.11.3.2 Transportation Corridor

Visual Impacts: Specific components of the transportation corridor would result in variable levels of visual contrast and scale dominance. Access roads could result in strong visual contrast in form, line, color, and texture against the surrounding landscape, as linear/curvilinear line and grey-brown color and coarse texture of road would contrast surrounding natural color, textures, and lines of the landscape. Mine-related traffic on the roadway could be visually

AMERICAN OVERSIGHT

evident due to movement and associated dust plumes. Movement of vehicles would be more apparent during dark sky conditions, as vehicle lighting would be evident. The access road and mine traffic are expected to result in the strongest contrast when viewed from higher elevation or superior viewer positions or aircraft, as roads would not be screened by vegetation.

The north and south ferry terminals would result in moderate to strong visual contrast when viewed in close proximity (i.e., 3 to 5 miles) from Iliamna Lake or higher elevation locations (see Appendix K4.11 for visual simulations from defined KOPs). The ferry terminals would appear distinct against the shoreline, as the form and line of the structures would contrast with the natural character of the surrounding landscape. Visual contrast would primarily result for the angular lines, varied colors, and smooth texture of cargo containers where they would be stockpiled at the terminals. Strong visual contrast would be expected to result from night lighting. Where lights are not visible because the terminals would be located outside of the seen area, haloing may still be visually evident, particularly in winter months when lighting is reflected off snow and ice surfaces. Terminal facilities would be not visible or visually subordinate from villages on the shoreline of Iliamna Lake, as the communities are either located outside of the seen area, or are situated greater than 25 miles away.

Ferry traffic would appear dominant from Kokhanok, as this community is located within 5 miles of the ferry route. Other communities are located more than 15 miles from the route; given the size and low stature of the ferries, visual contrast is expected to be weak and ferries would appear visually subordinate.

Impacts of the transportation corridor perceived from residents, recreationists, or subsistence users in the EIS analysis area would be of low to medium magnitude and localized geographic extent due to screening of the road corridor by vegetation and the low stature of the ferry terminals (see Appendix K4.11 for project viewshed models). The magnitude and geographic extent would be greater under dark sky conditions due to the contrast of night-lighting. Viewer exposure to the transportation corridor and associated uses would be intermittent to prolonged, depending on the activity of the viewer. The duration of impacts would be long term, extending beyond the life of the project. Visual impacts would not impact viewers located in areas identified by special designations. The likelihood of impacts is high.

Soundscape: During operations, truck traffic, light vehicles, and maintenance along the mine access road could result in impacts to soundscape that extend to up to 0.5 miles from the road corridor, as measured by the potential for a 45 dBA L_{max} value (maximum value level; see Section 4.19, Noise for more information). The presence of dense vegetation or terrain features like ridgelines or hills could narrow this distance. Impacts to soundscape from the access route would endure for as long as the project is in the operations phase.

Primary impacts to soundscape from operation of the ferry terminals would result from continuous (day and night) operation of the power supply (generator) at each ferry terminal. This feature would produce a reference sound level no greater than 70 dBA L_{eq} at 50 feet. Within approximately 2,250 feet from the ferry terminal, the estimated operational noise level would be at least 30 dBA L_{eq}, and thus, would risk causing sleep disturbance for recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient." Within approximately 1,000 feet, the estimated operational noise level would be at least 45 dBA L_{dn} at a building exterior. Anticipated impacts to soundscape would persist through operations.

Kokhanok East Ferry Terminal Variant: Potential impacts to aesthetic resources would be similar to that described for the south ferry terminal; however, the perception of impacts would be of high magnitude due to the close proximity of viewer and noise-receptors.

AMERICAN OVERSIGHT

Summer-Only Ferry Variant: Season-specific impacts to aesthetic resources during winter months primarily pertain to lighting, and the visual contrast created from ice break on the lake where the ferry would cross, and ferry noise associated with ice breaking. Visual impacts would be primarily experienced by residents of Kokhanok due to the proximity of this village to the ferry terminal and crossing route. Individuals engaged in winter subsistence activity may also experience impacts from vehicle lighting on access roads and facility lighting at the ferry terminals. Under the summer-only ferry variant, impacts from the transportation corridor would be reduced to low-medium magnitude due to the decrease in lighting-related impacts. The reduction in impacts would be primarily experienced under the Kokhanok East Ferry Variant, as residents of this community would experience fewer visual and soundscape-related impacts during winter months when the transportation corridor was not operational.

4.11.3.3 Amakdedori Port

Visual Impacts: Visual contrast of the Amakdedori port would be similar to that described for the north and south ferry terminals. Visual contrast may be stronger when viewed from close proximity due to the larger stature of this facility, as vertical lines and geometric shape of the facility would contrast against the low marshlands, with the backdrop of the rolling hills and mountains. As a result of the unobstructed horizon of the Cook Inlet, the geographic extent of impacts would extend until moderate to strong contrast attenuated to a weak level (anticipated beyond 10 miles). Refer to Appendix K4.11 for project viewshed models. Development of the port would change the configuration of the shoreline and create an industrial feature in an otherwise natural landscape in Kamishak Bay. Increased project-related boat traffic on Kamishak Bay in Cook Inlet would be visually evident from the foreground, middleground, and background distance zones. The port would not be visible from the mouth of McNeil River at the edge of McNeil State Game Refuge; however, vessel traffic including lightering at the southern location, would be evident and could be a dominant part of the viewers' experience. As discussed for ferry terminals, strong visual contrast is expected to result from night lighting and the potential for haloing during winter months when lighting is reflected off the snow's surface. Visual impacts could impact viewers located in areas identified by special designations, including the McNeil River State Game Refuge and Alaska Maritime National Wildlife Refuge. The likelihood of impacts is high. The duration of direct impacts would be long term, as an agreement with the landowner would leave the port facilities in place for use as an industrial port. Peak visitation and viewing is from early summer into fall, and would be extremely low during the winter.

Soundscape: Although the equipment and vehicle rosters are different, the technique used for estimating noise exposure attributable to Amakdedori port operations is similar to and uses the same conservative assumptions as the technique used for estimating aggregate noise emissions from mine site operations. Considering sound attenuation with distance and other factors, the findings of the predictive analysis are as follows:

- Within approximately 9,750 feet, the estimated operations-attributed noise level would be at least 30 dBA L_{eq}, and thus, would risk causing sleep disturbance for recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient."
- Within approximately 5,800 feet, the estimated operational noise level would be at least 45 dBA L_{dn} at a building exterior, and thus, would be 10 dBA greater than the existing outdoor ambient sound level.

The anticipated noise effects within the two latter above-stated distance buffers would last as long as the port operates during concentrate loading. See Section 4.19, Noise, for more detailed analysis.

AMERICAN OVERSIGHT

4.11.3.4 Natural Gas Pipeline Corridor

Because the natural gas pipeline corridor would follow the transportation corridor, it would not introduce additional visual contrast in form, line, color, or texture that is distinct from the access road. The compressor station, located on the Kenai Peninsula, would result in moderate to strong visual contrast against the surrounding landscape and would be visually evident against the natural landscape. The compressor station would not be seen from Anchor Point State Recreation Area or Stariski Campground.

While pipeline construction activities would create noise in conjunction with road construction, the duration would be limited to two years. No noise-producing sources would be located along the pipeline corridor during pipeline operation. Gas traveling through the buried pipeline would not emit audible noise; therefore, no noise impacts associated with pipeline operations would occur under Alternative 1.

4.11.3.5 All Components

Due to the scale of the project, many of the components are geographically isolated from each other and from population centers or areas of frequent visitation, and as a result, opportunity to experience visual contrast of more than one component is limited. An exception to this limitation applies to those experiencing views of the project from recreational or local low-altitude aircraft. When viewed from the air, the project would result in moderate to strong visual contrast due to vegetation removal and ground disturbance in access roads and the mine site. For air-based viewers flying to recreation destinations such as the McNeil River State Game Refuge, the transportation corridor and Amakdedori port would be visually evident. Visual impacts would be expected to be of medium to high magnitude, and would decrease with distance from the facilities.

4.11.4 Action Alternative 2 – North Road and Ferry

4.11.4.1 Mine Site

Impacts to aesthetic resources (visual and soundscape) under Alternative 2 would be the same or similar as those described for Alternative 1. The mine site component variants would not be substantial enough to change the impacts.

4.11.4.2 Transportation Corridor – North Road and Ferry

Visual Impacts: The transportation corridor under Alternative 2 would result in variable levels of visual contrast and scale dominance as described in Alternative 1. The magnitude of these impacts would be greatest when viewed from higher elevation or superior viewer positons, as roads would not be screened by vegetation, and visual contrast of the cleared vegetation of the roadway would contrast the surrounding landscape. When viewed from Nondalton or Fish Village, the north road would be expected to result in low visual contrast, as viewers would be primarily situated at a similar grade to the road and visibility would be minimized by vegetation screening. The north road would also be located greater than 5 miles from these villages, thereby further minimizing the potential for visual contrast or scale dominance. The North Road would result in strong visual contrast when viewed from higher elevations on Roadhouse Mountain. Located approximately 3 miles from the Roadhouse Mountain, the road would appear as a discrete curvilinear line that resulted in strong visual contrast against the landscape that would appear visually evident.

AMERICAN OVERSIGHT

Between Pile Bay and Diamond Point port, operation of the access road would result in high magnitude impacts, particularly in areas where the new access road would bypass the existing road as multiple roads would result in moderate to strong contrast.

As was described for the north and south ferry terminals, the ferry terminals at Eagle Bay and Pile Bay would result in moderate to strong visual contrast when viewed in close proximity (i.e., 3 to 5 miles) from Iliamna Lake or higher elevation locations. From this distance zone, the ferry terminals would appear distinct against the shoreline, as the form and line of the structures would contrast with the natural character of the surrounding landscape. Strong visual contrast is expected to result from night lighting. Where lights are not visible because the port is located outside of the seen area, haloing in the night sky may still be visually evident, particularly in winter months when lighting is reflected off the snow's surface.

The communities of Newhalen and Iliamna are the only residential areas located within approximately 10 miles of the ferry terminals. From these locations, visual contrast would be weak and the facilities would not be visually evident under daylight conditions. During periods of night lighting, visual contrast and scale dominance could increase to a moderate to strong level, and would be visually evident due to the contrast of lighting against the otherwise intact dark sky. Noise from ferry ice breaking activities could also be apparent to these communities.

Other villages on Iliamna Lake are located greater than 15 miles from the ferry terminals and route. Given the size and low stature of the ferries, visual contrast is expected to be weak and ferries would appear visually subordinate. There is one small research camp located on the peninsula of Pedro Bay. From this location, passing ferry traffic would be considered visually evident.

Viewer exposure would be intermittent to prolonged, depending on the activity of the viewer. The duration of impacts would be long term, extending beyond the life of the project. Visual impacts would not impact viewers located in areas identified by special designations (see the project viewshed models in Appendix K4.11). The likelihood of impacts is high.

Soundscape: Impacts to soundscape would be similar to those described for Alternative 1; however, noise-related impacts are not expected to affect local communities, as communities are located more than 0.5 miles from the transportation corridor.

Summer-Only Ferry Variant: As described in Alternative 1, season-specific impacts to aesthetic resources during winter months primarily pertain to those that would result from lighting, and the visual contrast created from ice break on the lake where the ferry crosses. Visual impacts would be primarily experienced by residents of Iliamna, Newhalen, Pedro Bay, and Pile Bay due to the proximity of these communities to the ferry terminals and crossing route. Individuals engaged in winter subsistence activity would also experience impacts from vehicle lighting on access roads and facility lighting at the ferry terminals.

4.11.4.3 Diamond Point Port

Visual Impacts: The magnitude of impacts from the Diamond Point port would be similar to that described for the Amakdedori port under Alternative 1. Visual contrast would appear strong when viewed from close proximity due to the larger stature of this facility; the vertical lines and geometric shape of the facility would contrast against the natural backdrop of the Iliamna Bay. The geographic extent of impacts would be more limited than Amakdedori port due to the steep landforms and enclosure of views created by topography surrounding the bay (see Appendix K4.11 for project viewshed models). For viewers situated in the bay, the port would appear dominant and focal due to the enclosure of the landscape in the bay.

AMERICAN OVERSIGHT

Increased project-related boat traffic in Cook Inlet would be visually evident from the foreground, middleground, and background distance zones. The port would be visible from the Alaska Maritime National Wildlife Refuge, and vessel traffic would be evident and could dominate the viewers' experience. As discussed for the ferry terminals, strong visual contrast is expected to result from night lighting and the potential for haloing during winter months when lighting is reflected off the snow's surface. The duration of impacts would be long term, extending beyond the life of the project if the port remains in operation. Visual impacts could impact viewers located in areas identified by special designations, including the Alaska Maritime National Wildlife Refuge. The likelihood of impacts is high.

Soundscape: Impacts to soundscape would be similar to those described for the Amakdedori port. Noise-related impacts would be largely contained in Iliamna Bay due to the steep topography of the surrounding landforms.

4.11.4.4 Natural Gas Pipeline Corridor

Visual Impacts: Under Alternative 2, the gas pipeline would be located on the north road and then follow the alignment of the north road of Alternative 3. The magnitude of impacts from the pipeline would be greatest between the junction with the Eagle Bay ferry terminal access road and the east ferry terminal access road, as visual contrast of the cleared right-of-way would contrast the existing natural landscape. Where aligned with the exiting Pile Bay-Williamsport Road, the pipeline would result in weak to moderate visual contrast resulting primarily from roadway upgrades.

Soundscape: As described in Alternative 1, no noise-producing sources would be located along the pipeline corridor during pipeline operation. Gas traveling through the buried pipeline would not emit audible noise; therefore, no noise impacts associated with pipeline operations would occur under Alternative 2.

4.11.4.5 All Components

Visual impacts from all components would be similar to those described for Alternative 1; however, the proximity of the access road to popular recreation destinations could result in increased viewer exposure to those features. For example, for air-based viewers flying to recreation destinations such as the Lake Clark National Park and Preserve, McNeil River State Game Refuge, Katmai National Park and Preserve, and area sport fishing lodges, the transportation corridor and Diamond Point port would be visually evident, although not as visually evident as the Amakdedori port under Alternative 1. Visual impacts would be expected to be of medium to high magnitude, and would decrease with distance from the facilities.

4.11.5 Action Alternative 3 – North Road Only

4.11.5.1 Mine Site

Impacts to aesthetic resources (visual and soundscape) under Alternative 3 would be the same as those described for Alternative 1.

4.11.5.2 Transportation Corridor

Impacts form the transportation corridor under Alternative 3 would be similar to Alternative 2 in portions of the network that are the same under both alternatives (mine site to junction leading to Eagle Bay ferry terminal; Pile Bay to Diamond Point port). However, because the access road would extend along the north shore of Iliamna Lake, impacts would be of higher magnitude and larger geographic extent (refer to Appendix K4.11 for project viewshed models). Visual contrast

AMERICAN OVERSIGHT

would be strong and the road would appear dominant when viewed from the close proximity of the community of Pedro Bay, and from areas within 3 miles of the shoreline of Iliamna Lake and from high points within Lake Clark National Park and Preserve.

4.11.5.3 Diamond Point Port

Impacts under Alternative 3 would be the same as those described for Alternative 2.

4.11.5.4 All Components

Visual impacts from all components would be similar to those described for Alternative 2; however, the magnitude of impacts would be greater due to operation of the north access road. The road would be visually evident, appearing as a curvilinear line with contrasting color and texture against the surrounding landscape.

4.11.6 Key Issues Summary

See Table 4.11-1 for a summary of key issues.

Table 4.11-1: Summary of Key Issues for Aesthetic Resources

Project component	Alt 1 (+variants)	Alt 2 (+variants)	Alt 3 (+variants)
Mine Site	Aesthetic resources would be affected by medium to high magnitude impacts that would appear dominant in the landscape. Impacts would be limited in geographic extent by rugged topography. Impacts from lighting would be visually evident, particularly during winter months. Impacts to soundscape would be limited to within 10 miles of the mine site.	Same as Alternative 1	Same as Alternative 1
Transportation Corridor	Aesthetic resources would be affected by low to medium magnitude impacts that would be visually evident in the landscape. Movement of vehicles and ferries could be more apparent during dark sky conditions, as lighting would be evident. Impacts to soundscape would be limited to within 0.5 miles of the transportation corridor. Kokhanok, and to a lesser extent Iliamna and Newhalen would be affected by transportation corridor and ferry activities.	Impacts would be similar to Alternative 1; however the northern route would affect residents of Iliamna, Newhalen, and Pile Bay due to proximity to the access route and ferry terminals. Impacts would include those that result from movement and lighting. Under the summer-only ferry variant, reduction of season-specific impacts to aesthetic resources during winter months would be similar to Alternative 1; however reduction in impacts would be experienced by residents in the communities along	Impacts would be the same as described in Alternative 2; however, high magnitude impacts would occur in the community of Pedro Bay due to the proximity to the transportation route.

AMERICAN OVERSIGHT

Table 4.11-1: Summary of Key Issues for Aesthetic Resources

Project component	Alt 1 (+variants)	Alt 2 (+variants)	Alt 3 (+variants)
	Under the Kokhanok East Ferry Terminal Variant, Potential impacts to aesthetic resources would be similar to that described for the south ferry terminal; however the perception of impacts would be of high magnitude due to the close proximity of viewer and noise-receptors. Under the summer-only ferry variant, the visual contrast would not be created from ice break on the lake where the ferry crosses. The reduction in impacts would be primarily experienced under the Kokhanok East Ferry Variant.	the northern shore of Lake Iliamna.	
Amakdedori Port and Diamond Point Port	Aesthetic resources would be affected by low-medium magnitude impacts that would be visually evident when viewed within 5 miles. Scale dominance of the port facility would decrease with distance. Lighting could be visible at distances of 10 miles from the port, particularly during winter months. Soundscape-related impacts could extend to almost 2 miles from port.	Impacts would be similar to that described for Alternative 1; however, the port site would be located in Iliamna Bay, where steep topography would limit geographic extent of visual and soundscape-related impacts.	Same as Alternative 2.
Natural Gas Pipeline	Because the natural gas pipeline corridor would follow the transportation corridor, it would not introduce additional visual contrast in form, line, color, or texture that is distinct from the roadway access road.	The magnitude of impacts from the pipeline would be greatest between the junction with the Eagle Bay ferry Terminal Access Road, as visual contrast of the cleared right-of-way would contrast the existing natural landscape.	Same as Alternative 1.
All Components	Visual impacts would appear dominant to viewers located in recreational or local low-altitude aircraft. When viewed from the air, the project would result in moderate to strong visual contrast due to vegetation removal and ground	Visual impacts from all components would be similar to those described for Alternative 1; however, the proximity of the access road to popular recreation destinations could result in increased viewer exposure to those features.	Visual impacts from all components would be similar to those described for Alternative 2; however, the magnitude of impacts would be greater due to operation of the north access road. The road would be visually evident, appearing as a curvilinear

	disturbance in access roads and the mine site. For air-based viewers flying to recreation destinations such as the McNeil River State Game Refuge, the transportation corridor would be visually evident. Visual impacts are expected to be of medium to high magnitude, and would decrease with distance from the facilities.		line with contrasting color and texture against the surrounding landscape.

4.11.7 Cumulative Effects

The reasonably foreseeable future actions (RFFAs) identified in Section 4.1 and Appendix K4.1 carried forward in this analysis include contiguous mining clams located roughly between Iliamna Lake and the Chuitna River, as well as more geographically isolated claims in the watershed, oil and gas development in Cook Inlet, and smaller scale onshore oil and gas, as summarized below:

- Pebble Project buildout- develop 55% of the resource over a 78 year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*

*Indicates exploration activities only.

- Donlin Gold
- Diamond Point Rock Quarry
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure and Energy Project

Reasonably foreseeable locatable mineral development in the project area of Iliamna Lake and the Chuitna River, and east to Lake Clark, could contribute cumulatively to high magnitude impacts that alter landscape character from naturally evolving to industrial across a large geographic extent. Such impacts could be experienced by recreationists in Lake Clark National Park and Preserve and surrounding areas, and would be of high magnitude and dominant when viewed from high elevations and recreational flightpaths. The RFFA for the expansion of the Pebble Project could include the impacts from both Alternative 1 and 3, which would contribute to the cumulative impacts of aesthetics in the region.

Aesthetic impacts could extend to the Cook Inlet, as port and shipping traffic would be more frequent due to the number of projects being serviced. Oil and gas development in Cook Inlet would contribute cumulatively to impacts in Cook Inlet, with the magnitude dependent on the level of on- and offshore oil and gas development. Transportation and infrastructure development in communities would contribute to cumulative impacts at a lesser extent;

AMERICAN OVERSIGHT

however, when combined with other RFFAs, these actions would contribute to overall change in character from one that is more remote and undeveloped to one that is more industrial. The project would contribute to cumulative impacts, and there would be no difference across action alternatives.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

4.25 THREATENED AND ENDANGERED SPECIES

Under the federal Endangered Species Act (ESA) of 1973, applicants for projects requiring federal agency action that could adversely affect Threatened and Endangered Species (TES) are required to consult with and mitigate impacts in consultation with US Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS). Adverse impacts are defined as "take" (defined as "to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, collect, or attempt to engage in such conduct"), which are prohibited except as authorized through consultation with USFWS and NMFS. The USFWS or NMFS may issue an Incidental Take Statement under Section 7 or Section 10 of the ESA, depending on whether there is a federal nexus (federal permit required or funding involved). Because the US Army Corps of Engineers is the lead federal agency for the project, the agency is required to consider the effects that a federal action may have on all listed species in the project's action area. To analyze the potential effects that a federal action may have on a listed species, a biological assessment has been prepared. Separate biological assessments for species under the jurisdiction of the USFWS and NMFS have been prepared. These biological assessments are included as Appendix G and Appendix H, and are referenced throughout this section because they provide additional details and analyses for Action Alternative 1, the applicant's proposed alternative.

This section details the potential impacts of the project and alternatives on TES in the project's action area. Marine mammals also protected under the Marine Mammal Protection Act (MMPA) are adiscussed in Sections 3.23 and 4.23. The action area for TES includes all areas of potential direct and indirect impacts from the project and alternatives. The action area encompasses all marine project components (all proposed port locations, lightering locations, and natural gas pipeline routes), plus a surrounding 5-mile radius buffer in the marine environment. No terrestrial components of the project (e.g., the mine site, ferry terminals, terrestrial portion of the transportation and natural gas pipeline corridors, and compressor station on the Kenai Peninsula) are included in the action area, because TES do not occur in the area; only marine components of the project are included in the action area. Potential direct and indirect impacts from the project and alternatives may include:

- behavioral disturbance (from noise and physical presence);
- injury and mortality (from vessels and aircraft); and
- habitat changes (from loss of foraging habitat and climate change).

The magnitude of impact from the project depends on the specific species' sensitivity to the disturbance and the type of disturbance; the duration and geographic extent of impacts depends on the location and season in which the disturbance occurs (e.g., during whale migrations); and the potential of impacts is how likely the project would overlap with TES and/or TES habitat.

Specific to habitat changes and potential impacts to marine mammal TES from climate change are included in the discussion with all marine mammal species in Section 4.23, and are not repeated here. Potential impacts from a spill or leak (including natural gas, oil, diesel, and all other substances being transported to and from the mine site) are not discussed in this section, but detailed in Section 4.27. [Note: data from 2018 baseline field surveys will be included in the DEIS].

Specific mitigation measures to minimize impacts are currently being developed. Impacts to TES species would be minimized or mitigated by implementation of mitigation measures that would be developed through the permitting process in consultation with the USFWS and NMFS. Some of the applicant's avoidance and minimization measures include the development of a

AMERICAN OVERSIGHT

Wildlife Management Plan that would detail management measures to minimize impacts to wildlife species (see Chapter 5, Mitigation). The Wildlife Management Plan would describe the equipment, methodology, training, and assessment techniques that would be used to minimize the potential for wildlife interaction and minimize impacts to species from all aspects of the project. Additionally, tug and barge speeds in northern sea otter (*Enhydra lutris kenyoni*) critical habitat would be controlled to minimize the potential impacts to northern sea otters. This would involve regulating vessel speeds to reduce the potential for collision and disturbance for all TES.

4.25.1 No Action Alternative

Under the No Action Alternative, the project would not be constructed, and there would be no new impacts on TES in the project area.

4.25.2 Action Alternative 1 – Applicant's Proposed Alternative

The project has the potential to directly and indirectly impact TES through behavioral disturbance (such as noise and physical presence of vessels and aircraft) and habitat changes (such as loss of foraging habitat and climate change impacts) as detailed in the following sections. Potential TES impacts specific to the Amakdedori port and natural gas pipeline corridor across Cook Inlet are described herein. Project sources of noise and physical presence that may disturb the natural behavior of TES include construction, operations, and decommissioning of the marine-portions of project components. This may occur through the presence of various project-specific vessels in Kamishak Bay; pile driving (under the pile-supported dock variant) and other construction noise associated with the construction of the Amakdedori port; and aircraft used during construction and operations. Potential noise resulting from the pile-supported dock variant of Action Alternative 1 would produce greater sound levels in the water than constructing a solid fill dock, and could cause greater potential effects to all marine mammal TES discussed in this section, as pile driving noise may exceed injury thresholds as defined by regulatory agencies. The specific noise sources that may impact TES are previously described in Section 3.23 and Appendix K4.25. Impacts from habitat changes generally include the loss of foraging habitat from fill into the marine environment from the earthen causeway and sheet pile wharf at Amakdedori port. Some of these impacts would occur to TES critical habitat. Overall, injury and mortality to TES have a low potential to occur and are only discussed per species, where applicable.

4.25.2.1 Cook Inlet Beluga Whale

Behavioral Disturbance

Underwater and Airborne Noise

Beluga whales (*Delphinapterus leucas*) are categorized as mid-frequency cetaceans with functional hearing in the 50-Hertz (Hz) to 200-kilohertz (kHz) range (Ciminello et al. 2012). Spatial displacements of beluga whales caused by loud sources of noise have been documented. Underwater noise from project-related activities during all phases of development could affect passage of Cook Inlet beluga whales in their critical habitat. Beluga whale responses to underwater noise include changes in behavioral states (Richardson et al. 1995), changes in vocalizations (Gervaise et al. 2012), and avoidance (Erbe and Farmer 2000). Lesage et al. (1999) observed vocal responses, which included a reduction in call rate, an increase in emissions of certain call types, repetition of specific calls, and a shift in frequency bands. A detailed discussion on noise impacts from project components can be found in Appendix K4.25.

AMERICAN OVERSIGHT

The magnitude of the impact from underwater noise on beluga whales is expected to be minimal with the implementation of industry-standard mitigation measures anticipated through consultation with NMFS. The extent to which project activity noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995); however, project activity noise is expected to be localized, only affecting the area in the immediate vicinity of the project activities (see Appendix K4.25). Noise as a result of construction of the port under pile-supported dock variant of Action Alternative 1 at Amakdedori port would have the greatest potential behavioral impact on Cook Inlet beluga whales. Underwater sound levels from pile driving vary with the size and type of piles; the size and type of hammer and will be further analyzed in subsequent permitting efforts required by the MMPA. The duration of time that beluga whales may be exposed to underwater sound from vessels would be short-term and temporary during pipeline installation and construction activities; however, the exposure would only be expected when seasonal distribution and habitat selection overlap in time and space with in-water project activities. Most Cook Inlet beluga whales spend the ice-free months in the upper portion of Cook Inlet (Goetz et al. 2012; Shelden et al. 2015), to the north of the action area. As Cook Inlet beluga whales shift south into the mid-inlet during fall and winter months (Hobbs et al. 2005), they have a higher likelihood of impacts from noise associated with the project compared to the summer (when they are generally outside of the action area). Decibel levels associated with transportation vessels during operations are expected to be below criteria. Potential impacts on beluga whale behavior are anticipated to be localized in the action area, and would not result in population-level effects.

Physical Presence (Vessel and Aircraft)

An increase in vessel traffic is expected to occur from offshore activities and construction and operations of Amakdedori port. NFMS researchers have witnessed avoidance and overt behavioral reactions by Cook Inlet beluga whales when approached by small vessels (Lerczak et al. 2000). Blackwell and Greene (2003) observed tolerance of beluga whales to large cargo-freight ships at the Port of Anchorage. Beluga whales reacted to aircraft flying 500 to 700 feet away, by diving for longer periods, reducing surfacing time, and sometimes swimming away; however, they did not respond to aircraft flying 1,640 feet away (Richardson et al. 1995).

Localized effects on the behavior, movement patterns, or habitat use of Cook Inlet beluga whales may occur as a result of disturbance from vessel traffic associated with project activities. In Cook Inlet, beluga whales, including adults with calves, appear to exhibit site fidelity, returning to estuary areas even after a disturbance (Moore et al. 2000). Beluga whales continue to occupy upper Cook Inlet despite oil and gas development, vessel and aircraft traffic, and dredging operations. Moore et al. (2000) concluded that beluga whales appear to have become habituated to offshore oil and gas activities in central Cook Inlet.

Impacts to Cook Inlet beluga whales from the physical presence of project components are expected at some level of intensity. Studies on Cook Inlet beluga whale activity near Amakdedori port are limited. Although high levels of vessel traffic occur in Cook Inlet from fishing and existing industry activity, especially during the summer and early autumn months, it is unlikely that the level of increased activity from the project would result in discernible disturbance of any beluga whales that happen to transit in areas where such vessel traffic is already occurring. Furthermore, the extent of physical presence that would occur is expected to be localized; therefore, only affecting the area around Amakdedori port. Vessels associated with activities would have a transitory presence in any specific location, as do beluga whales, so there is likely a limited effect on beluga whales.

AMERICAN OVERSIGHT

The duration of time that Cook Inlet beluga whales may be exposed to physical presence of aircraft would be temporary, because aircraft support is expected to be intermittent, and short in duration. Based on the short duration of potential exposure to aircraft-related noise and visual disturbance at any given location when an aircraft passes over, it is expected that effects on Cook Inlet beluga whales would be limited to brief behavioral responses such as reducing surface time and diving. Impacts are not likely, because physical presence is expected to occur infrequently and is likely to be short-lived, and therefore not expected to cause more than a temporary effect on Cook Inlet beluga whales.

Injury and Mortality

Vessel Collision

Vessels in Cook Inlet generally transit year-round, primarily in the standard shipping routes used by other large vessels in Cook Inlet. Generally, beluga whales are most often observed within a few miles of shore, so the probability of vessel strikes is lower in the middle of Cook Inlet, but may increase as vessels near Amakdedori port. When vessels are transiting nearshore, speeds would decrease, and standard marine mammal disturbance guidelines would be implemented to avoid vessel strikes (which will be outlined in the Wildlife Management Plan). The probability of a vessel strike being lethal is low at speeds less than 8 knots. There is no indication that strikes would become a major source of injury or mortality in the action area (NMFS 2017a).

There are no records of lethal vessel strikes involving Cook Inlet beluga whales; therefore, impacts to the Cook Inlet beluga whale as a result of injury or mortality from vessel collisions would not be expected. The extent and duration for which injury or mortality would occur is therefore not included in this analysis.

Habitat Changes

Cook Inlet beluga whale habitat use is discussed in detail in Section 3.25. The Cook Inlet beluga whale's primary foraging locations include the Susitna River Delta (the Big and Little Susitna rivers), Eagle Bay, Eklutna River, Ivan Slough, Theodore River, Lewis River, and Chickaloon Bay and River (NMFS 2008a; 2016b). All of these locations are considerably north of the project area. Cook Inlet beluga whales are found further south in Cook Inlet during the fall and winter months, resulting in a higher probability of overlap during that time. Disturbance to habitat is discussed in the critical habitat section below.

Critical Habitat

Cook Inlet beluga whale critical habitat is discussed in detail in Section 3.25. In summary, Critical Habitat Area 2, the only designation that exists in the action area, includes nearshore areas along western Cook Inlet and Kachemak Bay (Figure 4.25-1). Area 2 is known fall and winter foraging and transit habitat for beluga whales, as well as spring and summer habitat for smaller concentrations of beluga whales. This area consists of less-concentrated spring and summer beluga use; however, it also includes known fall and winter feeding and transit areas.

AMERICAN OVERSIGHT

Figure 4.25-1: Federally Listed Marine Mammal Critical Habitat and Location within the Action Area

AMERICAN OVERSIGHT

The potential exists for seafloor disturbance to impact Cook Inlet beluga whales' physical or biological features (intertidal and subtidal waters of Cook Inlet with depths less than 30 feet mean lower low water and within 5 miles of high- and medium-flow anadromous fish streams [50 Code of Federal Regulations Section 226.220(c)(5)]) due to temporary disturbance and resuspension of sediments in the water column, including areas within 5 miles of anadromous fish streams. A discussion on anadromous fish streams in the project area is provided in Section 3.24. Because Cook Inlet beluga whales rarely feed on benthic fauna, it is not expected that these animals would be exposed to disturbances of the benthic environment (NMFS 2017a). See Table 4.25-1 for anticipated TES critical habitat impacted per marine component per alternative.

Table 4.25-1: Estimated Beluga Whale and Northern Sea Otter Critical Habitat Intersection between Alternatives 1, 2, and 3

	Port Construction*		Pipeline Route*		Lightering Locations	
	Beluga Whale Critical Habitat	Northern Sea Otter Critical Habitat	Beluga Whale Critical Habitat	Northern Sea Otter Critical Habitat	Beluga Whale Critical Habitat	Northern Sea Otter Critical Habitat
Alternative 1	10.5 acres	10.5 acres	3.2 miles	10.7 miles	None	None
Alternatives 2 and 3	76 acres	76 acres	7 miles	14.6 miles	Primary lightering location in Iniskin Bay is within critical habitat	Primary lightering location in Iniskin Bay is within critical habitat

Notes: *Acreages and mileage were calculated based on the amount of critical habitat (derived from US Fish and Wildlife Service geographic information system layers) that overlaps with project components. Where there was a discrepancy between layers and the actual Cook Inlet coastline (per high resolution aerial), the mean high tide line was used to define the edge of critical habitat.

Seafloor disturbance and habitat alteration in the form of increased turbidity and physical partitioning from project activities may have small, localized impacts to Cook Inlet beluga whale habitat, including critical habitat, at some level of intensity. The extent that habitat alteration would occur is expected to be localized and only affect the area around the proposed port. Potential effects from seafloor disturbance are likely to limit the foraging quality of the disturbed area during construction. The duration of time that Cook Inlet beluga whales may be exposed to habitat alteration would be temporary, because activities are anticipated to be of short duration, and possibly for a few years afterward in some locations. Impacts are unlikely, because the amount of affected habitat in the project area would be small compared to that available foraging habitat for Cook Inlet beluga whales.

4.25.2.2 Humpback Whale

Behavioral Disturbance

Underwater and Airborne Noise

Humpback whales (*Megaptera novaeangliae*) would have the potential to be affected by vessel noise associated with the construction and operations of Amakdedori port; avoidance would be the most likely response. Humpback whales would be anticipated to interrupt their normal behavior and swim away if approached by a vessel; after this response, surfacing, respiration,

AMERICAN OVERSIGHT

and diving cycles could be affected, although vessels moving slowly and in directions not toward the whales usually would not elicit such strong reactions (Richardson and Malme 1993). After single-disturbance incidents, at least some whales would be expected to return to their original locations. Lower Cook Inlet has a high volume of vessel traffic, especially during the summer months when humpback whales are present. Incremental additional noise from the anticipated low number of vessels associated with the project per day is unlikely to add significantly to the existing levels of noise. A detailed discussion on noise sources from project components can be found in Appendix K4.25.

The low-frequency, percussive noise produced by pile driving would be detectable to humpback whales several miles away. Noise as a result of construction of the port site under the pile-supported dock variant of Action Alternative 1 at Amakdedori would have the greatest potential behavioral impact on humpback whales. Pile driving noise may exceed injury thresholds as defined by regulatory agencies. Underwater sound levels from pile driving vary with size and type of piles, as well as the size and type of hammer, and will be further analyzed in subsequent permitting efforts required by the MMPA. Potential impacts to humpback whales from pile-driving activities at Amakdedori port are unknown as species presence is not well documented. However, the project would implement a robust monitoring strategy during pile driving. Other construction noises during development may include dredging and trenching; humpback whales would likely have behavioral responses to these noises, such as avoidance.

Noise from aircraft during construction and operations would be likely to affect humpback whales. The sounds produced by aircraft above the surface of the water do not pose a direct threat to the hearing of marine mammals that are in the water; however, short-term behavioral responses of cetaceans to helicopters have been documented in several locations, including Alaska (Patenaude et al. 2002).

Impacts to humpback whales from underwater and airborne noise are expected at some level of intensity. The extent of which project activity noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995); however, it would be expected to be localized and only have an effect in the immediate vicinity of project activities. The duration of time for which humpback whales may be exposed to underwater sound from vessels would be short-term and temporary during pipeline installation and other construction activities. However, exposure would only be expected when seasonal distribution and habitat selection overlap in time and space with project vessel activities. Impacts are unlikely, because underwater noise is expected to occur infrequently. Any potential impacts on humpback whale behavior would be localized in the project area, and would not result in population-level effects.

Physical Presence (Vessel and Aircraft)

Humpback whales' reactions to approaching boats are variable; ranging from approach to avoidance (Salden 1993). Humpback whales show general avoidance behavior to cruise ships and tankers at distances from 1.5 to 2.5 miles (Baker et al. 1983), but no reaction at distances beyond 0.5 mile when the whales were feeding (Krieger and Wing 1986). Additionally, humpback whales are especially responsive to fast-moving vessels (Richardson et al. 1995), exhibiting aerial behaviors such as breaching or tail/flipper slapping. However, temporarily disturbed whales often remain in the area despite the presence of vessels (Baker et al. 1998, 1992).

Impacts to humpback whales from the physical presence of vessels and aircraft are expected at some level of intensity. Humpback whale sightings near Amakdedori port are limited (Shelden et al. 2013). The extent to which physical presence would occur is expected to be localized, and

AMERICAN OVERSIGHT

only affect the area near Amakdedori port. The duration of time that humpback whales may be exposed to physical presence of aircraft or vessels would be short-term and temporary during construction and operations for the life of the project. Based on the short duration of potential exposure to physical presence at any given location when aircraft or vessels pass over, it is expected that effects on humpback whales would be limited to brief behavioral responses. Impacts are unlikely, because aircraft or vessel presence would be expected to occur for short durations and infrequently, and likely short-lived; therefore, it would not be expected to cause more than a temporary effect.

Injury and Mortality

Vessel Collision

Worldwide, the number of humpback whales injured by ship strikes is exceeded only by fin whales (Jensen and Silber 2003). There were 93 reports of humpback whale-vessel collisions in Alaska waters between 1978 and 2011, with only one confirmed record in upper Cook Inlet (Neilson et al. 2012). Between 2008 and 2012, the mean minimum annual human-caused mortality and serious injury rate for humpback whales based on vessel collisions in Alaska was 0.45, as reported in the NMFS Alaska Regional Office stranding database (Allen and Angliss 2015).

Impacts to the humpback whale as a result of injury or mortality from vessel collision would not be expected in the action area due to a lack of sightings in the analysis area. The extent and duration of time for which injury or mortality would occur is therefore not included in this analysis.

Habitat Changes

Seafloor disturbance and habitat alteration in the form of increased turbidity and physical partitioning from project activities may have small, localized impacts to small schooling fish and krill, which are important prey species for humpback whales; however, the effects would not be expected to impact humpback whales. Impacts to humpback whales from habitat changes would be expected at some level of intensity. These effects should be consistent with, or less than, what has been occurring throughout Cook Inlet. There may be direct loss of habitat from project components; however, because humpback whales rarely feed on benthic fauna, these animals would not be expected to be impacted by disturbances to the benthic environment (NMFS 2017a). Direct loss of habitat from construction of the port site under the pile-supported dock variant of Action Alternative 1 at Amakdedori would result in negligible habitat loss. The extent of which habitat alteration would occur is expected to be localized, and only affect the area around the Amakdedori port site as well as areas of habitat directly lost from the pipeline alignment during route construction. There may be temporary impacts to water quality as a result of construction, which could potentially impact the presence of prey species during construction only. This project would not occur in seasonal areas or migration routes where whales concentrate (Bettridge et al. 2015). Potential effects from seafloor disturbance would likely limit the foraging quality of the disturbed area during construction. The duration of time that humpback whales may be exposed to habitat alteration would be temporary, because activities are anticipated to be of short duration, and possibly for a few years after construction in some locations. Impacts are unlikely, because the amount of affected habitat in the action area would be small compared to the overall amount of available foraging habitat.

Critical Habitat

No critical habitat has been designated for humpback whales.

AMERICAN OVERSIGHT

4.25.2.3 Fin Whale

Behavioral Disturbance

Underwater and Airborne Noise

Fin whales (*Balaenoptera physalus*) are generally observed in and prefer the deep marine waters in offshore areas. Vessels in transit to the analysis area for construction and operations of Amakdedori port have the potential to intersect with the fin whales' range. Sound masking is of special concern for baleen whales that vocalize at low frequencies over long distances, because their communication frequencies overlap with anthropogenic sounds, such as shipping traffic. Fin whales have been shown to reduce their calling rate in response to boat noise (Watkins 1986). A detailed discussion on noise sources from project components can be found in Appendix K4.25.

Impacts to fin whales from underwater and airborne noise are expected at some level of intensity; however, most fin whales are expected to occur outside of the action area; noise associated with Alternative 1 is unlikely to reach the offshore, deep water areas where the fin whales mainly inhabit. Noise as a result of construction of the port site under pile-supported dock variant of Action Alternative 1 at Amakdedori would have the greatest potential behavioral impact on fin whales. Pile driving noise may exceed injury thresholds as defined by regulatory agencies. Underwater sound levels from pile driving vary with the size and type of piles, as well as the size and type of hammer and will be further analyzed in subsequent permitting efforts required by the MMPA. A detailed discussion on project noise is presented in Appendix K4.25. The extent of which project activity noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995); however, it would be expected to be localized and only affect the immediate vicinity of project activities. The duration of time that fin whales may be exposed to underwater sound from vessels or aircraft noise would be short-term and temporary during pipeline installation and construction activities. However, the exposure would only be expected when seasonal distribution and habitat selection overlap in time and space with project vessel activities. Impacts are unlikely, because underwater and airborne noise is expected to occur infrequently. Any potential impacts on fin whale behavior would be localized in the action area, and would not result in population-level effects. Mitigation and monitoring measures required through further project permitting are expected to reduce the exposure of fin whales to noise associated with the project.

Physical Presence (Vessel and Aircraft)

Fin whales are rarely observed in Cook Inlet, with most sightings occurring near the entrance of the inlet (Shelden et al. 2013, 2015, 2016) approximately 80 miles south of the action area. Fin whales may exhibit varying reactions to the presence of vessels, ranging from attraction to avoidance (NMFS 2017b). Impacts to the fin whale as a result of physical presence of vessels and aircraft is not expected in the action areas. The extent and duration for which injury or mortality would occur are therefore not included in this analysis.

Injury and Mortality

Vehicle Collision

Globally, fin whales are injured in collisions with vessels more frequently than any other whale (Neilson et al. 2012). Three of the 108 reported whale-vessel collisions in Alaska between 1978 and 2011 have been reported as fin whales, none of which have occurred in Cook Inlet (NMFS

AMERICAN OVERSIGHT

2015). Jahoda et al. (2003) studied the responses of fin whales in feeding areas when they were closely approached by inflatable vessels. The study concluded that close vessel approaches caused the fin whales to swim away from the approaching vessel and to stop feeding. These animals also had increases in blow rates and spent less time at the surface (Jahoda et al. 2003).

Impacts to the fin whale as a result of injury or mortality from vessel collision is not expected in the project area. The extent and duration for which injury or mortality would occur is therefore not included in this analysis.

Habitat Changes

Fin whales in the North Pacific prefer euphausiids and large copepods, followed by schooling fish such as herring, walleye pollock, and capelin. Information on the effects of sound on prey items of fin whales is limited. Because fin whales are not benthic feeders or feed on benthic fauna only rarely (NMFS 2017b), it would not be anticipated that these animals would be exposed to disturbances to the benthic environment.

Impacts to fin whales from habitat changes are expected at some level of intensity. The extent of which habitat alteration would occur is expected to be localized, and only affect the area around Amakdedori port. Direct loss of habitat from construction of the port site under the pile-supported dock variant of Action Alternative 1 at the Amakdedori would result in negligible habitat loss. Potential effects from seafloor disturbance, such as water quality and turbidity, are likely to reduce the foraging quality of the disturbed area during construction. The duration of time that fin whales may be exposed to habitat alteration would be temporary, because activities are anticipated to be of short duration, and possibly for a few years afterward in some locations. Impacts are unlikely, because the amount of habitat affected in the action area would be small compared to the overall amount of available fin whale foraging habitat.

Critical Habitat

No critical habitat has been designated for the fin whale.

4.25.2.4 Steller Sea Lion

Behavioral Disturbance

Underwater and Airborne Noise

Noise sources (described in Section 3.23, Wildlife) for non-listed marine mammals are the same for listed marine mammals. Steller sea lions (*Eumetopias jubatus*) have the potential to be affected by vessel noise associated with the project components. Because sea lions are cautious by nature, it is likely that loud, pulsed, frequent, or unfamiliar noises, such as pile driving at Amakdedori port, are likely to disrupt resting sea lions or animals foraging near the sound source (NMFS 2005). The greatest potential impact from noise generally occurs at haul-outs, and near rookeries, where animals could stampede and cause trampling and abandonment of pups (discussed in the exposure to aircraft noise section below). Because there are no rookeries near project components and most haul-outs are in designated critical habitat, far south of the project area, these effects are not expected. A detailed discussion on noise impacts from project components can be found in Appendix K4.25.

There are no studies documenting Steller sea lion's responses to pile driving. It is likely pinnipeds are more tolerant of noise associated with pile driving and other construction activity than cetaceans, and are not likely affected by such noise.

AMERICAN OVERSIGHT

Impacts to Steller sea lions from underwater and airborne noise are expected at some level of intensity. Noise as a result of construction of the port site under pile-supported dock variant of Action Alternative 1 at the Amakdedori would have the greatest potential behavioral impact on Steller sea lions. Pile driving noise may exceed injury thresholds as defined by regulatory agencies. Underwater sound levels from pile driving vary with the size and type of piles, as well as the size and type of hammer and will be further analyzed in subsequent permitting efforts required by the MMPA. A detailed discussion on project noise is presented in Appendix K4.25. The extent to which project activity noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995), but is expected to be localized and only affect the area around the project area. The duration of time that Steller sea lions may be exposed to underwater sound from vessels and aircraft would be short-term and temporary during pipeline installation, dredging, and construction activities. However, the exposure would only be expected when seasonal distribution and habitat selection overlap in time and space with project vessel and aircraft activities. Impacts are unlikely, because underwater noise would be expected to occur infrequently. Any potential impacts on Steller sea lion behavior would be localized in the project area, and would not result in population-level effects.

Physical Presence (Vessel and Aircraft)

Generally, sea lions in water show tolerance to close and frequently approaching vessels, and sometimes show interest in fishing vessels. They are less tolerant when hauled-out on land; however, they rarely react unless the vessel approaches within 330 to 660 feet (Richardson et al. 1995). Sea lion pups on land are vulnerable to trampling if adults are panicked by low-flying aircraft. Some Steller sea lions use areas around Amakdedori port, particularly near the mouth of Kamishak Bay; those individuals or groups could be disturbed by project activities. However, Cook Inlet has a high level of vessel activity during summer from recreation, commercial fisheries, barging, and other forms of commercial and scientific vessel traffic. Because of the frequent vessel activity in Cook Inlet, Steller sea lions in the area could be partially habituated to vessel presence.

Calkins (1979) reported that the reaction of Steller sea lions to aircraft is variable. Aircraft associated with the project would not be expected to operate in the vicinity of Steller sea lion haul-outs or rookeries; therefore, no Steller sea lions haul-outs would be disturbed by the noise or presence of aircraft. If any responses of Steller sea lions associated with aircraft were to occur, they are likely to be short-lived, and therefore are not expected to cause more than a temporary effect on Steller sea lions (NMFS 2017a). Additionally, in recognition of this vulnerability, Steller sea lion critical habitat has been defined to include air zones 3,000 feet above the terrestrial zones of designated haul-outs and rookeries.

Impacts from the physical presence of vessels on Steller sea lions foraging within the action area may occur. The extent to which vessel presence would occur is expected to be localized and would only affect the area around the proposed Amakdedori port. The duration of time that Steller sea lions may be disturbed by vessel presence would be temporary with short duration. The impacts are considered likely; however, physical presence would be expected to occur infrequently and likely to be short-lived, and therefore would not be expected to cause more than a temporary effect on Steller sea lions.

Injury and Mortality

Vessel Collision

AMERICAN OVERSIGHT

There is one suspected vessel collision with a Steller sea lion in Cook Inlet, reported near Homer in 2002, approximately 80 miles east of Amakdedori port where the majority of vessel traffic would be expected to occur (NMFS 2017a). Sea lions may become accustomed to repeated slow vessel approaches, resulting in minimal response (NMFS 2008b). Although low levels of occasional disturbance may have little long-term effect, areas subjected to repeated disturbance may be permanently abandoned. Regulations are in place to minimize disturbance of animals by humans, especially on rookeries (NMFS 2008b).

Impacts to Steller sea lions as a result of injury or mortality from vessel collision are not expected in the project area. Steller sea lions are unlikely to be encountered during construction and operations for the project, because they are primarily encountered along the Kenai Peninsula. The extent and duration of which injury or mortality could occur is therefore not included in this analysis.

Habitat Changes

The extent that habitat alteration could occur is expected to be localized and only affect the area around the proposed port, because the project area is not a common foraging location for the species. Potential effects from seafloor disturbance are likely to limit the foraging quality of the disturbed area during construction of the Amakdedori port and pipeline across Cook Inlet from Kamishak Bay to Nikiski. Localized, temporary habitat alteration should not affect Steller sea lions because the animals are highly mobile and rarely feed on benthic fauna; therefore, they are not exposed to disturbances to the benthic environment (NMFS 2017a). Temporary effects from turbidity may displace Steller sea lions from accessing prey species in the water column, but these effects are expected to be temporary and last only for the duration of construction of the project components. The duration of time that Steller sea lions may be exposed to habitat alteration would be temporary, because activities are predicted to be of short duration, and possibly for a few years afterward in some locations. Impacts are unlikely, because habitat alteration in the project area is expected to occur infrequently. The amount of habitat affected in the project area would be small compared to that available to Steller sea lion species for foraging.

Critical Habitat

Critical habitat of Steller sea lions would not be expected to be impacted by project activities because it is located southwest of the action area.

4.25.2.5 Northern Sea Otter

Behavioral Disturbance

Underwater and Airborne Noise

Noise sources (described in Section 3.23, Wildlife) for non-listed marine mammals are the same for listed marine mammals. Sea otters (*Enhydra lutris*) are generally resistant to the effects of sound; changes in presence, distribution, and behavior resulting from acoustic stimuli have not been commonly observed (Ghoul and Reichmuth 2012). Sea otters have the potential to be affected by vessel noise associated with the Amakdedori port and construction of the natural gas pipeline. Sea otters could be disturbed by underwater noise from the project. Sea otters exposed to noise may respond behaviorally (e.g., escape response) or physiologically (e.g., increased heart rate or hormonal stress response) (Atkinson et al. 2009). A detailed discussion on noise impacts from project components can be found in Appendix K4.25.

AMERICAN OVERSIGHT

Sea otters spend a great deal of time at the surface feeding and grooming (Wolt et al. 2012); therefore, their potential exposure to noise from underwater anthropogenic sound sources is lower than that of many other marine mammal species. Most of the noises associated with the project are in the effective hearing range of sea otters (0.125 kHz to 32 kHz; Ghoul and Reichmuth 2014). Only animals in immediate proximity to the sound source would be expected to exhibit a response. To date, the USFWS has not documented and is not aware of any evidence that serious injury, death, or stranding of sea otters can occur from exposure to industry noise (USFWS 2016). Any disturbance to sea otters from underwater noise associated with the project would be expected to be, at most, temporary and localized.

Impacts to northern sea otters from underwater and airborne noise are expected at some level of intensity. The extent that project activity noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995); it would be expected to be localized and only affect the project area. Noise as a result of construction of the port site under the pile-supported dock variant of Action Alternative 1 at the Amakdedori would have the greatest potential behavioral impact on sea otters. Pile driving noise may exceed injury thresholds as defined by regulatory agencies. Underwater sound levels from pile driving vary with the size and type of piles, as well as the size and type of hammer and will be further analyzed in subsequent permitting efforts required by the MMPA. A detailed discussion on project noise is presented in Appendix K4.25. The duration of time that sea otters may be exposed to underwater sound from vessels would be short-term and temporary during pipeline installation, dredging, and construction activities. However, the exposure would only be expected when seasonal distribution and habitat selection overlap in time and space with project vessel activities. Impacts would be unlikely, because underwater noise would be expected to occur infrequently. Any potential impact from underwater noise on sea otter behavior would be localized in the project area, and would not result in population-level effects.

Physical Presence (Vessel and Aircraft)

Vessel disturbance was ranked low as a threat to recovery, and as 'low importance' in the northern sea otter recovery plan (USFWS 2013). The reaction of sea otters to disturbance: 1) is highly variable between seasons, sexes, and populations; and 2) may be modified by experience (reactions often decline in intensity with habituation, and may increase where populations are harassed or hunted) (USFWS 2013). Although male sea otters sometimes habituate to heavy boat traffic, female sea otters, particularly those with pups, are sensitive to disturbance. Boat traffic could disturb the resting patterns of sea otters.

Sea otters spend approximately 80 percent of their time on the water surface (Wolt et al. 2012). Sea otters are slow swimmers relative to other marine mammals, and spend much of their time at the surface resting, grooming, and nursing their young. The behavior of individual sea otters could be modified by the physical presence of project-related vessels. Because sea otters spend much of their time at the surface, they could also be disturbed by the presence of vessel traffic. The most likely impacts could be the disturbance of sea otters that are hauled-out, and the displacement of females and pups that occur near the proposed Amakdedori port (USDOI, MMS 2003). If negative behaviors occur at all, these effects would be expected to be localized and have no population-level impact.

Impacts to northern sea otters from physical presence of vessel and aircraft would be expected at some level of intensity. The extent that physical presence of vessel and aircraft would occur would be expected to be localized and only affect the area around the Amakdedori port. The duration of time that sea otters may be exposed to physical presence of vessel and aircraft would be temporary, because aircraft support is expected to be intermittent, and of short

AMERICAN OVERSIGHT

duration. Based on the short duration of potential exposure to physical presence at any given location when aircraft pass over, it is expected that effects on sea otters would be limited to brief behavioral responses.

Habitat Changes

Organisms commonly consumed by sea otters, such as urchins, crabs, and clams, may be damaged by seafloor disturbance from project activities. Potential effects from seafloor disturbance would possibly limit the foraging quality of the disturbed area during construction of the Amakdedori port and the pipeline across Cook Inlet from Kamishak Bay to Nikiski. Impacts to northern sea otter habitat would be expected at some level of intensity. These effects should be consistent with or less than what has been occurring throughout Cook Inlet. The extent to which habitat alteration would occur would be expected to be localized, and only affect the area around the proposed port, because the project area is not a common foraging location for the species. Habitat loss was ranked as 'low importance' in the recovery plan for the southwestern stock of northern sea otters (USFWS 2013). Sea otters may easily disperse to unaffected habitat nearby. The project would not create large areas of affected habitat or any barriers to animal dispersal. The duration of time that sea otters may be exposed to habitat alteration would be temporary, because habitat alteration activities are predicted to be of short duration, and possibly extend a few years following construction in some locations. Impacts to habitat would be considered likely. The amount of habitat affected in the project area would be small compared to the currently available foraging habitat for sea otters.

Critical Habitat

There could be a direct loss and permanent modification of northern sea otter critical habitat by project activities planned in Cook Inlet. See Table 4.25-1 for the anticipated critical habitat impacted per marine component. The project is in Critical Habitat Unit 5: Kodiak, Kamishak, and Alaska Peninsula (Figure 4.25-1). In particular, bottom-contact stages of construction, the permanent placement of a causeway, and construction of the natural gas pipeline have potential to temporarily adversely affect critical habitat. All sea otter critical habitat primary constituent elements (discussed in detail in Section 3.25) would be directly affected. Although there is potential for seafloor habitat disturbance from the project, only a small portion of sea otter critical habitat occurs in the project area.

4.25.2.6 Steller's Eider

All phases of mine site activities (including the summer-only ferry operations variant) are anticipated to have no direct or indirect impacts on Steller's eider (*Polysticta stelleri*) because the species is not known to breed, stage, or migrate through the mine site. Steller's eiders are generally not found more than 60 miles inland, and therefore would be unlikely to occur at the mine site (USFWS 2002). The mine site is anticipated to have no impact on breeding, molting, or staging of Steller's eiders, because these life history stages are geographically removed from the mine site.

Additionally, no impacts to Steller's eiders are anticipated from the terrestrial portion of the transportation corridor or natural gas pipeline corridor (the portion that occurs west of Cook Inlet, including all potential variants), because there would be no elevated structures that could pose a collision hazard, such as power lines. Towers, power lines, and other overhead structures may pose a collision hazard to Steller's eiders, because they are known to fly low and fast over land and water, and are believed to migrate at night (USFWS 2014). A migration study conducted between 2002 and 2004 of all four eider species around Northstar Island, documented eiders flying at a mean altitude of approximately 20 feet above ground/sea level in

AMERICAN OVERSIGHT

a straight-line direction, and at high mean velocities around 45 miles per hour (Day et al. 2005). This low, fast, and direct method of flying increases the risk of colliding with structures that are near the ground level.

There would be potential for impacts to Steller's eiders due to the presence of moored vessels at lightering locations in Kamishak Bay and Iniskin Bay, and from the Amakdedori and Diamond Point port locations. Steller's eiders are known to molt and winter in the nearshore waters of Kamishak Bay (generally from late November through early April) and winter within Iliamna and Iniskin bays (Figure 4.25-2). They undergo a 3-week flightless molt (which may occur anytime from late July through late October) in nearshore waters, including Kamishak Bay. In Kamishak Bay, the primary molt location is around the Douglas River Shoals area, approximately 17 miles south of Amakdedori port where birds have been recorded beginning in late August through early September. Birds tend to move further north up the west side of Cook Inlet later in the fall and winter, as stormy weather conditions and icing begin to push birds north. Therefore, birds using the nearshore waters around Amakdedori port and further north, are generally later in the season after molt is complete. Steller's eiders wintering in Kamishak, Iliamna, and Iniskin bays are prone to disturbance from aircraft and vessels. The potential direct and indirect impacts to molting and wintering Steller's eiders may potentially include:

- behavioral disturbance from aircraft and vessel traffic at port locations;
- injury or mortality from collisions with structures and vessels at port and lightering locations; and
- loss of foraging habitat at Amakdedori port.

Potential impacts to Steller's eiders from port construction noise are not considered herein because the port would be constructed primarily during the summer months, when Steller's eiders are generally not present. Impacts from construction of the natural gas pipeline are also not expected to occur as construction is anticipated to occur primarily during summer months when Steller's eiders are not present in Cook Inlet. Potential impacts to eiders from vessel and aircraft noise are discussed under behavioral disturbance, below. Potential impacts to Steller's eiders from a spill are discussed in detail under Section 4.27, Spill Risk.

Behavioral Disturbance

Studies on Steller's eiders show variable degrees of tolerance to vessel traffic. They commonly overwinter in areas of high activity near the Homer Spit and the Unalaska airport, and do not flee in response to human activities on adjacent shorelines; however, they have been observed to be sensitive to boat traffic in Izembek Lagoon (USFWS 2012). In a study of responses of wintering waterfowl to aircraft traffic, Ward and Stehn (1989) found that Steller's eiders flushed when aircraft came within approximately 984 feet. Disturbance from boat traffic can cause Steller's eiders to fly away from preferred foraging and resting sites, thereby disrupting foraging or resting periods. Disturbance of sufficient frequency, duration, or severity can lower individual fitness through increased time spent in flight, and reduced time spent feeding or resting (USFWS 2012).

AMERICAN OVERSIGHT

Figure 4.25-2: Steller's Eider Molting and Wintering Locations within the Action Area

AMERICAN OVERSIGHT

Some studies have documented a variety of behavioral responses to vessel-related disturbance, including increased alert behavior, flight, swimming, and a reduction in foraging (Agness 2006). Waterbird responses to vessel traffic may be dependent on species, biological cycle (e.g., breeding, migrating, stopover, and wintering), and/or vessel attributes (e.g., vessel type, size, speed, and distance from the birds). Schwemmer et al. (2011) found that flush distances of four sea duck species differed substantially, with flush distance being positively related to flock size. The study also found indications of habituation in sea ducks in areas of channeled traffic. Because vessel traffic would follow established travel lanes and would approach nearshore habitats (used by molting Steller's eiders) very slowly as they approach the port, the potential for disturbance or collisions in the vicinity of Amakdedori port is limited. The majority of Steller's eiders molt and winter approximately 17 miles south of Amakdedori port around the Douglas River Shoals area (Larned 2006). Although Larned (2006) documented small groups of Steller's eiders around Amakdedulia Cove, these small groups would likely move out of the way while vessels approached the port. Because Steller's eiders prefer nearshore areas where water depths are shallow, vessel speeds would be slow. Vessel and aircraft traffic are anticipated to occur year-round at the port. The summer is the only time when Steller's eiders are not expected to be in the nearshore areas around the port. Molting Steller's eiders may begin to appear in Kamishak Bay (primarily around the Douglas River Shoals area) in July, with the peak of molting between August and October. Wintering Steller's eiders are anticipated to reach their high numbers in late winter and early spring, prior to their departure for the Alaska coastline and northern spring migration.

Vessel speeds are anticipated to be slow (i.e., less than 10 knots) while approaching and departing the port, providing time for any Steller's eiders in the immediate vicinity to move out of harm's way. Therefore, Steller's eiders may be temporarily disturbed around the Amakdedori port while vessels are docking at the port. Additionally, aircraft flying in and out of the airstrip may cause Steller's eiders to avoid the area at the east end of the runway (closest to Cook Inlet), and any areas directly under the flight approach path. Depending on the height of aircraft above the water on approach (when landing from the east), Steller's eiders are anticipated to fly, dive, or move out of the way while aircraft use the airstrip. Based on a study of king eiders (*Somateria spectabilis*) (an appropriate surrogate for Steller's eiders) in western Greenland, they dove underwater when aircraft approached, and over 50 percent remained submerged until the plane passed (Mosbech and Boertmann 1999). King eiders appeared sensitive to aircraft engine noise and flushed, dove, or swam away, sometimes leaving the area for several hours (Frimer 1994). Steller's eiders are anticipated to return to the area from which they were flushed after vessels or aircraft have passed. Because eiders typically fly close and fast to the water's surface at low altitudes (i.e., less than 20 feet)(Day et al. 2005), they are unlikely to be struck by aircraft landing at the port locations.

Although the majority of molting and wintering Steller's eiders tend to prefer shallow waters around Douglas River Shoals, a few small flocks of eiders may occasionally forage in the nearshore waters around the port.

Injury and Mortality

Because Steller's eiders tend to fly low and fast over water, they are susceptible to collisions with stationary or slow-moving objects, especially during periods of poor visibility. The chance of collisions increases with fog or darkness, especially if the port and vessels have many lights that could attract and disorient birds. Steller's eiders are believed to be attracted to artificial light, which may increase their risk of collision with structures and vessels (USFWS 2014). Therefore, there would be potential for direct injury and mortality to Steller's eiders from collision with the port and vessels using the port. Steller's eiders have been documented to collide with

AMERICAN OVERSIGHT

illuminated crab boats, and power lines and towers, especially during periods of inclement weather (USFWS 2012). Permanent structures mounted on the causeway and or dock would include a fuel pipeline for unloading barges, a powerline for vessel shore power, a water supply line for firefighting, and illumination and navigation lights. While most of these components would be located along the causeway at ground level, the navigation lights (and any lights on the causeway or wharf) may pose collisions hazards in an area where there is currently no artificial light. Additionally, the large bulk carrier ships that are moored at the lightering locations, along with any cranes to load concentrate into the bulk carrier ships would pose a collision hazard for eiders flying in Kamishak Bay. This is especially important if the bulk carrier ships have large flood lights that are not adequately shielded and point inward, away from the open ocean. As sea ice shifts during the winter, there would be potential for eiders wintering along the west edge of Cook Inlet to fly between protected bays and collide with vessels moored at the various lightering locations. Because the federally listed Alaska-breeding population of Steller's eiders mixes with the non-listed Russian population on the wintering grounds (including Cook Inlet), and the listed population is estimated to account for less than 1 percent of the total Pacific wintering population (USFWS 2014), there would be low potential that a bird from the listed population would collide with the port or a vessel.

The USFWS calculated the collision risk for Steller's eiders in the Chukchi Sea based on actual collisions events during exploratory drilling operations in 2012, which are detailed in the project Biological Assessment in Appendix G. Per the project description in Chapter 2, bulk carriers (which pose the greatest collision risk to Steller's eiders due to their large size, high gunwales, crane, and external lights) would be moored at lightering locations for 4 to 5 days, each with 27 annual trips by Handysize ships (smaller bulk carriers) multiplied by the 20-year life of the mine. It was determined that based on this anticipated level of vessel traffic (i.e., 2,700 vessel days), the collision rate for the federally listed Steller's eider would be 0.1 eider collision over the life of the project. Therefore, the potential for injury or mortality on molting and wintering Steller's eiders from the project would be low.

Habitat Changes

The construction of the Amakdedori port would result in a loss of potential nearshore water foraging habitat for Steller's eiders. The species generally forages for a variety of benthic species (including bivalves, gastropods, and crustaceans) in marine waters up to 30 feet deep (USFWS 2000). Since Steller's eiders prefer to winter in shallow waters, they are usually found within 1,200 feet of shore (USFWS 2002). The Amakdedori port would be constructed of an earthen causeway with a sheet pile wharf structure. The earthen causeway would extend from the port terminal to the wharf. In total, 10.5 acres of the marine environment would be covered with fill material (from the mean high water line out to and including the sheet pile wharf structure). One variant of the port is a pile-supported dock. This variant would involve the placement of approximately 253 piles (48-inch diameter each) into the marine environment with a combined footprint of 0.07 acre. Therefore, under the proposed alternative, there would be a loss of 10.5 acres of Steller's eiders' foraging habitat, and under the pile-supported dock variant, there would be a loss of 0.07 acre.

Climate Change

Potential impacts from climate change on Steller's eiders are not well-studied for the species' wintering and molting range. However, in their breeding range, the listed population of Steller's eiders are considered moderately vulnerable due to increased rates of shoreline erosion (in part due to reduced sea ice coverage), alterations in water temperatures that may alter prey base and change nesting habitats (thermokarst ponds and adjacent upland habitats)(Liebezeit et al.

AMERICAN OVERSIGHT

2012). Climate change is likely to impact their breeding habitat through increased storm surges (resulting in loss of breeding habitat), increased salinity in the intertidal zone, melting of permafrost, and vegetation changes (USFWS 2016). Additional climate-induced changes may include arctic water bodies draining and drying out during summer; increased productivity in some ponds due to increased nutrient input from thawing soil and warmer days; changes in seas ice coverage; and small mammal population cycle changes (Steller's eiders tend to nest in high brown lemming [*Lemmus trimucronatus*] years) (USFWS 2012). Because the federally listed population of Steller's eiders breed almost exclusively in the habitat around Utqiaġvik, there is little opportunity for the species to relocate if climate-assisted changes result in habitat loss (Liebezeit et al. 2012). These potential impacts from climate change are more specific to the species' breeding habitat, which does not occur anywhere near the project area.

The most likely result of climate change as it relates to wintering and molting areas of Steller's eiders around the project area are decreased levels of sea and shorefast ice in the Cook Inlet. Steller's eiders travel around Cook Inlet during the winter in response to varying levels of ice. If climate change results in warmer ocean temperatures, sea ice may become a lower limiting factor to the location where Steller's eiders winter. There is a potential that climate change may influence the benthic species on which Steller's eiders feed (due to ocean acidification, warmer ocean temperatures, etc.). Overall, impacts of climate change on Steller's eiders in lower Cook Inlet are uncertain. Lower levels of sea and shorefast ice may expose more foraging areas for the species during winter and early spring before the species migrates north to the breeding grounds.

4.25.3 Action Alternative 2 – North Access Route (Road and Ferry)

4.25.3.1 Cook Inlet Beluga Whale

A discussion on the differences in the affected environment of the Cook Inlet beluga whale between Alternative 1 and Alternative 2 is presented in Section 3.25. Cook Inlet beluga whales are expected to occur in similar densities throughout the marine environment across the proposed alternatives, and all impacts are anticipated to be similar for the two alternatives, except for the potential for the temporary modification of habitat resulting from an increase in turbidity and water quality during construction activities, which may potentially have impacts on beluga whale prey, disturbance from vessel presence, and vessel collisions. The transportation corridor and natural gas pipeline route presented in Alternative 2 is shorter than that proposed for Alternative 1; therefore, the loss or modification of available habitat, the impacts from more vessel presence, as vessels are required to travel longer, and the potential for a vessel collision is lower. Potential noise resulting from the pile-supported dock variant of Action Alternative 2 would produce more sound in the water than constructing a solid fill dock and would cause greater potential effects to beluga whales. Project components presented in Alternative 2 intersect with more Cook Inlet beluga whale critical habitat, and therefore fewer whales would be impacted under this alternative. See Table 4.25-1 for anticipated Cook Inlet beluga whale critical habitat to be impacted per marine component.

4.25.3.2 Humpback Whale

A discussion on the differences in the affected environment of the humpback whale between Alternative 1 and Alternative 2 is presented in Section 3.25. Humpback whales are expected to occur in similar densities of the natural gas pipeline corridor for Alternatives 1 and 2; however, humpback whales have been more frequently sighted along the Action Alternative 1 natural gas pipeline corridor south of Augustine Island. The potential for temporary and permanent modification of habitat and vessel collisions would be different for the natural gas pipeline

AMERICAN OVERSIGHT

corridor between Action Alternatives 1 and 2. The transportation corridor in Action Alternative 2 is shorter than that proposed for Action Alternative 1 and fewer sightings of humpback whales have been observed in marine waters surrounding Alternative 2 (see Section 3.25); therefore, the potential for a vessel collision is lower. Likewise, the impact to foraging habitat would also be lower. During construction, there may be a temporary decrease in water quality parameters, resulting in a potential to impact humpback whale prey and disturbance from vessel presence. Potential noise resulting from the pile-supported dock variant of Action Alternative 2 would produce more sound into the water than constructing a solid fill dock and would cause greater potential effects to humpback whales. There is no critical habitat designated for the humpback whale, and therefore no potential impacts analyzed with regard to critical habitat.

4.25.3.3 Fin Whale

A discussion on the differences in the affected environment of the fin whale between Alternative 1 and Alternative 2 is presented in Section 3.25. Fin whales are considered extralimital for Cook Inlet, and are not expected to be encountered under each alternative's proposed project activity. Likewise, the densities of fin whales are similar between the two alternatives. There is no critical habitat designated for the fin whale, and therefore no potential impacts analyzed with regard to critical habitat. Potential noise resulting from the pile-supported dock variant of Action Alternative 2 would produce more sound into the water than constructing a solid fill dock and would cause greater potential effects to fin whales. Therefore, differences to the affected environment between the proposed Alternatives 1 and 2 would not be expected.

4.25.3.4 Steller Sea Lion

A discussion on the differences in the affected environment of the Steller sea lion between Alternative 1 and Alternative 2 is presented in Section 3.25. Critical habitat for the Steller sea lion does not occur in the project areas for either Alternative 1 or Alternative 2; however, it is closer to the marine environment of Alternative 1. All impacts are anticipated to be the same for the two alternatives, except for the potential of temporary modification of habitat and potential disturbance from vessel presence. During construction, there may be a temporary decrease in water quality parameters, resulting in a potential to impact Steller sea lion prey, as discussed in Section 4.25. Likewise, the impacts from increased vessel presence, as the vessels are required to travel longer, is expected to be lower. The transportation corridor in Alternative 2 is shorter than that proposed for Alternative 1; therefore, the loss or modification of available habitat is lower. Potential noise resulting from the pile-supported dock variant of Action Alternative 2 would produce more sound in the water than constructing a solid fill dock, and would cause greater potential effects to Steller sea lions.

4.25.3.5 Northern Sea Otter

A discussion on the differences in the affected environment of the northern sea otter between Alternative 1 and Alternative 2 is presented in Section 3.25. Northern sea otters are expected to occur in the same densities throughout the marine environment across Alternatives 1 and 2, and impacts are anticipated to be the same between both alternatives. All impacts are anticipated to be the same for the two alternatives, except for the potential for the permanent loss or modification of habitat and the disturbance from vessel presence. Project components presented in Alternative 2 intersect with more northern sea otter potential foraging habitat, as well as critical habitat; therefore, fewer sea otters would be impacted under Alternative 2. Likewise, impacts from increased vessel presence, as vessels are required to travel longer, would be expected to be lower. Potential noise resulting from the pile-supported dock variant of Action Alternative 2 would produce more sound in the water than constructing a solid fill dock

AMERICAN OVERSIGHT

and would cause greater potential effects to the northern sea otter. See Table 4.25-1 for anticipated critical habitat to be impacted per marine component.

4.25.3.6 Steller's Eider

As detailed in Section 3.25, surveys conducted by Agler et al. (1995), Larned (2006), and ABR (2011a, 2015c) indicate that Iniskin and Iliamna bays provide overwintering habitat for several hundred Steller's eiders (generally from late November through April). Steller's eiders were found primarily in offshore waters in the middle portions of Iniskin and Iliamna bays, and occasionally in nearshore waters. Most birds occurred around a shallow shoal in the lower part of Iniskin Bay and in the middle of the channel between Cottonwood and Iliamna bays. More specifically, Steller's eiders winter in the waters directly in front of the Diamond Point port (and in the vessel approach lanes). Additionally, eiders winter immediately adjacent to the proposed lightering location in Iniskin Bay (Figure 4.25-2). Of the Steller's eiders that winter in Cook Inlet, only a fraction (i.e., less than 1 percent) is assumed to belong to the Alaska breeding federally listed population.

Impacts to Steller's eiders are anticipated to be identical to those from Alternative 1, except impacts would be shifted geographically north to Iliamna and Iniskin bays. These bays are narrower, more protected than Kamishak Bay, and contain a variety of benthic marine foraging habitat, which may be one of the reasons more Steller's eiders are found there during winter months. All potential impacts detailed above (e.g., behavioral disturbance, habitat changes, and potential for injury and mortality) are similar for Action Alternative 2.

The primary lightering location at the mouth of Iniskin Bay represents an increased potential for eider collisions due to its location at the mouth of a protected bay where Steller's eiders winter. Based on estimates for vessel collisions presented under Action Alternative 1, there is a potential for 0.1 eider collisions over the life of the project. This is likely to be higher due to the more restricted mouth of Iniskin Bay and since hundreds of eiders winter directly adjacent to the lightering location (Figure 4.25-2). If bulk carriers are moored at the lightering location in Iniskin Bay during periods of dense fog or low visibility and the bulk carrier's lights are illuminated, the potential for eider collision would be increased. If bulk carriers are moved to the alternate lightering location on the western side of Augustine Island, the risk of eider collision is likely lower, since fewer birds winter around Augustine Island. This would reduce the risk of collisions for eiders in Iniskin Bay with the bulk carriers during stormy weather conditions. Overall, impacts to Steller's eiders from Action Alternative 2 are anticipated to be similar to, but higher than Action Alternative 1 due to the presence of several hundred eiders throughout Iliamna and Iniskin bays.

The construction of the port at Diamond Point would result in a loss of potential nearshore marine benthic foraging habitat for Steller's eiders. The port at Diamond Point would be constructed of an earthen causeway with a sheet pile wharf structure. In total, 15 acres of the marine environment would be covered with fill material extending from the mean high water line out to and including the sheet pile wharf structure. In addition, there would be 61 acres of the marine environment that would be periodically dredged to allow vessels to reach the port. This would result in a loss of approximately 76 acres of wintering and foraging habitat in the marine benthic environment of Iliamna Bay. One variant of the port is a pile-supported dock (with no earthen causeway), which would involve the placement of approximately 518 piles (48-inch diameter each) in the marine environment with a combined footprint of 0.15 acre. Dredging of 57 acres would be necessary for this variant and therefore there would be a loss of approximately 57.2 acres of habitat.

AMERICAN OVERSIGHT

4.25.4 Action Alternative 3 – North Access Route (Road Only)

There are no new geographical areas covered by this alternative, and therefore, no new information for any TES. All information for this alternative is previously covered by Action Alternatives 1 and 2 above.

4.25.4.1 Summary of Key Impacts

In summary, Table 4.25-2 details the key issues for TES across all three alternatives. The No Action Alternative is not included, as there would be no impacts from the project. Since potential impacts to TES may occur in the marine environment, all terrestrial components of the project (mine site and transportation corridor) are considered to have no impact on TES. When possible, acreages of habitat that will be directly or indirectly impacted are included. For all TES, it is not possible to quantify the exact number of individuals that may be impacted by vessel collisions or strikes; therefore, the number is considered less than significant.

Table 4.25-2: Summary of Key Issues for TES

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Port			
Behavioral changes	Underwater noise could exceed injury thresholds as defined by regulatory agencies. Physical presence of vessels and aircraft may temporarily displace marine TES. Wintering Steller's eiders may swim, dive, or fly away from approaching vessels and aircraft.		
Injury and mortality	Low potential for TES to collide with port infrastructure and vessels at lightering locations.		
Habitat changes	Loss of 10.5 acres of benthic marine foraging habitat with an earthen causeway port and 0.07 acre of habitat loss with a pile supported dock. These acreages are also within Cook Inlet beluga whale and Northern sea otter critical habitat. No lightering locations located inside Cook Inlet beluga whale and Northern sea otter critical habitat.	Loss of 76 acres of benthic marine foraging habitat with an earthen causeway port and 57.2 acres of habitat loss with a pile supported dock. These acreages are also within Cook Inlet beluga whale and Northern sea otter critical habitat. Primary lightering location in Iniskin Bay is within Cook Inlet beluga whale and Northern sea otter critical habitat.	Loss of 76 acres of benthic marine foraging habitat within Cook Inlet beluga whale and Northern sea otter critical habitat. Primary lightering location in Iniskin Bay is within Cook Inlet beluga whale and Northern sea otter critical habitat.

4.25.5 Cumulative Effects

A discussion on cumulative effects from potential future actions on non-threatened and endangered marine mammals is provided in Section 4.23, Wildlife, and is applied to threatened and endangered marine mammals in this section. Potential effects from an oil spill are discussed in Section 4.27, Spill Risk.

The following reasonably foreseeable future actions identified in Section 4.1, Introduction to Environmental Consequences, were carried forward in this analysis based on their potential to impact wildlife in the analysis area:

- Pebble Project buildout – develop 55 percent of the resource over 78 year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*
- Donlin Gold
- Diamond Point Rock Quarry

**Indicates exploration activities only*

4.25.5.1 Steller's Eiders

Past, present, and reasonably foreseeable future activities have the potential to contribute to cumulative impacts to Steller's eiders. Additional development in the Cook Inlet and regions along the Alaska Peninsula has the potential to impact molting and wintering areas for Steller's eiders. Industrial developments can affect species through habitat loss, alteration, disturbance, and direct mortality. For Steller's eiders, there is a risk of collision with structures such as drilling rigs, buildings, communication towers, transmission lines, vehicles, vessels, and aircraft. Cumulative impacts to other locations of Steller's eiders molting and wintering habitat may incrementally lead to a decrease in fitness for this long-lived species, which does not breed every year. Steller's eiders' life history strategy is one dependent on long-lived adults that reproduce in select years of high lemming abundance. Therefore, adult survival during the non-breeding season is important to allow the species to recover. Hence, cumulative impacts to any Steller's eiders molting and wintering areas in Alaska are included in this analysis. Additional potential cumulative issues related to Steller's eiders include increased disturbance from aircraft and vessels in important molting, wintering, and staging areas, and mortality from collisions with towers, various types of infrastructure, and powerlines especially during periods of low light or reduced visibility (e.g., low-lying fog). Additionally, facilities with lighting can cause birds to be disoriented and increase the chance of collisions.

The primary potential future impacts to Steller's eiders would be from increased vessel traffic at port locations along the west side of Cook Inlet, especially if the Amakdedori port or Diamond Point port is used. Increased vessel traffic would increase the potential for eiders to collide with

AMERICAN OVERSIGHT

ships during the winter (late November through early April), especially during inclement weather conditions. There would also be potential for increased oil, fuel, and other chemicals to spill into the environment during winter months when eiders are present. This may occur due to Cook Inlet Oil and Gas Lease Sales, and increased vessel traffic associated with other mining and resource extraction projects (such as the Pebble Project buildout and Pebble South/PEB). Only the Diamond Point rock quarry project has the potential to directly remove Steller's eiders' wintering habitat from Cook Inlet. All other projects are anticipated to have indirect impacts on Steller's eiders. The Donlin Gold Project has the potential for adverse impacts to Steller's eiders through behavioral changes from increased barge traffic; injury or mortality from collisions with barges; or contamination, injury, or death from a fuel or chemical spill. However, impacts from the Donlin Gold Project would occur along the Kuskokwim River and Yukon-Kuskokwim Delta, and not in the Cook Inlet. Finally, projects that involve the erection of structures, such as powerlines, telecommunication towers, and wind turbines (e.g., the Kokhanok wind power plant) have the potential to create collision hazards to eiders.

4.25.5.2 Cook Inlet Beluga Whale

Past, present, and reasonably foreseeable future actions have the potential to contribute to cumulative impacts to the Cook Inlet beluga whale. Although the best available information indicated that human activities, including those associated with oil and gas development, were not a contributing factor in the stock becoming in danger of extinction (Allen and Angliss 2014), the Cook Inlet beluga whale stock is not showing signs of recovery and potential effects from human activities impeding on beluga recovery remain a concern. The human activities potentially affecting beluga whales would be from subsistence hunting and continued increased commercial vessel traffic. Noise is listed as a primary potential stressor for beluga whales in the Cook Inlet Beluga Whale Recovery Plan, and the pile driving associated with the Proposed Action would result in short-term, temporary increases in noise with no long-term lingering effects on the species. Increased vessel traffic could have moderate effects on beluga whales, however, beluga whales have experienced high vessel traffic in Cook Inlet for decades; therefore, such effects would be short-term with no long-term lingering effects on the species as no vessel strikes have been recorded in Cook Inlet. Other activities are either limited in their effects to produce noticeable impacts on beluga whales, or lack overlap with beluga whale life cycles and requirements. The contribution of the Proposed Action to effects on beluga whales would be negligible because vessel traffic would be low and the amount of noise would be short term.

4.25.5.3 Humpback Whale

Past, present, and reasonably foreseeable future actions have the potential to contribute to cumulative impacts to humpback whales. Increased vessel traffic could have moderate effects from disturbance and potential vessel strikes on humpback whales; however, such effects would have no long-term lingering effects on the species in Cook Inlet. The potential greatest implications of future actions on humpback whales would be increased commercial vessel traffic. Other activities are either limited in their effects to produce noticeable impacts on humpback whales, or lack overlap with humpback whale life cycles and requirements. The contribution of the Proposed Action to effects on humpback whales would be negligible.

4.25.5.4 Fin Whale

Past, present, and reasonably foreseeable future actions have the potential to contribute to cumulative impacts to fin whales. Perry et al. (1999) list the following factors possibly influencing the status of fin whales in the North Pacific: offshore oil and gas development as a "present or

AMERICAN OVERSIGHT

threatened destruction or modification of habitat," and vessel collisions as an "other natural or man-made factor." Vessel traffic would have negligible short-term effects on fin whales, considering their scarcity in the analysis area. The greatest implications of potential future actions on fin whales would be commercial vessel traffic. Other activities are either limited in their effects to produce noticeable impacts on fin whales, or lack overlap with fin whale life cycles and requirements. The contribution of the Proposed Action to effects on fin whales would be negligible.

4.25.5.5 Steller Sea Lion

Past, present, and reasonably foreseeable future actions have the potential to contribute to cumulative impacts to Steller sea lions. Any potential increase in mortality of Steller sea lion prey species in sea lion critical habitat, which resulted in a large decrease in prey available to the western stock of Steller sea lions, could result in potentially significant cumulative effect on both the stock and on the critical habitat. The primary potential for significant incremental contributions to cumulative adverse effects on Steller sea lions from routine operations could result from incremental increases in noise and disturbance at key terrestrial and foraging critical and other habitats of the western population stock, if such incremental increase resulted in Steller sea lions avoiding important feeding habitats or resulted in direct mortality. NMFS (2003) has concluded that there is some concern for the take of Steller sea lions due to encroachment by humans near critical terrestrial habitat sites (for example, rookeries, haul-outs) for viewing, research, or intentional harassment. Though vessel traffic could have moderate effects on Steller sea lions, such effects would be short-term with no long-term lingering effects on the species. The greatest implication for potential future actions on Steller sea lions would be from commercial vessel traffic. Other activities are limited in their effects to produce noticeable impacts on Steller sea lions, or lack overlap with life cycle requirements. The contribution of the Proposed Action to effects on Steller sea lions would be negligible.

4.25.5.6 Northern Sea Otter

Past, present, and reasonably foreseeable future actions have the potential to contribute to cumulative impacts to northern sea otters. The historical record demonstrates the extreme vulnerability of the sea otter to overharvest and must be considered a potential current and future threat to the southwest Alaska stock of sea otters. Multiple human actions have had potentially negative effects on the southwest Alaska stock of sea otters. These include mortality due to marine oil spills, take by Alaska Natives for subsistence and handicrafts, illegal intentional take, incidental take in fisheries, exposure to environmental contaminants, habitat degradation and loss, heightened risk of disease, and disturbance (USDOI, MMS 2003). Vessel traffic could have moderate effects on northern sea otters and related effects are thought to be short-term with no long-term lingering effects on the species. The greatest human activity effect on northern sea otters would be vessel traffic. Other activities are limited in their effects to produce noticeable impacts on northern sea otters, or lack overlap with northern sea otters' life cycles and requirements. The contribution of the Proposed Action to effects on northern sea otters would be negligible.

HYDROMETEOROLOGY
(REF. NO. VA101-176/40-1)

EXECUTIVE SUMMARY

The objective of this report is to provide a hydrometeorological characterization of the Pebble Project Mine Study Area for a variety of purposes, including water balance modelling, engineering design, water rights applications, and environmental assessments. This report presents preliminary estimates, which will be updated as additional information is obtained from on-going data collection programs. The Mine Study Area (MSA) refers to the area surrounding the deposit that may contain the mine facilities and is comprised of the North Fork Koktuli River, South Fork Koktuli River, and Upper Talarik Creek watersheds.

The climate of the MSA is classified as maritime continental; summer temperatures are moderated by the open waters of the Bering Sea and Cook Inlet, while winter temperatures are more continental in nature largely due to the presence of sea ice in Bristol Bay. Hydrometeorological values for the MSA were estimated on the basis of short-term site-specific data and long-term regional information. Meteorological data were initially collected in the MSA at the Cominco climate station, which was located near the eastern extent of the known project ore body during the period of August 1991 to December 1993. These data include intermittent records of temperature, precipitation, evaporation, and wind speed and direction. Additional climate stations were installed in the MSA in 2004, 2005, 2006 and 2007, and are all named using the prefix Pebble. This report presents the data collected by the Cominco station and the Pebble 1, Pebble 3, Pebble 4, Pebble 5, Pebble 5A and Pebble 6 meteorology stations. Each of these stations has at least one year of meteorological data collected by the end of 2010. Long-term regional climate data suitable for comparison to data collected in the MSA are only available from the airport in Iliamna, which is located approximately 17 miles (27 km) southeast and approximately 1000 ft (305 m) below the deposit at an elevation of 190 ft (58 m).

This report focuses on streamflow data collected prior to the end of 2010 from twenty-six (26) stream gaging stations on the North Fork Koktuli River (NK), South Fork Koktuli River (SK), and Upper Talarik Creek (UT). Three (3) of these stations are operated by the US Geological Survey (USGS). Continuous streamflow data were collected at a further four (4) locations in the MSA for various periods between 1991 and 1993; however, these data are not presented in this report due to their short periods of record and concerns about data quality. Groundwater and snowpack distribution sampling were undertaken from 2004 through 2009, and groundwater modelling is ongoing. Preliminary results from these investigations are included in this report.

The key findings of this study are summarized below. All meteorological values presented below were calculated for the Pebble 1 meteorological station, unless stated otherwise. All hydrological values are generally presented for the MSA, unless noted otherwise.

- The long-term average annual temperature is estimated to be 30.4°F (-0.9°C), with average monthly temperatures ranging from a high of 51.0°F (10.6°C) in July to 11.5°F (-11.4°C) in January.
- On average, temperatures are 4.5°F (2.5°C) cooler at Pebble 1 than at Iliamna.

AMERICAN OVERSIGHT

- Wind data from the six Pebble climate stations indicate that the wind direction and magnitude varies in the MSA. The average annual wind speed at these stations varied from a low of 10.9 mph (17.5 km/hr) at Pebble 3 in 2008 to a high of 18.6 mph (29.9 km/hr) at Pebble 4 in 2007.
- The maximum instantaneous wind speed recorded during the measurement period was 149 mph (239 km/hr) at the Pebble 5A station.
- Maximum solar radiation occurs in May and minimum radiation occurs in December, with respective rates of approximately 220 W/m^2 and 10 W/m^2.
- Relative humidity is high all year round with an annual average of 83%, and monthly average values ranging from a low of 75% in May to a high of 88% in October.
- Pond ice accumulation was estimated to be 42 inches (1067 mm) per year. Pond ice is expected to consistently occur between November and May, and may also occur into October and June.
- The mean annual pond evaporation is estimated to be approximately 10.4 inches (264 mm), with a maximum mean monthly value of 2.6 inches (66 mm) in June.
- The mean annual actual evapotranspiration (AET) is estimated to be 8.1 inches (206 mm).
- The sublimation rate is assessed at 4 inches (102 mm) per year. The 4 inches is assumed to be distributed fairly evenly throughout months of October through May.
- The observed mean annual precipitation at Pebble 1 during 2006 through 2010 was 37 inches (948 mm). The long-term mean annual precipitation value for Pebble 1 is estimated to be approximately 57 inches (1440 mm). This value is derived from a watershed model that was calibrated with all available measured flow data. The large difference between the measured and estimated precipitation is largely attributed to the poor catch efficiency of the precipitation gage.
- The measured long-term mean annual precipitation at Iliamna is 27 inches (680 mm). This value is believed to underestimate actual conditions because of suspected poor catch efficiency of the gage.
- The maximum 1-day precipitation recorded at Iliamna was 3.5 inches (89 mm), which was recorded in July. This corresponds to an estimated 7.3 inches (185 mm) for Pebble 1.
- Approximately 50% of precipitation is estimated to fall as snow.
- Measured annual maximum snowpack values ranged from 5 to 20 inches (127 to 508 mm) of snow water equivalent (SWE), but typically averaged about 10 to 14 inches (254 to 356 mm). Modelled annual maximum basin average SWE values are generally in the order of 20 inches (508 mm).
- Runoff results from rainfall and snowmelt, producing an annual hydrograph with two peak flow seasons. The first peak occurs in May as a result of snowmelt, while the second peak occurs between August and October as a result of rainfall events.
- Mean annual streamflow values were estimated for each of the 26 stream gaging stations in the MSA. The mean annual unit runoff at the gages on the lower reaches of the SK, NK, and UT basins ranged from 2.3 to 2.4 cfs/mi^2 (25 to 26 l/s/km^2) over the period of record. Considerable variability in runoff is evident, with the mean annual unit runoff for tributary streams ranging from 7.1 cfs/mi^2 to 1.3 cfs/mi^2 (78 to 14 l/s/km^2).
- The streams can be classified as either upland or lowland channels. Scaling relationships for estimating peak instantaneous flows for both channel types, for various flood events, were developed. For a drainage area of 10 mi^2, 10 year peak flows are estimated to be approximately 929 cfs (26 m^3/s) for upland channels and 353 cfs (10 m^3/s) for lowland channels.
- Low flows occur during both the summer and winter months, although flows in late winter tend to be the lowest of the year. Reaches of certain streams can go completely dry, particularly during the winter months. Unit 10-year 7-day low flow estimates are quite variable, even at the outlets of the

AMERICAN OVERSIGHT

three primary watersheds, and range from 0.31 cfs/mi^2 (3.4 l/s/km^2) at the outlet of the North Fork Koktuli River to 0.88 cfs/mi^2 (9.6 l/s/km^2) at the outlet of Upper Talarik Creek.

- The probable maximum precipitation (PMP) was estimated to be 18 inches (457 mm) for a 24 hr storm.
- The probable maximum flood (PMF) is not presented in this report and needs to be calculated for each facility based on the specifics of its design and location.
- The mean annual temperature trends for climate stations in the general region indicate temperatures have increased at an average rate of approximately 0.08 °F/year over the past 50 to 60 years, for a net change of approximately 5 °F (3°C). However, it appears that temperature changes in Alaska over the last century, and particularly over the last 60 years, can be more attributed to large scale climate oscillations than to climate change. It appears that we have recently entered a cooling phase, and correspondingly it is possible that the annual mean temperature trend may actually decline or remain relatively constant over the next two to three decades.
- The annual precipitation trends for climate stations in the general region are weak and inconsistent, which generally suggests that there has been little or no change in patterns of total annual precipitation.
- It appears that the severity of extreme precipitation events is increasing.
- Regional historical streamflow data indicate that annual hydrograph shapes are changing, with increasing winter flows and decreasing summer flows. These patterns are consistent with the expected effects of increasing temperatures.

HYDROMETEOROLOGY
(REF. NO. VA101-176/37-1)

SECTION 1.0 - INTRODUCTION

The climate of the Pebble Project Mine Study Area is classified as maritime continental, with summer temperatures moderated by the open waters of the Bering Sea and Cook Inlet, and winter temperatures influenced by the presence of sea ice in Bristol Bay during the coldest months of the year. The Mine Study Area (MSA) refers to the area surrounding the deposit that may contain the mine facilities and is comprised of the North Fork Koktuli River, South Fork Koktuli River, and Upper Talarik Creek watersheds. The area consists of low, rolling hills separated by wide, shallow valleys with sinuous drainage channels. The elevation in the vicinity of the MSA varies from approximately 580 feet at the confluence of the south and north forks of the Koktuli River to 3,074 feet on Groundhog Mountain. The deposit area in the pass between the South Fork Koktuli River and Upper Talarik Creek lies at approximately 1,000 feet elevation.

Hydrometeorological values for the MSA were calculated on the basis of short-term site-specific data and long-term regional information. The values were specifically derived for water balance modelling and engineering design purposes, but are also generally appropriate for other requirements including water rights applications and environmental assessments. When using the values, the assumptions made in the analyses and the limitations of the hydrometeorological data presented should be carefully considered. The locations of twenty-six flow gaging stations and six meteorological stations that were operated in the MSA prior to 2010 are shown on Figure 1.1 and indicated in Table 1.1.

All meteorological values presented in this report are specified for the Pebble 1 meteorological station, unless noted otherwise. This station is located near the western edge of the Pebble ore deposit at elevation 1560 feet. The hydrological values presented in this report are for various points located throughout the three watersheds that comprise the MSA.

1.1 METEOROLOGY

Meteorological data were initially collected in the MSA at the Cominco Climate Station, which was located near the eastern extent of the known Project orebody and operated from August 1991 to December 1993. Intermittent records of temperature, precipitation, evaporation, and wind speed and direction were collected at this site, but only the wind and temperature data are considered valid because of errors associated with the precipitation and evaporation data collection. In October 2004, two new climate stations were established in the MSA. These stations, identified as Pebble 1 and Pebble 3, were not fully operational until August 2005 and November 2005, respectively. An additional climate station, known as Pebble 4, was established in January 2007, and finally, stations Pebble 5, Pebble 5A, and Pebble 6 were installed during July/August 2007. All six stations collected air temperature, precipitation, and wind data. In addition, Pebble 1, 4, 5 and 6 collected evaporation, relative humidity, and solar radiation data. Pebble 3 and 4 were discontinued in early 2009. The assessment of meteorological conditions in the MSA is primarily derived from the five year (2006 – 2010) record collected at Pebble 1, and is supported

AMERICAN OVERSIGHT

by shorter term data collected at the other five stations. The 2005 data for Pebble 1 have not been included in this report, with the exception of temperature data, because they are believed to be of relatively poor quality. Stations Pebble 1, 3, 4, 5, 5A and 6 are located at elevations of 1560 ft, 1000 ft, 1200 ft, 1400 ft, 2300 ft, and 800 ft (476 m, 305 m, 366 m, 427 m, 701 m, and 244 m), respectively.

Regional climate data suitable for comparison to the MSA data are available from the airport at Iliamna, which is located approximately 17 miles (27.4 km) southeast of the project orebody at an elevation of 190 ft (58 m). A climate station has operated intermittently at this location since 1920, but almost continuously since 1942. Data from other regional stations were also reviewed when appropriate, but were not used directly.

Some meteorological parameters, and in particular precipitation, are very difficult to accurately measure in the challenging conditions of the MSA. Therefore, a side water balance model, as developed by Slumberger Water Services (PLP, 2011a), was used to estimate or validate values. This model was run using monthly inputs of temperature and precipitation and was calibrated with six years of measured streamflow and water level data from numerous locations throughout the MSA. The calibrated model was run for 68 years.

1.2 HYDROLOGY

Hydrological data were collected on the three major stream/river systems that comprise the MSA. These are the North Fork Koktuli River, the South Fork Koktuli River, and Upper Talarik Creek. This report summarizes the data collected between July 2004 and September 2010 at twenty-six continuous flow gaging stations on these systems. Three of these stations are operated by the US Geological Survey (USGS). Continuous streamflow data were also collected at four locations in the MSA for various periods between 1991 and 1993, but these data are not presented in this report because of concerns about their quality. Regional streamflow data are limited and largely pertain to river systems that are much larger than those in the MSA. Nonetheless, the available data provide some basis for assessing expected long-term flow patterns and these were examined and considered as part of the analyses.

1.3 GROUNDWATER AND SNOWPACK

In addition to climate and streamflow data, information on groundwater and snow cover conditions is also collected in the MSA. Groundwater levels are monitored and hydraulic conductivity conditions are assessed with an extensive series of monitoring wells, while snowpack data such as depth and snow water equivalent are collected at a number of snow survey sites. This information is very briefly discussed in this report.

AMERICAN OVERSIGHT

SECTION 2.0 - METEOROLOGY

2.1 TEMPERATURE

Monthly average temperatures for the Pebble climate stations and concurrent monthly temperatures for Iliamna are summarized in Table 2.1. A nearly continuous temperature record is available for the Iliamna Airport from 1942 through 2010, while temperature data are available for three locations within the Pebble MSA for varying periods from 2005 to present. The only complete temperature record during this period was collected at the Pebble 1 Meteorological Station (Pebble 1), and it contains 65 months of data. The correlation of concurrent mean monthly temperature data for Iliamna Airport and Pebble 1 (Figure 2.1) indicates that mean monthly temperatures at Pebble 1 were typically 4.5 °F (2.5 °C) colder than at the Iliamna Airport, which equates to a lapse rate of 3.3 °F/1000 ft (6.0 °C/1000 m). This rate is generally consistent with the standard normal or environmental lapse rate of 3.6 °F/1000 ft (6.5 °C/1000 m).

Long-term mean monthly temperature values (1942 to 2010) were simulated for the Pebble 1 meteorological station (el. 1560 ft) by subtracting 4.5 °F ft from the monthly Iliamna Airport temperature values. The simulated temperatures range from a high of 51.0 °F (10.6 °C) in July to a low of 11.5 °F (-11.4 °C) in January, as summarized in Table 2.2 and shown on Figure 2.2. The long-term mean annual temperature for Pebble 1 was estimated to be 30.4 °F (- 0.9 °C). The maximum and minimum hourly air temperatures recorded at Pebble 1 during the period of 2005 to 2010 are 75.9 °F (24.4 °C) and - 33.3 °F (- 36.3 °C), respectively, while the maximum and minimum temperatures recorded over the long-term at Iliamna are 91 °F (33 °C) and – 47 °F (- 44 °C) (WRCC, 2011).

Correlations between the concurrent mean monthly temperature data for Pebble 1 and that for Pebble 3, 4, 5, 5A, and 6 are presented on Figure 2.3. An analysis of the temperature differences indicates lapse rates ranging from 1.1 °F/1000 ft (2.0 °C/1000 m) to 3.5 °F/1000 ft (6.4 °C/1000 m). Also, correlations between the concurrent data for Pebble 5 and that for Pebble 5A, and for Pebble 6 (Figure 2.4), which are all located within the drainage basin of NK119A (see Figure 1.1), indicate a lapse rate of 2.5 °F/1000 ft (4.6 °C/1000 m). These rates are generally lower than expected and indicate substantial localized temperature variability. Because of this variability, and the difficulty of determining what lapse rate should be applied in what location, it is recommended that the standard normal lapse rate of 3.6 °F/1000 ft be used to translate the long-term Pebble 1 values to different elevations in the MSA. This can be done using the formula:

$$T = Ts - (3.6)(E-Es)/1000 \qquad (2.1)$$

Where:

- T = temperature of middle of elevation band (°F).
- Ts = temperature at Site Pebble 1 (°F).
- E = elevation of middle of elevation band (feet).
- Es = elevation of Site Pebble 1 (1560 feet).

AMERICAN OVERSIGHT

2.2 WIND

The average monthly wind speeds recorded at Pebble 1, 3, 4, 5, 5A and 6, for various monitoring periods between 2006 and 2010, are summarized in Table 2.3. Mean wind speeds recorded at Iliamna between 2000 and 2010 are also included in Table 2.3 for reference. The MSA is exceptionally windy, both in terms of the frequency and intensity of wind. Higher wind speeds are typically experienced at stations with greater elevation and/or exposure, as indicated by comparing the wind speeds recorded at Pebble 5A, the highest and most exposed climate station, to those at Pebble 3, which is lower and less exposed. The monthly mean wind speeds at the stations are typically greatest during the winter and lowest during the summer, and range from an average monthly low of 6.3 mph measured during July 2007 and again in August 2008 at Pebble 3, to a high of 28.9 mph measured during November 2006 at Pebble 1. Summer wind speeds measured at Pebble 5A are considerably greater than concurrent measurements at any of the other Pebble stations, which suggests that winter wind speeds at that site are also likely greater than at the other stations. Measured annual average wind speeds range from 10.9 mph (17.5km/hr) at Pebble 3 in 2008 to a high of 18.6 mph (29.9 km/hr) at Pebble 4 in 2007, with likely even greater wind speeds occurring at Pebble 5A. The maximum instantaneous wind speed measured within the MSA was 149 mph (239 km/hr) at the Pebble 5A Station.

Hourly wind speed data have been collected from 2006 through 2010 at the Pebble 1 climate station. Wind roses were developed from these data by the Hoefler Consulting Group, as presented on Figure 2.5. Pebble 1 is located near the proposed Open Pit at a relatively high and exposed site, and accordingly Pebble 1 typically experiences relatively high wind speeds, which are considered to be fairly typical of the Project Area as a whole. The wind was calm (less than 1.1 mph) at Pebble 1 for only 1.9% of the time, while wind speeds exceeded 25 mph for more than 20% of the time. Pebble 1 predominantly experienced winds from the northwest (25% of the record period) and from the east-southeast and southeast (32% of the record). However, it is known that the dominant wind direction can vary throughout the Project Area according to the influence of local topography. For more information regarding wind speed and wind direction variability, please refer to the annual data reports published by Hoefler Consulting Group and SLR International for the Pebble Limited Partnership (example: Hoefler, 2010).

2.3 SOLAR RADIATION

Site-specific incident solar radiation data have been collected at Pebble 1, 4, 5 and 6 for varying periods between 2006 and 2010. Monthly mean hourly incident solar radiation values (W/m^2) are presented in Table 2.4. It is evident that solar radiation in the MSA varies slightly by location but substantially by date. It is typically greatest in May and least in December, with average respective values of approximately 220 W/m^2 and 10 W/m^2. It can be generally assumed that incident solar radiation is greatest in June in the northern hemisphere, when the sun is at its highest and daylight hours are the longest; however, the fact that incident solar radiation is nearly always greater in May than in June in Table 2.4 suggests that cloud cover is likely much greater in June than in May at the Pebble MSA.

2.4 RELATIVE HUMIDITY

Site-specific relative humidity data have been collected at Pebble 1, 4, 5 and 6 for varying periods between 2006 and 2010. Monthly average percent relative humidity values are presented in Table 2.5. It

AMERICAN OVERSIGHT

is evident that relative humidity in the MSA is high all year round with an annual average of 83%, and mean monthly values ranging from a low of 75% in May to a high of 88% in October.

2.5 ICE GROWTH

Cumulative ice formation on ponds (including tailings ponds) over the course of the winter months was calculated using the modified Stefan equation (US Army Corps, 2004):

$$t_i = C \cdot \sqrt{AFFD} \qquad (2.2)$$

Where:

t_i = ice thickness (inches)
C = a coefficient dependent on wind and snow conditions and water body size (^{o}F days)
AFFD = the accumulated freezing degree days index

The AFFD in the MSA was calculated from average daily temperatures estimated for the MSA based on Iliamna data, with the MSA assumed to be an average 4.9 ^{o}F cooler than Iliamna, based on an elevation of 1560 ft and a lapse rate of 3.6 ^{o}F/1000 ft, as per Section 2.1 above. The coefficient C was obtained from Table 1 in the US Army Corps of Engineers Technical Note 04-3 (US Army Corps, 2004). A value of 0.8 was selected because it pertains to windy lakes with no snow cover, which is generally consistent with conditions in the MSA. Assuming no snow cover, a mean annual cumulative ice thickness of 42 inches (1067 mm) was calculated, with corresponding minimum, 95th percentile, and maximum cumulative annual values of 26 inches, 50 inches, and 54 inches, respectively. These values are generally consistent with conditions at Port Alsworth on Lake Clark, where the maximum recorded ice thickness is 51 inches. Based on MSA temperature values and ice cover observations from Port Alsworth, ice on ponds in the MSA can be expected to consistently exist between November and May, with some ice also commonly present in October and June.

2.6 EVAPORATION

The average annual measured evaporation value for the Pebble Project area (meteorological stations Pebble 1, 4, 5 and 6) is approximately 11.1 inches for the months of May through October, as summarized in Table 2.6. This value assumes a standard Class A pan coefficient of 0.7, but a more appropriate value for areas of high relative humidity and strong winds such as those at the Pebble Project area is likely 0.6 (Maidment, 1992). Accordingly, the measured pan data equate to an equivalent or lake evaporation value of 9.5 inches. However, evaporation also occurs in April and October, which is not included in these measurements. Based on the Penman-Monteith potential evapotranspiration values estimated below, the PET values in April and October represent approximately 70% and 45% of the September value, respectively, which when accounted for, increases the effective annual evaporation to approximately 10.4 inches.

Accurately measuring evaporation in remote and windy locations such as the Pebble Project area is very challenging, and despite the great efforts made to ensure accurate data collection, there is the potential for possible data errors. The general consistency of the values in Table 2.6 provides some validation of the data, but in addition, potential evapotranspiration (PET) values, which are generally representative of lake evaporation, were calculated. A number of different PET equations are available in the literature, but

AMERICAN OVERSIGHT

for this purpose the Thornthwaite and Penman-Monteith equations were selected because they are reasonably simple, commonly applied, and tend to give reasonably accurate results.

Using the Thornthwaite method, as outlined by Ponce (1989), the potential monthly PET was estimated based on the average monthly temperature in degrees Celsius at Pebble 1 according to the equation:

$$PET\ (inches) = 0.63(10T/I)^{a}$$

Where:

T = monthly average temperature (^{o}C).
I = the sum of the i values for the year, where $i = (T/5)^{1.514}$.
$a = 6.751x10^{-7}(I^{3}) - 7.71x10^{-5}(I^{2}) + 1.792x10^{-2}(I) + 0.49239$.

The resultant annual PET for the Pebble 1 site is 12.0 inches (May to September), which is very similar to the measured evaporation value. The estimated monthly distribution of PET is presented in Table 2.7.

The Penman-Monteith (P-M) model is considerably more complex than the Thornthwaite model, and uses a combination of radiative and aerodynamic terms for a coupled energy and mass balance to calculate PET. The P-M model also attempts to account for the control on PET exerted by plants, in the form of stomatal resistance. Temperature, wind, solar radiation and relative humidity data collected at Pebble 1 were all input to the model, and considerations were also made for albedo and plant characteristics at the Pebble 1 site. The resultant annual PET estimated by the model was 9.3 inches, which is very similar to the Thornthwaite PET and measured pan evaporation values. The estimated monthly distribution of PET is presented in Table 2.7.

The estimated PET values provide reasonable validation for the measured evaporation values. The measured values, along with estimated April and October values, were selected as the best representative MSA values. These values indicate a mean annual pond evaporation of approximately 10.4 inches, with a maximum mean monthly value of 2.6 inches in June.

2.7 ACTUAL EVAPOTRANSPIRATION

Actual evapotranspiration (AET) was calculated as part of a site wide water balance model discussed in Section 1.1. Typically, PET represents the evapotranspiration for a full vegetated cover on relatively flat tilled ground with no shortage of water, whereas AET is limited by the water available each month. For example, if the sum of snowmelt and rainfall in a given month is less than the PET, then the AET is less than the PET. Evapotranspiration is also limited by the soil moisture condition. Soil moisture capacity was estimated to be 4 inches (102 mm) for most sites and 14 inches (356 mm) for the high evaporation sites (wetlands).

The 4 inches value for most sites was estimated using the following information:

$$S_m = S_{max} * R_d * A$$

Where:

AMERICAN OVERSIGHT

S_m = soil moisture capacity
S_{max} = the maximum soil moisture for the MSA, conservatively estimated to be 2.4 inches for a 6.5 ft soil depth (NCEP, 2011).
R_d = the available water adjustment for rooting depth, estimated to be 1/3
A = the availability coefficient, estimated to be 50% in the MSA

The R_d value of 1/3 is based on an estimated vegetation rooting depth in the MSA of 20 inches (Canadell, 1996), and the recognition that soil compaction increases with depth and therefore soil moisture decreases with depth. Accordingly, it is assumed that the 20 inch rooting depth, which equates to 1/4 of the 6.5 ft soil depth, contains 1/3 of the available moisture.

The 14 inch value for high evaporation areas was somewhat arbitrarily selected to ensure that soil moisture would not limit evapotranspiration losses in wetland areas.

When the soil moisture was below capacity, the PET was reduced linearly with soil moisture as follows:

Adjusted evapotranspiration = $(S_2 + S_1)$ *f* (PET)/$(2S_m)$

Where:
S_m = soil moisture capacity.
S_1 = soil moisture at the beginning of the month.
S_2 = soil moisture at the end of the month.
PET = the calculated full PET after allowance for latitude and land cover type and condition.
f = the reduction factor for non-ideal conditions for evapotranspiration (0.5 for most sites and 0.86 for high evaporation sites).

The result of this modelling is a mean annual AET estimate of 8.1 inches (206 mm) at the elevation of the Pebble 1 monitoring station. Mean monthly values are presented in Table 2.7. The modelled AET annual value is only slightly less than the estimated PET values, which suggests that evapotranspiration is only slightly inhibited by moisture availability in the MSA.

2.8 SUBLIMATION

Sublimation is the process by which moisture is returned to the atmosphere directly from snow and ice without passing through the liquid phase (Liston and Sturm, 2004). In areas where winter precipitation comprises a large proportion of annual precipitation, sublimation can play a significant role in the annual water balance. For example, Liston and Sturm estimate that sublimation can result in the loss of 10%-50% of the total winter snowfall in Arctic regions. The Pebble Project is situated in a sub-Arctic environment that is subject to mean monthly temperatures that are below freezing for seven months of the year, which results in a good portion of the annual precipitation falling as snow. Furthermore, the climate in the MSA is characterized by frequent high winds that often result in blowing snow which, according to Schmidt (1982), may increase the rate of sublimation by two orders of magnitude when compared to sublimation rates from a static snow surface under the same atmospheric conditions. Due

AMERICAN OVERSIGHT

to this combination of high winds and ample snowfall, sublimation likely plays a notable role in the annual moisture budget in the MSA.

Several studies have been undertaken to simulate sublimation in Alaska, primarily for Northern Alaska, from the foothills of the Brooks Range to the Arctic Coast. Two such studies were undertaken by Bowling et al. (2004) and Liston and Sturm (2002). Both of these studies modelled variations in sublimation along a continual gradient from rolling uplands to the coastal plain. The characteristics of the coastal plain zone appear most comparable to those in the MSA, with mean wind speed similar but slightly lower than and mean percent relative humidity very similar to values measured in the study area. However, precipitation is considerably higher in the study area than in the coastal plain zone. Bowling suggests that sublimation in the coastal zone is precipitation limited, insinuating that if more snow were to occur in this zone sublimation rates would be higher. Therefore, it is assumed that sublimation rates in the MSA are slightly greater than those simulated for the coastal plain zone.

Maximum sublimation rates predicted by Bowling et al. and Liston and Sturm for their coastal plain zones occurred in 1995 and were 3.94 inches (100 mm) and 3.15 inches (80 mm), respectively. Bowling also estimated a sublimation value of 3.51 inches (89 mm) for a nearby, similar coastal location. As sublimation rates are expected to be at least as high in the MSA, a rate of 4 inches per year (102 mm per year) was selected as representative. Many studies have presented wide ranges of sublimation rates as percentages of total winter precipitation, including the range of 10%-50% discussed above. Other ranges include 5%-50%, 15%-41%, 20%-47%, 21%-34% and 23%-41% (Liston and Sturm, 2002; Bowling et al., 2004). When the sublimation rate of 4 inches per year (102 mm per year) is assessed as a percentage of the total winter (Nov-Apr) precipitation in the study area, the result is approximately 17%. This value lies at the low end of the ranges presented above, but this is not surprising given that the winter precipitation is generally much greater than at the sites for which these ranges were derived. Furthermore, the value is consistent with sublimation values derived using a Blowing Snow Model developed by Pomeroy et al. (1997), which was run using wind data collected at Pebble 1.

During the operation of the project there is potential for airborne dust to settle on the snow surface and theoretically affect the rate of sublimation, which would in turn impact the water balance of the project. No literature could be found that addresses this possibility. However, as stated above, sublimation in the MSA is thought to be driven primarily by the wind-blown transport of snow. As the proposed dust particles are also transportable by wind, it is assumed that they should have little impact on the mobility of the snow surface. It is therefore estimated that the effects of snow surface dust particulate on sublimation rates will be negligible. The assumptions about the potential effects of dust will be re-assessed at such time that more information becomes available.

In summary, the sublimation rate in the MSA is assessed at 4 inches per year (102 mm per year), based upon sublimation modelling studies conducted for Northern Alaska, and supported by common sublimation ranges presented in the relevant literature and by basic modelling of sublimation using site wind data. The 4 inches is assumed to be distributed fairly evenly throughout the snow occurrence months of October through May according to the results of the Pomeroy blowing snow model mentioned above. Monthly estimates of monthly average sublimation are provided in Table 2.8, and are assumed to apply to the entire MSA.

AMERICAN OVERSIGHT

2.9 PRECIPITATION

2.9.1 General

Precipitation in the region of the MSA is very difficult to accurately measure because of the consistently strong wind conditions. These conditions result in poor precipitation gage catch efficiency, particularly during the winter months. Accordingly, the historical precipitation records for the region, and in particular those at Iliamna, undoubtedly underestimate actual precipitation. The situation is likely even more pronounced in the MSA, where wind speeds are even greater than at Iliamna. As a result, a water balance model, as discussed in Section 1.1, was used as the primary basis to develop realistic estimates of precipitation in the MSA. This model was calibrated with extensive measured streamflow and groundwater level data, which are believed to be much more accurate than the measured precipitation. Inputs of precipitation were adjusted during the model calibration process to produce flow and groundwater level predictions consistent with the measured values.

2.9.2 Iliamna Precipitation Data

The long-term total monthly precipitation record (1942 to 2010) collected at the Iliamna Airport was used as the initial basis for synthesizing a corresponding long-term precipitation record for the Pebble Site. Of the 816 months of data in the Iliamna record, 84 were found to be incomplete. In order to complete the Iliamna record, 80 of the 84 monthly data gaps were infilled using data collected at Port Alsworth, which is located about 35 miles NNE of Iliamna on the shore of Lake Clark. Concurrent data for the two sites were compared using mass and double mass curves to determine the relationship between precipitation at the two locations. The mass curves illustrated that measured precipitation was about 70% higher at Iliamna than at Port Alsworth. A short term mass plot was then prepared to verify that there were no important seasonal variations masked within the plotting scale, and it was found that the 70% increase applied to all seasons. Consequently, a multiplier of 1.7 was used to infill gaps during the period of 1961 to 2009 in the Iliamna precipitation record. The remaining four months of missing data that had no concurrent Port Alsworth data were infilled using monthly averages or site data collected at Pebble 1. The completed precipitation record for Iliamna is summarized in Table 2.9 in terms of monthly and annual mean, minimum and maximum values. The average annual measured precipitation at the Iliamna Airport is 26.7 inches (678 mm). It is believed that the actual precipitation is likely greater due to undercatch of the precipitation gage, as is discussed in the following section.

2.9.3 Correlation between Iliamna and Pebble Site 1 Meteorological Station

The monthly precipitation data from the Iliamna Airport station were compared to concurrent data from the Pebble Site 1 meteorological station for the purpose of developing relations between these two datasets. Variations in precipitation are expected between the two locations as a result of factors such as:

- Orographic effects that result in greater precipitation at higher elevations. This is an important factor for frontal storm precipitation, but has little effect on convective storm precipitation that predominantly occurs during the summer months.

AMERICAN OVERSIGHT

- Poor and variable catch efficiency for both stations. The Iliamna station was not fitted with a wind shield and the Pebble Site 1 station, though outfitted with a Wyoming wind shield, is consistently subjected to extremely high winds. Both sites experience undercatch, but the degree of undercatch for each station is not known.
- Variations in storm tracking. Despite the reasonably close proximity of the two stations, with the Pebble Site 1 station located approximately 17 miles NW of the Iliamna station, storm systems appear to track differently over the two locations.
- Rain shadow effects that typically result in less precipitation on the leeward side of orographic features. At the Pebble site, this would be the northwest side of the hills because most storms are expected to arrive from the southeast.
- Natural variation of precipitation within a storm system.

Concurrent precipitation data collected from 2006 through 2009 at both Iliamna and Pebble Site 1 were used in the comparison. Site data collected prior to 2006 were not used in the assessment since those data are of relatively poor quality. During the comparison it was discovered that precipitation correlated differently during the summer and winter periods, largely because of the predominance of different storm systems at different times of year. Frontal storms occur in the winter while convective storms, which are less affected by elevation, are common in the summer. For the winter months (November through March) an orographic scaling factor of 1.10 per 100 m (328 ft) change in elevation was assumed, which is consistent with generally observed patterns in Coastal British Columbia (Loukas, 1994). This approach required the addition of another factor of 1.476 to provide agreement between measured precipitation at Iliamna and Pebble Site 1. This factor accounts for the fact that precipitation due to winter frontal systems is highly dependent on location as well as differences in elevation. For the non-winter months (April through October), the data suggest an orographic factor of 1.059 per 100 m (328 ft) change in elevation.

2.9.4 Pebble Site 1 Synthesized Long-Term Precipitation

To develop a long-term monthly precipitation time series for the Pebble Site 1 station, the relations derived above were applied to the long-term historical precipitation record for Iliamna. This resulted in a synthetic 68 year (1942 to 2009) monthly precipitation series that reasonably represents the precipitation values that would have been recorded at the Pebble Site 1 station over that period. However, as noted previously, the precipitation gages at both Iliamna and Pebble Site 1 likely did not measure the true precipitation, particularly during the winter months when the wind speeds are greatest and precipitation primarily occurs as snow. To account for this undercatch condition, a factor of 1.60 was applied to all of the calculated winter (November to March) precipitation values (those representing what the gage would have measured), and a factor of 1.25 was applied to all non-winter data. These factors were determined during the calibration purpose for the site wide watershed model discussed previously. The resulting long-term precipitation series, which is presented in Table 2.10, provides an estimate of the monthly precipitation that occurred at Pebble Site 1 from 1942 to 2009.

To summarize, estimates of long-term precipitation for the Pebble Site 1 station were generated by adjusting the long-term precipitation record for Iliamna by factors of 1.059 per 100 m change in elevation (orographic) and of 1.25 (undercatch) for the non-winter months of April to October, and

AMERICAN OVERSIGHT

by factors of 1.10 per 100 m change in elevation (orographic), 1.476 (location) and 1.60 (undercatch) for the winter months of November to March. The resulting mean annual precipitation is 56.6 inches (1438 mm).

2.9.5 Long-Term Precipitation for Locations Throughout the Mine Study Area

The previous sections discuss the generation of a long-term precipitation record for Pebble Site 1. However, precipitation estimates will almost certainly be required at other locations in the MSA. In order to generate precipitation estimates at these other locations, orographic and location factors can be applied to the Pebble Site 1 values. Different orographic factors were selected for winter and summer according to the coefficients determined when comparing the Iliamna and Pebble Site 1 data, and location factors were determined using a watershed model calibrated with streamflow records for multiple locations. To adjust Pebble Site 1 precipitation data to account for elevation changes, the following equation applies:

P = PS1*a^(H/328.1)

Where:

P = the monthly precipitation at the selected location (inches).
PS1 = the monthly precipitation at Pebble Site 1 (inches).
a = the orographic factor,
a_{winter} = 1.10
a_{summer} = 1.059
H = the difference in elevation between two locations (feet).

An example application of this scaling equation is as follows:

Location of Interest: X
Elevation of X: 1000 ft
Elevation of Pebble Site 1: 1560 ft
Month of Interest: June
Orographic factor for June (a): 1.059
Mean precipitation in June at Pebble Site 1: 2.4 inches

Therefore:

P = PS1*a^(H/328.1)
P = 2.4 *1.059^((1000-1560)/328.1)
P = 2.2 inches

Once precipitation has been adjusted for orographic effects, a location factor must be applied. Site specific location factors were determined through the water balance modelling process discussed previously. The location factors were derived through calibration of the model with the measured streamflow, and were determined for 21 sub-watersheds that are monitored with a hydrologic monitoring station. The summer and winter undercatch values for Pebble Site 1, presented above, were selected such that the location factor that applies to the Pebble Site 1 station is equal to 1. A summary of the location factors is provided in Table 2.11. To apply these

AMERICAN OVERSIGHT

factors, simply multiply the orographically corrected precipitation estimate by the location factor associated with the nearest downstream hydrologic monitoring station that is located within the same watershed for which the precipitation estimate is being calculated. In an attempt to simplify the above methodology for estimating precipitation in the study area, all of the previously discussed adjustments and corrections have been incorporated into the delineation of a precipitation map of the study area, which is presented on Figure 2.6. In order to estimate precipitation anywhere within the North Fork Koktuli, South Fork Koktuli or Upper Talarik watersheds, simply locate the point of interest on Figure 2.6 and read off the corresponding mean annual precipitation value.

2.9.6 Snowpack

The precipitation records from the MSA meteorological stations (2006 - 2010) do not differentiate between rainfall and snowfall. The portion of total annual precipitation falling as snow at Iliamna is in the order of 25% to 30%. Due to consistently lower temperatures in the MSA, it is reasonable to conclude that a greater portion of the total annual precipitation in the MSA will fall as snow. For the purpose of the monthly water balance model discussed previously, precipitation type was modelled as rain if the average monthly temperature was greater than -2 $^{\circ}$C and as snow if the average monthly temperature was below -3 $^{\circ}$C. Between these temperatures, the portion of precipitation falling as snow was varied linearly with the temperature. Using this methodology, snowfall at Pebble 1 was determined to comprise approximately 48% of the annual precipitation.

SNOTEL data for three locations southeast of the MSA (McNeil Canyon, Cooper Lake, and Anchor River Divide) are available from the US National Weather and Climate Centre, and are summarized in terms of snow water equivalent (SWE) on Figure 2.7. These stations, which range in elevation from 1200 to 1653 feet, indicate that the snowpack typically accumulates until early to mid-April, and then rapidly melts throughout late April and May. This pattern is consistent with the annual hydrograph patterns of streams in the MSA.

Snowpack depth is highly variable in the MSA site due to the occurrence of frequent and sustained high winds that redistribute the snowpack. To help quantify such a diverse snowpack, snow survey work was initiated in 2004, which included establishing numerous snow survey transects, including four permanent snow courses, and annually monitoring a further 12 to 23 transects within the Upper Talarik Creek and the North and South Fork Koktuli River watersheds. The snow survey transects were located such that they measured a variety of elevations and aspects, and surveys were conducted in early to mid-April in an effort to measure the maximum annual snowpack. Maximum annual snowpack depths from the snow survey are presented in Table 2.12. Measured snowpack values ranged from 5 to 20 inches of snow water equivalent (SWE), but typically averaged about 10 to 14 inches. Modelled basin average SWE values for the three watersheds, as presented in the 2004 through 2008 Pebble Project Environmental Baseline Document (PLP, 2011a), are generally in the order of 20 inches.

Ablation rates were also investigated during compilation of the Environmental Baseline Document. Ablation rates were calculated for approximately two week periods from early to mid-

AMERICAN OVERSIGHT

April until mid to late May at Pebble Snow Courses 1, 1A and 2 for the years of 2004 through 2008. The values were highly variable, and ranged from a low of -0.09 inches SWE per day to a high of 0.58 inches SWE per day, with an average ablation rate of 0.24 inches SWE per day. For more detailed information on ablation and snowpack data please refer to Chapter 7 of the Pebble Project Environmental Baseline Document (PLP, 2011a).

AMERICAN OVERSIGHT

SECTION 3.0 - HYDROLOGY

3.1 STREAMFLOW

The hydrologic analyses in this report are based primarily on streamflow data collected from twenty-six (26) stream gaging stations on the North Fork Koktuli River (NK), South Fork Koktuli River (SK), and Upper Talarik Creek (UT). These data are for the period of July 2004 to September 2010. Figure 1.1 shows the gage locations and identification codes.

Period of record monthly unit-discharge hydrographs for stream gaging stations that are near the outlets of three (3) major catchments in the MSA are presented on Figure 3.1, and corresponding average annual unit discharge hydrographs are provided on Figure 3.2. It is evident from these figures that all three primary drainages have very similar hydrograph patterns and annual unit runoff. There are some notable differences, however, with the NK having the lowest and highest monthly flows, and the SK and UT having the highest and lowest annual flows, respectively. Average monthly unit runoff values for the twenty-six (26) stations are presented in Table 3.1.

Chapter 7 Appendix 7.2A of the Environmental Baseline Document (PLP, 2011a) presents the methodology of the hydrologic analysis, includes detailed information on the locations of the stations, and presents the following findings based on the collected hydrology data:

- The mean annual discharge (MAD) values for all the MSA gages are presented in Table 3.2.
- The mean annual runoff at the gages on the lower reaches of the SK, NK, and UT basins (Stations SK100B, NK100A, and UT100APC3, respectively) ranged from 2.3 to 2.4 cfs/mi^2 over the period of record. Elsewhere, annual unit runoff varied from gage to gage because of catchment topography and precipitation, surface and subsurface flow exchanges along stream channels, and the inter-basin transfers of groundwater.
- The annual hydrographs for each gage show that large portions of the annual runoff occurred during the spring period due to snowmelt (30 percent to 35 percent of the annual runoff volume) and during the late summer/autumn period due to rainstorms (40 percent to 60 percent of the annual runoff volume).
- Groundwater plays a prominent role in the flow patterns of all the creeks and rivers that were studied, but its role was especially notable at SK100C, which goes dry seasonally because of upstream losses of surface flow to groundwater, and at UT119A, which gains such a substantial amount of flow from the SK that its hydrograph is dominated by baseflow.
- The highest mean annual unit runoff value was recorded at UT119A (7.1 cfs/mi^2), which is attributed to the substantial amount of groundwater that is transferred to it from the SK basin. An anomalously low mean annual unit runoff value was recorded at SK100C (1.3 cfs/mi^2), which is attributed to upstream losses of groundwater to the UT watershed, and the bypassing of additional groundwater beneath the gage prior to upwelling into the channel further downstream.
- High annual unit runoff values were recorded at SK119A (3.3 cfs/mi^2) and NK119A (3.1 cfs/mi^2) because of their high catchment elevations and the associated orographic enhancement of precipitation. SK124A recorded considerably lower annual unit runoff (around 2.3 cfs/mi^2), despite

AMERICAN OVERSIGHT

having similar basin characteristics, because of losses of surface flow to groundwater just upstream of the gage.

3.2 PEAK FLOW

Scaling curves generally appropriate for estimating peak instantaneous flows for natural drainages in the MSA are presented on Figures 3.3 and 3.4. Figure 3.3 is for lowland streams and Figure 3.4 is for upland streams. These figures were generated by combining mean annual peak flow data from the MSA with USGS regionally based flood-frequency relations. Details of this approach are provided in Appendix 7.2C of the Pebble Project Environmental Baseline Document (PLP, 2011a).

Figures 3.3 and 3.4 provide general scaling relations for the MSA. However, localized variability occurs even at specific scales, as is evident on Figure 3.5, which presents scaling trendlines and the mean annual maximum daily discharge values for the MSA gaging stations. These trendlines provided the foundation for the curves on Figures 3.3 and 3.4, and accordingly the variability of the data points about the trendlines should be considered when making peak flow estimates for particular drainages.

3.3 LOW FLOW

The 10-year, 7-day low flow (7Q10) is a commonly cited statistic in hydrology and fisheries studies. The 7Q10 for each gaging station was estimated by performing a frequency analysis on the annual series of minimum 7-day average flows in the record of each station. Separate analyses were performed for winter and summer low flows because different concerns may exist for each season. Summer was defined as July through September, and the rest of the year was considered winter. The Environment Canada frequency analysis program "LFA" was used to fit a Gumbel III distribution to the annual minima at each station for each season.

The results of the analysis are presented in Table 3.3. The summer low flows are greater than the winter low flows at all stations by an average factor of 2.4. The gaging stations that are known to go dry (SK100C, SK124A, NK119B) have 7Q10 values of 0 cfs, as expected.

The low flows are plotted versus drainage area on Figure 3.6 (winter) and Figure 3.7 (summer). The values for mainstem channel stations are connected by solid lines. The two plots show the following main patterns:

- Generally, low flows in the winter are lower than those in the summer.
- At any given drainage area, low flows in Upper Talarik Creek are equal to or greater than flows in the South or North Fork Koktuli Rivers. This is explained mainly by the more abundant aquifer storage in the UT basin, and also by the interbasin transfer of groundwater from the SK basin that enters the UT.
- At drainage areas of approximately 20 to 60 mi^2, the SK has lower flows than the NK and UT, because of the loss of surface flow to groundwater. Low flows increase in the SK at larger drainage areas due to the upwelling of groundwater further downstream.

Additional discussions regarding the low flows in the MSA are presented in Appendix B of the "Pebble Project Surface Water Hydrology Annual Technical Report 2009 -2010" (PLP, 2011b).

AMERICAN OVERSIGHT

SECTION 4.0 - FREQUENCY-MAGNITUDE ANALYSIS

4.1 INTENSITY-DURATION-FREQUENCY CURVES

Intensity-Duration-Frequency (IDF) curves for the MSA were generated according to the NOAA Atlas 14 Volume 7: Precipitation-Frequency Atlas of the United States, Alaska (NOAA, 2012), with adjustments for specific location and orographic effects. Since the extreme precipitation is derived from an annual maximum dataset, with no distinction of whether the storms were in the summer or winter, and since it's not possible to tell whether future extreme events will occur in summer or winter, a combined winter and summer orographic/location/undercatch factor of 2.1 was selected for the analysis. Discussions of the different factors are provided in Section 2.9. It should be noted that there is considerable uncertainty associated with this factor.

To validate the NOAA baseline values, the 2-year, daily precipitation event was calculated for Iliamna from the annual maximum daily precipitation series (1943 – 2010). This value was then converted to a 24-hour value using a factor of 1.13 (NOAA, 1973). A 24-hour precipitation depth of 1.95 inches was calculated, which agrees with the depth of 1.90 inches determined from the NOAA Atlas. The resulting IDF curves at the Pebble 1 Climate Station (elevation 1560 ft), for 30-minute to 10-day durations, are shown on Figure 4.1 and Table 4.1. Example 100 year values are 1.77 inches and 8.21 inches for the 1 hour and 24 hour storms, respectively.

4.2 PROBABLE MAXIMUM FLOOD

The probable maximum flood (PMF) is the flow resulting from the most severe combination of probable maximum precipitation (PMP) and basin hydrological conditions. The PMP is the precipitation that results from the worst possible meteorological conditions and is presented in Table 4.1 as 18 inches for 24 hours. The PMF is generally used for the design of facilities where substantial environmental risk or loss of life exists in the event of failure. It should be noted that the PMF is a purely hypothetical event that is sufficiently large to ensure that it is never exceeded, yet at the same time not so excessively large that design requirements are unnecessarily conservative.

In the MSA, snowmelt is an important consideration of the PMF and is dependent on the design of a facility. For example, a larger snowmelt component of the PMF is appropriate for a facility with no outlet as opposed to a facility with an outlet. Snowmelt is also dependent on the available snowpack within a catchment due to snowblow and varying annual accumulation based on location. Due to these varying snowmelt values, PMFs are not presented in this report and need to be calculated for each facility based on their design and location.

AMERICAN OVERSIGHT

SECTION 5.0 - CLIMATE CHANGE

The climate of the MSA has undergone substantial changes over the past century, most notably in terms of general trends of increasing seasonal and annual temperatures, and increases in the severity and duration of extreme precipitation events. Accordingly, there have also likely been some changes to snow accumulation, snow melt and streamflow patterns. Many of these changes, and particularly those pertaining to temperature, appear to be the result of strong atmospheric and oceanic climate forcings, rather than climate change, as it is commonly defined, and they are quite variable and localized. Regardless, however, it's important to be aware of the potential magnitude of possible future changes, and to incorporate this knowledge into the design process and planned operating procedures for the Pebble Project.

A report titled "Climate Change at the Pebble Project Site" was completed by Knight Piésold Ltd. in September 2009 (KP, 2009). The key findings of this report are as follows:

- A number of published works on climate change in Alaska are fairly consistent in stating that:
  - Alaska's climate has shown a strong warming trend over the past few decades and has experienced the largest regional warming of any state in the U.S.
  - Average annual temperatures have increased by approximately 5 °F (3 °C) since the 1960's.
  - Temperature increases are greatest in the winter months and lowest in the summer months.
  - Much of the recent warming occurred suddenly around 1977, coincident with the shift in the Pacific Decadal Oscillation (PDO), a large scale atmosphere and ocean regime shift.
  - Alaska has generally gotten wetter over the past few decades, although historical precipitation trends are not particularly strong or consistent. Increases in annual precipitation of up to 30% over the past century are often quoted.
  - The proportion of annual precipitation falling as snow is likely decreasing, which is consistent with increasing temperatures.
  - Trends in extreme precipitation are quite variable and dependent on the region, and
  - Projected future climate scenarios, as modeled by the UN Intergovernmental Panel on Climate Change (IPCC), indicate that over the next 100 years mean annual temperatures in the West Coast Region of Alaska, including the MSA, might increase in the order of 6 °F to 7 °F (3.5 to 4 °C) and mean annual precipitation might increase in the order of 15% to 20%. Other studies suggest similar increases in precipitation, but add that increased evaporation due to warmer temperatures will exceed precipitation increases, resulting in decreases in soil moisture and runoff. In contrast to this, the IPCC predicts increases of 20% to 40% for mean annual runoff.
- The mean annual temperature trends for climate stations in the general region of the MSA are generally consistent with the published information, with temperatures increasing at an average rate of approximately 0.08 °F/year, for a net change of approximately 5 °F (3°C) over the past 50 to 60 years.
- The most pronounced temperature increases in the region appear to be during the winter months of January to March, with a net change of approximately 8 °F (4.5°C) over the past 50 to 60 years.
- The smallest temperature increases in the region appear to be during the summer months of July to September, with a net change of approximately 3 °F (1.7°C) over the past 50 to 60 years.
- It appears that temperature changes in Alaska over the last century, and particularly over the last 60 years, can be more attributed to large scale climate oscillations than to climate change.

AMERICAN OVERSIGHT

- If one accounts for the fact that the major shift in the regional temperature patterns is coincident with a shift in the Pacific Decadal Oscillation (PDO), the increasing temperature trends for climate stations in the general region of the MSA reduce from approximately 0.08 °F/year to a more moderate average rate of approximately 0.02 °F/year, which corresponds to a net climate change related temperature increase of approximately 1 °F (0.5 °C) over the past 50 to 60 years.
- It appears that we have recently, or are currently, entering a cooling phase of the PDO. Correspondingly, it is possible that the annual mean temperature trend may actually decline or remain relatively constant over the next two to three decades.
- The annual precipitation trends for climate stations in the general region of the MSA are weak and inconsistent, which generally suggests that there has been little or no change in patterns of total annual precipitation.
- It appears that the proportion of annual precipitation that falls as snow is decreasing, which is consistent with IPCC findings.
- It appears that the severity of extreme precipitation events is increasing.
- Regional historical streamflow data indicate that annual hydrograph shapes are changing, with increasing winter flows and decreasing summer flows. These patterns are consistent with the expected effects of increasing temperatures, as demonstrated by the results of hydrologic models.
- Trends of annual peak instantaneous discharge are relatively flat or stable, but could possibly increase due to potential increases in extreme precipitation and/or snowmelt rates, and
- The uncertainty of hydroclimatic conditions are typically considered in the design process for a mine through the use of factors of safety and by incorporating adaptability into the designs and operating plans for the mine. Consequently, mine structures are inherently well-suited to accommodate possible effects due to climate change.

For additional details regarding the climate change refer to the climate change report (KP, 2009).

AMERICAN OVERSIGHT

SECTION 6.0 - CONCLUSIONS

The key findings of this study are summarized below. All meteorological values presented below were calculated for the Pebble 1 meteorological station, unless stated otherwise. All hydrological values are generally presented for the MSA, unless noted otherwise.

- The long-term average annual temperature is estimated to be 30.4°F (-0.9°C), with average monthly temperatures ranging from a high of 51.0°F (10.6°C) in July to 11.5°F (-11.4°C) in January.
- On average, temperatures are 4.5°F (2.5°C) cooler at Pebble 1 than at Iliamna.
- Wind data from the six Pebble climate stations indicate that the wind direction and magnitude varies in the MSA. The average annual wind speed at these stations varied from a low of 10.9 mph (17.5 km/hr) at Pebble 3 in 2008 to a high of 18.6 mph (29.9 km/hr) at Pebble 4 in 2007.
- The maximum instantaneous wind speed recorded during the measurement period was 149 mph (239 km/hr) at the Pebble 5A station.
- Maximum solar radiation occurs in May and minimum radiation occurs in December, with respective rates of approximately 220 W/m^2 and 10 W/m^2.
- Relative humidity is high all year round with an annual average of 83%, and monthly average values ranging from a low of 75% in May to a high of 88% in October.
- Pond ice accumulation was estimated to be 42 inches (1067 mm) per year. Pond ice is expected to consistently occur between November and May, and may also occur into October and June.
- The mean annual pond evaporation is estimated to be approximately 10.4 inches (264 mm), with a maximum mean monthly value of 2.6 inches (66 mm) in June.
- The mean annual actual evapotranspiration (AET) is estimated to be 8.1 inches (206 mm).
- The sublimation rate is assessed at 4 inches (102 mm) per year. The 4 inches is assumed to be distributed fairly evenly throughout months of October through May.
- The observed mean annual precipitation at Pebble 1 during 2006 through 2010 was 37 inches (948 mm). The long-term mean annual precipitation value for Pebble 1 is estimated to be approximately 57 inches (1440 mm). This value is derived from a watershed model that was calibrated with all available measured flow data. The large difference between the measured and estimated precipitation is largely attributed to the poor catch efficiency of the precipitation gage.
- The measured long-term mean annual precipitation at Iliamna is 27 inches (680 mm). This value is believed to underestimate actual conditions because of suspected poor catch efficiency of the gage.
- The maximum 1-day precipitation recorded at Iliamna was 3.5 inches (89 mm), which was recorded in July. This corresponds to an estimated 7.3 inches (185 mm) for Pebble 1.
- Approximately 50% of precipitation is estimated to fall as snow.
- Measured annual maximum snowpack values ranged from 5 to 20 inches (127 to 508 mm) of snow water equivalent (SWE), but typically averaged about 10 to 14 inches (254 to 356 mm). Modelled annual maximum basin average SWE values are generally in the order of 20 inches (508 mm).
- Runoff results from rainfall and snowmelt, producing an annual hydrograph with two peak flow seasons. The first peak occurs in May as a result of snowmelt, while the second peak occurs between August and October as a result of rainfall events.
- Mean annual streamflow values were estimated for each of the 26 stream gaging stations in the MSA. The mean annual unit runoff at the gages on the lower reaches of the SK, NK, and UT basins ranged from 2.3 to 2.4 cfs/mi^2 (25 to 26 l/s/km^2) over the period of record. Considerable variability in runoff is

AMERICAN OVERSIGHT

evident, with the mean annual unit runoff for tributary streams ranging from 7.1 cfs/mi^2 to 1.3 cfs/mi^2 (78 to 14 l/s/km^2).

- The streams can be classified as either upland or lowland channels. Scaling relationships for estimating peak instantaneous flows for both channel types, for various flood events, were developed. For a drainage area of 10 mi^2, 10 year peak flows are estimated to be approximately 929 cfs (26 m^3/s) for upland channels and 353 cfs (10 m^3/s) for lowland channels.
- Low flows occur during both the summer and winter months, although flows in late winter tend to be the lowest of the year. Reaches of certain streams can go completely dry, particularly during the winter months. Unit 10-year 7-day low flow estimates are quite variable, even at the outlets of the three primary watersheds, and range from 0.31 cfs/mi^2 (3.4 l/s/km^2) at the outlet of the North Fork Koktuli River to 0.88 cfs/mi^2 (9.6 l/s/km^2) at the outlet of Upper Talarik Creek.
- The probable maximum precipitation (PMP) was estimated to be 18 inches (457 mm) for a 24 hr storm.
- The probable maximum flood (PMF) is not presented in this report and needs to be calculated for each facility based on the specifics of its design and location.
- The mean annual temperature trends for climate stations in the general region indicate temperatures have increased at an average rate of approximately 0.08 °F/year over the past 50 to 60 years, for a net change of approximately 5 °F (3°C). However, it appears that temperature changes in Alaska over the last century, and particularly over the last 60 years, can be more attributed to large scale climate oscillations than to climate change. It appears that we have recently entered a cooling phase, and correspondingly it is possible that the annual mean temperature trend may actually decline or remain relatively constant over the next two to three decades.
- The annual precipitation trends for climate stations in the general region are weak and inconsistent, which generally suggests that there has been little or no change in patterns of total annual precipitation.
- It appears that the severity of extreme precipitation events is increasing.
- Regional historical streamflow data indicate that annual hydrograph shapes are changing, with increasing winter flows and decreasing summer flows. These patterns are consistent with the expected effects of increasing temperatures.

NOTES:

1. PEBBLE WIND SPEED VALUES ARE BASED ON SITE DATA COLLECTED BY HOEFLER CONSULTING GROUP.
2. THE PEBBLE 5A CLIMATE STATION DID NOT COLLECT RELIABLE WIND SPEED DATA DURING THE WINTER MONTHS, LIKELY DUE TO THE EFFECTS OF ICING ON THE ANEMOMETER.

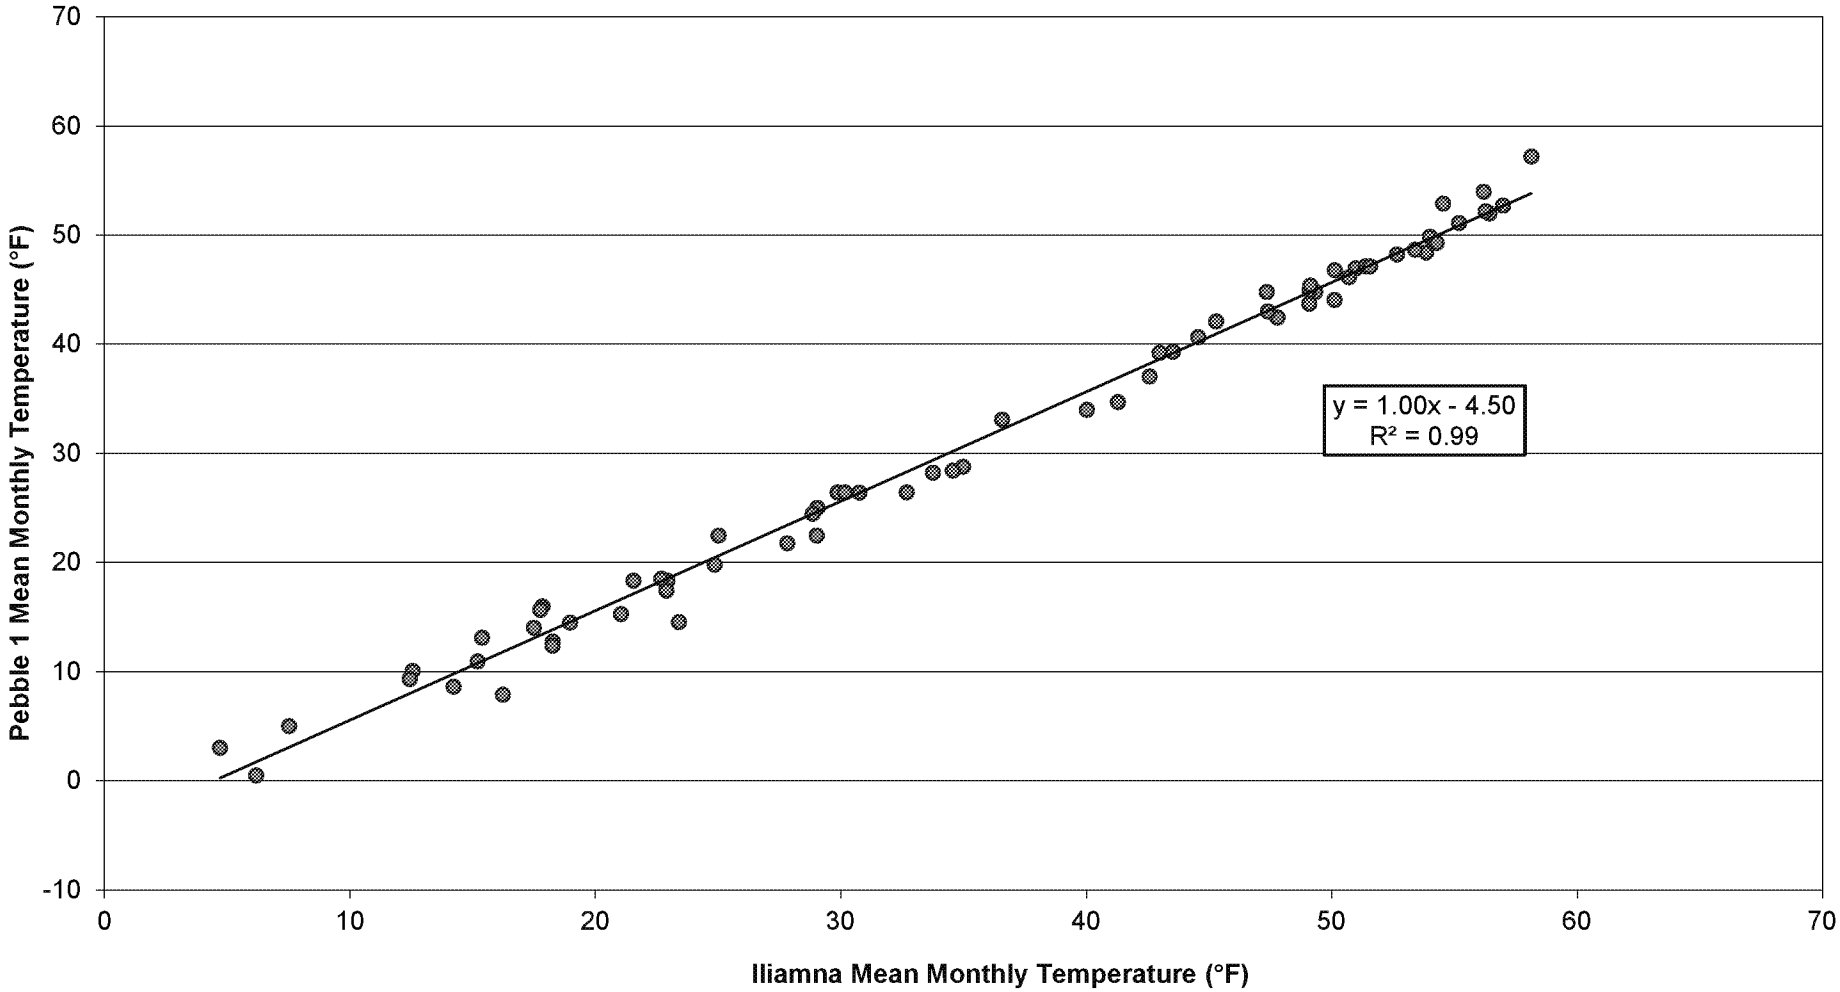
M:\1\01\00176\40\A\Data\Hydromet\[IDF-II.xls]IDF Curve Data 1560

NOTES:



1. PROJECT VALUES ARE ESTIMATED FOR THE PEBBLE 1 CLIMATE STATION AT EL. 1560 FT.
2. ILIAMNA VALUES WERE GENERATED ACCORDING TO THE NOAA ATLAS 14 VOLUME 7: PRECIPITATION-FREQUENCY ATLAS OF THE UNITED STATES, ALASKA.
3. THE LOCATION AND OROGRAPHIC FACTOR FOR TRANSLATING THE 24-HR VALUES FROM ILIAMNA TO THE MINE SITE AT PEBBLE 1 (ELEVATION 1560 FT) WAS ESTIMATED TO BE 2.1. THIS VALUES WAS DERIVED ON THE BASIS OF THE SWS WATER BALANCE MODEL.
4. THE IDF VALUES CAN BE TRANSLATED TO OTHER LOCATIONS AT THE PEBBLE PROJECT USING LOCATION AND OROGRAPHIC FACTORS.
5. THE PMP ESTIMATE DOES NOT USE THE OROGRAPHIC FACTOR, BUT RATHER CONSIDERS THE LOWER VARIABILITY OF THE PMP ISOHYETS COMPARED TO THE CORRESPONDING RETURN PERIOD ISOHYETS.

RFI 002
Pebble Project EIS

Request for Information

Title/Subject:	**Grouped Vegetation Type GIS Data**
Requestor:	**Sasha Forland, AECOM**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/3/2018**
Rationale:	**EBD Chapter 13 (Vegetation, BB) and Chapter 38 (Vegetation, CI) describe Project Vegetation Types (~50 types) and Grouped Vegetation Types (10 types). These chapters also include separate figure sets for these two classifications, indicating that spatial data exists for both. The 10 Grouped Vegetation Types were created for clearer display on maps, which is what is proposed for use in the EIS. However, the GIS dataset received to date does not include the layers for Grouped Vegetation Types (only the Project Vegetation Types). The spatial data is also necessary because the current alignment for the transportation corridor is not the same as what was studied as part of the 2004 – 2008 environmental baseline studies, so the cross-walk tables in the reports cannot be used directly. This gap was identified in the PDGA.** **The requested data is necessary to succinctly describe the affected environment and to analyze impacts to vegetation from the proposed project.**
Describe the Information Requested and Level of Detail:	**Please provide:** • **Spatial GIS vegetation data for the 10 Grouped Vegetation Types discussed in the Pebble Project EBD 2004 through 2008 (Chapters 13 and 38).** • **If GIS spatial data are not available, non-spatial data such as the crosswalk table(s) that PLP applied would be acceptable.** • **SEBD chapters for vegetation if available.**

Recipient Response Form

Date Received from USACE:	**4/27/2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1. Spatial data (GIS format) for the 10 Grouped Vegetation Types will be provided to USACE no later than 5/18/2018. 2. N/A 3. SEBD chapters for vegetation are not available.
List Number and Type of Response Attachments:	**None**
Date Returned to USACE:	**5/11/2018**

Request for Information

Title/Subject:	**SEBD 07 SW Hydrology OCT15 - Missing Appendix 7A-E Figures and Tables**
Requestor:	**James Dietzmann/Nancy Darigo, AECOM**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/3/2018**
Rationale:	**We are requesting all figures and some tables that accompany Appendix 7A, and all of Appendix 7D and Appendix 7E of the *Pebble Project Supplemental Environmental Baseline Data Report 2004 – 2012, 7. Surface Water Hydrology*. AECOM received the SEBD 07 SW Hydrology OCT15.pdf, and discovered that some tables and all figures from Appendix 7A, as well as Appendix 7D and Appendix 7E, were missing. Note that Appendix 7A is only missing Tables 30 through 64.** **The requested data is necessary to understand and succinctly describe the environment affected by the proposed action in accordance with CEQ regulations (40 CFR 1502.15), and to analyze impacts to hydrologic resources from the proposed project.**
Describe the Information Requested and Level of Detail:	**We need the missing figures and tables referenced above in Appendices 7A through 7E. There are at least 144 figures referenced starting on page 31/72 of the SEBD 07 SW Hydrology OCT15.pdf.**

Recipient Response Form

Date Received from USACE:	**4/27/2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**Revised SEBD Chapter 07 (Surface Water Hydrology—Bristol Bay), inclusive of appendices 7A-7F. The attached version is complete and supersedes all previously submitted versions of this chapter.**
List Number and Type of Response Attachments:	1. SEBD 07 SW Hydrology MAY2018.pdf

RFI 005
Pebble Project EIS

Request for Information

Title/Subject:	**Stability of Port Structures**
Requestor:	**Nancy Darigo/Craig Freas, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/18**
Rationale:	**The Project Description and EBD (Chapters 27, 29, and 30) provide limited information regarding geotechnical conditions at the Amakdedori port site and the stability of proposed structures. Additional information is needed to evaluate the potential for seismic and other geohazards impacts on port structures and related effects on the environment in accordance with CEQ regulations and EPA and Corps of Engineers dredge permitting. The requested information is part of typical state-of-engineering-practice for port structures in seismically active areas. Experience at similar structures in Cook Inlet suggest that, in the absence of such baseline data and stability analysis, the potential exists for structural failure and impacts to the environment.**
Describe the Information Requested and Level of Detail:	**1) Provide additional information (borehole data) on subsurface geotechnical conditions at the terminal, sheet pile cell jetty/wharf, and dredge stockpile.** **2) Provide a report of the "on-shore geophysical information" at the port mentioned on p.73 of the Project Description.** **3) Provide additional information on the geotechnical and chemical conditions (suitability) of the dredged material that would be used to construct the terminal, causeway, and jetty/wharf. Describe contingencies to the use of this material for construction if found to not be suitable.** **4) Provide additional design details for the sheet pile cell wharf structure; e.g., would it be closed cell, open cell, vertical walls with tie rods, etc? What is the proposed embedment depth of the sheet pile?** **5) Would the design of the sheet pile wharf take into account potential surcharge of the cells by the ship loaders? Would the wharf be pile-supported in this area?** **6) Provide stability analyses for the sheet pile wharf, dredge stockpile, sediment pond berm, and terminal patio under static and seismic loads, and at low tide for marine structures.** **7) Provide a description of materials, internal zoning, and seepage controls that would be used in construction of the containment berm around the Dredge Stockpile and Sedimentation Pond.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1) No borehole data has been collected for the proposed terminal. Initial data will be collected to support feasibility level engineering with those data supplemented prior to construction. Geophysical data collection that will confirm most of the design assumptions is being collected this summer (2018) and will be available in the fall. 2) Provided with this RFI. 3) PLP contractors will collect samples for geochemical analyses from the updated project footprint this summer. The updated project plan will require the use of imported fill to complete causeway and jetty construction. This material will either be trucked in from the closest material site on the road (a distance of three miles) or imported by barge from existing commercial sources.

AMERICAN OVERSIGHT

	4) The geotechnical conditions at the port site are expected to be variable and will be evaluated further by investigations planned for summer 2018; however, it is assumed so far that the bedrock at the marine terminal is sufficiently deep that marine structures will not need to be socketed and that sheet piles will be able to be designed for installation to a design embedment depth.Based on assumed geotechnical conditions, conceptual design development and experience with construction of similar structures at other sites, the following installation description may be expected at the Amekdedori marine terminal: Construction of the terminal will require installation of approximately 2200 lineal feet of protected rock slope along an access causeway and 2000 lineal feet (in plan) of steel sheet piles that may be 110-ft in length, with tie backs into the fill behind the sheets to provide sufficient lateral capacity. The sheet piles are in in 15 to 20 feet of water. The causeway will be constructed by infilling on top of the seabed with competent fill and rock protection for the slopes. The sheet piles will be installed using a vibratory hammer. If it is found that bedrock or similarly hard soil is found within 20-30 feet of the design seabed elevation, driving of the sheets for the last 1-2 feet may be required to anchor the sheets in the ground. If bedrock or similarly hard soil is found to be very shallow, pile socketing and a revised concept may be required. If investigations find that the seabed is susceptible to liquefaction under seismic conditions, soil improvement work such as stone column installation may be required. 5) If ship loaders are required for project, the design would address the potential surcharge. However, with the current concept of handling concentrate in containers, it is assumed that pile support will not be required. This will be confirmed by ongoing studies prior to detailed design and construction. 6) These analyses will be completed prior to detailed design to support engineering and construction. 7) The updated proposed project no longer requires the construction of a large dredge stockpile pile and sediment pond. Please notify us if any further action is required on this question.

RFI 010
Pebble Project EIS

Request for Information

Title/Subject:	**Tailings Characteristics**
Requestor:	**Nancy Darigo/Cecil Urlich, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/17/18**
Rationale:	**The Project Description and EBD Chapter 11 (Geochemical Characterization) provide limited details on 1) the planned bulk and pyritic tailings split of 88%-12% that determines the size of their respective TSF impoundments, and the location and size of the TSF Internal Embankment; and 2) the tailings thickening process to achieve 55% solids slurry. Additional information is needed to evaluate the overall constructability of the TSF, and potential risks to embankment stability and seepage chemistry from changed conditions during operations.**
Describe the Information Requested and Level of Detail:	**1) Describe how the 88%-12% split between bulk and pyritic tailings was determined and the confidence level in achieving the split during operations.** **2) Describe how much flexibility there is in the split percentage that would still allow the TSF Internal Embankment and impoundments to be constructed as planned.** **3) Describe contingency plans to adjust process operations and/or modify the TSF cell configurations if the planned split cannot be achieved. Explain if and how the TSF Internal Embankment design and construction would be impacted or adjusted.** **4) If higher than expected pyritic tails are produced from the process plant, would they be directed to the bulk tails impoundment? If so, how would that change the geochemistry of the bulk tailings?** **5) Describe the steps taken to reach the concept of a thickened 55%-solids slurry for the bulk tailings, versus a lower %-solids aqueous slurry.** **6) Provide examples of successful thickened TSFs in cold regions.** **7) Describe water balance mitigations if 55% thickening cannot be achieved.** **8) Provide any additional geochemical test work (e.g., acid-base accounting, net acid generation tests, humidity cell tests, etc.) on bulk or pyritic tailings conducted since 2010.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1: The split between the NPAG tailings and PAG tailing was estimated from batch flotation tests conducted on samples derived from core from drill holes throughout the pit area. The locations and intervals were selected to produce a representative sample set of ore grade material from the pit shell. The batch flotation tests simulated the processing of the ore in a process plant. The rougher flotation tailings (or NPAG tailings) content for each sample was obtained from the flotation test results. The rougher flotation tailings mass ranged from 81% to 94% of total tailings content of the individual ore samples. The average fraction was 88%. The pyritic tailings content for each sample was predicted from the cleaner flotation Lock Cycle test results. The cleaner flotation tailings mass ranged from 5.2% to 17.6% of total tailings content of the individual ore samples. The average fraction was 12%. 2: The current proposed alternative has been revised to remove the LGO stockpile. A separate pyritic tailings and PAG storage facility will be located in the area formerly designated for the LGO stockpile. Consequently, the current plan no

AMERICAN OVERSIGHT

	longer includes an internal embankment in the TSF. 3: If the split between the bulk and pyritic tailings deviated significantly from the predicted split, the embankment raise schedules for the TSF and pyritic tailings and PAG storage facility would be adjusted to accommodate the tailings volumes. 4: Pyritic tailings would not be directed to the bulk tailings storage facility. 5. A tradeoff study was conducted to optimize the water content of the tailings to pump to the TSF to minimize the volume of tailings slurry transferred from the process plant to the bulk and pyritic tailings storage facilities, and reduce the need to re-handle water from the slurry after settlement of the solids (supernatant water in the bulk and pyritic tailings storage facilities, and water from the seepage ponds associated with the bulk tailings storage facility). 6. To be provided no later than 5/30/18. 7. There would be no changes to the overall site water balance, the bulk or pyritic tailings storage facility embankment heights, or the embankment raise schedules if the 55% thickening could not be achieved. Additional tailings storage capacity would not be required as the differences in the settled density of the 55%-solids thickened tailings and higher water content tailings will be minimal. Additional pumping capacity would need to be provided to transfer the tailings slurry from the process plant to the tailings storage facilities, and for pumping additional supernatant water from the tailings storage facilities and water from the bulk tailings storage facility seepage ponds. 8: PLP will provide an update to the geochemistry EBD (SEBD) with the data transfer on 5/11/2018. Laboratory test work continued through 2013 and is therefore not all included in the SEBD. The data is currently being evaluated and a technical memorandum addressing the data will be submitted by 5/30/2018. Initial feedback is that the additional data period does not show any changes in observed trends.
List Number and Type of Response Attachments:	**One Report, delivered as part of the data transfer on May 11, 2018:** **The Pebble Partnership, 2018. Pebble Project Supplemental Environmental Baseline Data Report (2004-2012), Chapter 11, Geochemical Characterization, Bristol Bay Drainages. May.**
Date Returned to USACE:	May 11, 2018

AMERICAN OVERSIGHT

RFI 011
Pebble Project EIS

Request for Information

Title/Subject:	**Pipeline HDD and Bluff Erosion**
Requestor:	**Nancy Darigo, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/17/2018**
Rationale:	**The Project Description provides limited information on: 1) the horizontal directional drilled (HDD) part of the pipeline at East Cook Inlet bluff, and 2) construction details where the pipeline crosses several incised drainages at the top of the bluff. Information on pipeline safety and erosion control is required under PHMSA and ADEC regulations, and the requested information is needed to evaluate the potential for bluff erosion/slope stability impacts and related effects on the environment.**
Describe the Information Requested and Level of Detail:	**1) Provide additional HDD details such as length, depth, and angle; and a cross-section from the HDD work area to the pipeline emergence at the seafloor.** **2) The Project Description indicates the west end of the HDD would be in "waters that are deep enough to avoid navigation hazards." What is this proposed water depth?** **3) Describe how the pipeline would be constructed across incised drainages at the top of the bluff, which either currently exist in several places along the proposed route, or could erode to the pipeline position over the project life.** **4) Describe plans for monitoring and maintenance of potential unexpected erosion beneath the pipe during both operations and after closure.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1) A conceptual HDD section is provided attached to this response. PLP contractors are currently collecting offshore data that will provide additional high-resolution sea bottom bathymetry data that will allow for refinement of the design during project detailed engineering. Based on NOAA chart data, an 1800' HDD would exit in approximately 12 feet of water at mean lower low water, while a 2000' HDD will exit in approximately 18-24 feet of water at mean lower low water. Current technology can easily accommodate a 2000' plus HDD for pipe in the 12" diameter range. 2) PHMSA code (49CFR 192.327) requires burial of a natural gas transmission pipeline with 36" of cover to at least 12' water depth, with the top of the pipe below the natural bottom, or protected by alternate means in deeper waters. Final details will be determined during detailed design, but PLP will at a minimum comply with PHMSA code requirements for pipeline cover. 3 and 4) The first approximately 9 miles of the alignment along the Stirling Highway are no longer proposed for construction as there is sufficient capacity in the existing Enstar line that runs past the compressor station location. It is our understanding that Questions 3 and 4 are therefore no longer relevant to the updated project. Please notify us if any further action is required on these questions.
List Number and Type of Response Attachments:	Pipeline Anchor Point Bluff HDD.pdf
Date Returned to USACE:	**May 10, 2018**

RFI 013
Pebble Project EIS

Request for Information

Title/Subject:	**Iliamna Lake and Pipeline Landfall Hazards**
Requestor:	**Nancy Darigo/Jack Colonell/James Dietzmann, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**Limited information is available in the literature or EBD/SEBD (Chapter 7, Appendix B) on Iliamna Lake physical conditions and hazards such as wave heights, bathymetry, water level, shoreline erosion, ice conditions, or seiches (from major earthquakes or slumping). In addition, limited information is provided in the Project Description regarding potential ferry effects on shore erosion, or pipeline landfalls at the port and ferry terminals. Evaluation of pipeline safety and shore erosion is required under PHMSA and USACE regulations. The requested information is needed to evaluate potential impacts to ferry operations, lake port facilities, and the pipeline, and related impacts from project components on shore erosion. Ice rideup on the north shore of Iliamna Lake was a concern identified in scoping comments.**
Describe the Information Requested and Level of Detail:	**1) Provide additional available in-house data or anecdotal information from villages regarding: Iliamna Lake maximum wave height, bathymetry, seasonal and historical water level changes, shoreline erosion, ice coverage/seasons, ice thickness, ice movement/ridges, potential for shore ice rideup, and historical seiches or unusual flooding events.** **2) The Project Description indicates that the pipeline would be buried beneath 36" depth of cover on land, and that pipeline burial in Lake Iliamna would be similar to that of Cook Inlet crossing, which is described as "sufficiently deep to ensure that the top of the pipe is below the ground surface" from the point west of the HDD emergence on the seafloor at east Cook Inlet. This implies that the depth of cover would be minimal in shoreline areas of the port and ferry terminals. Clarify the depth of cover in the landfall transitions from offshore to onshore at the port and ferry terminals that would minimize potential shoreline erosion or navigation hazards.** **3) Provide additional information on ferry draft, speed, propeller size, ferry-generated wave heights, and the potential for ferry-induced shoreline or lake bottom erosion.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1) The current version of an assessment of lake ice conditions is attached (Iliamna Lake Ice Technical Memo.pdf). The coverage does not include the full proposed ferry route. PLP has requested a timeline from the consultant to expand the coverage to include the proposed route this and will notify USACE as soon as the schedule is confirmed. PLP has no additional data. 2) PLP contractors are currently collecting marine offshore data and will collect lake bottom data next month that will provide additional high-resolution sea bottom bathymetry data that will allow for refinement of the pipeline design during project detailed engineering. PHMSA code (49CFR 192.327) requires burial of a natural gas transmission pipeline with 36" of cover to at least 12' water depth, with the top of the pipe below the natural bottom, or protected by alternate means in deeper waters. Final details will be determined during detailed design, but PLP will at a minimum comply with PHMSA code requirements for pipeline cover. The pipeline will either

AMERICAN OVERSIGHT

	be HDD or trenched offshore to at least 12' water depths for both the lake and the Amakdedori shore transitions. 3) Please see attached Ferry Wave Modeling report for additional detail. a. Ferry draft – 16'-0" b. Speed – 6 knots on shore approach, 11 knots in open water c. Propeller size – 6'-0" – Note that there are 4 motors driving 4 propellers. Two are only used when breaking ice. d. Please see attached wave size model run's from PLP's consultant using Computational Fluid Dynamics (CFD) Numeca software. At the 6 kn berth approach speed, the hull generates a wave height of 4" at the hull, which dissipates within 30 ft from the hull. The ferry route is from north to south across the lake and the ferry will approach the shore perpendicularly. As such, there is limited potential for wake induced shoreline erosion associated with ferry operations. e. The hull is designed with two symmetrical ice breaking bows and the propellers are located away from the bows up in hull recesses. The ferry draft is 16'-0", the propeller diameter is 6'-0" and the propeller center is located at 12'-0" depth. The propellers will therefore not protrude below the keel of the vessel. The vessel will maintain a minimum under keel clearance of 6' when running and will be operating at low power as it approaches the shore. The ferry route is from north to south across the lake and the ferry will approach the shore perpendicularly. As such, there is limited potential for propeller induced lake bottom erosion associated with ferry operations.

Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/3/2018**
Rationale:	**EBD/SEBD Chapters 3 and 6 provide figures showing geotechnical data collected at the Mine Site, but GIS layers with the locations of these data are not available in the current GIS data log, and some test pit data are missing from EBD Appendix 6A. A preliminary review indicates that little or no geotechnical data may be available in certain areas of the TSF. Geotechnical information forms the basis of dam foundation design and stability analysis, and is required under the Alaska Dam Safety Program. The information is needed in GIS to correlate to current mine plan details in order to evaluate the adequacy of data coverage for embankment stability impacts.**
Describe the Information Requested and Level of Detail:	• **Provide GIS layer(s) with test pits, geotechnical drillholes, and seismic line locations for the Mine Study Area (e.g., those shown on EBD Chap.6, Figures 6-3, 6-5, and 6-8; and SEBD Chapter 3, Figures 3-4 and 3-6).** • **Provide test pit data that is missing from the pdf file of EBD Chapter 6, Appendix 6A: pages 5 to 16 of Appendix 6A are not in the pdf.** • **Clarify what geotechnical data exists for the TSF South, Internal, and East Embankments and pyritic tailings storage cell. If data are lacking for embankment-specific design and stability analysis, collect additional drillhole data at these locations, and/or provide plans for additional data collection as design progresses.**

Recipient Response Form

Date Received from USACE:	**4/27/2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**1) GIS data (geodatabase) attached for test pit, geotechnical drill hole, and seismic line locations.** **2) See attached pdf of EBD Chapter 6 – Appendix 6A** **3) The proposed project has been updated and a revised footprint will be provided by 5/30/18. The 2018 site investigation program will include drilling and associated test work for all embankments where data is not currently available. Preliminary results are expected in September 2018.**
List Number and Type of Response Attachments:	1. GeotechnicalLocations.gdb 2. EBD Chapter 6 – Appendix 6A.pdf
Date Returned to USACE:	**05/11/2018**

Pebble Project EIS

Request for Information

Title/Subject:	**TSF Quarries**
Requestor:	**Nancy Darigo/Cecil Urlich, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**EBD Chapter 6 provides summary descriptions of geotechnical information by general area within the Mine Site, and some rock quality data for individual drillholes, but no analyses of the data for embankment fill purposes. Geotechnical analysis of fill suitability and seepage potential is required under the Alaska Dam Safety Program. The information is needed to evaluate embankment stability, seepage impacts, and overall constructability of the Tailings Storage Facility (TSF).**
Describe the Information Requested and Level of Detail:	• **Describe the types of rock that are available and suitable from Quarries A, B, and C for tailings and pond embankment construction, along with their durability and suitability for use as embankment fill and filter zones.** • **Quantify the available materials in the proposed quarries compared to the tailings and pond embankment tonnage needs.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**1. Rock types in Quarries A, B and C comprise one or more phases of the Kaskanak Batholith. These phases predominantly consist of medium-grained, equigranular to weakly porphyritic, hornblende-bearing biotite granodiorite. This rock type assignment is based on surface geological mapping and drill intersections in geotechnical drill holes within and adjacent to the quarries.** **The 2018 site investigation program will include investigation of Quarry A, B and C materials, including core drilling and associated material testing. Preliminary results are expected in September 2018.** **2. Quantification of available and required materials for the updated project will be provided no later than 5/25/18. Gross quantities for the material to be sourced from the quarries and the required tailings and pond embankments for the current project are listed in Table 21-4 of the project 404 permit application.**

Title/Subject:	**SEBD Chapter for Trace Elements (Bristol Bay)**
Requestor:	**Allison Payne, AECOM**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/3/2018**
Rationale:	**We have EBD Chapter 10 (Trace Elements) for Bristol Bay (BB) and Chapter 35 (Trace Elements) for Cook Inlet (CI), as well as SEBD Chapter 35 (Trace Elements) for CI. However, we have not received the SEBD trace element chapter for BB and it is not available on the pebble research website. This document is needed for describing the affected environment in the substrate/sediment quality sections of the EIS.**
Describe the Information Requested and Level of Detail:	**If available, provide the SEBD Trace Element chapter for BB.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**No additional trace element data was required for BB and therefore no SEBD for BB was produced.**
List Number and Type of Response Attachments:	Click here to enter text.
Date Returned to USACE:	**May 10, 2018**

Pebble Project EIS

Request for Information

Title/Subject:	**LGO Stockpile Liner**
Requestor:	**Nancy Darigo/Cecil Urlich, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**The Project Description and associated figures provide limited construction details on the installation of the Low Grade Ore (LGO) stockpile. Additional information is needed to evaluate impacts to the project from potential slope instability and foundation conditions, and potential related effects on the environment.**
Describe the Information Requested and Level of Detail:	• **Would the liner be placed all at once or in stages? If in stages, how would each stage be anchored without benching on the long continuous side slopes (as shown on DA Application, Attachment A, Figure MX-003)? If all at once, would the liner be protected in some way from exposure to the elements, prior to LGO fill placement which could take years to build out?** • **Would the stockpile be constructed from the middle of the valley outward and then up both side slopes, or one side of the valley first?**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**PLP has updated the proposed project and the LGO stockpile is no longer required. Please notify us if any further action is required on this RFI.**
List Number and Type of Response Attachments:	Click here to enter text.
Date Returned to USACE:	**May 11, 2018**

RFI 020
Pebble Project EIS

Request for Information

Title/Subject:	**Water Treatment**
Requestor:	**Steve Rusak/Nancy Darigo, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/17/2018**
Rationale:	**Limited information is available in the Project Description on the proposed water treatment methodologies as applied to Mine Site wastewater. Testing data that describe the performance of proposed water treatment technologies specific to Mine Site wastewater streams are required under ADEC water discharge permitting. The information is needed to evaluate the feasibility of water treatment, the quality of discharged water, and evaluation of water quality impacts.**
Describe the Information Requested and Level of Detail:	**Provide bench scale testing data to describe the performance of proposed water treatment technologies.**

Recipient Response Form

Date Received from USACE:	**4/26/2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**Benchmarking studies summarizing information on water treatment plants using the technologies proposed at the Pebble Project have been prepared and are included as attachments to this response. The existing treatment plant information demonstrated that these technologies have been applied at other locations at treatment rates similar to those that will be required at the Pebble Project. Please note that the Pebble Project water treatment plant flows cited in these reports are not specific to the current proposed project. Updated flow information will be provided when the Water Management Plan is completed (RFI #19).**
List Number and Type of Response Attachments:	**Two Documents:** **Water Engineering Technologies, Inc., 2012. White Paper on Water Treatment Processes, prepared for Pebble Limited Partnership. July 24.** **HDR, 2017. Pebble Project, Water Treatment Process – Benchmark Update. December 6.**
Date Returned to USACE:	**May 10, 2018**

Request for Information

Title/Subject:	**Pit Wall Stability**
Requestor:	**Nancy Darigo, AECOM**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**The Project Description provides limited information necessary to evaluate the stability of the pit walls, the risk of slope failure, and potential related effects on the surrounding environment.**
Describe the Information Requested and Level of Detail:	**Provide stability analyses for representative pit wall sections, under both static and earthquake conditions, and during both operations (dewatered) and closure phases.**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	The pit walls design criteria for the proposed project were based on information developed for previous renditions of the Pebble open pit. Given these previous pits were both larger and deeper than the current concept, PLP believes the slopes to be reasonable. Mining studies for the proposed project, including the details of the pit design and the stability analysis are ongoing, and will be completed this year. The stability analyses work is expected to be completed by July 31, 2018.

AMERICAN OVERSIGHT

RFI 024
Pebble Project EIS

Request for Information

Title/Subject:	**Plans for Reclamation and Restoration**
Requestor:	**Sasha Forland, AECOM**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/24/2018**
Rationale:	**There is limited information in the Project Description on reclamation that provides an understanding of short-term, long-term, and permanent effects on vegetation. We are requesting the additional information to assess the duration of effects on vegetation as a key impact characterization to analyze impacts to wildlife, wetlands and vegetation in the EIS.**
Describe the Information Requested and Level of Detail:	**For each project component (Mine Site, Transportation Corridor, Amakdedori Port, and Natural Gas Pipeline Corridor):** • **Identify which features (e.g., pads, access roads, material sites) are considered short-term disturbance (i.e., will be removed and restored or reclaimed after construction).** • **Identify which features are considered long-term disturbance (i.e., will removed and restored or reclaimed during or after operations).** • **Identify which features are considered permanent (i.e., will remain through closure or post-closure).** • **Provide details on the reclamation and restoration plan (i.e., plans for grading/contouring, seeding or natural revegetation; identify areas that would be returned to pre-construction conditions, or those areas that would reclaimed as modified habitat).** • **Provide the percent of the disturbed area to be reclaimed or restored (for each main project component).** • **Provide details on restoration or reclamation material (seedbed preparation practices; seed, seed mix, plant parts, transplant, in situ material proposed; proposed fertilizer use; hydric soil considerations; alpine vegetation considerations; soil/materials stockpile plan; erosion prevention considerations; success monitoring).** • **Provide timing of planned restoration or reclamation activities (during or after operations, construction, closure, or post-closure phases).**

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	**1)** No facilities will be reclaimed or restored after construction. All road material sites will be stabilized and progressively reclaimed, but will remain active to support ongoing road maintenance requirements through operation. Mine laydown areas will be retained for use through operations. All construction roads will continue to serve as site access roads. **2)** All features, except those listed in Question 3 below, are considered long-term disturbance and will be reclaimed after operations and closure activities are completed. As the project has no permanent Waste Rock Storage facility, no areas for progressive reclamation during operations have been identified. Interim reclamation of the growth medium stockpiles will be undertaken as material is placed to stabilize the facilities and maintain the viability of the material for use in final reclamation. **3)** The mine pit will be stabilized to meet the requirements of 11 AAC 97.200(c) and will become a pit lake. The bulk TSF will undergo dry closure and become a new landform. The pyritic tailings and PAG waste will be placed into the pit, the liner will be removed and the embankments flattened, and the facility will be reclaimed. When no longer required for

AMERICAN OVERSIGHT

post closure water management and treatment the seepage and water management ponds and the main water treatment plant will be removed and reclaimed. Power generation facilities, limited camp and storage facilities, access roads required for site maintenance and monitoring, and the mine water treatment plant will remain to support post closure water treatment, and site monitoring and stabilization activities. The site access road will be retained to support post closure access. The marine and lake port facilities will be removed and reclaimed after closure activities are completed.

4) All disturbed facilities will be reclaimed in accordance with post mining land use. Embankments associated with reclaimed facilities will be breached and flattened. Gravel pads and areas of fill will be contoured and graded to conform with the surrounding landscape and promote natural runoff and drainage.
5) All facilities, except those required for post closure operations, will be fully reclaimed.
6) All facilities will be reclaimed in accordance with State of Alaska requirements.

Seedbed Preparation - Growth media (whether applied or in situ) and the underlying subsurface will be prepared in such a manner as to retain moisture and allow adequate root development and penetration in those areas where infiltration and surface water retention are desired. The method of primary seedbed preparation will be ripping or scarifying (depending on the area) using heavy equipment. Highly compacted areas such as equipment lots and roads will be ripped in a linear fashion. If needed, the surface of growth media will be scarified after application just prior to seeding. The broken, roughened surface will serve to trap moisture, reduce wind shear, minimize surface erosion by increasing infiltration, and create micro habitats conducive to seed germination and development.

Soil Amendments - Vegetation test plots and/or interim reclaimed sites will be evaluated to determine the revegetation potential of applied growth media. It is not currently assumed that fertilizer will be required or desirable for establishing a permanent perennial cover. However, soil amendment will be utilized if required. In the event future, nutrient testing indicates a need for soil amendments, the procedures described below will be employed.

Prepared seedbeds will be amended prior to, after, or during (when a hydro-seeder is used) the seeding operation. Specific soil amendment requirements will depend on the quality of growth media used for an area. Growth media will be tested for standard soil agricultural constituents, including organic matter, nitrogen (N), phosphorus (P), and potassium (K). Based on results at other locations within Alaska, the general recommended rate of fertilizer application would be on the order of 100 to 500 lbs. per acre of 20N-20P-10K.

Seed and Seeding - The general reclamation seed mixes proposed for use are listed in the tables included below. The seed mixes consist of native species that have been used extensively in other Alaska reclamation activities. The mix may be modified over time to include forbs and woody species, depending on factors such as research results, changes in technology, changes in land management philosophy, and commercial availability. Native species would be the preferred mix. Seeding would be done via drill seeding, broadcast seeding via ground or aerial application, and/or hydro-seeding.

7) The timing of closure activities will be as described in Questions 1-3 above.

AMERICAN OVERSIGHT

Proposed Reclamation Seed Mix – (Hydric) Wetland

Common Name	Scientific Name	Percentage of Mix
'Egan' American sloughgrass	*Beckmannia syzigachne*	45%
'Norcoast' Bering Hairgrass	*Deschampsia beringénsis*	40%
'Arctared' Red Fescue	*Festuca rubra*	10%
'Alyeska' Polargrass	*Artagrostis latifolia*	5%

Proposed Reclamation Seed Mix – (Mesic) Upland

Common Name	Scientific Name	Percentage of Mix
'Arctared' Red Fescue	*Festuca rubra*	40%
'Norcoast' Bering Hairgrass	*Deschampsia beringénsis*	40%
'Wainwright' slender wheatgrass	*Elymus trachycaulus*	10%
'Gruening' Alpine Bluegrass	*Poa alpina*	10%
'Nortran' Tufted Hairgrass	*Deschampsia caespitosa*	0% unless substituted for Norcoast

RFI 026
Pebble Project EIS

Request for Information

Title/Subject:	**Detailed Land Status**
Requestor:	**Jessica Evans**
Date Transmitted:	**4/26/2018**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**The only publicly-available land status GIS data is from the BLM, and is 'general', which is accurate only to the scale of one square mile (one Section). The scale of the general land status is sufficient for analysis of land use, which is what was used in the Land Use EBD. However, this is an inappropriate scale to analyze land status for components like the road and the pipeline right-of-way.**
Describe the Information Requested and Level of Detail:	**GIS data for land status that is more detailed than the General Land Status available through BLM public information. Information should include owner of the land (e.g. the name of the Native Corporation in ownership).**

Recipient Response Form

Date Received from USACE:	**4/27/2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	All requested information was provided to USACE on February 23, 2018 (see LandStatus.gdb). Please advise if any additional information is required.
List Number and Type of Response Attachments:	None
Date Returned to USACE:	**May 10, 2018**

Describe any Follow-up Related to this RFI (Communications, Clarifications):	Click here to enter text.

AMERICAN OVERSIGHT

RFI 027
Pebble Project EIS

Request for Information

Title/Subject:	**Project Logistics and Employment for Socioeconomics and Transportation**
Requestor (Name):	**Jessica Evans**
Date Transmitted:	**4/26/2015**
Recipient (Individual or Agency):	**Pebble Limited Partnership**
Response Requested by:	**5/10/2018**
Rationale:	**There is little information in the Project Description regarding project logistics. More detailed information is needed in order to fully analyze the impacts to current transportation systems and determine the effects to the region's economy. Specifics like goals for local hire, the movement of employees to the work site, and the status of public access, are necessary for a NEPA-level review of impacts.**
Describe the Information Requested and Level of Detail:	**1.** How many flights per day (or week) would be coming into the airport at Iliamna, for workers and cargo? **2.** The PLP website states that the Transportation Corridor would be beneficial to the public. How? The road, ferry, ferry terminals, and Amakdedori port are described as "private" in the application document. At what point along the road would it be closed for public use? Will the road system remain in place after mine closure? Will a conveyance over the path of the ice breaking ferry be provided for winter travel by local residents? **3.** Would travelers on ATVs or snowmachines be allowed to cross the mine access roads, if the roads are not open to the public? **4.** What percent of employees would be local hire? The PLP website notes 75 percent Alaskan employees. Is this the goal for the project, or the makeup of the current operations of the company in Alaska? **5.** Would transportation or be provided for employees living in smaller communities in the region (e.g. Levelock or Dillingham)? **6.** Would local communities be able to tap into the natural gas pipeline as a source of fuel? As a follow up, if that is the case, would the pipeline remain in place for community use following the closure of the mine?

Recipient Response Form

Date Received from USACE:	Click here to enter text.
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1) Employees will work a two week on/two week off rotation during operations. For the purposes of evaluating logistics, it is assumed that 250 employees will come from surrounding communities, of which 50 will come from communities connected to the project sites by road, while 200 will require air transportation to Iliamna or Kokhanok. The remaining 600 employees will be flown in from Anchorage or Kenai. All employees will be bused between Iliamna and the mine site or between Kokhanok and the port site. Perishables and other consumables would be flown from Anchorage. Aircraft requirements are as follows: a. Weekly Twin Otter flights - 1 from outlying villages, 1 from King Salmon, 2 from Dillingham, 4 from Kenai (8 total) b. Weekly Q400 flights – 2 from Anchorage c. Weekly cargo flights – 1 from Anchorage (aircraft TBD DC6, 737 or similar) d. Unscheduled cargo – 6 x C130 flight/year as required e. Construction air travel – Similar regional schedule, 1 x Q400 daily from Anchorage, 1 x Q400 weekly from Kenai, 3 x weekly cargo flights, 12 x C130 flights/year as required

AMERICAN OVERSIGHT

	2) a. PLP will work with all local communities to identify the best solutions for use of the road & ferry for community transportation. This would most likely consist of escorted, scheduled conveys for private vehicle transport and coordination with PLP on third party commercial haul traffic on the road. Road traffic would be coordinated with scheduled third-party transportation by the ferry. Access to infrastructure would be limited to local residents and businesses. b. Gates will be located at appropriate points on the spur roads to Kokhanok and Iliamna to keep traffic off the main haul roads. c. The road will remain in place after closure as it will be required for closure and post-closure activities. d. PLP will work with local communities to identify the best solutions. This would most likely include the marking and maintenance of N-S and E-W routes on the lake that either avoid the ferry path by routing around the ports on land, or possibly that include the provision of crossing points on the ice. 3) Yes, known trails and crossing points would be signposted and appropriate traffic controls would be established to ensure public safety. 4) The 75% number referenced is the current mining industry level of Alaska hire. It is PLP's objective to maximize opportunities for local hire, firstly directly to residents of the project area, or those with close ties to the area, and then secondly to Alaska residents in general. However, it is likely that through construction significant non-Alaskan labor will be required to fill the anticipated 2,000 jobs required, potentially as high as 50%. During operations that number is expected to be substantially lower, with the great majority of jobs going to Alaskans. 5) Yes, as outlined in 1) above. 6) PLP will facilitate access to the pipeline for any entities that wish to connect. Furthermore, this is required by regulation for open access carriers. PLP anticipates requiring some pipeline gas to support post closure water management and treatment in the years after closure, although this demand is expected to decrease over time. The final disposition of the pipeline will be addressed in consultation with all stakeholders, including land owners and those who may utilize the gas supply.

Pebble Project EIS

Request for Information

Title/Subject:	**TSF IDF and Freeboard**
Requestor:	**Nancy Darigo/Cecil Urlich/James Dietzmann, AECOM**
Date Transmitted:	**4/26/18**
Recipient:	**Pebble Limited Partnership**
Response Requested by:	**5/24/18**
Rationale:	**Limited information is available in the Project Description regarding water balance and precipitation inputs to ensure that water discharge at the Tailings Storage Facility (TSF) can be managed sufficiently. Establishing precipitation inputs to the Inflow Design Flood (IDF) and freeboard is required under the Alaska Dam Safety Program, and is needed to evaluate dam stability and potential related effects on the environment.**
Describe the Information Requested and Level of Detail:	**1) Describe the weather data used to select the inflow design flood (IDF) and support TSF embankment design (freeboard, water management, dam raise schedule). 2) Demonstrate that water management and discharge can be adequately achieved on a continuous basis to allow for the development and continual maintenance of a tailings beach and the IDF volume and freeboard above the beach.**

Recipient Response Form

Date Received from USACE:	**April 26, 2018**
Response from Recipient (Describe Information Requested to the Level of Detail Requested; Provide Attachments as Needed):	1: **The weather data used to select the inflow design flood is contained in the Pebble Limited Partnership Hydrometeorology Report, which is included as an attachment to this response.** **2: The demonstration that water management and discharge can be adequately achieved on a continuous basis to allow for the development and continual maintenance of a tailings beach and the IDF volume and freeboard above the beach will be addressed in the Water Management Plan, which will be submitted in response to RFI #19.**
List Number and Type of Response Attachments:	**One report:** **Knight Piésold Consulting, 2012. Pebble Limited Partnership, Pebble Project, Hydrometeorology. February 24.**

Subject: [Non-DoD Source] RE: comments on CH 3; scoping comments

Hello Shane -

EPA has reviewed the draft scoping report and we have no comments on the report, except that it should incorporate additional scoping comments received, including our scoping comments that will be submitted by the June 29 deadline.

Regarding comments on the draft sections of chapter 3 sent to us on June 5. We are reviewing sections 3.1, 3.5, 3.11, 3.14, 3.17, 3.18, and 3.22 and will submit comments by the July 5 deadline discussed during the cooperating agency meeting - sooner if we are able.

On June 6 and 7, I sent you emails regarding sections 3.16 (surface water hydrology) and 3.26 (vegetation). In your June 5 email, you sent us the figures from those sections, but not the text. If you would like us to review the text of those sections (as was identified for our review in the EIS outline), then please send the text to Molly and I.

Thanks -
Patty

Subject: comments on CH 3; scoping comments

All,
Please provide any comments for the draft chapters as soon as you can, please remember we are looking for "what we missed" and if your agency does not believe it is capturing the correct information.

Also, a little reminder that scoping comments need to be submitted by 29 June.

VR

Shane McCoy

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

3.16 SURFACE WATER RESOURCES

The Mine Site and most of the onshore Transportation and Natural Gas Pipeline corridors west of the Amakdedori Port site are within watersheds that drain into Bristol Bay (Figure 3.16-1). The combined drainage area of the Bristol Bay watershed is approximately 41,900 square miles (mi2) – an area bound by the Aleutian Range to the east and southeast, the Kuskokwim Mountains to the west, and the Kuskokwim River watershed boundary to the north.

3.16.1 Mine Site

The Mine Site is located within the upper portions of the North Fork Koktuli (NFK), South Fork Koktuli (SFK), and Upper Talarik Creek (UTC) watersheds (Figure 3.16-2 and Figure 3.16-3). As shown on Figure 3.16-2, the majority of the Mine Site facilities would be within the NFK watershed. The open pit, as well as the overburden stockpile, water management pond, and water treatment discharge – south, would be in the SFK watershed. Only the water treatment plant discharge – east and a short portion of the Mine Access Road would be in the UTC watershed.

3.16.1.1 Drainage Basins / Watersheds

Drainage basin characteristics of the NFK and SFK rivers and the UTC are described in this section, and features are summarized in Table 3.16-1.

Table 3.16-1: Mine Site Area Watersheds

Drainage Basin	Drainage Area (mi^2)	Channel Length (mi)	Basin Relief (ft)	Mean Basin Elevation (ft amsl)
NFK River	113	36	580 to 3,074	1,300
SFK River	107	40	580 to 2,760	1,150
UTC	135	39	46 to 3,074	1,000

amsl = above mean sea level

mi^2 = square miles

Source: Knight Piésold 2011

The watersheds listed in Table 3.16-1 are within the Nushagak-Big River Hills physiographic region, consisting of low rolling hills and wide, shallow valleys (Knight Piésold 2011). Glaciers are not present in the project area watersheds. Glacial and fluvial sediments of varying thickness cover most of the region at elevations below approximately 1,400 feet (ft) above mean sea level (amsl). Elevations above 1,400 ft amsl generally exhibit exposed bedrock mixed with thin veneers of surficial material. The hills tend to be moderately sloped with rounded tops, and the valley bottoms are generally flat. Occurrence of permafrost has not been recorded in the project area.

General characteristics common to the watersheds listed in Table 3.16-1 include:

- Main streams occupy valley bottoms 0.5 to 2 miles wide.
- Tributaries to the main streams are incised into the hilly terrain and typically occupy narrow valleys with bottom widths of only 0.1 to 0.2 mile.

AMERICAN OVERSIGHT

- The three main stream channels in the project area are highly sinuous and flow within floodplains containing wetlands and oxbow lakes.
- The upper parts of the three main valleys are represented by flat, poorly drained terrain.
- Areas of glacial drift deposits occur along lower hillslopes and near the headwaters of the main stream valleys, characterized by undulating terrain and numerous kettle lakes.

North Fork Koktuli River

The Koktuli River forms at the confluence of the NFK and SFK rivers, approximately 17 miles west of the Mine Site (Figure 3.16-3). The Koktuli River flows into the Mulchatna River, which is a tributary of the Nushagak River, the largest drainage within the Bristol Bay watershed. The Nushagak River watershed area is approximately 12,700 mi2 and flows into Bristol Bay near Dillingham, Alaska.

The NFK River watershed extends northeast from the confluence with SFK River to Groundhog Mountain, approximately 7 miles northeast of the Mine Site (Figure 3.16-3). The majority of the mine facilities would be in the upper NFK River watershed, including the tailings storage facility, low-grade ore stockpile, water management ponds, mill site and mill camp, and water treatment plant discharge location – north (Figure 3.16-2).

The watershed topography is relatively gentle, with elevations ranging from around 600 ft amsl near the confluence with SFK River to roughly 3,000 ft amsl at Groundhog Mountain. Lakes and small ponds are common in the upper portions of the NFK watershed, including Big Wiggly Lake, Lilly Lake, and Black Lake (Figure 3.16-3). Fewer lakes and ponds exist in the middle and lower portions of the watershed.

South Fork Koktuli River

SFK River extends east and north from the NFK River confluence (Figure 3.16-3). The open pit and associated sediment pond, overburden stockpile, and water treatment plant discharge location – south would be in the upper SFK River watershed (Figure 3.16-2).

The watershed topography is relatively gentle, with elevations ranging from approximately 600 ft amsl near the NFK/SFK confluence to 2,760 ft amsl on Kaskanak Mountain, a high point along the NFK/SFK watershed boundary. Lakes and small ponds are common in the upper and lower portions of the watershed, and are less common in the central portion. "Frying Pan Lake," approximately 1.5 miles south of the open pit, is a shallow residual waterbody in the upper SFK River valley (Knight Piésold 2011) (Figure 3.16-2). Frying Pan Lake is the largest lake in the project area, approximately 1 mile long and 0.5 mile wide, with a relatively uniform depth of approximately 3 ft.

Upper Talarik Creek

The UTC watershed extends north from the creek outlet at Iliamna Lake to the southern end of the Groundhog Mountain block (Figure 3.16-3). The water treatment plant discharge location – east, and a portion of the Mine Access Road, would be in the UTC watershed (Figure 3.16-2).

UTC flows south from its headwaters to Iliamna Lake, roughly 10 miles west of the Newhalen River outlet. The Iliamna Lake outlet is the Kvichak River, which flows into Bristol Bay northwest of King Salmon, Alaska. The watershed topography is relatively gentle, with elevations ranging from approximately 46 ft amsl at Iliamna Lake to 3,074 ft amsl on Groundhog Mountain. Lakes and small ponds exist throughout the watershed, present in relatively flat, poorly drained terrain.

AMERICAN OVERSIGHT

3.16.1.2 Streamflow

The majority of streamflow in the Bristol Bay region is generated from spring snowmelt runoff and runoff from fall rain events. The Mine Site watersheds are undisturbed; therefore, baseline streamflow presented in this section is representative of existing natural conditions. The annual pattern of streamflow in the Mine Site watersheds is characterized by high flows in spring due to snowmelt; lower flows occur during early to mid-summer; and a high flow period during late summer and fall due to rain events (Knight Piésold et al. 2011). Baseline surface water quality conditions at the Mine Site are presented in Section 3.18, Water Quality.

Groundwater/surface water interaction in the Mine Site watersheds is characterized by glacial and fluvial deposits of varying thicknesses that cover most of the project area below elevations of approximately 1,400 ft amsl. These deposits are an important factor related to surface water runoff and groundwater storage and exchange. In several locations, project studies concluded that subsurface flows follow former pre-glacial surface drainage pathways that were eventually buried by sediment deposits, resulting in cross-drainage transfer of subsurface flow relative to surface topography (Knight Piésold et al. 2011).

3.16.1.3 Gaging Stations

Since 2004, streamflow monitoring has been conducted on the NFK River, SFK River, and the UTC, as well as tributary streams within each watershed. Figure 3.16-3 depicts gaging station locations. Three gaging stations are operated by the U.S. Geological Survey (USGS), and the remaining 25 are operated by Pebble Limited Partnership (PLP). Stream gaging stations that collect continuous flow data during the open water season and the period of record are listed in Table 3.16-2. Table 3.16-3 presents periodic manual streamflow measurements collected at both continuous monitoring sites and at select locations within each watershed during early spring to capture low-flow conditions. The following gaging station summaries provide a description of streamflow at stations closest to the Mine Site. Specific stations were selected for the discussions that represent streamflow in the upper portion of each watershed near the Mine Site and streamflow near the mouth.

North Fork Koktuli River

There are six gaging stations along the main stem of the NFK River (Figure 3.16-3). Station NK100C is in the upper reaches of the NFK River, approximately 20 miles upstream of the SFK River confluence. NK100C is the closest gaging station to the Mine Site on the main stem of the NFK River, roughly 3.5 miles west of the NFK/SFK rivers watershed divide. At NK100C, the river drains an area of approximately 24 mi^2, including a large complex of lakes and wetlands, and flows through a narrow valley cut through glacial outwash and drift deposits. Channel habitat features in this reach are dominated by riffles and runs, and the instream sediments are dominated by coarse gravel. Flows at this site are buffered by upstream lakes and wetland storage (Knight Piésold et al. 2011). The average annual discharge at NK100C is 48 cubic feet per second (cfs) (Table 3.16-4). The lowest annual discharge was 37 cfs during the 2010 – 2011 water year, and the highest annual discharge was 63 cfs during the 2004 – 2005 water year. Streamflow measurements were recorded at NK100C during March and early April to characterize low-flow conditions (Table 3.16-3). At NK100C, low-flow discharge ranged from 8.3 cfs in March 2010 to 21.5 cfs in March 2005. Peak instantaneous discharge measurements were recorded in both spring and fall to characterize peak flows (Table 3.16-5). The lowest peak instantaneous discharge recorded was 117 cfs, between August and November 2011. The maximum peak instantaneous discharge recorded was 586 cfs, between April and July 2009.

AMERICAN OVERSIGHT

Station NK119A is in a tributary of the NFK River (the tributary is designated by PLP as Tributary 1.190). The mine bulk tailings storage cell would be within Tributary 1.190 (Figure 3.16-2). This tributary is a relatively steep, upland stream, with headwaters along the NFK/SFK rivers' watershed divide. The drainage area above NK119A is approximately 8 mi^2. The channel habitat features in this reach are dominated by short rapids with irregular scour pools; and the instream sediments are dominated by coarse gravels, some cobbles, and numerous boulders (Knight Piésold et al. 2011). The average annual discharge at NK119A is 24 cfs (Table 3.16-4). The lowest annual discharge was 15 cfs during the 2010 – 2011 water year, and the highest annual discharge was 36 cfs during the 2004 – 2005 water year. Streamflow measurements were recorded at NK119A during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge measurements ranged from 2 cfs in April 2011 to 4 cfs, measured in March 2005 and March 2009. Peak instantaneous discharge measurements were recorded in both spring and fall to characterize peak flows (Table 3.16-5). The lowest peak instantaneous discharge measured was 110 cfs, between April and July 2007. The maximum peak instantaneous discharge measured was 690 cfs, between August and November 2004.

South Fork Koktuli River

There are six gaging stations along the main stem of the SFK River (Figure 3.16-3). Station SK100F is in the upper reaches of SFR River, approximately 29 miles upstream of the NFK River confluence. SK100F is roughly 2.5 miles south of the Mine Site, just downstream from the outlet of Frying Pan Lake, and drains an area of approximately 12 square miles. The river at SK100F flows in a narrow valley between hillslopes of moraine deposits and weathered bedrock. The channel habitat features in this reach are riffles and runs, and a large pool. The instream sediments are dominated by very coarse angular gravels and some cobbles. The channel is entrenched, and the stage record indicates that high flows have not exceeded bankfull stage during the period of record (Knight Piésold et al. 2011). The average annual discharge at SK100F is 30 cfs (Table 3.16-4). The lowest annual discharge was 24 cfs during the 2006 – 2007 water year, and the highest annual discharge was 37 cfs during the 2010 – 2011 water year. Streamflow measurements were recorded at SK100F during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge ranged from 1 cfs between March and early April 2007, to 8 cfs in March 2005. Peak instantaneous discharge measurements were recorded in both spring and fall to characterize peak flows (Table 3.16-5). The lowest peak instantaneous discharge measured was 54 cfs, recorded between April and July 2007. The maximum peak instantaneous discharge measured was 249 cfs, recorded between April and July 2006.

Station SK119A is in an SFK River tributary (a tributary designated by PLP as Tributary 1.190), approximately 3.5 miles south of Kaskanak Mountain, a high point along the NFK/SFK rivers watershed divide. Tributary 1.190 enters SFK River approximately 21 miles upstream of the NFK River confluence. The tributary at the gaging station drains approximately 11 square miles near the outlet of a relatively steep, narrow tributary valley. At the gaging station, the creek flows within a narrow alluvial plain bounded by low terraces and colluvial hillslopes. The channel habitat features in this reach are riffles and runs, and the instream sediments are dominated by coarse gravels and cobbles. The stage record indicates that high flows have exceeded bankfull stage during the study period (Knight Piésold et al. 2011). The average annual discharge at SK119A is 35 cfs (Table 3.16-4). The lowest annual discharge was 27 cfs during the 2010 – 2011 water year, and the highest annual discharge was 51 cfs during the 2004 – 2005 water year. Streamflow measurements were recorded at SK119A during March and early April to characterize low flow conditions (Table 3.16-3). Low-flow discharge ranged from 2 cfs in March 2008 to 8 cfs in March 2005. Peak instantaneous discharge measurements were recorded in both spring and fall to characterize peak flows (Table 3.16-5). The lowest peak instantaneous

AMERICAN OVERSIGHT

discharge measured was 158 cfs, between April and July 2007. The maximum peak instantaneous discharge measured was 606 cfs, between August and July 2005.

Upper Talarik Creek

There are nine gaging stations along the main stem of UTC (Figure 3.16-3). Station UT100D is in the upper reaches of UTC, approximately 26 miles upstream of the mouth at Iliamna Lake, and roughly 2.5 miles east of the Mine Site (Figure 3.16-3). The drainage area above the station is approximately 12 square miles, consisting of mostly low-gradient wetlands and some adjacent upland, including the general deposit location. UTC meanders through floodplains and associated low terraces within a glacio-lacustrine basin. Channel habitat features in this reach are dominated by riffles and pools, and the instream sediments are dominated by medium gravel. The stage record indicates that high flows have exceeded bankfull stage during the study period (Knight Piésold et al. 2011). The average annual discharge at UT100D is 28 cfs (Table 3.16-4). The lowest annual discharge was 24 cfs during the 2006 – 2007 water year, and the highest annual discharge was 32 cfs during the 2007 – 2008 water year. Streamflow measurements were recorded at UT100D during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge ranged from 6 cfs in late March 2010 to 11 cfs in March 2005. Peak instantaneous discharge measurements were recorded in both spring and fall to characterize peak flows (Table 3.16-5). The lowest peak instantaneous discharge measured was 103 cfs, between August and November 2009. The maximum peak instantaneous discharge measured was 272 cfs, between August and November 2007.

Notes:

1. Calendar years that stream stage data were collected.

2. Complete water years of record (measured or estimated).

3. Refers to the number of years that stream stage data were collected for at least 3 months and used to compute discharge.

4. Station NK100B1 and NK100C1 were installed in 2011 for the purpose of verifying measured flows at NK100B and NK100C.

mi2 = square miles

AMERICAN OVERSIGHT

3.16.1.4 Meteorological Inputs to Water Balance Modeling

The Mine Site analysis area is in a transitional climatic zone with strong maritime influence. Summer temperatures are moderated by the open waters of Iliamna Lake, the Bering Sea, and Cook Inlet. Winter temperatures are more continental because of the presence of ice on Iliamna Lake and sea ice in Bristol Bay during the coldest months. Winter weather systems typically travel into the region from the Bering Sea to the west, from along the Aleutian Island chain to the southwest, and from the Gulf of Alaska to the south (Hoefler 2010).

Design and implementation of a Mine Site water management plan is essential for developing fresh water requirements and supply for mine process water, appropriate design of water management and treatment systems, and minimizing the potential for uncontrolled discharges of untreated contact or tailings water. As part of the water management plan, surface water and groundwater balance models were developed for the Mine Site that are used to understand surface water and groundwater systems and interaction (Schlumberger 2011). The groundwater balance model is discussed in in Section 3.17, Groundwater.

The surface water balance model was calibrated using continuous streamflow records from 15 streamflow gaging stations for the period of record between 2004 and 2008. [Note: Ongoing efforts are focused on validating and recalibrating the Site Water Balance Model using data collected since 2008]. The model was also used to validate site meteoric data and precipitation variability across the site. A meteorological data collection program was designed and implemented to provide data representative of the Mine Site analysis area. Meteorological data have been collected from eight monitoring stations (Figure 3.16-4) (SLR 2013). The stations are labeled Pebble 1, Pebble 3, Pebble 4, Pebble 5, Pebble 5A, Pebble 6, Pebble 8 in the general Mine Site analysis area, and the Iliamna Air Quality station in Iliamna, Alaska. The closest long-term meteorological records are from the Iliamna Airport; where possible, the Iliamna Airport data were adjusted to site conditions by correlating the airport data with site data (Schlumberger 2011).

Precipitation

Monthly precipitation data from the Iliamna Airport were adjusted for location and elevation, and then correlated with precipitation data from the Pebble 1 meteorological station. Two correlation factors were applied for developing a relationship between the airport and Pebble 1 locations. One correlation factor was applied to account for undercatch of snow at the Iliamna Airport precipitation gage. The other correlation factor was applied to address orographic factors for winter and summer periods to account for the elevation difference between the Iliamna Airport and Pebble 1 locations (Schlumberger 2011).

The watersheds of the NFK and SFK rivers and the UTC were divided into subcatchments, and each subcatchment is associated with a gaging station (Figure 3.16-5). To account for rain shadow and wind transfer of snow, and to balance the precipitation and measured flows, each subcatchment was provided a multiplier of precipitation that ranged from 1.0 to 1.5 (Schlumberger 2011). The Iliamna precipitation multiplier applied to each subcatchment was adjusted to match subcatchment streamflow. Table 3.16-6 provides a summary of the precipitation multiplier, annual net precipitation, and recharge by subcatchment.

Snowmelt

Snowmelt was estimated for each month of the water balance model using a temperature index method (Schlumberger 2011). Comparison of the snow pack data, measured precipitation at Iliamna Airport, and measured snow pack at a regional station (Fishtrap Creek) indicated that

AMERICAN OVERSIGHT

measured precipitation from Iliamna Airport provided an adequate index for snowpack in the analysis area. The water available each month was determined based on the sum of snowmelt and rainfall, after accounting for available snow after sublimation.

Other Meteorological Data

Other meteorological data collected include temperature, radiation, wind speed, relative humidity, evaporation, and sublimation. Where applicable, the site data sets were correlated with the Iliamna Airport data set for each water balance model component. Site meteorology is further discussed in Chapter 3.1.

Water Balance Calibration

The water available for runoff in each subcatchment was calculated based on climate and meteorological inputs and outputs, surface detention and storage, and groundwater storage and discharge. The input parameters of the water balance were adjusted until streamflows calculated by the water balance were reasonably close to measured streamflows (Schlumberger 2011). In addition to calibrating the model to measured streamflows, the model was used to verify that changes in storage calculated by the water balance model were consistent with observed changes in groundwater elevation. The relationship between water balance calculated streamflow and measured streamflow for subcatchments NK119A, SK100F, and UT100D are shown in Figure 3.16-6, Figure 3.16-7, and Figure 3.16-8, respectively. [Note: Figures are in preparation] These stations were selected to show subcatchment calibration results from each watershed (NFK and SFK rivers and UTC watersheds), as well as their downstream proximity to the Mine Site.

3.16.1.5 Surface Water Use

With the exception of the local communities of Iliamna, Nondalton and Newhalen, the project area encompasses remote areas with very little documented public water use. Domestic water use in the communities surrounding the project area is largely supplied by groundwater wells, but some residents likely collect surface water for personal use. Within the Mine Site itself, limited surface water is used by local residents for hunting, fishing and other subsistence activities.

AMERICAN OVERSIGHT

PLP has applied for surface water rights for some of the main drainages within the Mine Site area, including the SFK, the NFK (PLP designated tributary 1.190), and UTC (DNR 2018). PLP has received multiple Temporary Water Use Permits (TWUPs) for exploration activities between 2004 and 2013. The TWUPs give PLP permission to withdraw a certain number of gallons of water per day, up to a specified annual limit, from specified sources.

3.16.1.6 Flood Magnitude and Frequency

[NOTE: RFI placeholder for figures and tables from Appendix 7A and all of Appendix D and Appendix E of Pebble Project Supplemental Environmental Baseline Data Report 2004-2012, Chapter 7 Surface Water Hydrology requested in RFI 004. This section will be revised following receipt of RFI response.]

3.16.2 Amakdedori Port

3.16.2.1 Drainage Basins/Watersheds

Amakdedori Port is within the Tuxedni-Kamishak Bay watershed of the greater Cook Inlet watershed. The Aleutian Range west of the port forms the divide between the Kvichak and Cook Inlet watersheds. The terrain is rocky and undulating at elevations of some 800 ft AMSL at the divide, and drops down to more gentle slopes and wetlands around the port area. There are fewer kettle ponds east of the divide. Streams flow generally south and eastward in the port area, draining into Kamishak Bay. The port site is just north of the mouth of Amakdedori Creek, a meandering stream fed by snowmelt, rainfall and groundwater (Glass 1999). No detailed hydrologic data is available for Amakdedori Creek.

3.16.2.2 Streamflow

No streamflow gaging stations are present within the port area (USGS 2018). The closest known stream gage data are from Williams Creek and an unnamed creek (Y valley) approximately 30 miles northeast of the port. Data from these streams are limited, and the watersheds are more mountainous and likely hydrologically distinct from the port area.

3.16.2.3 Flood Magnitude and Frequency

The port site area is listed as a mapped area in the Federal Emergency Management Agency (FEMA) Flood Mapping database (FEMA quadrant 0200125250A), but no flooding data are available for this area (FEMA 2018 https://msc.fema.gov/portal/search). Amakdedori Creek, just south of the port site, meanders within a floodplain containing wetlands.

3.16.2.4 Surface Water Use

There is no known or documented surface water use at the proposed port site.

The mouth of Amakdedori Creek is just south of the proposed port. The Creek has been advertised as a destination for recreational fishing, but its use has not been documented.

3.16.2.5 Marine Water

Available Information

Environmental baseline data (EBD) for the western landfall of the Natural Gas Pipeline were collected in the Iniskin and Iliamna bays area, 25 to 30 miles north of the proposed Amakdedori Port site. Amakdedori lies on the western shore of Kamishak Bay, with meteorology and

AMERICAN OVERSIGHT

oceanography characteristics more similar to Lower Cook Inlet (LCI) than the more sheltered locations where EBD were collected. Therefore, the EBD relate to a distinctly different marine environment than that of Amakdedori, and the EBD data cannot be used to describe the meteorology of the proposed Amakdedori Port site and west-side Cook Inlet Natural Gas Pipeline landfall.

The Supplemental EBD (SEBD) includes observations in Ursus Cove and Rocky Cove (UCRC), 15 to 20 miles northeast of Amakdedori, at the northern extent of Kamishak Bay. The SEBD includes physical and chemical water quality data that could be considered representative of Amakdedori, and were considered in developing the following discussion. Because site-specific meteorological and oceanographic information pertinent to Amakdedori was not included in either EBD or SEBD, the following discussion was developed based on data available in publicly available sources, as well as relevant anecdotal descriptions provided by residents and others who have personal familiarity with the region.

Meteorology and Wave Climate

With regard to Amakdedori's suitability as a port site, the most important meteorological aspects are its exposure to wind and the resultant waves (especially from northeast and east), and the presence of sea ice (Section 3.16.2.5.5). Meteorological data for the vicinity of Amakdedori are available from the National Oceanic and Atmospheric Administration (NOAA) weather station AUGA2, on the northeast-facing shore of Augustine Island. Data provided from this station are well-suited for evaluating Amakdedori's exposure to winds from the northeast and east, but not to exposure to winds from the southeast.

Since 2005, wind speed and direction, atmospheric pressure, air temperature, and dewpoint have been measured and recorded at AUGA2 at 30-minute intervals. Data capture have been nearly perfect (> 99 percent) in all years except 2014, when the station apparently was inoperative January through April. Table 3.16-7 lists results of analysis of AUGA2 wind speeds for the 5 complete years of data recording (2012 through 2017, excluding 2014) for wind directions between true north and east, and lists the occurrences of wind speeds exceeding 20 meters per second (m/s). The criterion of 20 m/s was chosen because, for fetch lengths typical of LCI (e.g., 40 to 60 kilometers), waves of 3 to 4 meters in height are attainable at this wind speed, and waver occurrence will be similar to that for wind speeds exceeding 20 m/s.

Table 3.16-7: Augustine Island wind speeds > 20 m/s from North to East (0 to 90°)

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Total records > 20 m/s	278	434	106	34	1	0	0	8	56	134	163	466

AMERICAN OVERSIGHT

Direct measurements of waves collected at two NOAA buoys were used to assess wave conditions in LCI:

- NOAA buoy #46106 was deployed 7 miles west of Anchor Point (59.760°N, 152.090°W) from December 15, 2007 to February 19, 2010 (http://www.ndbc.noaa.gov/station_page.php?station=46106)
- NOAA buoy #46108 was deployed 9 miles west-southwest of Homer (59.597°N, 151.829°W) on May 11, 2011, and has continued to collect data to date, although with some interruptions, usually occurring in winter months(http://www.ndbc.noaa.gov/station_page.php?station=46108)

Of the two, NOAA buoy #46106 was best situated to monitor waves from all directions that might affect Kamishak Bay. Records from this buoy (as well as NOAA buoy #46108) include wave height, dominant wave period, and mean wave direction measured at 1-hour intervals. Maximum wave heights from both northeasterly and southwesterly directions often ranged from 3 to 3.5 meters and occasionally exceeded 4 meters.

To assess the reasonableness of using these measured wave conditions as design criteria for Amakdedori Port, a wave forecast was performed with wave forecasting equations from the U.S. Army Corps of Engineers (USACE) Coastal Engineering Manual [REFERENCE]. Wave height and period were computed for wind speeds of 20 and 25 m/s, for fetch lengths typical of LCI and exposure of Kamishak Bay (Table 3.16-8). In addition, minimum storm durations were calculated to develop the wave conditions and the depths at which the waves begin to "shoal" as they enter shallower water.

Table 3.16-8: Amakdedori Port – Estimated Wave Conditions

Wind Speed		Fetch Length[1]		Significant Wave Height[2]		Dominant Wave Period[3]	Minimum Duration Required[4]	Deepwater Wave Length[5]		Shoaling Depth[6]	
m/s	kt	kilometers	n. mi.	meters	feet	s	hours	meters	feet	meters	fathom
20	40	80	43	4.0	13.2	8.0	5.5	100	328	25	14
		50	27	3.2	10.6	7.0	4.0	76	249	19	11
		30	16	2.6	8.6	6.3	3.0	62	203	15	9
25	50	80	43	5.3	17.5	9.0	5.0	126	413	32	18
		50	27	4.2	13.9	7.5	3.7	88	289	22	12
		30	16	3.3	10.9	6.5	2.7	66	217	16	9

n. mi. = nautical mile

1 Fetch = length of water surface over which wind is generating waves

2 Significant wave height = mean height of highest one-third of waves

3 Dominant wave period = period of waves most evident in sea surface

4 Minimum duration = length of time required for seas to be fully developed

5 Deepwater wave length = length of waves before seabed restricts waves

AMERICAN OVERSIGHT

6 Shoaling depth = depth at which waves begin to "feel" effect of seabed

The extent to which waves would affect the immediate vicinity of the Amakdedori Port site will require a detailed analysis of wave interaction with the complex seabed topography, as well as refractive effects of Augustine Island and the southern shore of Kamishak Bay. A more detailed statistical analysis of data from both NOAA buoys would provide an evaluation of probabilities and consequent risks associated with extreme conditions of wind and waves.

During Environmental Impact Statement (EIS) scoping meetings in April 2018, the following remarks were recorded from Mr. Chester Passic, Commander in the U.S. Coast Guard (USCG):

> *MR. CHESTER PASSIC: "I'm a commander in the United States Coast Guard. I'm the captain of a Coast Guard vessel Hickory stationed here in Homer. I do all of the aids to navigation in the Cook Inlet, the buoys and the lights. We maintain them year-round. We do not keep buoys in Cook Inlet for six months a year because of the weather and ice, and we can't keep buoys in Cook Inlet at that time. Kamishak Bay where the deepwater port is proposed is one of the worst places in the world to operate in terms of combination of tide, current, winds, weather. And I don't know if -- I think the Corps needs to investigate the deepwater port there. My concern would be that we can't keep aids to navigation for the vessels going in and out of there."*

Marine Water Properties

The proposed Amakdedori Port site is on the open coast of Kamishak Bay. Water properties such as salinity and temperature can be expected to be similar to those of LCI (see Muench and Schumacher 1980 for typical values). However, some freshening of surface waters in the immediate vicinity of Amakdedori Creek might occur; while under southerly winds, greater freshening could occur as a result of flows from sources to the south, such as McNeil and Kamishak rivers. The extent of any freshening is dependent on the flows from those sources and the persistence of southerly winds. The freshening of surface waters would be manifest as a thin, low-salinity lens overlying the saltier water, which would be mixed quickly into the water column by any wave action produced by brisk winds.

The SEBD include physical and chemical data from UCRC, which are more likely to be similar to the Amakdedori Port site because of greater exposure of UCRC to LCI oceanographic conditions. However, these data also include measurements from Ursus Lagoon, and therefore evidence of freshening by upland sources. For the 2012 sampling period (August), mean water temperatures for the several stations occupied ranged from 12.9 degrees Celsius (^{0}C) to 14^{0}C, while mean salinities ranged from 22.8 to 25.7 parts per thousand (‰). Maxima and minima for both temperature and salinity were within a unit (i.e., ≤ 1^0 or 1‰) of the mean, suggesting a fairly homogenous water column. Turbidity ranged from near zero to 13 Nephelometric Turbidity Units (NTU), and was probably more reflective of different exposures to wave activity.

In the SEBD report water quality summary, seasonal trends in temperature and salinity were stated in general terms. Although temperatures exhibited the usual seasonal warming trend to mid-summer and then subsequent cooling, temperatures were also a function of water depth, indicating the role of insolation as a factor in temperature trends. Salinity decreased from spring to late summer, reflecting the influence of upland water sources on coastal waters, and then increased in autumn months. The SEBD report states that turbidity was: "generally moderate, except near the shoreline during windy periods, and did not exhibit any obvious trends that would indicate point-source inputs."

Chemical analyses were reported in the SEBD for most water sampling stations, but only one (about 17 miles northeast of Amakdedori), might be considered analogous to the port site. Listed in SEBD Table 34-8, Station MRC20 is about 2 miles east of Tignagvik Point in water depth of about 15 meters. Analyses were performed for both surface and bottom water samples,

AMERICAN OVERSIGHT

and none of the inorganic constituents exceeded the corresponding National Recommended Water Quality Criteria (USEPA 2009). Total suspended solids were 5 milligrams per liter (mg/L) at both surface and bottom, indicating a well-mixed and relatively clear water column. Organic constituents in marine water were analyzed only in 2004 (EBD Table 34-7), with the majority not being detected. The water quality summary in the SEBD [reference specific SEBD] states: "hydrocarbon concentrations, as well as metal and trace element concentrations in 2008, showed little to no effect from anthropogenic sources."

The amount of suspended solids and accompanying turbidity in waters adjacent to the proposed Amakdedori Port site would be a function of seabed composition (e.g., silt, mud, sand), for which no information is available. Nautical chart #16640 for the area suggests that seabed nearby is "hard." If this is representative of seabed at the port site, it would suggest that suspended solids are of naturally low concentrations and that water is relatively clear (i.e., low turbidity). However, under energetic wave conditions, any loose sediment on the seabed would be stirred upward into the water column, thereby increasing suspended solids and turbidity until wave activity subsided. Further inferences cannot be reliably made without knowledge of seabed composition at the proposed site.

Marine Water Dynamics – Tides, Currents, and Storm Surge

At Nordyke Island (about 6 miles south-southeast of Amakdedori), the mean tide range is 3.93 meters, while the maximum diurnal range is 4.63 meters. Prevailing currents are those associated with the tide, and will generally be aligned with bottom contours of the seabed.

Storm surge occurs when strong winds cause a change in mean sea level. An elevation of sea level is called a "positive" surge, while a depression of sea level is a "negative" surge. Strong winds from the northeast or east could produce a positive storm surge in Kamishak Bay. However, the relatively steep slope of the seabed near the proposed port site would minimize the effect of a storm surge if it occurred. The small inlets to the north and south of the proposed port site would be more vulnerable to storm surge. Anecdotal information would be useful as an initial approximation of the probability of occurrence of surge, and such information could support more formal evaluation regarding possible surge conditions.

Although storm surge is unlikely to be a major concern, the exposure of the Amakdedori Port site to waves from directions ranging from northeast around to southeast is noteworthy. Although some sheltering from waves arising from northeasterly winds might be provided by Augustine Island, the port site's exposure to waves from the Gulf of Alaska through Kennedy Entrance should be evaluated. Neither the Augustine weather stations, nor the NOAA buoy near Homer, are situated to gather data on winds from east to southeast. Some anecdotal information on wave conditions at Amakdedori is available, but has not yet been explored to its fullest extent.

Sea Ice

The Marine Ice Atlas for Cook Inlet (Mulherin et al. 2001) includes three sets of maps depicting various measures of ice conditions for each biweekly interval between December 1 and March 31 for the period of January 1986 to April 1999 (14 winters). The maps were developed from ice charts constructed by the National Weather Service (NWS), using a combination of remote sensing observations (aerial and satellite photography) and visual reports.

The first map set shows mean sea ice concentration and stage of its development. The second set shows probability of occurrence for ice at *any* stage of development. The third set shows probability of occurrence at any stage of sea ice development *and at least* 5/10 concentration, meaning the sea surface is 50 percent covered by sea ice. Table 3.16-9 presents a distillation of

AMERICAN OVERSIGHT

the information provided by the map sets for the segment of Kamishak Bay that encompasses the Amakdedori Port site. Distances listed in Table 3.16-9 were scaled from the maps in Mulherin et al. (2001), and are accurate to within 3 km of the sea ice features to which they apply.

The EBD report contains several maps of maximum ice concentrations observed in Cook Inlet and published by National Ice Center (NIC 2008). The NIC maps are all from either January or February; one each for years 2001-2008. The ice coverage of the Amakdedori area is generally consistent with the more detailed representations from Mulherin et al. (2001), presented in Table 3.16-9.

Table 3.16-9: Ice Conditions: West Kamishak Bay, vicinity of Amakdedori (January 1986 – April 1999)

Dates	Map Set 1		Map Set 2		Map Set 3	
	Ice Thickness (cm)	Distance (km) to ice-free area	Probability of any ice coverage	Distance (km) to < 25% prob. of occurrence	Probability of > 5/10 coverage	Distance (km) to < 25% prob. of occurrence

3.16.3 Iliamna Lake

3.16.3.1 Available Information

Iliamna Lake is the largest lake in Alaska. Approximately 120 km long by 35 km wide, its surface area is about 2,600 square kilometers. Its greatest depth is more than 300 m, but its mean depth is only 44 meters. Iliamna Lake discharges into the Kvichak River, which flows into Bristol Bay.

Environmental information for Iliamna Lake is contained in Appendix B, "Iliamna Lake Study" (ILS) of the EBD. Study objectives of the ILS were to describe existing water quality through collection of water and sediment samples, and zooplankton from deeper-water locations, in addition to studying contaminant accumulation in mussels, related to nearby water quality and sediment content. No meteorological information or limnological data, other than the water quality observations, were included in the ILS. Consequently, that information was developed for this discussion as needed from publicly available sources.

AMERICAN OVERSIGHT

3.16.3.2 Meteorology and Wave Climate

With regard to the viability of the proposed ferry crossing of Iliamna Lake, the most important meteorological aspects are its exposure to wind and the resultant waves (especially from northeast and east), and the presence of lake ice. Meteorological data for Iliamna Lake are available from Iliamna Airport, for which the record extends from the 1940s; however, no statistical summary other than the Iliamna wind rose was located (Figure 3.16-9) [Note: Figure is in preparation, based on Fig. B23 from EBD-App.B].

Figure 3.16-9 indicates winds at Iliamna are essentially bimodal, either from the east or north, with direction likely governed by local terrain. For the 4 years of meteorological studies included in the EBD (2005-2008), maximum hourly mean wind speeds ranged from 9 to 10 m/s (summer), to 19 to 21 m/s (winter) for 2005-2007, but were somewhat less at 7 to 11 m/s for least windiest year of 2008.

A cursory (i.e., non-statistical) review of data from both Iliamna and Igiugig (at the western end of Iliamna Lake), available at National Climatic Data Center (https://www.ncdc.noaa.gov/data), showed that maximum wind speeds of 40 miles per hour (mph) are common, and therefore a useful estimator for properties of wind-generated waves.

Using wave forecasting equations from the USACE Coastal Engineering Manual (REF), for a fetch[1] length of 35 miles from the proposed ferry crossing to the northeastern end of Iliamna Lake, a significant wave height[2] of 3 meters and dominant wave period[3] of 6.5 seconds were calculated. Anecdotal information, collected at scoping meetings, suggests that 40 mph might be a gross underestimate of maximum wind speeds experienced on Iliamna Lake, as noted below:

Pg. 49 [REFERENCE]

> *"You know, I'm looking at their new travel plan, and I spent many years in Igiugig in the fall, and it probably blows 100 miles an hour at Lake Iliamna three to five times a year. 100 miles an hour. They want to cross it all the time."*

3.16.3.3 Lake Water Properties

Included in the ILS are results of monthly collections (May-October, 2005-2007) of water quality conditions at five "deeper-water" stations (sample depths to 20 meters) in bays (Knutson, Northeast, Pile, and Roadhouse), as well as UTC at the northeastern end of Iliamna Lake. Talarik Creek is the station closest to the North Ferry Terminal. Four shallow nearshore stations (Bucket Lake, Whistlewing Bay, Flat Island, and Finn Bay) were also sampled.

At the five deeper-water stations, samples were collected for analysis of water quality, sediment, and zooplankton. At the shallow nearshore stations, mussels were also collected for analysis of muscle tissue (see Section TBD). Ambient water measurements included dissolved oxygen, temperature, specific conductance, oxidation reduction potential, pH, turbidity, and water clarity. Sediment samples were collected for laboratory analysis of major ions and trace elements. The physical and chemical data collected and presented in the ILS provide a robust base for evaluation of Iliamna Lake water quality in the vicinity of the North Ferry Terminal.

In their summary, investigators noted that concentrations of nutrients and major ions found during the 2005-2007 study were similar to concentrations from a study conducted at Iliamna Lake nearly 40 years before. The single exception was for sodium, which was present at nearly

[1] Fetch = length of water surface over which wind is generating waves
[2] Significant wave height = mean height of highest one-third of waves
[3] Dominant wave period = period of waves most evident in sea surface

AMERICAN OVERSIGHT

twice the concentration found in the earlier study. However, only a few ions (copper, lead, aluminum, iron, manganese, and alkalinity) had concentrations outside benchmarks established by the Alaska Department of Environmental Conservation (ADEC) for freshwater. The investigators attributed the latter to geological influences, and noted their consistency with previous studies conducted at Iliamna Lake and other area watersheds. Implications of the biological sampling are addressed in Section TBD.

3.16.3.4 Lake Ice

Although ambient air temperatures are sufficiently cold for lake ice to form November through March each winter (Figure 3.16-10) [Note Figure is in preparation based on Figure B22 from EBD-App. B], Table 3.16-10 denotes start of freezeup as early as mid-Novembe,r and final breakup often as late as mid-May for years 2002-2015.

Table 3.16-10: Iliamna Lake Freezeup and Breakup Dates (2002 – 2015)

Year	Freeze Start	Freeze Final	Breakup Start	Breakup Final
2002	12/4/2001	2/9/2002	5/5/2002	5/22/2002
2003	12/29/2002			4/18/2003
2004	12/21/2003	1/9/2004	4/21/2004	5/11/2004
2005	1/8/2005	2/7/2005	3/13/2005	5/5/2005
2006	11/25/2005	1/21/2006	5/19/2006	5/27/2006
2007	11/27/2006	12/26/2006	5/4/2007	5/22/2007
2008	12/18/2007	1/7/2008	5/11/2008	5/23/2008
2009	11/20/2008	12/30/2008	5/11/2009	5/28/2009
2010	12/12/2009	1/18/2010	5/9/2010	5/24/2010
2011	12/4/2010	12/30/2010	5/12/2011	5/30/2011
2012	11/30/2011	12/25/2011	5/15/2012	5/25/2012
2013	11/19/2012	12/19/2012	4/10/2013	5/16/2013
2014	12/12/2013	2/16/2014	4/19/2014	5/5/2014
2015	1/24/2015			4/8/2015

Source: [Note: Reference to be added]

Figure 3.16-10 depicts ice coverage in Iliamna Lake for years 2002-2015, with the lighter shade indicating at least 10 percent ice coverage, and the darker shade at least 50 percent coverage.

The foregoing data and graphs suggest that winter crossings of Iliamna Lake could be problematic, at least January through April. Anecdotal information collected during scoping appears to support this conclusion. An example is provided below.

Pg. 19 [REFERENCE]

> *"Any construction along that corridor will require maximum construction and maintenance efforts as mitigation for the unfriendly territory environmentally. East winds during the May to June break-up period on Iliamna Lake propagating from the Kokhanok/Bruin Bay area tend to pile up* [sic] *humongously large piles of ice on the north shore of Iliamna Lake, sometimes 40 to 60 feet high."*

AMERICAN OVERSIGHT

3.16.3.5 Lake and Sea Ice Hazards

The ice-covered season at Iliamna Lake is highly variable. Complete freeze-over can start between late October and mid-March, and last 2 to 5 months before breakup. The average length of the ice-covered season is expected to be about 115 days, based on 15 years of data collected in several southwestern Alaska lakes (Verrier and Kirchner 2016). Limited data are available on ice thickness in Iliamna Lake; anecdotal reports indicate that it can be about 4 feet thick in late spring (Billmeier 2016), but can range from several inches to several feet at the same time over a short distance (ADF&G 2008). Lake ice hazards, such as pressure ridges driven by wind, are known to occur in Iliamna Lake (Billmeier 2015; Andrew 2017). Ridges that are big enough to be pushed up on shore have been documented in similar lakes in other cold regions of North America and Europe (Lake Ice 2018). Ice jams, piles, and over-ice flooding can also occur at river mouths entering the lake during breakup. [Note: RFI Placeholder: Request submitted for additional Iliamna Lake ice information in RFI 013; to be inserted here if available.]

Sea ice in lower Cook Inlet has been documented by Mulherin et al. (2001), Pentec et al. (2011), and NOAA National Ice Center (2018) based on several decades of data. Ice in Kamishak Bay typically starts forming by mid-December with floes several inches thick, and reaches its maximum extent by late January to mid-February, occurring as pancake ice up to 1 foot thick in inner Kamishak Bay by this time. Sea ice reaches Augustine Island at its maximum extent in about half of the years. Thicker stamukhi ice, caused by tidal stranding of ice cakes on top of each other, can also form along the shore of Kamishak Bay. Sea ice typically recedes from Augustine Island by mid-March, with floes often present in inner Kamishak Bay into April. Although landfast ice is rare in Kamishak Bay, floe density is quite variable, ranging from ice-free to 100 percent coverage at its maximum extent. Sea ice floes propelled by tidal currents have been known to cause damage to vessels and docks, and related oil spills in areas of similar ice coverage in upper Cook Inlet.

The eastern side of lower Cook Inlet is typically ice-free most winters, although ice may extend as far south as Anchor Point during colder winters (Mulherin et al. 2001; Pentec et al. 2011). The probability of any sea ice occurring in this area ranges from zero to 25 percent.

3.16.4 Transportation Corridor

The sections below summarize baseline surface water data, where available, across the Transportation Corridor. The road corridor spans multiple watersheds, from its starting point at the southeastern edge of the Nushagak watershed within the Mine Site, across the greater Kvichak watershed, including Iliamna Lake, to the Aleutian Range watershed divide, and finally entering the greater Cook Inlet watershed east of the divide.

The surface water hydrology in the watersheds surrounding the Mine Site is well characterized, as described above (e.g., HDR 2011; Knight Piésold 2011; SLR 2011). The northernmost segment of the Transportation Corridor (northern half of the Mine Access Road) is within the well-studied UTC watershed, for which abundant data are available. Limited data are available for the southern segment of the Mine Access Road. No known surface water investigations have been conducted along the South Access Road.

Climatic factors influencing surface water across the corridor are the same or similar to those described above for the Mine Site. There are no glaciers within the road corridor watersheds. There is no known permafrost within the Transportation Corridor; however, permafrost has been observed within the general area (Detterman and Reed 1973), and may be present at depth in isolated zones, such as on north-facing slopes. Section 3.14, Soils, addresses the occurrence of permafrost.

AMERICAN OVERSIGHT

3.16.4.1 Drainage Basins/Watersheds

Mine Access Road

The Transportation Corridor begins at the Mine Site, which straddles the watershed divide between the SFK and UTC watersheds, within the greater Bristol Bay watershed. The road begins at an elevation of approximately 1,700 feet amsl among gently rounded hills and wide valleys of the Nushagak-Big Hills physiographic region (Wahrhaftig 1965, 1994). The northern half of the Mine Access Road would roughly parallel the UTC watershed, crossing a number of small tributaries by way of culverts, with a bridge across the main stem of the UTC.

Iliamna Spur Road

The Iliamna Spur Road Corridor heads eastward out of the UTC drainage and enters the Newhalen River watershed. The Newhalen River is one of the larger streams in the area, with a drainage area of 3,451 square miles at the mouth (Knight Piésold et al. 2011). It is the main outlet of the large glacial Lake Clark to the north/northeast of the project area, draining glaciated mountainous headwaters, and therefore has high suspended sediments. The Newhalen River flows southward through poorly drained lowland/wetland areas with abundant kettle ponds. Numerous small tributaries feed into the river before it reaches its outlet into Iliamna Lake, 3 miles southwest of the village of Iliamna. A bridge would be constructed across the Newhalen River along the Iliamna Spur Road.

Just south of the intersection with the Iliamna Spur Road, the Transportation Corridor turns southwest, paralleling an unnamed drainage that flows southward and drains into Iliamna Lake just south of the North Ferry Terminal. The corridor drops in elevation southward as the terrain flattens out over glacial and fluvial deposits, with abundant kettle ponds and wetlands (Wahrhaftig 1965, 1994). The Mine Access Road terminates at the North Ferry Terminal at an elevation of approximately 50 feet amsl.

South Access Road

The northern two-thirds of the South Access Road and the Kokhanok Airport Spur Road are in the Kvichak watershed, west of the Aleutian Range divide. Here within the Aleutian Range physiographic province, the terrain consists of low, rounded ridges of exposed bedrock, and valley bottoms dominated by wetlands, streams, and abundant kettle ponds (Wahrhaftig 1965, 1994). Bedrock exposures are common, with less-abundant surficial deposits of ground moraine and alluvium (Detterman and Reed 1973). Elevations range from 50 feet amsl at the shores of Iliamna Lake to about 800 feet amsl near the divide. Streams flow in sinuous patterns through the varied upland terrain, eventually meandering downgradient northward into Iliamna Lake.

This segment of the road would require four bridges, including the Gibraltar River Bridge near Iliamna Lake, Bridge Lake Bridge, and two unnamed creek bridges just west of the divide. The corridor passes within a mile of Gibraltar Lake, a prominent elongate lake trough approximately 7 miles long by 0.5 mile wide, of unknown depth. Gibraltar lake is fed by small streams on the southern and western sides, including Dream Creek and Emerald Creek, and likely by groundwater; and drains north into the Gibraltar River and then into Iliamna Lake.

East of the Aleutian Range divide, the final segment of the Transportation Corridor drops into the Tuxedni-Kamishak Bay watershed of the greater Cook Inlet watershed. The terrain east of the divide is rocky and undulating, with elevations close to 800 feet amsl at the divide, dropping down to more gentle slopes and wetlands nearing the coast at sea level. There are fewer kettle ponds east of the divide. Streams flow in sinuous patterns through the varied terrain, eventually draining south and east into Kamishak Bay. The road corridor here would include two bridges,

AMERICAN OVERSIGHT

including Bridge Lake Bridge just east of the divide, and an Unnamed Creek Bridge close to the port. The terminus of the road corridor is adjacent to Amakdedori Creek, a meandering stream fed by a number of small lakes and tributaries, which drains eastward into Kamishak Bay.

3.16.4.2 Streamflow

Mine Access Road

The Mine Access Road would cross multiple small tributaries within the UTC watershed by way of culverts before crossing the main stem channel of the UTC by way of a bridge. UTC flow is supplied by snowmelt, rainfall runoff, and groundwater, and has a drainage area of 135.2 square miles, and a mean annual discharge of 225 cfs (Knight Piésold 2011). Streamflow of the UTC watershed is fully described under Section 3.1.6.1, Mine Site, above. Smaller drainages and tributaries of the Kvichak watershed that drain into Iliamna Lake are also generated by snowmelt and rainfall runoff, and likely have significant groundwater interaction. Streams within the Mine Access Road corridor flow southward and drain into Iliamna Lake.

Iliamna Spur Road

The Iliamna Spur Road would include a substantial bridge over the Newhalen River, which is one of the highest flow streams in the area, with a drainage area of 3,451 square miles at the mouth (Knight Piésold et al. 2011). A USGS gaging station was installed at the Newhalen River (ID 15300000) close to the village of Iliamna in 1951, and was active through 1986. PLP installed two new gaging stations in 2008: one at the same USGS site (NH100-APC3), and the other installed 8 miles downstream (NH100-APC2). The Newhalen River has a mean annual unit runoff rate of 2.6 cubic feet per square mile (or approximately 35 inches of annual basin runoff depth) (Knight Piésold et al. 2011). There is a substantial hydrograph peak in spring/early summer from snow and glacial melt. Snowmelt runoff is stored in several large lakes upstream of the gaging station, resulting in delayed peak flows in July and August, which are the highest annual flows. As with other local drainages, flows decline within late summer/autumn months, with the lowest flows occurring in late winter (Knight Piésold et al. 2011).

South Access Road

Drainages in the project area south of Iliamna Lake have not been the focus of any known hydrologic studies to date. Streams and tributaries along the South Access Road corridor are likely generated by spring snowmelt, runoff from rain events, and groundwater. Groundwater contributes to streamflow east of the divide, within the Tuxedni-Kamishak watershed, particularly in the winter months (Glass 1999). There is no known stream gage data in proximity to the road corridor here. The closest known stream gage data are from Williams Creek and an unnamed creek in locally named Y valley, about 30 miles northeast. Data from these streams are limited, and the watersheds are more mountainous and likely hydrologically distinct from the road corridor area.

3.16.4.3 Flood Magnitude and Frequency

The Mine Access Road would require a bridge across the UTC east of the Mine Site. At the proposed bridge site, the UTC meanders within a floodplain containing wetlands, oxbow lakes, and associated low terraces. The Iliamna Spur Road would require construction of the Newhalen River Bridge. Upstream of the bridge site, the Newhalen River flows within a wide floodplain containing wetlands, which narrows at the bridge site.

Along the South Access Road, the Gibraltar River meanders within a floodplain containing wetlands and oxbow lakes at the site of the proposed bridge. Limited information is available on

AMERICAN OVERSIGHT

floodplains and flood data for other streams that would require bridge and culvert crossings. The southernmost section of the South Access Road is listed as a mapped area in the FEMA Flood Mapping database (FEMA quadrants 0200125250A and 0200124875A), but no flooding data are available for this area (FEMA 2018 https://msc.fema.gov/portal/search).

3.16.4.3 Surface Water Use

Most of the length of the Transportation Corridor passes through remote areas with no documented public water use.

The Iliamna Spur Road would cross the Newhalen River, addressed above. A hydropower project (Tazimina Hydro) was installed 9 miles upstream from the confluence of the Newhalen and Tazimina rivers. As of 2012, the run-of-the-river–type hydropower plant supplied over 95 percent of the power for the communities of Iliamna, Newhalen, and Nondalton (INNEC 2012 – http://innelectric.com/index.html). The hydropower system uses the natural waterfalls at the site to provide the mechanical energy to spin power-generating turbines, and there is no dam required. Streamflow is therefore not significantly affected, and no water is removed from the drainage for power production.

The community of Kokhanok is just east of the South Ferry Terminal, and the Kokhanok Spur Road extends to the community. Unlike most nearby communities that use groundwater, the Kokhanok Water System extracts surface water from Iliamna Lake for drinking water supplies (ADEC Drinking Water Watch 2018).

3.16.4.4 Surface Water Extraction Sites

[NOTE: Section will be developed based on response to RFI 022.]

3.16.4.5 Stream Crossing Bank Erosion/Scour

Erosion of stream banks is generally caused by an increase in flow during flooding events. There are no known studies of current stream bank erosion along the Transportation Corridor.

A total of seven bridges would be constructed along the corridor, with the remaining crossings using culverts. Bridges and culverts modify stream morphology, and can lead to scour, or localized erosion around the infrastructure. The Mine Access road would include a bridge over the Upper Talarik Creek; the Iliamna Spur Road would include a bridge over the Newhalen River; and the South Access Road corridor would include five bridges over various ponds and streams. Freshwater fish field studies planned for the 2018 season include stream crossing identification and habitat mapping, which may include sampling of stream substrate along the South Access Road (PLP 2018).

3.16.5 Natural Gas Pipeline Corridor

Available surface water data in the Natural Gas Pipeline Corridor are the same as that described above for the Transportation Corridor, with the exception of the Cook Inlet crossing and the segment of corridor along the Kenai Peninsula. [Note: This section will be updated with more information regarding the affected environment of the main Cook Inlet crossing of the Pipeline Corridor.]. Recent project updates no longer include pipeline construction along the 9-mile stretch south of Happy Valley (citation? Info from Bill, PLP communication May 10, 2018), so the project area will no longer include sections of corridor close to Stariski Creek. When the revised project area is available, this document will be updated to describe surface water characteristics along the revised pipeline corridor.

AMERICAN OVERSIGHT

3.16.5.1 Drainage Basins/Watersheds

The drainage basin/watershed descriptions for most of the Natural Gas Pipeline Corridor are the same as those already provided for the road corridor. See Section 3.16.4, above under Transportation Corridor.

3.16.5.2 Streamflow

The streamflow data for most of the pipeline corridor are the same as the data already provided for the road corridor. See Section 3.16.4, Transportation Corridor.

3.16.5.3 Surface Water Use

The surface water use data for most of the Natural Gas Pipeline Corridor are the same as the data already provided for the road corridor. See Section 3.16.4, Transportation Corridor.

3.16.5.4 Surface Water Extraction Sites

[NOTE: Section will be developed based on response to RFI 022.]

3.16.5.5 Stream Crossing Bank Erosion/Scour

The stream crossing bank erosion/scour information for most of the Natural Gas Pipeline Corridor is the same as that already provided for the road corridor. See Section 3.16.4,Transportation Corridor.

AMERICAN OVERSIGHT

3.26 VEGETATION

The analysis area for vegetation is the same as that described in Wetlands/Special Aquatic Sites and Waterbodies (Section 3.22). It encompasses the nine Hydrologic Unit Code (HUC) 10 watersheds that could potentially be directly or indirectly impacted by the project, with a total area of approximately 6,420,000 acres. Due to the area size, it was not possible to obtain detailed information on all vegetation communities within it. A subset of this area was therefore chosen for detailed study and mapping, referred to hereafter as the "mapping area." The mapping area is approximately 45,000 acres, divided by major project component: the Mine Site mapping area, the Transportation/Natural Gas Pipeline Corridor mapping area, the Amakdedori Port mapping area, and the Natural Gas Pipeline Corridor mapping area (Figure 3.26-1). The project area, or area of the direct project disturbance footprint, is contained entirely within the mapping area.

The description of vegetation in the mapping areas is based on information provided in Chapters 13 and 38 of the Environmental Baseline Document (EBD) (3PPI and HDR 2011, HDR and 3PPI 2011), as well as more recent information provided in the Preliminary Jurisdictional Determination Report (HDR 2018) (Appendix J) and associated Geographic Information System (GIS) database that reflects changes in the project area since publication of the EBD. The affected environment for vegetation overlaps with and provides support for other resources that are addressed in other sections of this Environmental Impact Statement (EIS), primarily Wildlife Values (Section 3.23) and Wetlands/Special Aquatic Sites and Waterbodies (Sections 3.25). Vegetation is also important aspect of social environment disciplines such as Recreation (Section 3.5) and Food and Fiber Production (Subsistence) (Section 3.9).

The affected environment for vegetation includes predominant vegetation communities and other land cover types, such as open water and barren areas, which may be directly or indirectly affected by project activities. The affected environment for vegetation will be described in terms of the extent and characteristics of predominant types found in the four mapping areas. Confirmed or reported populations of species on the Alaska Center for Conservation Science (ACCS) rare vascular plant species list are also addressed in this section. There are no federally listed threatened, endangered, or candidate plant species expected to occur within the project area.

3.26.1 Analysis Methodology

As part of the project's environmental baseline study program, researchers analyzed vegetation field data and aerial photo signatures to develop a system for describing and identifying vegetation types (EDB Chapter 13 - 3PPI and HDR 2011, EBD Chapter 38 - HDR and 3PPI 2011). This classification system is based on the Alaska Vegetation Classification (Viereck et al. 1992), supplemented by Wibbenmeyer et al. (1982), and expanded as necessary to accommodate interpretation of available aerial imagery. Vegetation data were collected within the mapping area and included estimates of the percent cover of each plant species, site photographs, and classification of vegetation types. The vegetation classification system incorporated information on canopy cover, needleleaf versus broadleaf tree species, shrub height and density, and dominant species. Mapping was digitized on aerial photography at a scale between 1:1,200 and 1:1,500. Details on vegetation study methodology and field data collection can be found in Chapters 13 and 38 of the EBD (3PPI and HDR 2011, HDR and 3PPI 2011) and a quick reference guide to the environmental baseline study classification system, including vegetation type definitions and representative photos, is in included in Appendix C of the Preliminary Jurisdictional Determination Report (HDR 2018 – included as Appendix J).

AMERICAN OVERSIGHT

Field studies and mapping conducted as part of the environmental baseline program encompass the portion of the mapping area within the Bristol Bay watershed and the west side of the Cook Inlet watershed. The pipeline crossing of Cook Inlet and the pipeline corridor and compressor station on the Kenai Peninsula were not included in the field studies and mapping prepared for the project. Therefore, this analysis makes use of existing landcover classification data for Northern, Western, and Interior Alaska developed by the ACCS (Boggs et al. 2016) to expand the mapping for this project component. ACCS landcover types were developed using best-available data derived from 18 regional landcover maps that have been developed over the last 31 years. For maps derived from satellite imagery, a 30 meter (m) pixel size or finer was used and for maps derived from aerial photography a scale of 1:63,360 or finer was used (Boggs et al. 2016) In order to make the data comparable to the data collected for the Pebble Project, ACCS landcover types were reclassified with the best-corresponding vegetation types based on comparison of the dominant growth forms (tree, shrub, or herb), vegetation density (open or closed canopy), and average height (tall, low, or dwarf) from each classification system. A segment of the Cook Inlet pipeline crossing, where there were no data, was classified as open water.

Forty-eight project vegetation types were identified in the mapping area (Table 3.26-1). For clearer display on maps, the project vegetation types were aggregated into 10 vegetation structure types (Table 3.26-2), based on dominant growth form (forested, shrub, or herbaceous), vegetation density (open or closed canopy), and average height (dwarf, low, or tall) (EBD Chapter 13 - 3PPI and HDR 2011, EBD Chapter 38 -HDR and 3PPI 2011). A complete list of plant species from project vegetation and wetlands plots is included in Appendix B of the Preliminary Jurisdictional Determination Report (HDR 2018 – included as Appendix J). The following discussion will focus on the grouped vegetation communities, which are summarized in this section for each of the four project component mapping areas.

AMERICAN OVERSIGHT

Figure 3.26-1: Vegetation Mapping Overview

AMERICAN OVERSIGHT

Table 3.26-1: Summary of Project Vegetation Types in the Mapping Area

Project Vegetation Type	Abbreviation	Definition[1]	Predominantly Occurs in Wetlands or Uplands
Forest (≥10% cover of trees over 10 feet in height)			
Closed White Spruce Forest	CWSF	Closed forest dominated by white spruce	Upland
Open White Spruce Forest	OWSF	Open forest dominated by white spruce	Upland
White Spruce Woodland	WSW	Woodlands dominated by white spruce. The openings between the trees may be dominated by mosses and lichens, herbs, and/or shrubs.	Upland
Black Spruce Woodland	BSW	Woodlands dominated by black spruce. The openings between the trees may be dominated by mosses and lichens, herbs, and/or shrubs.	Wetland
Closed Broadleaf Forest	CBF	Closed forests dominated by broadleaf tree species	Upland
Open Broadleaf Forest	OBF	Open forests dominated by broadleaf tree species	Upland
Broadleaf Woodland	BW	Woodland dominated by broadleaf tree species	Wetland / Upland
Closed Mixed Forest	CMF	Closed forests co-dominated by needleleaf and broadleaf tree species	Upland
Open Mixed Forest	OMF	Open forests co-dominated by needleleaf and broadleaf tree species	Upland
Mixed Forest Woodland	MFW	Woodlands co-dominated by needleleaf and broadleaf trees	Upland
Dwarf White Spruce Scrub	DWSS	Open forests and woodlands dominated by white spruce. If trees 10 feet or taller cover at least 10% of the area, the scrub class does not apply.	Upland
Scrub (<10% cover of trees over 10 feet in height, >25% shrub cover)			
Closed Willow Tall Shrub	CWTS	Thickets of tall willows. In some sites, shrub birch may be mixed with the willow.	Upland
Closed Alder Tall Shrub	CATS	Thickets of tall alder	Upland
Closed Alder-Willow Tall Shrub	CAWTS	Mixed species thickets of tall alders and willows	Wetland / Upland
Open Alder Tall Shrub	OATS	Open stands of tall alder	Upland
Open Alder-Willow Tall Shrub	OAWTS	Tall, open shrub stands co-dominated by alder and willow	Upland
Open Willow Tall Shrub	OWTS	Open stands of tall willow	Upland
Closed Willow Low Shrub	CWLS	Thickets of low willow. In some	Wetland

AMERICAN OVERSIGHT

Project Vegetation Type	Abbreviation	Definition[1]	Predominantly Occurs in Wetlands or Uplands
		sites, shrub birch may be mixed with the willow.	
Closed Alder-Willow Low Shrub	CAWLS	Mixed-species thickets of low alder and willows	Wetland / Upland
Closed Alder Low Shrub	CALS	Thickets of low alder	Upland
Open Sweetgale-Graminoid Bog	OSGB	Bogs and fens dominated by sweetgale (>25 percent cover)	Wetland
Open Mixed Shrub-Sedge Tussock	OMSST	Tussock tundra co-dominated by low shrubs and tussock-forming graminoids	Wetland
Open Dwarf Birch-Ericaceous Shrub Bog	ODBESB	Bogs with abundant mosses, ericaceous shrubs, and dwarf birch	Wetland
Ericaceous Shrub Bog	ESB	Bogs with abundance mosses and ericaceous shrubs, but only sparse dwarf birch	Wetland
Low Ericaceous Shrub Tundra	LEST	Shrublands dominated by low ericaceous shrubs	Upland
Open Dwarf Birch Scrub	ODBS	Open stands of dwarf birch and/or shrub birch (>8 inches tall)	Wetland / Upland
Shrub Birch-Willow	SBW	Open or dense shrub stands co-dominated by willows and birch	Upland
Open Willow Low Shrub	OWLS	Open stands of low willow	Wetland
Open Willow Low Shrub Fen	OWLSF	Fens characterized by open stands of low willows	Wetland
Open Alder-Willow Low Shrub	OAWLS	Low, open shrub stands co-dominated by alder and willow	Wetland
Open Alder Low Shrub	OALS	Open stands of low alder	Upland
Dwarf Ericaceous Shrub Tundra	DEST	Dwarf ericaceous shrublands that do not satisfy the requirements of other Project Vegetation Types	Upland
Dwarf Ericaceous Shrub Tundra - Hummocks	DEST-H	Dwarf ericaceous shrublands growing on moderate to large hummocks (> 6 inches tall)	Upland
Dwarf Ericaceous Shrub Tundra - Equisetum	DEST-EQ	Dwarf ericaceous shrublands with abundant horsetails (>25 percent coverage)	Upland
Dwarf Ericaceous Shrub Tundra - Carex	DEST-C	Dwarf ericaceous shrublands with abundant sedges (>25 percent coverage)	Upland
Dwarf Ericaceous Shrub-Lichen Tundra	DESLT	Dwarf ericaceous shrublands on lichen dominated (>60 percent coverage) ground	Upland
Herbaceous (<10% of tree cover and <25% of shrub cover)			
Halophytic Dry Graminoids	HDG	Dominated by beach rye grass; site	Upland

AMERICAN OVERSIGHT

Table 3.26-1: Summary of Project Vegetation Types in the Mapping Area

Project Vegetation Type	Abbreviation	Definition[1]	Predominantly Occurs in Wetlands or Uplands
		may be dry or wet	
Bluejoint Tall Grass	BTG	Abundant bluejoint reedgrass; other herbs and grasses may be present but are not co-dominant	Upland
Bluejoint-Herb	BH	Abundant bluejoint reedgrass interspersed with other low-growing species	Upland
Subarctic Sedge-Moss Wet Meadow	SSMWM	Graminoid-dominated communities, found on wet soils, that do not satisfy the requirements of other Project Vegetation Types	Wetland
Fresh Sedge Marsh	FSM	Dominated by members of the sedge family (e.g., sedges, cottongrass) rooted in standing water, and often near open water	Wetland
Mesic Herbs	MH	Herb-dominated communities that occur on mesic sites and do not satisfy the requirements of other Project Vegetation Types	Upland
Fresh Herb Marsh	FHM	Dominated by emergent in persistent standing water	Wetland
Aquatic Herbaceous	AH	Dominated by submerged plants or plants with floating leaves	Wetland
Other			
Partially Vegetated	PV	Sparse (10-25 percent) cover of vascular plants	Upland
Barren	BARE	Very sparse (<10 percent) cover of vascular plants	Wetland / Upland
Open Water	OW	Unvegetated to very sparsely vegetated open water, including streams, rivers, lakes, and ponds	Waters
Snow	SNOW	Persistent snowfields	Upland

1 Forest density classes (closed, open, woodland) are differentiated base on tree canopy coverage (>60%, 25-59%, 10-24%, respectively). Shrub density classes (closed thickets, open) are differentiated based on shrub canopy cover (>75%, 25-75%, respectively). Shrub height classes (tall, low, dwarf) are differentiated based on average shrub height (>5 feet tall, 5 feet to 8 inches tall, <8 inches tall, respectively).

Closed Low Shrub	352	<1
Dwarf Shrub	18,983	42
Dry to Moist Herbaceous	1,354	3
Wet Herbaceous	1,818	4
Open Water	5,317	12
Other	1,928	4
Total Mapping Area	**45,007**	**100**

1 Project Vegetation Types were aggregated into vegetation type groups based on the dominant growth form (tree, shrub, or herb), vegetation density (open or closed canopy), and average height (tall, low, or dwarf).

2 All numbers are rounded. Apparent inconsistencies in sums are the result of rounding.

3 Includes approximately 3 acres from a Tall Shrub (Open-Closed) landcover class that could not be cross-walked with certainty in to an "Open" or "Closed" group; for the purposes of this summary table it was divided evenly between the Open Tall Shrub and Closed Tall Shrub groups.

NOTE: Source: EBD Chapter 13 - 3PPI and HDR 2011, EBD Chapter 38 - HDR and 3PPI 2011.

The predominant vegetation throughout the mapping area includes white spruce forests and woodlands, mixed forests, tall and low shrubs of birch, willow, and alder, and low ericaceous shrub. Forests and woodlands are generally restricted to valley bottoms and toe slopes. Across peatlands, black spruce woodlands and low ericaceous and shrub birch scrub are common, often with tussock-forming sedges, or various sedges and grasses. Dwarf alpine scrub with considerable lichen cover and bare ground is common in the higher elevations with shallow soils (3PPI 2008).

3.26.2 Mine Site Affected Environment

The Mine Site mapping area comprises 20,526 acres of the overall mapping area and is located in the upper watersheds of the North Fork and South Fork Koktuli River It also includes a small portion of the Upper Talarik Creek watershed. The mapping area was selected to provide coverage of potential development areas and alternative development areas as well as additional surrounding area to provide comparative context (EBD Chapter 13 - 3PPI and HDR 2011).

The Mine Site lies within the Nushagak-Big River Hills physiographic division, which is an area of low, rolling hills separated by wide shallow valleys. The main streams occupy wide valley bottoms and tributaries are incised into the hilly terrain and typically occupy narrow valleys. (Netterman and Reed 1973; EBD Chapter 4 - Knight Piesold Ltd. 2001).

The mapping area consists of the Lime Hillsecoregion characterized by sharp mountain ridges with steep headwalls and broad U-shaped valleys. The ridges and mountainsides are covered with colluvial rubble, while the valleys contain glacial moraines and outwash with some alluvial deposits along rivers. This ecoregion supports predominately tall and low shrub communities of willow, birch, and alder. Spruce forests and woodlands are confined to valley bottoms and mountain toeslopes. (Nowacki et al. 2000, Nowacki et al. 2001).

Based on field observations during vegetation studies for the environmental baseline program, the Mine Site mapping area is characterized as one ecological zone (low scrub shrub) that supports a dense low or dwarf shrub understory. In general the vegetation of the low scrub shrub ecological zone is made up of dwarf ericaceous (heath family) shrubs, willows, and

AMERICAN OVERSIGHT

alders. Dwarf ericaceous shrubs and barren patches cover the mountain tops and the mountain hillsides area is covered in with tall shrubs interspersed with low willow stands and patches of bluejoint grass or wet sedge and shrub meadows. Dwarf ericaceous shrubs cover the dry, gravelly glacial terraces, with bluejoint grasses lining numerous swales. (EBD Chapter 13 -3PPI and HDR 2011).

Vegetation types in the Mine Site mapping area, including the area and proportion of the mapping area that each type comprises, are listed in Table 3.26-3 and shown in Figure 3.26-2. The Mine Site mapping area is characterized by a predominance of shrub types, representing approximately 80 percent coverage. Among the shrub types, the dwarf shrub group was the most common, accounting for over half of the mapped area. Herbaceous vegetation types represent approximately 10 percent. Forested vegetation types represent less than one percent of the entire mapped area and other land cover types such as open water, partially vegetated, snow, and barren represent less than 10 percent of the mine mapping area. Table 3.26-3 shows the grouped vegetation types within the Mine Site mapping area, the project vegetation types that grouped types are comprised of, and the acreage and percentage of the study area that each type comprises.

Human-caused soil or vegetation disturbance in the Mine Site mapping area was minimal and appeared to be limited to four-wheeler trails or campsites (EBD Chapter 14 - 3PPI and HDR 2011).

Table 3.26-3: Summary of Grouped Vegetation Types and Associated Acreages in the Mine Site Mapping Area

AMERICAN OVERSIGHT

Figure 3.26-2: Mine Site Mapping Area Vegetation

AMERICAN OVERSIGHT

3.26.3 Transportation and Natural Gas Pipeline Corridor Affected Environment

The Transportation/Natural Gas Pipeline Corridor mapping area covers approximately 20,128 acres of the overall mapping area. The mapping area extends eastward from the Mine Site and is generally 2,000-feet wide, centered on the proposed road centerline. It ranges up to 8,000-feet wide for approximately 8 miles on the north side of Iliamna Lake to account for other potential road alignments in this area. The mapping area includes the 24 miles of the Mine Access Road (5 miles of this road falls within the Mine Site mapping area) from the Mine Site to the north ferry terminal at Iliamna Lake, an 18-mile crossing of the lake to the south ferry terminal, and the South Access Road (37 miles) between the lake and Amakdedori Port on Cook Inlet. It also includes spur roads to Iliamna Airport (7 miles) and Kokhanok Airport (1 mile). The pipeline would run adjacent to the road bed shoulder within this mapping area and would cross Iliamna Lake on the lake bed.

The Transportation/Natural Gas Pipeline Corridor crosses multiple watersheds in the Bristol Bay drainage, including the Upper Talarik Creek, Newhalen River on the north side of Iliamna Lake, Gibraltar Lake on the south side, and Iliamna Lake watershed on both sides of the lake. The corridor crosses one main watershed in the Cook Inlet drainage (the Amakdedori Creek-Kamishak Bay watershed) with a very small section crossing the Paint River watershed.

This corridor is located within three physiographic divisions: Nushagak-Big River Hills, Nushagak-Bristol Bay Lowlands, and Aleutian Range. The terrain includes a range of types, from flat to moderately undulating near the Pebble Deposit, gently sloping and colluvial terrain along the north shore of Iliamna Lake, and mountainside slopes and generally rolling terrain to narrow valley bottoms through the Aleutian Range. (Netterman and Reed 1973; EBD Chapter 4 – Knight Piesold Ltd.).

Two ecoregions comprise the Transportation/Natural Gas Pipeline Corridor mapping area, Lime Hills and the Alaska Peninsula. The ecoregion divide starts near Iliamna Lake with most of the Mine Access Road falling within the Lime Hills ecoregion and the ferry terminal and South Access road falling within the Alaska Peninsula ecoregion. The Lime Hills ecoregion is characterized by sharp mountain ridges with steep headwalls and broad U-shaped valleys. This ecoregion supports predominately tall and low shrub communities of willow, birch, and alder. Spruce forests and woodlands are confined to valley bottoms and mountain toeslopes. The Alaska Peninsula ecoregion is characterized by smooth glacial moraines and colluvial shields on the north side and rugged deeply cut fjordlands on the south side. Dominant vegetation is low shrublands of willow, birch, and alder interspersed with ericaceous heath and Dryas-lichen communities. Alpine tundra and glaciers are on mountaintops. (Nowacki et al. 2000, Nowacki et al. 2001).

Vegetation types in the Transportation/Natural Gas Pipeline Corridor mapping area, including the area and proportion of the mapping area that each type comprises, are listed in Table 3.26-4 and shown in Figures 3.26-3 and 3.26-4. This mapping area is characterized by a predominance of shrub types, representing approximately 74 percent coverage. Among the shrub types, the dwarf shrub group was the most common, accounting for approximately 41 percent of the mapped area. Forested vegetation types represent approximately 14 percent of the cover types. Herbaceous vegetation types represent 4 percent of the entire mapped area and other land cover types such as open water, partially vegetated, and barren represent less than 10 percent of the mapping area.

Human-caused soil or vegetation disturbance in the Transportation/Natural Gas Pipeline Corridor mapping area was minimal and appeared to be limited to four-wheeler trails, roads and building pads near the village of Iliamna, Kokhanok Airport, and the shore of Iliamna Lake (EBD Chapter 14 – 3PPI and HDR).

3.26.4 Amakdedori Port Affected Environment

The Amakdedori Port mapping area comprises approximately 3,973 acres of the overall mapping area and is located in the Amakdedori Creek-Frontal Kamishak Bay watershed on the western shoreline of the Cook Inlet. This mapping area is within a region composed of marine, coastal, and estuarine habitats. The mapping area includes an onshore area to encompass shore-based facilities at the port as well as an off-shore area for waterside structures and improvements associated with the marine facility.

The Amakdedori Port lies within the northern part of the Aleutian Range physiographic division (Netternman and Reed 19973) and the Alaska Peninsula ecoregion (Nowacki et al. 2000, Nowacki et al. 2001). Topography is generally flat with dunes located closer to the gravel beach shoreline of Cook Inlet. Dominant vegetation in the Alaska Peninsula ecoregion is low shrublands of willow, birch, and alder interspersed with ericaceous heath and Dryas-lichen communities. Alpine tundra and glaciers are on mountaintops.

Vegetation types in the Amakdedori Port mapping area, including the area and proportion of the mapping area that each type comprises, are listed in Table 3.26-5 and shown in Figure 3.26-5. The Amakdedori Port mapping area extends into the Cook Inlet and therefore is comprised primarily of open water, representing approximately 85 percent of the mapping area. Among the vegetated community types, shrub types are the most common, accounting for approximately 10 percent of the mapped area. Herbaceous vegetation types represent less than 2 percent and other land cover types such as partially vegetated and barren represent approximately 2 percent of the Amakdedori Port mapping area. Forested vegetation types are absent from this mapping area.

No human-caused soil or vegetation disturbance was reported for the Amakdedori Port mapping area.

Table 3.26-5: Summary of Grouped Vegetation Types and Associated Acreages in the Amakdedori Port Mapping Area

Grouped Vegetaion Type[1]	Project Vegetation Types	Number of Acres[2]	Percent of Mapping Area[2]
Open Tall Shrub	OATS, OAWTS, OWTS	34	<1
Closed Tall Shrub	CATS, CAWTS, CWTS	65	2
Open Low Shrub	OALS, OWLS, OAWLS, OSGB, OMSST, LEST, ESB, ODBESB, ODBS	31	<1
Closed Low Shrub	CAWLS, CWLS	1	<1
Dwarf Shrub	DESLT, DEST, DEST-H	317	8
Dry to Moist Herbaceous	BTG, BH, MH, HDG	48	1
Wet Herbaceous	FHM, FSM, SSMWM	24	<1
Open Water	OW	3,381	85
Other	BARE, PV	73	2

Figure 3.26-5: Amakdedori Port Mapping Area Vegetation

AMERICAN OVERSIGHT

3.26.5 Natural Gas Pipeline Corridor Affected Environment – Kenai Peninsula/Cook Inlet

The Natural Gas Pipeline mapping area comprises approximately 380 acres of the overall mapping area and is located in the Stariski Creek-Frontal Cook Inlet. This mapping area includes a 30-foot wide corridor to account for potential temporary construction impacts associated with a buried steel pipeline that would extend eastward from the Amakdedori Port, crossing the seafloor of Cook Inlet for approximately 94 miles, then transition onshore on the Kenai Peninsula to connect to an existing pipeline near Happy Valley. Beginning at the port, the pipeline would be located within the Transportation/Natural Gas Pipeline Corridor, which is discussed above.

The Natural Gas Pipeline Corridor on the Kenai Peninsula lies within the Cook Inlet Basin ecoregion characterized by gently sloping lowlands. Ericaceous shrubs are dominant in open bogs. Mixed forests of white and Sitka spruce, aspen and birch grow on better-drained sites and grade into tall shrub communities of willow and alder on slopes along the periphery of the basin. (Nowacki et al. 2000, Nowacki et al. 2001).

Vegetation types in the Natural Gas Pipeline Corridor mapping area, including the area and proportion of the mapping area that each type comprises, are listed in Table 3.26-6 and shown in Figure 3.26-6. The Natural Gas Pipeline Corridor mapping area crosses the Cook Inlet and therefore is comprised primarily of open water, representing approximately 90 percent of the mapping area. Among the vegetated community types, open/closed forest accounts for approximately 3 percent. Shrub and herbaceous vegetation types each represent less than 1 percent of the mapped area.

Human-caused disturbance in this mapping area is evidenced by the ACCS landcover types Urban, Agriculture, and Road, listed in Table 3.26-6, which were grouped into the “other” vegetation type. This represents 6 percent of the mapping area.

AMERICAN OVERSIGHT

Table 3.26-6: Summary of Grouped Vegetation Types and Associated Acreages in the Natural Gas Pipeline Mapping Area

Grouped Vegetation Type	Landcover Classes[1]	Number of Acres[2]	Percent of Mapping Area[2]
Open/Closed Forest	White Spruce or Black Spruce-Deciduous (Open-Closed), White Spruce or Black Spruce (Open-Closed)	13	3
Open Tall Shrub	Tall Shrub (Open-Closed)	3	<1
Closed Tall Shrub			
Dry to Moist Herbaceous	Herbaceous (Mesic)	2	<1
Wet Herbaceous	Herbaceous (Wet)	<1	<1
Open Water	Freshwater or Saltwater	341	90
Other	Urban, Agriculture, Road	21	6
Total Acreage in Natural Gas Pipeline Mapping Area		**380**	**100**

1 Vegetation mapping for the Natural Gas Pipeline mapping area on the Kenai Peninsula is based on the Alaska Natural Heritage Program, Alaska Center for Conservation Science, Vegetation Map and Classification for Northern, Western, and Interior Alaska (Boggs et al. 2016). The landcover classes were cross-walked into corresponding Grouped Vegetation Types for this project based on the review of dominant growth form (tree, shrub, or herb), vegetation density (open or closed canopy), and average height (tall, low, or dwarf) from each data set. In some instances, a direct correlation was not applicable so the data is summarized using a broader scale. For example, Boggs et al. (2016) vegetation classification does not break down the Tall Shrub landcover type by "Open" and "Closed", so the acreages for this group is combined to report totals for one Tall Shrub category (Open-Closed).

2 All numbers are rounded. Apparent inconsistencies in sums are the result of rounding.

3.26.6 Rare and Sensitive Plants

The ACCS maintains a rare plant list for Alaska, tracking occurrences of over 300 rare plant species (ACCS 2018a; Nawrocki et al. 2013), some of which occur in the project area. However, no special statewide protections are afforded species on this list. ACCS ranks the species with a code that describes their population status on a global level (G-rank) and on a statewide level (S-rank). The status levels are ranked on a scale of one to five, where five is a common species with demonstrably secure populations, and one is a critically imperiled species whose populations are vulnerable to extirpation or extinction. Locations of rare and sensitive plants known or suspected in the mapping area are listed in Table 3.26-7. Precise coordinates of rare or sensitive plants are not provided on the ACCS online database to protect the location of the plants, but general locations are described.

Table 3.26-8 depicts locations of incidental observations of ACCS tracked vascular plant species that were recorded during Pebble Project surveys. In order to be confirmed and receive a state herbarium accession number, voucher specimens must be collected or carefully photographed for review and approval by a qualified botany expert. Researchers collected specimens in some but not all cases. The plant identification status is listed in Table 3.26-8. Observations that have not been confirmed by the University of Alaska Fairbanks herbarium should be considered unverified reports of tracked species.

[Note: Rare and Sensitive Plant Data will be added at a later time].

Table 3.26-8: Rare Plant Species Observed during Project Surveys

Common Name	Scientific Name	ACCS Ranking (Global and State)[1]	Project Vegetation Type	Plot No., Location Description	Plant Identification Verification Status (Voucher Specimen Number)
Mine Site Mapping Area					
Carex bebbii	Bebb's sedge	G5S1	Bluejoint Herb	3PP3845, N of Kaskanak Mt.	Identity not positively confirmed (no voucher specimen)
Transportation/Natural Gas Pipeline Corridor Mapping Area					
Rumex beringensis	Bering Sea dock	G3S3	Dwarf Ericaceous Shrub Tundra	3PP5207,	Dwarf Ericaceous Shrub Tundra
Within Pebble Project Survey Area but Outside of EIS Mapping Area					
Carex crawfordii	Crawford's sedge	G5S3	Bluejoint Herb	3PP13707; Two miles SE of Crazy Lady Lake	Confirmed[2] – voucher transferred to UAF Herbarium
Eriophorum viridicarinatum	Green-keel cottongrass	G5S2	Subarctic Sedge Moss Wet Meadow	3PP16383, NE of sharp Mt.	Identity not positively confirmed (no voucher specimen)
Primula tschuktschorum	Chukchi primrose	G2G3, S2S3	Subarctic Sedge Moss Wet Meadow	3PP9789, Three miles N of Kaskanak Mt.	Confirmed[2] – voucher transferred to UAF Herbarium
			Bluejoint Herb	3PP20066a -20067, 1.5 miles E of Cone (Black) Mt.	Identity not positively confirmed (no voucher specimen)
			Subarctic Sedge Moss Wet Meadow	3PP09557, One Mile N of Cone (Black) Mt.	Identity not positively confirmed (voucher specimen collected)
Rumex beringensis	Bering Sea dock	G3S3	Mesic Herb	3PP16329, Between Newhalen and Upper Talarik River	Confirmed[2] – voucher transferred to UAF Herbarium
			Partially Vegetated	3PP2147, Six miles SE of Koktuli River confluence	Confirmed[2] – voucher transferred to UAF Herbarium

AMERICAN OVERSIGHT

Table 3.26-8: Rare Plant Species Observed during Project Surveys

Common Name	Scientific Name	ACCS Ranking (Global and State)[1]	Project Vegetation Type	Plot No., Location Description	Plant Identification Verification Status (Voucher Specimen Number)
			Mesic Herb	3PP10506, Between Newhalen and Upper Talarik River	Confirmed[2] – voucher transferred to UAF Herbarium
			Partially Vegetated	3PP7947, Between Newhalen and Upper Talarik River	Confirmed[2] – voucher transferred to UAF Herbarium
			Open Willow Low Shrub	3PP8369, Unknown	Identity not positively confirmed (no voucher specimen)
Stellaria umbellata	Unspecified starwort	G5, S2S3	Open Willow Low Shrub	3PP8369, Unknown	Identity not positively confirmed (no voucher specimen)
Elocharis kamtschatica	Kamchatka spikerush	G4, S2S3	Halophytic Graminoid Wet Meadow	HDR 1265 Iniskin Bay	Confirmed[2] - voucher specimen was transferred to UAF Herbaruim (MD04-388 and HDR 1265)

1 ACCS ranks plants with a code that describes their population status on a global (Gx) and on a statewide (Sx) level, where X represents a rank from 1 to 5, where 5 is a common plant with demonstrably secure populations, and 1 is a critically imperiled plant whose populations are vulnerable to extirpation or extinction. If a rank is uncertain, it is described as a range between two numbers (for example, S2S3) or with a question mark (for example, G5?). Tracked species are those with a state ranking of S1 through S4.

2 Identify of voucher specimen was confirmed by C. Parker of the University of Alaska Fairbanks herbarium.

Subject: RE: Pebble Project Draft EIS - Chapter 2 Figures

Hello everyone – I want to note that there are five figures that are not yet ready. We believe these figures will add value to the chapter for lay readers but are not necessary for agency reviewers to understand the alternatives. We will provide the missing figures when available. Thanks, Bill

All,
Attached are some of the documents for your agencies review. I will continue forwarding information including an agenda and location, draft scoping report, draft Chapter 2 and draft chapter and other materials, so your team has a chance to review and provide you with items to bring up at the managers meeting. Please also note the project website will have this info on it as soon as possible.

I will send all of the information received to date, not requesting comments, but rather for visibility for all. It will be in several emails.

VR,

Shane

Subject: Pebble Cooperating Agency Meeting
When: Wednesday, October 24, 2018 12:30 PM-4:30 PM (UTC-09:00) Alaska.
Where: Atwood Conference Center Room 106, 550 W 7th Avenue, Anchorage

Attached are slides for today's cooperating agency meeting.

<< File: 20181024 Cooperating Agency Meeting.pdf >>
Shane will be providing additional information on the meeting next week but asked that I send the teleconference and WebEx information. Additional materials/handouts will be distributed before the meeting for those calling in.

Draft Agenda:
1. Review of alternatives to be analyzed in detail
2. Format and level of detail for Chapter 2
3. Update on Appendix B (addressing USACE/CA comments, next version will be Draft EIS)
4. Review of select alternatives:
a. Filtered tailings (dry stack)
c. Other mine locations
d. Underground mining

AMERICAN OVERSIGHT

APPENDIX B – ALTERNATIVES DEVELOPMENT PROCESS

AMERICAN OVERSIGHT

1.0 PURPOSE OF APPENDIX

This appendix further explains the alternatives development process for the Pebble Project; summarizes each step of the process; and provides the option screening criteria and results for evaluation of a reasonable range of alternatives in the Environmental Impact Statement (EIS).

1.1 CONTEXT AND REQUIREMENTS

The federal regulations governing the National Environmental Policy Act (NEPA) state in 40 CFR 1502 that the alternatives section "is the heart of the environmental impact statement." The regulations require federal agencies to "rigorously explore and objectively evaluate all reasonable alternatives and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated." The Council on Environmental Quality (CEQ) guidance clarifies that:

> *In determining the scope of alternatives to be considered, the emphasis is on what is 'reasonable' rather than on whether the proponent or applicant likes or is itself capable of carrying out a particular alternative. Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant.* [1]

Alternatives screening is also pertinent to Clean Water Act (CWA) 40 CFR Part 230 Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material (hereafter identified as 404(b)(1) guidelines), which require the analysis of practicable alternatives to the proposed discharge. The 404(b)(1) guidelines specify that:

> *Except as provided under Section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. (40 CFR 230.10(a)).*

The 404(b)(1) guidelines define a practicable alternative as one that is "available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes" (40 CFR 230.10(a)(2)).

For actions subject to NEPA, where the U.S. Army Corps of Engineers (USACE) is the permitting agency, the analysis of alternatives required for NEPA environmental documents will in most cases provide the information for the evaluation of alternatives under the 404(b)(1) guidelines. The alternatives development process for the Pebble Project considers a broad range of alternatives in sufficient detail to address both NEPA and CWA Section 404(b)(1) requirements.

1.2 OVERVIEW OF THE ALTERNATIVES DEVELOPMENT PROCESS

Scoping yielded a wide variety of comments that provide input to the alternatives development process. The EIS team used a structured alternatives development process to recognize the project's large geographic footprint, the various project components, and the substantive input in scoping by the public, stakeholders, and agencies.

To fully consider the wide range of issues identified in the scoping comments, this alternatives development process used the concept of "options," which consist of variations of components of the proposed project. For example, an option for transporting concentrate from the mine site could

[1] Council on Environmental Quality, Executive Office of the President, Memorandum to Agencies: Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations. 46 Fed. Reg. 18026 (March 23, 1981) As Amended (1986).

AMERICAN OVERSIGHT

be a slurry pipeline instead of using trucks. Individual pipeline route variations would also be considered as options.

The four steps followed for alternatives development are summarized below.

Step 1: Developed the criteria for screening options to the proposed action. To narrow the range of options considered in detail in the EIS, criteria were organized around four screening tests. Each option must: 1) meet the purpose and need; 2) be reasonable; 3) be practicable in light of the overall project purpose; and 4) not increase adverse environmental impacts. The screening criteria are more fully described in Section 1.4, below.

Step 2: Identified options to address scoping concerns, compiled options that were suggested during the scoping process, and identified options that were previously evaluated by Pebble Limited Partnership (PLP) when developing the proposed project design. These options represented the initial range of alternatives and are identified in Table B-1, and organized by project component.

Step 3: Applied screening criteria from Step 1 to the options developed in Step 2. The criteria were used to determine reasonable options for detailed analysis in the EIS. Results of this screening are included in Table B-1, including rationale for the options dismissed from further analysis.

Step 4: Packaged options that met all of the screening criteria into viable action alternatives for detailed analysis in the EIS (i.e., an action alternative is a complete functioning project that includes power, a port, transportation, and mine site facilities).

1.3 SCREENING CRITERIA FOR THE FULL RANGE OF ALTERNATIVES

The EIS team screened options around four criteria, described below. The criteria screening steps were followed sequentially. If an option clearly did not meet one of the test-screening criteria, it was dismissed from further consideration, and did not proceed to the subsequent screening tests.

The objective of these criteria was to guide the screening process, but not to mechanically generate outcomes that substitute for professional judgment. By nature, these criteria were not fine filters. It was not the purpose of the option screening process to judge between trade-offs or make close calls, which would instead be addressed in the analyses within the EIS.

1.3.1 Screening – Purpose and Need

The project purpose and need is a key element of alternatives development. The purpose and need statements for the project are provided in Chapter 1 of the EIS.

The overall project purpose, determined solely by USACE, is used for evaluating practicable alternatives under the 404(b)(1) guidelines, and was therefore used as the first screening test. The overall project purpose must be specific enough to define the applicant's needs, but not so restrictive as to preclude discussion of a range of alternatives. USACE has determined that the overall project purpose is to develop and operate a copper-gold-molybdenum mine in Alaska to meet current and future demand for commodities, including copper, gold, and molybdenum.

Options that did not meet the USACE's determination of overall project purpose were dismissed from consideration as an action alternative option for evaluation in the EIS, and did not proceed to the subsequent screening test.

AMERICAN OVERSIGHT

1.3.2 Screening – Reasonable Options

Screening criteria for reasonable options drew on the NEPA regulatory intent of reasonable alternatives, which includes those that are practical or feasible, using common sense. Options that would not pass this test of reason include:

- Those that are not practical because they would not allow the mine operator to generate profit.
- Those that could not feasibly attain most of the basic objectives of the project.
- Those suggested during scoping that are not specific or are substantially similar to other options being considered.
- Those suggested during scoping that were based on a misunderstanding of the proposed project, regulations, or conclusions of other reports or studies.

This screening test for reasonable options is limited to the general factors listed above. Screening for technical, economic, and logistic considerations is included in the subsequent screening test for practicable options.

Options that were assessed as not reasonable were dismissed from consideration as an action alternative option for evaluation in the EIS, and did not proceed to the subsequent screening test.

1.3.3 Screening – Practicable Options

Only options that are determined to be practicable based on the 404(b)(1) guidelines can be considered by USACE during the permit decision process. Therefore, options that progressed through the screening criteria above were evaluated for practicability.

In terms of practicability, the 404(b)(1) guidelines provide a two-fold definition of a practicable alternative (40 CFR 230.10(a)(2)):

1. A practicable alternative is one that is available and capable of being done after taking into consideration cost, existing technology, and logistics.
2. The three practicability criteria (cost, existing technology, and logistics) apply in light of the overall project purpose.

Cost or economic practicability considers the relative cost effectiveness of technologically feasible and operationally efficient component options. If project costs of implementing an option exceed reasonable or practical limits, the option could be considered not practicable. In the screening stage, rough order-of-magnitude cost comparisons were made, because detailed engineering and costs could not reasonably be developed for each option. Where the order-of-magnitude cost review is not sufficient to decide whether an option is economically practicable, it will be advanced for additional review, and additional information will be gathered before reaching a screening conclusion.

The practicability considerations of existing technology and logistics are evaluated to minimize the risk of an option causing a component to be unable to perform its intended function efficiently. Options that make project components too complex or use unproven technology increase the risk of operational failure and accidents. Options identified for a specific project component may be subject to technical constraints that affect the workability of the option. For example, topography, resource needs, spatial relationships of one component to another, temporal sequences, operating considerations, or engineering data for a specific option may influence whether a particular option is capable of meeting the project objectives. The existing technology and logistics criteria consider the ability of each option in meeting these challenges.

AMERICAN OVERSIGHT

Options that were assessed as clearly not practicable in terms of cost, existing technology, and logistics in light of the overall project purpose were dismissed from consideration as an action alternative option for evaluation in the EIS, and did not proceed to the subsequent screening test.

1.3.4 Screening – Environmental Impacts

The 404(b)(1) guidelines require an evaluation of both practicability and environmental effects to determine whether there are practicable alternatives to the proposed project that would have less adverse impacts on the aquatic ecosystem, so long as the alternative does not have other significant environmental consequences (40 CFR 230.10(a)). Therefore, options that progressed through the screening criteria above were evaluated and compared for their relative extent and nature of impacts on the physical, biological, and socioeconomic environments.

Based on this assessment, options that clearly have a high potential to increase the overall adverse environmental impacts were dismissed from further consideration as an action alternative option for evaluation in the EIS. Options that have potentially greater adverse impacts to one or more resources, but potentially fewer adverse impacts to other resources (i.e., trade-off of adverse impacts but may not be an overall increase), and options that clearly provide avoidance or minimization advantages (i.e., an environmental benefit) progressed as viable options to be evaluated as components of action alternatives in the EIS. Additionally, should two feasible options be generated to avoid or minimize an impact, but one of those options was determined to have potentially greater adverse impact on the environment—the option with greater impacts may be recommended for elimination from further study.

1.4 ALTERNATIVES DEVELOPMENT RESULTS

The USACE and cooperating agencies reviewed the outputs of each step in the alternative development process. The end result was to identify a reasonable range of action alternatives for full analysis in the EIS. PLP's proposed project is the proposed action for analysis in this EIS. Table B-1 provides details on the options considered, the screening results, and the status of each option (i.e., proposed action, alternative, or dismissed). The components and subcomponents of PLP's proposed action are included in Table B-1 for comparative purposes. Figure B-1 depicts the access and pipeline alignments considered. Figure B-2 illustrates the mine layout option considered.

The options that met screening criteria and marked as alternatives in Table B-1 were packaged into action alternatives (i.e., an alternative must be a functioning project and include power, a port, transportation, and mine facilities). As a result of this alternatives development process, two action alternatives were identified for detailed analysis in the EIS. The action alternatives vary from the proposed action in key engineering design, siting, and operational features. These alternatives address concerns raised in scoping and provide a reasonable range of alternatives for comparison. Action alternatives are described in Chapter 2 of the EIS.

NEPA regulations also require that a No Action alternative be analyzed. In this case, the No Action alternative would assume that the mine, transportation facilities, port, and pipeline would neither be permitted nor constructed as currently proposed.

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Location – Pebble Project / Deposit	LOC-001	***Origination*** – Pebble Limited Partnership (PLP) Proposed Action ***Description*** – The proposed project involves development of a copper-gold-molybdenum porphyry deposit (Pebble Deposit) located on state land in the Bristol Bay region of southwest Alaska.	☑ Proposed ☐ Alternative ☐ Dismissed
Location – Whistler Project	LOC-002	***Origination*** – Evaluation of alternative mine location options for mining copper, gold, and molybdenum was suggested during scoping. Based on the project Purpose and Need Statement "to develop and operate a copper-gold-molybdenum mine in Alaska in order to meet current and future demand for commodities, including copper, gold, and molybdenum", potential copper-gold-molybdenum porphyry and massive sulfide deposits in Alaska that are in exploration or advanced exploration were assessed. ***Description*** – The Whistler mineral property is a gold-copper porphyry deposit located in the Yentna mining district northwest of Anchorage. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Whistler was classified as an exploration-phase project by Giroux (2016). Exploration to date at the Whistler property has characterized 122 million tons (versus 6.5 billion tons of measured and indicated for Pebble) of resources (gold, copper, and silver) as indicated—no resources have been characterized as measured. Gold resources are estimated at 1.77 million oz, copper at 343 million lb, and silver at 6.13 million oz. To date, over 230,000 feet of core have been drilled, and exploration expenditures exceed $50 million. By comparison, exploration to date at Pebble has characterized 6.5 billion tons of measured and indicated resources; measured and indicated gold estimates are 70.6 million oz, copper at 56.9 billion lb, silver at 345 million oz, and molybdenum at 3.4 billion lb (note that there are no molybdenum resources identified in the Whistler deposits); and PLP expenditures to date on exploring	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		and developing the Pebble Project are over $850 million. Based on the exponential difference in resources and expenditures, it is concluded that this option is not reasonable because it is not economically feasible for PLP to acquire and develop the Whistler property. The Whistler property is not as advanced as the Pebble Project—no environmental, social, or community studies have been undertaken for the Whistler property; capital and operating costs have not been developed; and no economic analysis has been completed (Giroux 2016). Recommendations presented by Giroux (2016) are for additional drilling throughout the Whistler deposits. ***Why Dismissed*** – This option is not reasonable because it would not allow the mine operator to generate a profit.	
Location – Pyramid Project	LOC-003	***Origination*** – Evaluation of alternative mine location options for mining copper, gold, and molybdenum was suggested during scoping. See LOC-002 regarding Purpose and Need. ***Description*** – Pyramid is a copper-gold-molybdenum porphyry deposit located on the southwestern tip of the Alaska Peninsula southwest of Anchorage. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Pyramid was classified as an early-stage exploration project by SRK (2018). Exploration to date at the Pyramid property has characterized only inferred resources of 24.5 million tons of copper,74 million tons of molybdenum, and 488,000 ounces of gold. Through 2017, the amount of core drilling at Pyramid was 42,100 feet, compared with over 1 million feet of core drilling at Pebble. Therefore, it is concluded that this option is not reasonable because resources at Pyramid are inferred, but not measured/indicated; are	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		exponentially less than those measured/indicated at the Pebble Project; and that based on the amount of money expended to date by PLP (over $850 million) to explore and develop the Pebble Project, it is not economically feasible for PLP to acquire and develop this property. ***Why Dismissed*** – This option is not reasonable because it would not allow the mine operator to generate a profit.	
Location – Outside of Alaska	LOC-004	***Origination*** – Evaluation of alternative mine location options for mining copper, gold, and molybdenum was suggested during scoping. ***Description*** –This option involves acquisition, development, and operation of a copper-molybdenum massive sulfide deposit located outside of Alaska. ***Screening*** – 1. Purpose and Need Test: Does not meet the U.S. Army Corps of Engineer's (USACE's) overall project purpose to develop and operate a copper-gold-molybdenum mine in Alaska. ***Why Dismissed*** – This option does not meet the purpose and need of the project.	☐ Proposed ☐ Alternative ☑ Dismissed
Location – within Alaska	LOC-005	***Origination*** – Evaluation of alternative mine location options for mining copper, gold, and molybdenum was suggested during scoping. ***Description*** –This option involves development and operation of a multi-metals massive sulfide deposit located in of Alaska. ***Screening*** – 1. Purpose and Need Test: Meets the Purpose and Need 3. Reasonable Test: Five massive sulfide deposits in Alaska (Arctic, Delta, Niblack, Palmer, and Sun) were evaluated. Indicated resources ranged from 26	**Status under review**

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		million tons (Arctic) to no indicated resources (Delta and Palmer). By contrast, for the Pebble deposit over 12 billion tons of measured (591 million tons), indicated (6.5 billion tons), and inferred (4.9 billion tons) resources are reported. Therefore, it is concluded that this option is not reasonable because resources at the five massive sulfide deposits are at best indicated at 26 million tons but mostly inferred, and are exponentially less than those measured/indicated at the Pebble Project. Based on the amount of money expended to date by PLP (over $850 million) to explore and develop the Pebble Project, it is not economically feasible for PLP to acquire and develop these properties. ***Why Dismissed*** – This option is not reasonable because it would not allow the mine operator to generate a profit.	
Layout – Mine Layout Option 3	LAY-001	***Origination*** – PLP's May 11, 2018 update changed the proposed mine layout to Mine Layout Option 3, which will be the basis for PLP's application moving forward. ***Description*** – This option is part of the Proposed Action, which is based on a mining plan that sends all ore directly to the mill. It has two separate Tailings Storage Facilities (TSFs); a lined pyritic TSF with space to store potentially acid-generating (PAG) waste in the North Fork Koktuli River (NFK) East site; and an unlined bulk tailing TSF in the NFK West site. A lined water management pond (WMP) would be situated in the NFK North site. The bulk TSF would have a dry closure. The pyritic tailings and PAG waste would be relocated to the pit lake at closure, and the pyritic TSF and WMP would be reclaimed. This option facilitates post-closure placement of PAG waste and pyritic tailings in the pit lake, and enables a higher efficiency for the storage of bulk tailings. This option removes the need to store low-grade ore and manage associated runoff, and provides greater water storage capacity for upset conditions. The WMP is downgradient of impacted areas, facilitating capture and storage of extreme runoff events. This option	☑ Proposed ☐ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		also allows for safe, passively managed long-term storage of the pyritic tails and PAG waste in the pit lake.	
Layout – Mine Layout Option 1	LAY-002	***Origination*** – This mine layout option was PLP's Proposed Action in the December 2017 Department of the Army (DA) permit application. PLP's May 11, 2018 update changed the proposed mine layout to Option 3 (LAY-001). ***Description*** – This option is based on a mining plan that requires stockpiling capacity for lower-grade ore (LGO) that is processed late in the mine life. A single TSF with separate cells for bulk and pyritic tailings would be constructed in the NFK West site, with an internal embankment between the cells. The pyritic TSF would be lined. The bulk TSF would not be lined. PAG waste and LGO would be stored in a lined facility in the NFK East site. WMPs would be constructed north of the NFK East site. The bulk TSF would have a dry closure. The pyritic TSF would have a wet closure. The LGO/PAG waste storage facility would be reclaimed. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable mine layout option. 3. Practicable Test: This layout was originally part of PLP's proposed action, and is assumed practicable in terms of cost, existing technology, and logistics. 4. Environmental Impacts Test: The smaller WMP would reduce the total footprint and impacts to wetlands. However, this option requires maintenance of the pyritic TSF in a subaqueous state, and seepage collection into perpetuity. The exposed LGO and PAG waste rock would also be likely to become acidic when exposed to the atmosphere, resulting in acidic drainage and increased metals leaching. There is significant public concern that tailings could flow from a dam failure, and doubt that a TSF can be maintained in a subaqueous state into perpetuity.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Why Dismissed – This option would increase overall adverse impacts. Although there would be a reduction in some impacts from the smaller WMP, the need to maintain the pyritic TSF and capture and treat seepage water into perpetuity makes this option more environmentally damaging than the proposed LAY-003. Additional water quality impacts would result from storing the LGO and PAG waste rock in open stockpiles. Although mitigation in the form of collecting and treating the water could be effective, preventing the LGO and PAG waste rock from becoming acidic is preferable.	
Layout – Mine Layout Option 2	LAY-003	***Origination*** – This mine layout option was evaluated by PLP when developing the proposed project design. ***Description*** – This option is based on a mining plan that would send all ore directly to the mill. The TSF would be constructed in the NFK West site, and consist of a single cell with an internal area to store the pyritic tailings so that they remain subaqueous. A lined WMP with space to store PAG waste would be constructed in the NFK East site. The tailings would have wet closure, and the WMP would be reclaimed. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable mine layout option. 3. Practicable Test: This option is practicable. It requires less fill material, because there is no internal embankment, and it requires that all tailings be maintained in a subaqueous state in perpetuity. There are no proven methods of segregating two tailings streams in one cell that would permanently keep the pyritic tailings separate from the bulk tailings during operations, as the TSF progressively increases in size, to prevent the co-mingling of the two supernatant waters, and prevent contact of the two entrained waters concurrently with maintaining the flow-through seepage concept of the bulk TSF.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		4. Environmental Impact Test: Seepage water quality for the main embankment would be impacted by the pyritic tails. Re-handling of the pyritic tails for storage in the pit lake would be precluded, and they would need to be maintained in a subaqueous state into perpetuity. The dam would need to be inspected and maintained into perpetuity to prevent dam failure and tailing flows. Removes need to store LGO and manage associated runoff. Provides greater water storage capacity for upset conditions. ***Why Dismissed*** – This option would increase overall adverse impacts from reduced seepage water quality and the requirement to maintain the TSF into perpetuity.	
Mine Size – EPA Restricted Mine Size	LAY-004	***Origination*** – An alternative suggested during scoping was to restrict the size of the mine to what the EPA found appropriate in the 2014 Watershed Assessment. ***Description*** – This option would restrict the size of the mine to what the EPA found appropriate in the 2014 Watershed Assessment. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This option is not reasonable because EPA did not make a determination in the Watershed Assessment that any of the three mine scenarios they considered would be "appropriate." ***Why Dismissed*** – This is option is not reasonable. See LAY-005, which considers the smallest mine size scenario EPA considered. LAY-004 is dismissed because the suggestion is based on a misunderstanding of the EPA Watershed Assessment, and is likely the same—or very similar to—LAY-005.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Mine Location and Layout Options			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Mine Size – Smaller Mine Pit Size	LAY-005	***Origination*** – Consideration of a smaller pit mine size was evaluated by USACE as a potential means to reduce project footprint, as well as surface, water, and other environmental impacts. ***Description*** –This option examines the Pebble 0.25 mine scenario, the smallest mine size considered by the EPA in the 2014 Watershed Assessment. Under this option, 0.23 billion metric tons of ore would be mined, with a throughput of 31,100 metric tons per day (tpd). ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This option is not reasonable because it would not allow a profitable project, considering the investment in infrastructure that would be required. See TPD-002 for evaluation of the 50,000 tpd option. An optimization study showed that option TPD-002 would not have a positive net present value, due to the fixed infrastructure component of the costs. ***Why Dismissed*** – This option is not reasonable because it would not allow the mine operator to generate a profit. See also TPD-002.	☐ Proposed ☐ Alternative ☑ Dismissed
Mine Size – Larger Mine to Develop More of the Known Deposit	LAY-006	***Origination*** – Evaluation of options to maximize the potential economic benefits of developing the deposit, such as a larger and longer-lived mine, was suggested during scoping. ***Description*** –This option would increase the mine site and duration of operations to develop more of the known and inferred resource of the overall deposit. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

		2. Reasonable Test: The proposed project would only develop 10 percent of the measured, indicated, and inferred resource. It is reasonable to consider if additional resources can be developed without increased impact. 3. Practicable Test: Practicability is unknown at this time, but Northern Dynasty has communicated to shareholders that expanded development is possible (Northern Dynasty 2013). 4. Environmental Impacts Test: This option would increase environmental impacts by generating additional tails and other noneconomic material that would need to be stored on site. Additionally, the mine would operate longer, prolonging the duration of operations impacts. ***Why Dismissed*** – This option would increase overall adverse impacts. Although this option fails the test to be considered as an alternative in the Environmental Impact Statement (EIS), an expanded mine will be considered in cumulative effects in Chapter 4 of the EIS.	

AMERICAN OVERSIGHT

Mining Type – Surface Mining	MNG-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action, which includes developing the resource using open pit mining methods.	☑ Proposed ☐ Alternative ☐ Dismissed
Mining Type – Underground Mining	MNG-002	***Origination*** – Underground mining was evaluated by PLP when developing the proposed project design, and was suggested for consideration during scoping. ***Description*** – This option would develop the resource using underground mining methods. The proposed project would develop the portion of the deposit that is close to the surface. If the mine were expanded in the future (see LAY-006), underground methods such as block caving would likely be proposed. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Evaluating underground mining methods is reasonable for an EIS. 3. Practicable Test: The portion of the Pebble Deposit proposed to be mined is at the surface, with minimal overburden or overlying waste rock. Underground mining of this portion of the deposit would be expected to result in a mine roof collapse, ground surface subsidence, and sinkhole formation. Existing underground mining techniques cannot be used to mine the proposed project because the remaining surface material would collapse. ***Why Dismissed*** – This option is not practicable using existing technology for the portion of the deposit that is proposed to be mined. Underground block caving is a method that would be considered in the future if mine expansion is proposed (PLP RFI 062 Response). An expanded mine scenario is considered in the EIS, Chapter 4, under cumulative impacts.	☐ Proposed ☐ Alternative ☑ Dismissed

Material Handling – Truck and Shovel	MNG-004	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action, which involves use of large shovels to load ore into haul trucks. The trucks would transport the ore from the pit to the crusher.	☑ Proposed ☐ Alternative ☐ Dismissed
Material Handling – In-Pit Crushing and Conveying	MNG-005	***Origination*** – In-pit crushing and conveying was evaluated by PLP when developing the proposed project design. PLP completed an engineering evaluation of in-pit crushing and conveying in response to Request for Information (RFI) 032, which requested feasibility information for several project options. ***Description*** – This option would use in-pit crushing and conveying methods for material handling that would begin several years into the start of operations, and operate through the end of the mine life. This option would require the excavation of a dedicated crusher pocket and ramp to transport ore via a conveyor to the processing facility. The additional excavation associated with the crusher pocket and ramp would generate additional PAG waste, which would exceed the space available for PAG waste storage in the pyritic TSF, and require the development of a separate PAG waste storage facility. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable material handling option. 3. Practicable Test: In-pit crushing is a practicable material handling option, but it is more commonly implemented at some point later in mine life, as the open pit is developed, and the installed crushing and conveying system can remain stationary for an extended period. 4. Environmental Impacts: This option would provide only a limited net reduction in trucking, and therefore diesel consumption and emissions; but would increase the overall impacted footprint and wetland impacts because of the crusher	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Mining			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		pocket and ramp infrastructure and the need to create a separate PAG waste storage facility. ***Why Dismissed*** – This option would increase overall adverse impacts, with only a limited net saving in terms of diesel fuel usage and net emissions.	
Truck Fuel – Diesel	MNG-006	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action, in which large-haul trucks are equipped with diesel engines and would use most of the anticipated diesel supplies. This option requires the shipment of diesel to the Mine Site.	☑ Proposed ☐ Alternative ☐ Dismissed
Truck Fuel – Liquefied Natural Gas	MNG-007	***Origination*** – Liquefied natural gas (LNG) for truck fuel was evaluated by PLP when developing the proposed project design. Use of alternative truck fuel was also suggested during scoping. ***Description*** –Under this option, LNG would be produced using an on-site plant consisting of modules that could be trucked, and LNG storage tanks manufactured off site. An engineered footprint for the facility has not been developed, but it would have a footprint of approximately 1 acre, based on similar facilities reviewed. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Using LNG haul trucks is reasonable, because equipment manufacturers such as Caterpillar have been actively working to develop commercially available LNG powered haul trucks. 3. Practicable Test: On-site production of LNG would be feasible because there would be a natural gas pipeline to the Mine Site and LNG plants of the size required are readily available and transportable. However, LNG powered haul trucks are not commercially available for the mining industry and are not proven	☐ Proposed ☐ Alternative ☑ Dismissed

Table B-1: Preliminary List of Project Options Being Considered

Processing			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Facility Location/ Process Type – On-site Concentrate Production	PRO-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action in which the initial processing of ore would be conducted on site to produce a concentrate that would be transported off site for smelting. PLP estimates the annual production to be approximately 660,000 tons of copper-gold concentrate and 16,500 tons of molybdenum concentrate.	☑ Proposed ☐ Alternative ☐ Dismissed
Facility Location– Off-site Ore Processing	PRO-002	***Origination*** – Off-site ore processing was evaluated by PLP as an option when developing the proposed project design. Evaluation of alternative locations for ore processing was also suggested during scoping. ***Description*** – Off-site ore processing would involve transporting all ore away from the project area for processing. This would involve transportation of 180,000 tons of ore from the mine site to the mill site daily. This would require approximately 100 times the proposed truck, ferry, lightering barge, and ship traffic. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider off-site transport if it would reduce the size and impact of mine site facilities such as the tailings storage facilities. 3. Practicable Test: Off-site processing presents a series of challenges in terms of cost and logistics which likely make this option not practicable. Associated issues are as follows: • Introduces inefficiencies as it requires the use of large amounts of energy and equipment to transport the non-mineralized portion of the ore. • Requires transportation of more than 100 tons of unprocessed rock every minute which would require almost continuous truck traffic, 24 hours per day every day of the year.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Processing			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		• The increased amount of infrastructure required off site and for transportation purposes would broaden the project footprint. • Off-site processing would result in increased project costs. 4. Environmental Impact Test: There would be increased traffic and potentially additional infrastructure required to transport the rock resulting in elevated air emissions, diesel consumption, visual impacts, noise levels, dust, wildlife impacts, and wetland impacts. Increases risk of accidents and spills caused by adverse road conditions, inclement weather, landslides, debris blockages, etc., that would require emergency vehicles and could further impact the environment and temporarily block the transport corridor. ***Why Dismissed*** – This option would increase overall adverse impacts and would likely not be practicable in terms of costs and logistics.	
Facility Location /Process Type – On-site Ore Processing (Metal Production)	PRO-003	***Origination*** – On-site metal processing was evaluated by PLP as an option when developing the proposed project design. ***Description*** – On-site ore processing would construct a smelter and produce metals on site (copper, gold, and molybdenum) instead of a concentrate product. On-site smelting would require additional land for the facility and disposal of smelting waste. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider this option if it would reduce transportation impacts. 3. Practicable Test: On-site ore processing is likely feasible in terms of technology but smelting at a large existing established ore processing facility would be much less expensive.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Processing			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		4. Environmental Impacts Test. On-site smelting would reduce trucking and ship traffic but increase mine site air emissions. Increased air emissions would result from increased natural gas usage (thermal heating of the ore and increased power generation) and heavy metals escaping the ore heating step. The additional smelting and waste disposal facilities would increase wetland impacts. ***Why Dismissed*** – This option would increase overall adverse impacts.

Throughput			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
180,000 tons per day	TPD-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which includes mine throughput of 180,000 tpd over a 20 year mine life. It is a revision of the previously proposed 160,000 ton per day throughput. A throughput of 180,000 tpd eliminates the need for a LGO/PAG storage facility that would require four additional years of processing at the end of operations. This option reduces the mine footprint from the originally proposed 160,000 tpd throughput.	☑ Proposed ☐ Alternative ☐ Dismissed
50,000 tons per day	TPD-002	***Origination*** – This option was evaluated by PLP as an option when developing the proposed project design. ***Description*** – Mine throughput of 50,000 tpd with a mine life of 71 years. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: An optimization study showed that this option does not provide a positive financial return. The small throughput of the 50,000 tons per day project does not have a positive net present value, due to the fixed component of the costs. It is not reasonable to consider an option that would not provide a positive financial return. ***Why Dismissed*** – This option is not reasonable because it would not allow the mine operator to generate a profit.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Throughput			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
160,000 tons per day	TPD-003	***Origination*** – This option was evaluated by PLP as an option when developing the proposed project design. ***Description*** – This throughput option of 160,000 tpd would require construction of a large lined pad for storing potentially acid generating LGO until this ore would be processed during the later years of mine operations. This option was replaced by the 180,000 tpd throughput as the Proposed Action production parameter. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider this option because it was proposed by PLP originally. 3. Practicable Test: This size plant is appropriately sized to efficiently process the targeted 1.5 billion ton ore resource using a standard processing plant design and equipment. An optimization study has demonstrated that this option produced a positive financial return. 4. Environmental Impacts Test: A lower throughput is based on previous project designs to store the LGO and PAG waste rock in a separate location for processing in the last four years of operation. This design would create additional mine facility footprint that would need to be restored at the time of closure. There would be no change in the footprint of other mine and transportation facilities compared to the 180,000 tons per day option. The LGO stockpile would generate poor quality run-off water and seepage (acid rock drainage and metals leaching) that would need to be collected, managed, and treated. ***Why Dismissed*** – This option would increase overall adverse impacts.	☐ Proposed ☐ Alternative ☑ Dismissed
320,000 tons per day	TPD-004	***Origination*** – This option was evaluated by PLP as an option when developing the proposed project design.	☐ Proposed ☐ Alternative

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Throughput			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Description – Mine throughput of 320,000 tpd over an 11 year mine. It is assumed that this throughput option would result in the same mine pit and TSF footprint over a shorter period. Due to higher production levels, it would likely increase the size of the processing facilities, accelerate the tailings deposition rate and TSF embankments raise schedule, and increase the volume of concentrate transported over a shorter period of time. This in turn would increase the volume of truck and ferry traffic on the transportation system, and increase activities associated with the port facility, including the number of lightering and marine ore transport vessels. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider higher throughput rates. 3. Practicable Test: Construction and commissioning of a new plant this size would present significant execution, manpower, logistical, cost management, and other challenges that elevate project risk. It would require additional processing facilities. The significantly shorter mine life is not long enough to ensure that project operations can pass through several economic cycles and potential fluctuation in metals prices. However, it is likely practicable. 4. Environmental Impacts Test: This option would cut the life of mine operations nearly in half, reducing the time period of operational impacts. The footprint of mine pit and tailings storage facilities would remain the same, but would require addition footprint for processing facilities. This throughput level would nearly double the volume of ore processed over the Proposed Action, increasing the volume of ore concentrate truck traffic on the road and ferry system. It would also increase the frequency of activities associated with marine transport, including lightering operations and marine ore ship traffic.	☑ Dismissed

Gold Recovery			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
Gravity	GR-001	***Origination*** – PLP Proposed Action ***Description*** – The proposed option is to use gravity separation methods to recover gold.	☑ Proposed ☐ Alternative ☐ Dismissed
Secondary Gold Recovery	GR-002	***Origination*** – The use of a cyanide leach circuit for ore recovery was examined by PLP and recommended for consideration in scoping comments as a means to increase the efficiency of ore recovery. ***Description*** –This option involves construction of a cyanide leach circuit at the mine site to process the pyritic tails. A cyanide leach circuit could recover additional gold from the process. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable option. 3. Practicable Test: Cyanide leaching is a common practice and would likely be technologically and economically feasible. 4. Environmental Impacts Test: Cyanide is toxic to aquatic organisms, wildlife, and humans. PLP has proposed to forgo a cyanide leach circuit and the additional gold recovery it would provide because of public concern for the use and transportation of cyanide. The leach facility would have a large footprint that would impact wetlands. ***Why Dismissed*** – This option would increase overall adverse impacts.	☐ Proposed ☐ Alternative ☑ Dismissed

Table B-1: Preliminary List of Project Options Being Considered

Power			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Power Source – Thermal (Burn Natural Gas)	POW-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which involves power generation using natural gas as a fuel source. PLP is proposing to build a power plant at the Mine Site with a capacity of 270 MW. The plant would be fueled with natural gas delivered from the Kenai Peninsula to the Mine Site.	☑ Proposed ☐ Alternative ☐ Dismissed
Power Source – Renewable Energy	POW-002	***Origination*** – Renewable energy power options were evaluated by PLP when developing the proposed project design. ***Description*** – Under this option, PLP would construct and power the mine using renewable energy resources such as wind turbines and run of river hydropower. Also considered under this option is supplementing the natural gas power plant production with renewables. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Using renewable energy is a reasonable option to consider. 3. Practicable Test: The two separate renewable options listed below were considered under this option. These options would supply power intermittently and in small quantities relative to the need and would not eliminate the need for the proposed natural gas power plant and pipeline. These options would intermittently supply power that would decrease the demand on the proposed natural gas power plant, potentially resulting in decreased usage of natural gas. Both options would require additional access roads and ground disturbance to transmit power to the mine. • Wind – Wind energy generation is intermittent and must be paired with other energy sources or storage mechanisms to provide a stable consistent supply.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Power			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		There are no identified wind energy resources in the vicinity capable of providing a significant and consistent portion of the project energy. • Run of River (ROR) Hydropower – No suitable locations that could generate a significant amount of ROR hydropower could be identified. Additionally, in winter, rivers may freeze making this power source intermittent and additional energy sources would be needed. 4. Environmental Impacts Test: The construction of wind farms, ROR hydropower plants, and associated infrastructure would be additive to the proposed power plant and would increase the project footprint. The option likely would result in additional impacts to wetlands, wildlife, and aquatic resources but potentially decrease emissions from burning natural gas. ***Why Dismissed*** – While this option would potentially decrease the consumption of natural gas and associated emissions, it would not replace the need for the natural gas power plant and pipeline. The additional costs of building renewable energy systems for what would be supplemental power make the option not practicable. Also, the potential reduction in emissions does not appear to offset the likely additional impacts to wetlands, wildlife, and aquatic resources.	
Power Source – Purchase Power from Existing Grid	POW-003	***Origination*** – Purchasing power from the existing grid was evaluated by PLP when developing the proposed project design. ***Description*** – Under this option, power would be purchased from existing third party providers and transmitted to site via a High Voltage Direct Current (DC) transmission. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Purchasing power is a reasonable option to consider.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Power			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		3. Practicable Test: There is no significant power generating capacity in the Cook Inlet area in general, and on the Kenai Peninsula in particular, to service the anticipated project demand. Construction of additional generation capacity would be required regardless of where it is situated. This option is not practicable. ***Why Dismissed*** – The option is not practicable; there is no excess capacity in the existing grid.	
Power Source – Use Alternative Fuel Sources/Delivery Methods	POW-004	***Origination*** – Evaluation of alternative fuel sources and delivery methods was suggested during scoping due to concern with gas line leaks or ruptures and potential long term consequences that a subsea pipeline can have on the environment. ***Description*** – The most likely alternative energy sources would be diesel fuel and LNG, both of which could be delivered to the proposed Amakdedori Port via barge. Transportation from the port to the Mine Site could be by truck or pipeline. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Considering alternative energy sources is reasonable. 3. Practicable Test: Both diesel and LNG options are technologically feasible. The Donlin Gold Final EIS looked at a diesel power plant alternative and estimated that a similar sized power plant (227 MW) would require approximately 80 million gallons of diesel per year. Use of diesel would require increased storage at the port and a pipeline or 4,200 truck trips per year, each truck hauling three tank trailers. Diesel is readily available in Cook Inlet. Use of LNG would require a supply of LNG, a purpose built LNG barge, an LNG receiving terminal and storage tanks at Amakdedori. It would also require regasification at Amakdedori for transportation to the mine site by pipeline or	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Power			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		trucking LNG to a mine site storage tank where it would be regasified and fed to the power plant. The former ConocoPhillips LNG export facility in Nikiski has been sold and the export permit was allowed to expire and LNG is not currently barged in Alaska. 4. Environmental Impacts Test: Transporting an additional 80 million gallons of diesel increases the potential for spills. Emissions from the proposed power plant would be increased if diesel was used instead of natural gas. See also Section 4.21 which explains there would be few expected effects from natural gas pipeline leaks to soil or water bodies because the gas would dissipate rapidly. Use of LNG would avoid the need for the natural gas pipeline segment under Cook Inlet between the Kenai Peninsula and Amakdedori. ***Why Dismissed*** – Diesel would increase environmental impacts from spills and increased emissions. LNG is not practicable; it is not currently barged in Alaska, would require costly infrastructure, and provides no obvious benefit over the proposed natural gas pipeline other than avoiding the segment between the Kenai Peninsula and Amakdedori. The EIS will assess the risk to the pipeline from seismic events.	
Power Plant Location – On-site	POW-005	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which includes construction of a new 270 MW power plant at the Mine Site to power the mine. This option would not require the construction of high voltage transmission lines to the Mine Site.	☑ Proposed ☐ Alternative ☐ Dismissed
Power Plant Location – Off-site with High Voltage Transmission Lines	POW-006	***Origination*** – Off-site location of the power plant was evaluated by PLP when developing the proposed project design. ***Description*** –This option would require a new power plant to be built at an alternative location such as the Kenai Peninsula or Amakdedori. High voltage transmission lines would be constructed and used to transmit the power to the Mine Site.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Power			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		Screening **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider off-site generation combined with high-voltage and transmission lines. 3. Practicable Test: Off-site power production is technologically feasible. If power generation was located on the Kenai Peninsula, it would require high-voltage transmission lines via underwater cables crossing both Cook Inlet and Iliamna Lake, and overhead lines on the Kenai Peninsula, from Amakdedori to a south ferry terminal, and the North Shore Ferry Terminal to the Mine Site. Underwater cables would be more costly to install and maintain than a natural gas pipeline. Overhead lines would be subject to wind and ice buildup, resulting in potential reliability risks. Undergrounding the overland portions of the transmission lines would be cost prohibitive, as undergrounding generally costs an order of magnitude greater than overhead lines, and would be more costly than the gas line. In addition, transmission losses occur over long distances, making this less efficient than a gas line to provide on-site generation. If power generation was located proximate to Amakdedori, similar issues would remain, though lessened given the reduced distance. However, the gas line under Cook Inlet would still be required. In addition, off-site generation would not offer sufficient redundancy in the event of a disruption to the transmission line and associated power supply. This option is likely not practicable due to cost. 4. Environmental Impacts Test: Construction and operation of high voltage transmission lines would result in greater visual impacts than a gas line. ***Why Dismissed*** **–** Off-site power production while practicable considering technology, would be much more costly and does not provide the stability and reliability benefits that	

AMERICAN OVERSIGHT

Power			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		would come from on-site power production. In addition, overhead transmission lines, and possibly the power plant (depending on location) would result in increased visual impacts.	
Gas Source – Pipeline to a Source on the Kenai Peninsula	POW-007	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action. Under this option, the proposed pipeline (about 177 miles in length) would tie in to the existing natural gas distribution system on the Kenai Peninsula and be routed to Amakdedori and then follow the transportation corridor to the Mine Site. The pipeline would be on the bottom of Cook Inlet and Iliamna Lake. The pipeline would be twelve inches in diameter.	☑ Proposed ☐ Alternative ☐ Dismissed
Gas Source – Pipeline to a Source on the West side of Cook Inlet	POW-008	***Origination*** – This option was evaluated by PLP when developing the proposed project design. ***Description*** – This option would follow an alternative route to the north to access existing natural gas supplies such as Beluga on the west side of Cook Inlet. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider a route that avoids crossing deep water in Cook Inlet. 3. Practicable Test: There is no accessible gas infrastructure, pipeline capacity, and available tie-in locations on the south-western side of the Cook Inlet. A potential tie-in location on the west side would be at Beluga, approximately 170 miles to the north (requiring an approximately 250+ mile pipeline to accommodate terrain). 4. Environmental Impacts Test: Accessing existing gas supplies for this option would require crossing Lake Clark National Park or if a subsea route would increase the length of the pipeline route in critical habitat for the endangered	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Power			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Cook Inlet beluga whale and the threatened northern sea otter (compared to the proposed route). ***Why Dismissed*** – This option would increase overall adverse impacts.	
Gas Source – Connect to Donlin Gold Gas Pipeline	POW-009	***Origination*** – Evaluation of an alternative pipeline route to connect with the natural gas pipeline for the proposed Donlin Gold Mine was suggested during scoping. ***Description*** –Under this option, the pipeline would follow an alternative route to the north allowing it to connect to the proposed Donlin Gold natural gas supply pipeline. A tie-in route to the nearest point along the proposed Donlin Pipeline would be longer than 155 miles and would cross at least 8 to 10 substantial rivers. Routing could avoid major mountain ranges. The proposed Donlin Gold Mine natural gas pipeline has not yet been constructed; timing for development and operation is not known. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider connection to the proposed pipeline given that Donlin Gold recently received federal permits for construction of the pipeline. 3. Practicable Test: The Donlin Gold Pipeline is planned to be 14-inch diameter, serving a 230MW power plant, based on an operating flow rate of 47 million standard cubic feet per day (mmscfd), with a design capacity of up to 73.1 mmscfd. The Pebble Project proposes a 270MW power plant, which could more than double the necessary capacity of the pipeline, which would not be practicable given its design. ***Why Dismissed*** – The Donlin Gold Pipeline, as planned, is unlikely to provide sufficient natural gas capacity to support the Pebble Project. In addition, the Donlin Pipeline is not	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		yet constructed and timing for its development is not certain, making this option not practicable.	
Gas Source – Northern Gas Pipeline Route to Kenai Peninsula (Ursus Cove)	POW-010	***Origination*** – Evaluation of a pipeline alignment north of Augustine Island was suggested during scoping due to concern that placing the pipeline near Augustine Island/Volcano would make it vulnerable to seismic and volcanic hazards. ***Description*** –Increasing the distance from Augustine Island by routing to the north is impracticable for the Amakdedori Port but routing the pipeline to Diamond Point to the north would achieve the purpose of the suggested option. Access option ACC-014 considers a port at Diamond Point in Iliamna Bay and routing the pipeline to this port would achieve the goal of increasing separation from Augustine Island. The pipeline under this option would be routed into Ursus Cove, run overland to Cottonwood Bay, and then continue to Diamond Port. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable option for the North Access Route (ACC-002). 3. Practicable Test: Practicability – The route to Ursus Cove is relatively free of seabed obstructions and rock-like features all the way into the cove, compared to a route through Iliamna Bay to a proposed Diamond Point port. Rocks, boulders, and boulder type features in Ursus Cove only appear much closer to the shore which makes routing and installation safer and easier and also allows for moored installation. A route to Amakdedori north of Augustine Island would place the pipeline approximately the same distance or closer than the proposed route and therefore is not a practicable route to achieve the goal of this option. Access Options ACC-014 and ACC-015 evaluate port sites in Iliamna Bay, more than 20	☐ Proposed ☑ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		miles north of Augustine Island. It is feasible to route the natural gas pipeline to that location. 4. Environmental Impacts Test: A route to Ursus Cove and then to Diamond Point would have additional impacts from the overland portion but would have a shorter segment in Cook Inlet. The option represents tradeoffs and is carried forward for detailed analysis.	
Gas Source – Northern Gas Pipeline Route to Kenai Peninsula (Direct Route to Iliamna Bay)	POW-011	***Origination*** – This option was evaluated by PLP as a conceptual route directly into Iliamna Bay and Diamond Point. ***Description*** – Under this option, the pipeline route would follow a more direct route to Iliamna Bay and Diamond Point than POW-010. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider a more direct, shorter pipeline. 3. Practicable Test: A 12-inch diameter subsea pipeline has a specific minimum curvature radius and therefore a limited ability to navigate areas of the seafloor with dense obstructions. A direct pipeline route into Iliamna Bay is not practicable because of boulders and rocky seabed near to and into the Bay that could not be avoided with this option. RFI 063 summarizes PLP's reconnaissance data for a direct route which indicated the presence of, and progressive increase in, rocks, boulders, and rock like features on the seabed. The concentration of rocks and boulders reaches its maximum density at the mouth of Iliamna Bay and continues into the bay. The rock-prone area starts approximately 13 miles from the landing point and is consistent to the landing point. It is interpreted that the rocks and boulders are likely from a combination of glacial outwash and ice-rafted deposits.	☐ Proposed ☐ Alternative ☑ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Why Dismissed – This option is not practicable due to boulders and other seabed issues.	
Gas Source – Other	POW-012	***Origination*** – Evaluation of practicable alternatives for reducing the amount of natural gas pipeline that is installed in the Sterling Highway right-of-way, which is managed by the Alaska Department of Transportation and Public Facilities, was suggested during scoping. ***Description –*** The commenter requested evaluation of alternative pipeline routes but did not suggest specific locations. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: PLP's Proposed Action in the December 2017 DA permit application included a gas pipeline alignment that would connect to existing infrastructure near Happy Valley on the Kenai Peninsula and travel south, paralleling the Sterling Highway for 9 mines to a compressor station near Anchor Point. PLP's May 11, 2018 update changed the pipeline origin point to a compressor station north of Anchor Point, removing the requirement for the first 9 miles of pipeline construction along the Sterling Highway. Therefore, this option is no longer reasonable as it pertains to an old project design. ***Why Dismissed*** – This option is not reasonable because it is based on an old design.	☐ Proposed ☐ Alternative ☑ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
Access Road – South Access Route (Road and Ferry)	ACC-001	***Origination*** – PLP Proposed Action ***Description*** – This road and ferry route option is part of the Proposed Action which includes the construction of two double-lane roads as the main access route to the mine for the transportation of materials, equipment, and concentrate. Road route: The mine access road would go from the Mine Site to the North Shore Ferry Terminal Site (ACC-006) on the north shore of Iliamna Lake. As a variant of the proposed action, an alternative ferry terminal site location would be considered just to the east of the proposed ferry terminal site in the bay, the North Shore East Ferry Terminal Site (ACC-006a). On the south shore of Iliamna Lake, the port access road would go from the Kokhanok West Ferry Terminal Site (ACC-010) to the Amakdedori Port Site (ACC-013). As a variant of the Proposed Action, the port access road would go from the Kokhanok East Ferry Terminal Site (ACC-011) to the Amakdedori Port Site (ACC-013). This option would also include an Iliamna spur road (which would include a crossing of the Newhalen River) and a Kokhanok spur road (which would include a crossing of the Gibraltar River if the Kokhanok West Ferry Terminal Site is included). Ferry route: The route would include a ferry crossing of Iliamna Lake from north to south. Natural Gas Pipeline route: The natural gas pipeline would follow the mine and port access roads and ferry route. This option would require the following: Total miles of road: 77 (Kokhanok West Ferry Terminal); 72 (Kokhanok East Ferry Terminal) Miles of road from Mine Site to the North Shore Ferry Terminal Site: 29	☑ Proposed ☐ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		Total number of stream crossings: 39 (Kokhanok West Ferry Terminal site to Amakdedori Port site); 30 (with variant Kokhanok East Ferry Terminal site to Amakdedori Port site) Total number of major river crossings: 2 (Kokhanok West Ferry Terminal site to Amakdedori Port site); 1 (with variant Kokhanok East Ferry Terminal site to Amakdedori Port site)	
Access Road – North Access Route (Road Only)	ACC-002	***Origination*** – Evaluation of an access road option north of Iliamna Lake to eliminate the need for a lake crossing was suggested during scoping. ***Description*** – This road-only route option was evaluated by PLP when developing the proposed design as an option that would not require a ferry to cross Iliamna Lake. Road route: The mine/port access road would stay north of Iliamna Lake, connect with the existing Pile-Bay Williamsport Road in the vicinity of Pile Bay, and then continue to the Diamond Point/Iliamna Bay Port Site (ACC-014) on Cook Inlet. The road would bypass all but 5 miles of the existing Pile Bay-Williamsport road. The road would traverse approximately 1.7 miles of tidal flats between Williamsport and Diamond point. This option would eliminate the need for a spur road to Iliamna as the route would cross an existing road that connects Iliamna with Nondalton, providing access to infrastructure at Iliamna. Ferry route: The route would not include use of a ferry. Natural Gas Pipeline route: The western portion of the natural gas pipeline would follow the road route. The eastern portion of the pipeline would follow a route overland between Cottonwood Bay and Ursus Cove. Concentrate Pipeline: A concentrate transport pipeline may be included with this option. This option would require the following:	☐ Proposed ☑ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		Total miles of road: 82 Number of stream crossings: 71 Number of major river crossings: 4 ***Screening –*** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a route that PLP has evaluated and studied extensively and is a reasonable route. 3. Practicable Test: A road only route provides the advantages of reliable year-round access and minimizes the need to re-handle cargo/concentrates. The option may also allow the inclusion of a concentrate pipeline for the project. There is no need to build the associated infrastructure for a ferry. This option would provide access to Cook Inlet which is generally accessible year round. This option would require a large number of stream crossings. This option also crosses many wetlands. The route is also more mountainous than other access routes, traversing side slopes and crossing perpendicular to drainages, including crossings of larger streams and minor rivers. Five miles of the existing Pile Bay-Williamsport Road require improvements to accommodate large trucks. The Diamond Point/Iliamna Bay Port Site (ACC-014) and access road would be subject to tidal flat filling. The port would require some dredging to 20 feet of Mean Lower Low Water (MLLW) (RFI 063) and may require blasting for access roads. This location could not accommodate deep draft vessels and would require lightering barges to transfer ore concentrate to deep draft bulk ships anchored at mooring locations.	

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		4. Environmental Impacts Test: This route would cross fewer wetland acres than a southern route (ACC-001) but more than a road and ferry northern route (ACC-003), resulting in a difference in acres of fill. The Iliamna Spur Road would be eliminated, reducing impacts along these road miles. The road portion from Pile Bay to Williamsport would require more maintenance compared to a southern route (ACC-001) given the steep terrain. This route would require more stream crossings than a southern route (ACC-001) or a road and ferry northern route (ACC-003). There would be less subsistence concerns and no lake navigation or transportation concerns compared to a road and ferry route (ACC-001 or ACC-003). The route would place mine traffic near Pedro Bay. The option represents tradeoffs and is carried forward for detailed analysis. If a concentrate pipeline was also included, the footprint would be slightly larger but there would be a decrease in truck traffic.	
Access Road – North Access (Road and Ferry)	ACC-003	***Origination*** – This road and ferry route option is a route evaluated by PLP while looking at routes that remain entirely north of Iliamna Lake. Use of the existing road and resources at Pile Bay and Williamsport was suggested during scoping. ***Description*** – Road route: The mine access road would stay north of Iliamna Lake from the Mine Site to the Eagle Bay Ferry Terminal Site (ACC-008) on the northern shore of Iliamna Lake. On the eastern shore of Iliamna Lake, the port access road would go from the Pile Bay Ferry Terminal Site (ACC-009) to the Diamond Point/Iliamna Bay Port site, using parts of the existing Pile-Bay Williamsport Road, continuing to the Diamond Point/Iliamna Bay Port Site (ACC-014) on Cook Inlet. This road would bypass all but 5 miles of the existing Pile Bay-Williamsport road. The road would traverse approximately 1.7 miles of tidal flats between Williamsport and Diamond Point.	☐ Proposed ☑ Alternative ☐ Dismissed

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		This option would eliminate the need for a spur road to Iliamna as the route would cross an existing road that connects Iliamna with Nondalton, providing access to infrastructure at Iliamna. Ferry route: The route would include a ferry crossing of Iliamna Lake from west to east. Natural Gas Pipeline route: The natural gas pipeline would follow the road alignment for ACC-002 because Iliamna Lake is too deep on the east of the lake for laying the pipeline on the bottom (the steep underwater cliffs would stress the pipeline bends). The eastern portion of the pipeline would follow a route overland between Cottonwood Bay and Ursus Cove. This route was proposed as an option by PLP. This option would require the following: Total miles of road: 50 Number of stream crossings: 34 Number of major river crossings: 1 ***Screening –*** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a route that PLP has evaluated and is a reasonable route. 3. Practicable Test: Thicker lake ice on the eastern side of the lake would make ferry operation more challenging; however, feasibility has been demonstrated by the long-term operation of an ice breaking ferry on Williston Lake in British Columbia. Water depth and lake bed topography may preclude the use of s sub-lake gas pipeline along this alignment.	

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Creation of open leads in the lake ice would prevent cross ice traffic intersecting the ferry route and requiring the delineation of alternate traffic routes. Five miles of the existing Pile Bay-Williamsport Road require improvements to accommodate large trucks. The Diamond Point/Iliamna Bay Port Site (ACC-014) and access road would be subject to tidal flat filling. The port would require some dredging to 20 feet of MLLW (per RFI 063) and may require blasting for access roads. This location could not accommodate deep draft vessels and would require lightering barges to transfer ore concentrate to deep draft bulk ships anchored at mooring locations. 4. Environmental Impacts Test: This route would cross fewer wetland acres than a southern route (ACC-001) or an all-road northern route (ACC-002), resulting in fewer acres of fill. The Iliamna Spur Road would be eliminated, reducing impacts along these road miles. The road portion from Pile Bay to Williamsport would require more maintenance compared to a southern route (ACC-001) given the steep terrain. The addition of a ferry route would require construction of two ferry terminals, resulting in placement of fill, and would result in greater transportation and potential navigation concerns along the ferry route in the eastern portion of the lake. There would be subsistence concerns with the ferry route being within areas important for subsistence seal harvesting. The option represents tradeoffs and is carried forward for detailed analysis. The route would place mine traffic near local communities including Iliamna, Nondalton, Pedro Bay, and Pile Bay. Additional transfer of materials with barges increases the risk of spills or loss of fugitive material during transfer operations.

Access Road – West Access Route	ACC-004	***Origination*** – This road option is a road-only access route evaluated by PLP when developing the proposed design as an option that would not require a ferry to cross Iliamna Lake. ***Description*** – Road route: The road would go from the Mine Site around the west end of Iliamna Lake and continue to the Amakdedori Port site on Cook Inlet. This option would also include an Iliamna spur road. Ferry route: This option would not require a ferry. Natural Gas Pipeline route: The natural gas pipeline would likely follow the road. Concentrate Pipeline: A concentrate transport pipeline may be included with this option. This option would require the following: Total miles of road: 160 Total number of stream crossings: 129 Total number of major river crossings: 4 ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider routing the road around the west end of Iliamna Bay. 3. Practicable Test: A road-only route provides the advantages of reliable year-round access and minimizes the need to re-handle cargo/concentrates. The option would also allow the inclusion of a concentrate pipeline for the project.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		There is no need to build the associated infrastructure for a ferry. This option would provide access to Cook Inlet which is generally accessible year round. This option has a longer road footprint, with more wetlands and streams crossed. 4. Environmental Impacts Test: This access route has the highest occurrence of wetlands, with the highest environmental impact to wetlands. If a concentrate pipeline were also included, the footprint would be slightly larger. ***Why Dismissed*** – This option would increase overall adverse impacts.	
Access Road – Bristol Bay Access Route (Road Only)	ACC-005	***Origination*** – Evaluation of alternative port sites was suggested during scoping due to concerns with the potential ecological impact of the project. ***Description*** – This road option is a road-only access route that was evaluated by PLP when developing the proposed design as an option that utilized other port sites than Cook Inlet. Road route: The road would go from the Mine Site to a port site on Bristol Bay. Ferry route: This option would not require a ferry. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider alternative port locations. 3. Practicable Test: This would be the longest road route option. Construction of associated port would have the potential for logistical conflicts with fishing operations in Bristol Bay. Additionally, Bristol Bay is ice bound for a large portion of the year. As Bristol Bay is shallow, a long trestle or causeway into the bay would be required, or alternatively lightering to a moored bulk vessel.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		4. Environmental Impacts Test: This option would have increased impacts associated with the construction of a port road and the longest road route. Resulting impacts include increased emissions and visual impacts. The route would traverse mainly lowlands, which would have more impact to wetlands. There would be impacts to local residents in communities near the road. ***Why Dismissed*** – This option would increase overall adverse impacts.	
Ferry Terminal Location – North Shore Ferry Terminal	ACC-006	***Origination*** – PLP Proposed Action ***Description*** – This ferry terminal site option is part of the Proposed Action which includes the construction of a ferry terminal on the north shore of Iliamna Lake for an ice-breaking ferry to transport materials, equipment, and concentrate across the lake. The ferry route would be north-south. This location is associated with the South Access Route (Road and Ferry), ACC-001. As a variant to this option, an additional site slightly to the east within the same bay as the North Shore Ferry Terminal is included, the North Shore East Ferry Terminal Site variant. This option would include the following: Number of ferry miles to Kokhanok West Ferry Terminal Site (ACC-010): 19 Number of ferry miles to Kokhanok East Ferry Terminal Site (ACC-011): 25	☑ Proposed ☐ Alternative ☐ Dismissed
Ferry Terminal Location – North Shore East Ferry Terminal	ACC-006a	***Origination*** – Evaluation of this ferry terminal location was suggested during scoping. ***Description*** – This ferry terminal site option is a variant of the Proposed Action which includes the construction of a ferry terminal on the north shore of Iliamna Lake for an ice-breaking ferry to transport materials, equipment, and concentrate across the lake. The ferry route would be north-south. This location is associated with the South Access Route (Road and Ferry), ACC-001. The site is slightly east of the North Shore Ferry Terminal Site (ACC-006) within the same bay.	**Status under review**

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Screening – This option is currently being evaluated.	
Ferry Terminal Location – Iliamna and Kokhanok Ferry Terminals	ACC-007	***Origination*** – Evaluation of ferry terminals closer to existing infrastructure was suggested during scoping to reduce impacts to Gibraltar River and Upper Talarik Creek. ***Description*** – Under this option, the north shore ferry terminal would be located in or near the communities of Newhalen and Iliamna but away from the Newhalen River. The Iliamna spur road would therefore be the main mine access road route to connect the Mine Site to this ferry terminal. This option location could be included with South Access Route (Road and Ferry), ACC-001. The south shore ferry terminal would be located north of the Kokhanok airport. The road from this ferry terminal to Amakdedori Port would follow a route similar to that described under ACC-001 for the Kokhanok East Terminal Site variant to avoid crossing the Gibraltar River. The ferry route would be north-south and approximately 21 miles. This option location could be included with South Access Route (Road and Ferry), ACC-001. ***Screening –*** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider options that have potential to avoid and minimize impacts. 3. Practicable Test: Ice conditions and water depth at Iliamna are not suitable for a ferry terminal. Existing community use of the area may not be compatible with ferry route and a terminal. 4. Environmental Impacts Test: There would be additional impacts to the communities of Iliamna, Newhalen, and Kokhanok caused by changes in vessel traffic impacting current vessel and floatplane use, and heavy mine trucks traversing through the community. This location is closer to high use areas for subsistence seal harvesting.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Why Dismissed – This option would increase overall adverse impacts.	
Ferry Terminal Location – Eagle Bay Ferry Terminal	ACC-008	***Origination*** – This ferry terminal option was evaluated by PLP when developing the proposed design as an alternative north shore ferry terminal location suitable for either a north-south lake transit or an east-west transit. ***Description*** – Under this option, the north shore ferry terminal would be located in Eagle Bay. A road would connect the Mine Site to the terminal. A spur road to Iliamna would not be included in this option as the mine access road would cross the existing road from Iliamna to Nondalton and provide community access. This option location is associated with the North Access Route (Road and Ferry), ACC-003. The location could be included with South Access Route (Road and Ferry), ACC-001. This option would include the following: Number of ferry miles to Kokhanok West Ferry Terminal Site (ACC-010): 24 Number of ferry miles to Kokhanok East Ferry Terminal Site (ACC-011): 27 Number of miles to Pile Bay Ferry Terminal Site (ACC-009): 33 ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This location appears to be a reasonable option with ability to accommodate ferry traffic and road connection. 3. Practicable Test: This location is sheltered for ferry operations and protected from prevailing winds. There may be navigability issues associated with the water depth in the area. Ice in the bays is thicker and more persistent than in the open lake west of Newhalen.	☐ Proposed ☑ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		This option minimizes the road footprint within the Upper Talarik Creek drainage. 4. Environmental Impact Test: This site may have different or additional impacts such as shallower water, persistent ice within Eagle Bay, and more navigational hazards.	
Ferry Terminal Location – Pile Bay Ferry Terminal	ACC-009	***Origination*** – This ferry terminal option was evaluated by PLP when developing the proposed design. ***Description*** – This option considers an eastern shore ferry terminal location suitable for use with a northern access route and the Eagle Bay Ferry Terminal as a western ferry terminal site. This option location is associated with the North Access Route (Road and Ferry), ACC-003. This option would include the following: Number of ferry miles to Eagle Bay Ferry Terminal Site (ACC-008): 33 ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is an existing port facility and reasonable to consider. 3. Practicable Test: There may be navigability issues associated with the water depth in the area. Ice within the bay may be more persistent than in the open lake to the west. This location would use portions of existing infrastructure and the more sheltered port location at Diamond Point. 4. Environmental Impacts Test: There may be possible impacts to subsistence seal harvesting, and additional impacts to the community of Pile Bay.	☐ Proposed ☑ Alternative ☐ Dismissed
Ferry Terminal Location –	ACC-010	***Origination*** – PLP Proposed Action	☑ Proposed ☐ Alternative

AMERICAN OVERSIGHT

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Kokhanok West Ferry Terminal		***Description*** – This ferry terminal option is part of the Proposed Action which includes the construction of a ferry terminal on the south shore of Iliamna Lake for an ice-breaking ferry to transport materials, equipment, and concentrate across the lake to a port site on Cook Inlet. The ferry route would be north-south. The south ferry terminal would be at the Kokhanok West Ferry Terminal Site approximately five miles west of Kokhanok. This option would include a Kokhanok spur road. This option is associated with the South Access Route (Road and Ferry), ACC-001.	☐ Dismissed
Ferry Terminal Location – Kokhanok East Ferry Terminal	ACC-011	***Origination*** – Evaluation of alternative ferry terminal locations was suggested during scoping. ***Description*** – This ferry terminal option was evaluated as a variant of the Proposed Action for an alternative southern shore ferry terminal location. The south ferry terminal would be approximately five miles east of the community of Kokhanok at the Kokhanok East Ferry Terminal Site. This option would include a Kokhanok spur road. This option is associated as a variant of the South Access Route (Road and Ferry), ACC-001. The port access road would follow a shorter route (five miles shorter) than from ACC-010 to the Amakdedori Port Site and would not require a crossing of the Gibraltar River. ***Screening – This option is currently being evaluated.***	**Status under review**
Ferry Terminal Location – Utilize Alternative Ferry Terminal Sites	ACC-012	***Origination*** – Evaluation of alternative ferry terminal locations was suggested during scoping. ***Description*** – The suggested option requested consideration of alternative ferry sites and locations compared to the Proposed Action but did not specify locations. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		2. Reasonable Test: The six ferry terminal options described in this table are the most feasible locations, and cover a variety of logistical and environmental considerations. This option is not reasonable to carry forward because other substantially similar but more specific locations are being considered, meeting the intent of the scoping comment. ***Why Dismissed*** – Several ferry terminal location options were developed and incorporated into this table. This option is not reasonable to carry forward because other substantially similar but more specific locations are being considered, meeting the intent of the scoping comment.	
Port Location – Amakdedori Port Site	ACC-013	***Origination*** – PLP Proposed Action ***Description*** – This port site option is part of the Proposed Action which includes the construction of a port on Cook Inlet to transfer diesel fuel, materials, equipment, and concentrate using barges. The port location would be at Amakdedori. This option is associated with the South Access Route (Road and Ferry), ACC-001 option. This port site would utilize the Offshore Lightering-Amakdedori option (ACC-022).	☑ Proposed ☐ Alternative ☐ Dismissed
Port Location – Diamond Point/Iliamna Bay Port Site	ACC-014	***Origination*** – Evaluation of an option for a port site at Diamond Point in Iliamna Bay was suggested during scoping. ***Description*** – This port site option was examined by PLP in the process of developing the Proposed Action. The port site would be located at Diamond Point in Iliamna Bay. This port site option is associated with the North Access Routes (ACC-002 and ACC-003). This port site would utilize the Offshore Lightering-Iniskin option (ACC-023). The approach at the Diamond Point port would use a channel for barges and tugs to access the loading dock, requiring dredging to a depth of 20 feet MLLW (per RFI 063).	☐ Proposed ☑ Alternative ☐ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		Channels are typically more prone to sedimentation requiring maintenance dredging and therefore greater under keel clearance is recommended compared to the depth of 15 feet MLLW described at the Amakdedori Port Site (ACC-013). Dredged material would either be utilized in construction of the causeway and dock or disposed of onshore. The total volume of dredged material for the 20 feet MLLW channel is 650,000 cubic yards, of which a minimum of 50% is estimated to be used in the barge dock construction which will require approximately 615,000 cubic yards of fill for construction. Any rocks encountered in the channel would be moved to the side of the channel or used in the dock construction. Any remaining dredged material and any material from maintenance dredging would be disposed of on-shore in a bermed facility located on uplands west of the dock site. ***Screening*** **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Diamond Point appears to be a reasonable option. 3. Practicable Test: The port location is sheltered and access for this option could utilize portions of the existing Pile Bay road. The port site and access road includes construction and placement of fill within the intertidal zone in Iliamna Bay. The port would require initial and maintenance dredging and blasting for access roads. This location could not accommodate deep draft vessels and would require lightering barges to transfer ore concentrate to deep draft bulk ships anchored at mooring locations. 4. Environmental Impacts Test: This option uses some areas already impacted by development and may avoid bear migration areas. Dredge and fill impacts would be greater in the intertidal zone.	
Port Location – Knoll	ACC-015	***Origination*** **–** This port site option was examined by PLP in the process of developing the Proposed Action.	☐ Proposed ☐ Alternative

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Head/Iniskin Bay Port Site		***Description*** – This port site would be located at Knoll Head in Iliamna Bay and is associated with the North Access Routes (ACC-002 and ACC-003). This port site would utilize the Offshore Lightering-Iniskin option (ACC-023). ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider alternative port locations. 3. Practicable Test: This option requires challenging access and port site construction and would require significant earthworks with associated impacts. This option would have prohibitive road construction cost. 4. Environmental Impacts Test: Access to this port would require crossing Iliamna Bay via a causeway and includes substantial placement of fill within the intertidal zone in Iliamna Bay and Iniskin Bay. ***Why Dismissed*** – The environmental impacts would be greater than the Proposed Action (and ACC-014 – Diamond Point).	☑ Dismissed
Port Location – Fortification Bluff/Rocky Point Port Site	ACC-016	***Origination*** – This port site option was examined by PLP in the process of developing the Proposed Action. ***Description*** – Under this option the port location would be at Fortification Bluff/Rocky Point which is approximately 15 miles north of Amakdedori, and would require 26 additional road miles from the port access road route to this port site, compared to the Proposed Action (ACC-001). This option is associated with the South Access Route (Road and Ferry), ACC-001 option. The natural gas pipeline would not be co-located along the road, and would be routed through Amakdedori as described in ACC-001. This port site would utilize the Offshore Lightering-Amakdedori option (ACC-022).	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		Screening **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider other port locations. 3. Practicable Test: This option requires a longer access road and more challenging port site construction than other options which would increase the total amount of road construction for the project. Shore approach routing options for the gas pipeline are not available due to the proximity to Augustine volcano. This option has a requirement for a steep access road to the shore which poses operational safety challenges. 4. Environmental Impacts Test: Baseline data indicates that this offshore area is a more a productive habitat with higher utilization by a wider variety of species than other options. ***Why Dismissed*** **–** This option would increase overall adverse impacts.	
Port Location – Williamsport Port Site	ACC-017	***Origination*** **–** Use of the existing road and resources at Pile Bay and Williamsport was suggested during scoping. ***Description*** **–** This port site option was examined by PLP in the process of developing the Proposed Action. The port location would be at the existing Williamsport location in Iliamna Bay. This port site option would be included with the North Access routes (ACC-002 and ACC-003) and may include the Eagle Bay Ferry Terminal Site (ACC-008) and Pile Bay Ferry Terminal Site (ACC-009) options. This option would require improvements to the existing port facilities. This port site would utilize the Offshore Lightering-Iniskin option (ACC-023). ***Screening*** **–**	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider use of existing facilities. 3. Practicable Test: Williamsport is inaccessible by sea except for brief periods at the peak of extreme high tides which occur a few days each month (USACE 1995). A 1995 Environmental Assessment by USACE (Navigation Channel Feasibility Report and Environmental Assessment: Williamsport) indicates that a considerable amount of initial and ongoing maintenance dredging would be required to accommodate barges between the mouth of Iliamna Bay and Williamsport. The existing sea bottom is two or three feet above mean lower low water (MLLW) near the landing and it would be necessary to dredge 22 to 23 feet of material to obtain the desired depth of -20 feet MLLW. The dredged material would need either onshore or offshore disposal. Existing uses of Williamsport may not be compatible with the level of activity proposed by PLP. ***Why Dismissed*** – The initial and maintenance dredging requirements make this option impracticable.	
Port Location – Utilize Alternative Port Sites	ACC-018	***Origination*** – Utilizing alternative port sites was suggested during the scoping period. ***Description –*** The commenter requested consideration of alternative port sites and locations compared to the Proposed Action but did not suggest specific locations. ***Screening –*** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: The five port site options described in this table are the most feasible locations, and cover a variety of logistical and environmental considerations. The suggested option is not reasonable because it is not	☐ Proposed ☐ Alternative ☑ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		specific; however, the intent of the suggestion is fulfilled through evaluation of ACC-013 through ACC-017. ***Why Dismissed*** – Several port site options were considered (see ACC-013 through ACC-017). This non-specific option is not a reasonable option and can therefore be dismissed in favor of the five location specific options.	
Dock Type – Fill Dock	ACC-019	***Origination*** – PLP Proposed Action ***Description*** – PLP has proposed to construct a fill dock and sheetpile bulkhead at the port location.	☑ Proposed ☐ Alternative ☐ Dismissed
Dock Type – Pile Supported Dock	ACC-020	***Origination*** – USACE is evaluating an option for a pile supported dock to satisfy requirements for minimization of impacts to Waters of the U.S. ***Description*** – This option would construct a pile supported dock rather than a fill dock at the port site. ***Screening – This option is currently being evaluated.***	**Status under review**
Port Operations– Shore Side Loading	ACC-021	***Origination*** – Shore side loading was evaluated by PLP when developing the proposed project design. ***Description*** – This type of loading was originally proposed as an option by PLP when developing the Proposed Action, but was eliminated in project design updates in May 2018. Bulk carriers would be loaded directly at the port site (rather than at lightering locations) and would require a deep draft navigation channel and turning basin of approximately 50 feet of water depth. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable option. This was PLP's original proposed action so is assumed economically and technologically feasible.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		3. Practicable Test: This option involves the loading of a bulk carrier directly at the dock side which minimizes concentrate re-handling and leads to improved safety and reliability. All locations where this could take place require dredging or causeway construction to allow for shore side loading of bulk carriers. It is estimated that initially, 10 million cubic yards would need to be dredged and another 10 million yards may need to be dredged over the life of the mine to maintain the design depth. Dredging operations for this option would increase impacts to waters of the US and requires the placement of dredge spoils. 4. Environmental Impacts Test: Dredging would have environmental impacts to marine habitat and shoreside habitat where dredged material would be placed; dredging would result in a higher volume of fill compared with other loading options such as lightering; maintaining the deep-draft navigation channel and turning basin would require annual maintenance dredging that would be a long-term effect. Shoreside loading would potentially lessen impacts to ESA-listed species or habitat including sea otter critical habitat. ***Why Dismissed*** – This option would increase overall adverse impacts.	
Port Operations– Offshore Lightering - Amakdedori	ACC-022	***Origination*** – PLP Proposed Action ***Description*** – The lightering option is the Proposed Action developed by PLP and requires approximately 15 feet of water depth at the dock which can be achieved naturally at Amakdedori without dredging.	☑ Proposed ☐ Alternative ☐ Dismissed
Port Operations– Offshore Lightering - Iniskin	ACC-023	***Origination*** – The Iniskin Bay lightering option was developed as an alternative by PLP when looking at alternative port sites such as Diamond Point/Iliamna Bay (ACC-014). ***Description*** – Under this option, concentrate would be offloaded from trucks to transfer barges at port sites to be transported to lightering locations where larger transport barges would be moored. Concentrate would then be loaded to transport barges for	☐ Proposed ☑ Alternative ☐ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		transport across Cook Inlet. An additional mooring location from those identified in ACC-022 has been identified at Iniskin Bay off the Iniskin Peninsula that is closer to the Diamond Port site. ***Screening*** **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: The Iniskin Bay option has adequate water depth for the bulk carrier ships and affords good protection; it is a reasonable option. 3. Practicable Test: Similar to ACC-022. 4. Environmental Impacts Test: This option would have less environmental impact to the marine environment than a large dock facility. There would be less removal or placement of fill required. There is risk of material spills during transfer to/from lighter barges.	
Other Access Options – Mandatory Bridges at Stream Crossings	ACC-024	***Origination*** **–** An option to require bridges at all anadromous stream crossings was suggested during scoping. ***Description*** **–** This option would make it mandatory for bridges to be built any time the access route crosses a stream or river that supports anadromous fish. ***Screening*** **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Not reasonable as ADF&G would specify the crossing requirements necessary to protect anadromous fish which may be achieved by other means such as culverts rather than bridges. ***Why Dismissed*** **–** This option is not reasonable. Other forms of stream crossings such as culverts are often appropriate structures. The design and permitting process would select appropriate crossing structures to address the environmental concerns and reduce impacts.	☐ Proposed ☐ Alternative ☑ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
Other Access Options – Revised Project Alignment via Micro-Siting	ACC-025	***Origination*** – Consideration of micro-siting practices for the access roads was evaluated by USACE as a potential means to avoid environmental impacts. ***Description*** – Use micro-siting practices to avoid local impacts to wetlands, stream crossings, guiding, lodges, wildlife, visual resources, archeological, and historical resources. Avoid or minimize or stay outside a buffer area important to resources. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This option is not reasonable to consider as a component of an action alternative for evaluation in the EIS because it lacks specificity and is essentially mitigation. Additionally, the intent of this option will be accomplished as impact assessment is completed for the Draft EIS, resource agencies and the public review and comment on the Draft EIS, and the Applicant is asked to revise the proposed project to better avoid and minimize impacts. Additionally, micro-siting practices will be demonstrated by the Applicant when they document the steps and measures they have taken to avoid and minimize environmental impacts of their proposed action. Mitigation measures included in PLP's design, which are integral components of the proposed action, will be included in Chapter 5 of the EIS and will be considered during the NEPA impact analysis in the EIS for the proposed action and applicable components of other action alternatives. ***Why Dismissed*** – This option is not reasonable. Dismissal of this option would not preclude future consideration of micro-siting as mitigation to avoid or minimize specific impacts identified through the NEPA impact analysis or as required by resource agencies during project permitting as the project design and permitting advances.	☐ Proposed ☐ Alternative ☑ Dismissed

Concentrate Transport			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Concentrate Transport – Truck	CTR-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which involves containerized transport of ore concentrate by utilizing the road and ferry access route (South Access Route (Road and Ferry), ACC-001). This option would use trucks to carry concentrate containers truck from the Mine Site. Concentrate would be transported to the port location, loaded onto a ferry, and re-handled at lightering locations. This option does not allow for the inclusion of a concentrate pipeline in the proposed project. This option may also be included with the North Option Route (Road and Ferry), ACC-003.	☑ Proposed ☐ Alternative ☐ Dismissed
Concentrate Transport – Pipeline	CTR-002	***Origination*** – Evaluation of an option for an ore concentrate pipeline was suggested during scoping due to concerns with ferrying ore concentrate across Iliamna Lake. ***Description*** – This option would not require the re-handling of cargo/concentrate and allows for the inclusion of a concentrate pipeline in the proposed project. A single, approximately 7-inch diameter, steel pipeline with appropriate corrosion protection, would be used to transport the concentrate. The concentrate pipeline and the gas pipeline would be collocated in a single trench located at the toe of the road embankment, which would increase the average width of the road corridor footprint by 3 to 5 feet. Pump stations would be required to move concentrate through the pipeline. This option may be applied with North Access routes and considered with the South Access routes. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need 2. Reasonable Test: This is a reasonable option. 3. Practicable Test: This option is technologically feasible and would be an efficient way to move large volumes of material and reduce truck traffic. This option would require a water treatment plant and a discharge permit at the port site and would result in a small reduction (<1 cfs) in water available for discharge at the Mine Site. Treatment at the port site would remove toxic pollutants, including	☐ Proposed ☑ Alternative ☐ Dismissed

Concentrate Transport			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		metals, to limits identified in an Alaska Department of Environmental Conservation (ADEC) and/or EPA discharge permit. Additionally, water depth and lake bed topography would likely preclude the use of a sub-lake gas pipeline along the South Access routes alignments or the lake portion of the North Access Route 2. 4. Environmental Impacts Test: This route includes trade-offs in terms of the environmental impacts. This route would result in additional fill impacts associated with a wider corridor but reduced trucking. This option is carried forward as an alternative to be considered in detail in the EIS.	
Concentrate Transport – Rail	CTR-003	***Origination*** – Transporting ore concentrate by rail was evaluated by PLP when developing the proposed project design. ***Description*** – This option would require the construction of railroad from the Mine Site for the transportation of ore concentrate. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is a reasonable option to consider. 3. Practicable Test: Construction of a railroad to move the volume of materials necessary for the proposed project would not be efficient or cost effective. The cost to construct railroads in Alaska is about five times the cost to construct roads. Railroads grades are typically limited to grades of 1 percent or less, with longer bridges. The additional cost of the track, railroad ballast, hardware, and associated equipment is a significant investment. Railroad construction in Alaska costs roughly $9 million per mile, remote road construction costs roughly $1.7 million per mile. Railroads can provide greater efficiencies where high volumes of materials are transported daily, but the total volume of transported	☐ Proposed ☐ Alternative ☑ Dismissed

Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		materials projected for the Pebble project is low compared to typical railroad operations. Transport of concentrate, fuel, reagents and consumables is estimated to be 35 truck round trips per day for the project. The large cost to construct a railroad for the relatively low volume of freight would not be cost effective. ***Why Dismissed*** – This option would increase overall adverse impacts. It may not be practicable to achieve grade requirements.	

AMERICAN OVERSIGHT

Reclamation and Closure Access			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Closure – Retain Mine Road	RCA-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which includes utilizing and maintaining mine access roads for all mine reclamation and closure transportation needs after operations. This option utilizes the existing infrastructure for mine access during post closure support activities.	☑ Proposed ☐ Alternative ☐ Dismissed
Closure – Iliamna Airport and Existing Roads	RCA-002	***Origination*** – This closure option was evaluated by PLP when developing the proposed project design. ***Description*** –This option would utilize existing infrastructure (Iliamna airport and Pile Bay-Williamsport Road) for all mine reclamation and closure transportation needs after operations. The mine access road would be reclaimed. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable option to consider. 3. Practicable Test: This option utilizes Iliamna airport and/or the existing Pile Bay road; however, neither have the capacity to meet the post closure logistical requirements. The existing Pile Bay Road, if utilized as part of an alternative, would not by itself meet the ground transportation needs for reclamation and closure if other access roads are not maintained. The option would rely on helicopter transport of fuel, materials, WTP reagents, and supplies which would be inefficient, very expensive, and less safe than surface transportation. ***Why Dismissed*** – This option is not practicable because the existing infrastructure would not support the reclamation and closure transportation needs.	☐ Proposed ☐ Alternative ☑ Dismissed

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Storage Method– Thickened Tailings Storage	TSF-001	***Origination*** – PLP Proposed Action ***Description*** – Thickened tailings storage is the Proposed Action for bulk tailings. The option is not suited for pyritic tailings that need to remain saturated to prevent them from oxidizing and generation ARD and metals leaching. Thickened tailings are slurry tailings that have been mechanically dewatered, sometimes with settling additives, to create a more viscous molasses-like material. They typically have a solids content (mass of solids to total mass of the combined solids and liquid mixture) of 45 to 65 percent. They are piped to the TSF by centrifugal pumps or positive displacement pumps depending on the topography, distance, head loss, and viscosity. They still require an embankment dam for containment, either a full dam like for slurry tailings, or a lower dam depending on the viscosity. These dams need to be periodically raised to hold the tailings and supernatant water. Some mines discharge thickened tailings from the dam and create a slurry tailings type of TSF with a steeper beach. Other mines discharge thickened tailings from a central tower to produce a cone-shaped TSF with a tailings surface sloped towards the dams. Thickened tailings do not segregate as much as slurry tailings so that they are relatively consistent particle distributions across the TSF. The yield strength (applied pressure that must be exceeded to make the fluid flow) of the consolidated tailings is 0.4 to 1.6 pounds per square foot (psf), partly depending on the degree of initial thickening.	☑ Proposed ☐ Alternative ☐ Dismissed
Storage Method– Slurry Tailings Storage	TSF-002	***Origination*** – This option is the Proposed Action for the pyritic tailings and was considered by PLP for the bulk tailings. ***Description*** – Slurry tailings are a slightly dewatered product of the milling process. The slurry is a water-like material that is moved by pipeline to the TSF. The slurry typically has a solids content of 10 to 40 percent and can flow down-gradient by gravity or be moved by centrifugal pumps depending on the topography, distance and head loss. The high water content requires that the tailings be stored behind a dam that must be periodically raised to hold the tailings and supernatant water. The tailings gradually segregate as they flow away from the discharge with coarser particles closest to the discharge points and finer particles further away. A beach slopes away from each	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		discharge point to the supernatant the pond. The tailings consolidate to a yield strength of up to 0.4 psf. The supernatant water is removed to the extent possible and reclaimed for mill use or treated and discharged. Some mines use cyclones to split the slurry into coarser and finer fractions and use the coarser fraction as dam raise fill. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable tailing method to consider. 3. Practicable Test: Slurry tailings are the most common method of tailings disposal and have been successfully produced and managed under a wide range of operating conditions for both bulk and pyritic tailings. The feasibility of this method is reliable and proven at the proposed Pebble scale under these environmental conditions. 4. Environmental Impacts Test: Slurry TSFs entrain more water and have larger supernatant ponds than thickened tailings TSFs. Therefore they have more potential energy than thickened tailings, and pose a greater risk to the environment should there be an operational problem or a dam failure. PLP has proposed thickened tailings to conserve water and reduce this risk (TSF-001). ***Why Dismissed*** – This option would increase overall adverse impacts.	
Storage Method– Paste Tailings Storage	TSF-003	***Origination*** – Paste tailings storage was suggested via scoping comments as a potentially efficient and effective method of storage. ***Description*** –This option is only applicable to the bulk tailings and not the pyritic tailings that would need to stay saturated to prevent ARD generation and metal leaching. Paste tailings are essentially thickened tailings, thickened with high-density thickeners, cement, and other additives to a toothpaste-like material. They typically have a solids content of 60 to 75 percent and a yield strength of 1.6 to 2.0 pounds per square foot. They are typically moved by pipeline, but require positive displacement	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ **Option Details: Origination, Description** ❖ **Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test** ❖ **Why Dismissed (as applicable)**	**Status**
		pumps. Paste tailings particles do not segregate so tailings characteristics would be relatively uniform throughout the TSF. However, paste tailings are mostly used as backfill in underground mine workings where transport and placement of the paste is aided by gravity, and are typically not disposed of in TSFs. ***Screening*** **–** 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: TBD 3. Practicable Test: Paste tailings require specialized high density thickeners and are the least common TSF. Positive displacement pumps are usually required for transportation to the TSF site resulting in potential plugging of pipelines with high-density tailing and increased pumping energy requirements. Producing a consistent paste would be a major challenge with the processing as small changes in the orebody, especially clay-sized particles, can greatly influence the paste characteristics such as yield strength and beach slope. 4. Environmental Impacts Test: Paste tailings require additional transportation infrastructure and on-site facilities for handling cement and other thickeners which would require a large footprint and added impact to the environment. The method would produce a more stable TSF than thickened tailings, but essentially offers no more environmental benefits than thickened tailings. ***Why Dismissed*** **–** Paste tailings are mostly used in underground workings, and have minimal surface TSF history and interest. A paste TSF would be significantly more costly to operate than a thickened TSF and would provide minimal environmental benefit above that of the Proposed Action.	
Storage Method– Dry Stack	TSF-004	***Origination*** **–** This storage method was evaluated by PLP when developing the proposed project design.	**Status under review**

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Tailings (for Bulk Tailings only)		***Description*** – This option of dry stack tailings is only suited for bulk tailings because the pyritic tailings need to stay saturated to prevent ARD generation and metal leaching. Filtering tailings removes water using mechanical filters and results in tailings with 75 to 85 percent solids content and a yield strength of over 3 pounds per square foot. This creates a soil-like material or "dry cake" that is transported by conveyor or truck to a "dry stack" TSF. These TSFs do not require dams unless possibly for perimeter berms. The tailings are placed by bulldozers and compactors as in conventional earthwork construction. ***Screening – This option is currently being evaluated.***	
Storage Method– Submarine Disposal Storage	TSF-005	***Origination*** – This storage method was evaluated by PLP when developing the proposed project design. ***Description*** – This option would place the tailings and other mine waste in a water body such as in a lake or seawater to maintain a saturated condition into perpetuity. The concept is to discharge tailings by gravity to a location and depth where they are less likely to oxidize and leach out toxic metals, and where marine life is less abundant. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This option would maintain PAG material in a saturated condition without the need for an on-land TSF and maintenance of dams and other water control features. However, there are concerns about performance histories of previous and current submarine disposal operations. It is likely not possible to obtain permits for storing tailings in an existing waterbody in or near Bristol Bay, as well as significant public opposition to the storing of bulk tailings in water bodies in general. This is not a reasonable option. ***Why Dismissed*** – This option is not reasonable.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Storage Method– Remove or Make All Tailings Inert	TSF-006	***Origination*** – This method was proposed via scoping comments as a measure to reduce local environmental impacts due to tailings storage. ***Description*** –This option would involve transporting all of the tailings from the project area to another disposal area, or making the tailings inert to eliminate the ARD and metal leaching potential. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Trucking tailings away from the project area is not reasonable because it would require round-the-clock transport. The project would generate tailings at a rate that would require a truck with triple trailers to leave the mine site approximately every minute. This would require new roads to connect to the existing road system. The costs to transport the tails hundreds of miles would be exorbitant and cost prohibitive. Treating the tailings appears to be a reasonable option to consider. 3. Practicable Test: Treating the pyritic tailings to make them inert (the bulk tailings are considered inert) would require additional treatment facilities that would need space in the project area and would introduce new containment structure needs. Methods of making tailings inert include separating pyritic tailings to create a larger bulk TSF and smaller pyrite TSF (this is already the proposed action), returning the pyritic tailings to the completed pit at closure to allow natural subaqueous storage (this is also already the proposed action), adding cement to create a cementitious-type material, buffering by mixing in alkaline material like crushed limestone to neutralize the acidity, and refining processes to extract more metals and reduce their metals content in the tailings.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		4. Environmental Impacts Test: Treating the tailings to make them inert by separating the bulk and pyritic tailings and returning the pyritic tailings to the completed pit at closure is the Proposed Action. Adding cement or limestone to make tailings inert would require the transport of very large volumes of these additives including possibly developing quarries, and constructing additional infrastructure and treatment facilities in the project area. Revising mining methods to extract richer ore would result in more waste rock with higher ARD and ML potential. Treatment facilities and associated containment structures would require additional space, with resultant increased environmental impacts. ***Why Dismissed*** – The option to move the tailings to another area is not reasonable and is cost prohibitive. Treating the pyritic tailings with cement or limestone provides no environmental benefits over the Proposed Action, which would separate the pyritic from the bulk tails and keep them inert by maintaining them during mining in a subaqueous condition, and return them to the completed pit during closure for permanent subaqueous storage.	
Storage Method– Truck Tailings to Canada	TSF-007	***Origination*** – Evaluation of an option to truck all waste to Canada was suggested during scoping. ***Description*** –This option would involve transporting all of the tailings from the project area to a disposal area in Canada. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Trucking tailings away from the project area is not reasonable because it would require round-the-clock transport. The project would generate tailings at a rate that would require a truck with triple trailers to leave the mine site approximately every minute. This would require new roads	☐ Proposed ☐ Alternative ☑ Dismissed

		to connect to the existing road system. The costs to transport the tails hundreds of miles would be exorbitant and cost prohibitive. ***Why Dismissed*** – This option is not reasonable and is cost prohibitive.	
Tailings Dam – Centerline Construction	TSF-008	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which includes the use of centerline construction for the bulk tailings TSF embankment. Centerline construction optimizes the robustness and stability advantages of downstream construction, with the efficiency advantages of upstream construction. The centerline dam begins with a starter dam, and subsequent raises are placed directly above the starter dam or previous raise, and over the downstream face, and over the tailings adjacent to the dam. The centerline of the dam crest is maintained in the same vertical plane. The outer part of the dam expands downstream as the dam is raised. The inner part of the dam has raises that stagger over the tailings with the upstream toe of each raise on the same vertical plane. A variation of the centerline method is to bend the centerline either in either the upstream or downstream direction to optimize stability and cost. Centerline dams can be built out of rock, soil and tailings.	☑ Proposed ☐ Alternative ☐ Dismissed
Tailings Dam – Downstream Construction	TSF-009	***Origination*** – This construction method was evaluated by PLP when developing the proposed project design. ***Description*** – Under this option downstream tailings dam construction is considered only for the bulk TSF instead of the centerline method (the pyritic TSF is proposed as a downstream dam). Downstream tailings dams can be constructed using rock, soil or tailings in various combinations. Construction starts with a starter dam in the same way as for a centerline dam. Subsequent stages (raises) are built on top of the downstream slope of the previous dam. The centerline of the dam crest moves downstream. Downstream dams are constructed in the same way as conventional water storage dams, except for being raised in stages as mining progresses instead of all at once.	**Status under review**

AMERICAN OVERSIGHT

Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Screening – This option is currently being evaluated.	
Tailings Dam – Upstream Construction	TSF-010	***Origination*** – This construction method was evaluated by USACE. ***Description*** – Tailings dams built by the upstream method of construction are raised by using rock, soil and tailings in various combinations as dam fill. A starter dam is first built in the same manner as a centerline or downstream dam. Trapezoidal shaped raises are built on top of each other at an offset toe-to-crest design, moving the dam crest and centerline upstream so that the upstream part of the dam is located over tailings in the TSF. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider alternative dam construction methods. 3. Practicable Test: Upstream raises are the oldest and most economic type of tailings dam construction. An upstream dam contains about one-third of the fill volume of a downstream dam, and one-half the volume of a centerline dam. This would result in construction time savings conducive to Pebble's short construction seasons, and hence reduced costs. However, fill can only be placed on tailings that have had time to consolidate and thereby provide a strong foundation for the raises. Otherwise, the underlying tailings could be saturated to the extent they could liquefy as a result of seismic activity and cause the dam to fail. A rate of tailings rise of 15 to 30 feet per year is considered to be the upper limit of allowing sufficient time for tailings consolidation to provide a stable tailings foundation for upstream raise construction. The planned rate of tailings rise at Pebble is at the upper end of this range and likely too fast to allow enough time for consolidation. Therefore	☐ Proposed ☐ Alternative ☑ Dismissed

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		an upstream raise is likely not feasible because of the fast rate of tailings rise and liquefaction potential in a high seismic potential area. 4. Environmental Impacts Test: The need for less dam material means less material needs to be quarried or borrowed for dam fill resulting in less environmental impacts. However, the higher potential for tailings liquefaction results in a higher risk of dam failure and inundation of the land and water bodies by tailings. ***Why Dismissed*** – PLP is proposing a centerline dam for the bulk TSF and downstream dam for the pyritic TSF which are considered more stable construction methods and reduce the risk of dam failure. Upstream construction is dismissed from further consideration because of potential environmental impacts from a higher risk of dam failure.	
Storage Method– Emergency Storage for TSF	TSF-011	***Origination*** – Scoping comments expressed concern regarding the stability of and environmental impacts of a TSF failure due to an unexpected event such as seismic activity or unexpected water volumes. ***Description*** –This option would require an emergency storage/overflow containment area to minimize risk of tailings spills from excessive buildup of water in the TSF. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: The dam design would require that the dams accommodate a 200 year flood event when the TSF was at maximum capacity (both events at the same time). An emergency storage facility would provide redundancy but at the expense of having to build a separate facility that would require the disturbance and use of additional land. Any redundancies that could be achieved would be more economically achieved by more robust TSF, WMP,	**Status Under Review**

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		seepage collection and sediment pond facilities. The concerns this option are intended to address are already designed into the proposed project so this option is not reasonable. ***Why Dismissed*** – The option is not reasonable because the suggestion is already part of the proposed project.	
Tailings Production – Segregated Bulk/Pyritic Tails	TSF-012	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which involves keeping both bulk and pyritic tailing streams separate. Separate tailings streams are a by-product of the mining process so no additional steps are required. This option would require separate TSFs for bulk and pyritic tails.	☑ Proposed ☐ Alternative ☐ Dismissed
Tailings Production – Blended Bulk/Pyritic Tails	TSF-013	***Origination*** – This option was evaluated by PLP as a potential tailings production and storage method. ***Description*** – Under this option bulk and pyritic tailings streams would be combined into one for the purpose of having a single TSF. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This is a reasonable option to consider. 3. Practicable Test: This option requires an additional step to blend tailings streams and maintaining more water in the TSF to keep the pyritic tailings subaqueous to mitigate ARD and metal leaching potential. The entire facility would need to be managed in perpetuity to maintain the wet closure and to collect and treat seepage. A blended facility would also need to be lined, which would hinder the flow-through design concept of the bulk TSF and thereby prevent the bulk tailings from dewatering over time and becoming a stable landform.	☐ Proposed ☐ Alternative ☑ Dismissed

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		4. Environmental Impacts Test: The blended tails would result in a large volume of tailings, and hence seepage water, that would need to be managed for potential ARD metal leaching. The wet closure would have a long-term post-closure dam failure risk higher than the proposed project. ***Why Dismissed*** – This option would increase overall adverse impacts because the pyritic tails would "contaminate" the bulk tails and require subaqueous storage in perpetuity.	
Bulk Tailings Basin –Unlined	TSF-014	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which would discharge thickened bulk tailings into an unlined basin and provide TSF solids and water management in a manner that results in the TSF groundwater level sloping down towards the main embankment, and the seepage passing through a collection system built under the main embankment and being collected by the bulk TSK main seepage collection pond.	☑ Proposed ☐ Alternative ☐ Dismissed
Bulk Tailings Basin – Lined	TSF-015	***Origination*** – This option was evaluated by PLP when developing the proposed project design. ***Description*** – This option has the bottom of the bulk TSF fully lined so that the bulk tailings would not be in contact with the ground surface. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: TBD 3. Practicable Test: It would be possible to fully line the bulk TSF although it would increase costs. However, lining of the bulk TSF will create a bathtub of water in the lower part of the TSF because the liner will impede the planned flow through of seepage through the tailings and main embankment. This will	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		result in saturated lower tailings that could be susceptible to static and seismic liquefaction during operations and through closure and post-closure, even in thickened tailings several hundred feet deep. Technologies have been evaluated to connect drains into bottom liners to enhance seepage, but they have not been proven and implemented on a similar scale. 4. Environmental Impacts Test: This option would result in poor consolidation of tailings that would lead to long term saturation of the deeper tailings and susceptibility to static and seismic liquefaction. This would defeat the drainage objective of the proposed thickened TSF. The ultimate result would be higher potential mobility of the tailings and prevention of the tailings from consolidating over time by gradual drainage and ultimately become a stable landform as proposed. ***Why Dismissed*** – This option would increase overall adverse impacts because the liner would retain water in the bulk tails and increase the risk of dam failure and tailings mobility.	
Pyritic Tailings Basin – Lined	TSF-016	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which has the bottom of the pyritic tailings TSF fully lined so that the pyritic tailings would not be in contact with the ground surface. Additionally, this option allows for pyritic tailings to be stored sub-aqueously without the circulation of seepage water.	☑ Proposed ☐ Alternative ☐ Dismissed
Pyritic Tailings Basin – Unlined	TSF-017	***Origination*** – This option was evaluated by PLP when developing the proposed project design. ***Description*** – Under this option the pyritic TSF would be unlined. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		2. Reasonable Test: It is reasonable to consider an unlined facility. 3. Practicable Test: It is practicable with existing technology to build an unlined TSF and it would reduce costs. 4. Environmental Impacts Test: PLP has proposed a lined pyritic TSF to allow subaqueous storage during operations. The liner would also reduce the volume of pyritic tailings-contaminated seepage from the facility that would need to be collected and treated. PLP has also proposed to move the pyritic tails and PAG waste to the completed pit at closure and reclaim the TSF, eliminating the need for the pyritic TSF to be perpetually maintained. ***Why Dismissed*** – This option would increase overall adverse impacts.	
TSF Location – NFK West TSF Location	TSF-018	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action and would store the bulk tails two to three miles west of the proposed pit. The pyritic tails would be stored at the NFK East location (TSF-021).	☑ Proposed ☐ Alternative ☐ Dismissed
TSF Location – NFK North TSF Location	TSF-019	***Origination*** – This TSF location was evaluated by PLP when developing the proposed project design. ***Description*** – This option would store pyritic tailings about two miles north of the proposed open pit. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This location has been studied previously and is a reasonable option to consider.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		3. Practicable Test: This site is close to the process plant, has sufficient storage capacity for all tailings, and allows for the segregation of bulk and pyritic tailings. This option has the highest efficiency making it the least costly option. 4. Environmental Impacts Test: The catchment area of the site is high and the total anadromous stream miles impacted and impacted acres of wetlands for this site are high. ***Why Dismissed*** – This option would increase overall adverse impacts.	
TSF Location – NFK East TSF Location	TSF-020	***Origination*** – PLP Proposed Action ***Description*** – This location is proposed by PLP to store the pyritic tailings about one mile west of the proposed open pit. The bulk tailings would be stored at the NFK West location (TSF-019).	☑ Proposed ☐ Alternative ☐ Dismissed
Combined TSF and Operating Pond	TSF-021	***Origination*** – This option was evaluated by USACE to avoid impacts associated with a separate water management pond. ***Description*** – This option would add the Operating Pond (part of the main water management pond) to the bulk TSF. It would result in additional water stored in the bulk TSF and would eliminate the need for or reduce the size of the main water management pond. The objective would be to perform all bulk tailings and water management operations at one facility instead of two facilities. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It is reasonable to consider options that potentially reduce footprint. A combined pond is proposed for the Donlin Gold Mine. 3. Practicable Test: This option is compatible only with the slurry tailings disposal method (TSF-002). The option is not compatible with the thickened tailings disposal objective of ultimate drainage and consolidation of the tailings to a	**Status under review**

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Tailings Management			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		stable landform. Production of thickened tailings requires the dewatering of tailings as part of the milling process. The bulk TSF is planned to store thickened tailings that have been previously dewatered to the extent that they would be discharged to the bulk TSF at a solids content of 55%. This plan will result in a drier and more stable tailings deposit than would result from slurry tailings discharge. A combined bulk TSF/Operating Pond facility could be achieved by either not thickening the tailings and thereby depositing slurry tailings, or building an internal embankment within the combined facility to separate the thickened tailings from water. 4. Environmental Impacts Test: The proposed main water management pond has a footprint of approximately 925 acres, of which about 750 acres contains the normal operating pond level, and the remaining 175 acres is for the maximum operating pond level and probable maximum flood (PMF). Much of this area is wetlands. If the bulk TSF also contained the Operating Pond, there would be a reduction in impacts to Waters of the U.S. However, a combined bulk TSF/Operating Pond facility that combined non-thickened tailings and water would be a slurry TSF that is contrary to the environmentally safer consideration of a thickened TSF, and in conflict with current global mining objectives of developing drier TSFs as best available technology regardless of water supply factors, and moving the industry towards zero tailings dam failures. A combined bulk TSF/Operating Pond facility with separate thickened tailings and water storage areas would require a bulk TSF area and a water retention area separated by a divider dam, and would require a footprint that will be larger than the planned bulk TSF footprint, but could be similar to the combined footprints of the proposed separate bulk TSF and main water management pond facilities.

PAG Waste Rock			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Storage Method– Store PAG with Pyritic Tails	PAG-001	***Origination*** – PLP Proposed Action ***Description*** – All potentially acid generating waste rock would be stored in the pyritic TSF. All PAG waste rock would be returned to the pit at closure with the pyritic tailings for permanent subaqueous storage.	☑ Proposed ☐ Alternative ☐ Dismissed
Storage Method– Store PAG in LGO stockpile	PAG-002	***Origination*** – This option was PLP's Proposed Action in the December 2017 DA permit application. PLP's May 11, 2018 update changed the process and would place all PAG in the pyritic tails TSF. ***Description*** – This option would store PAG with the LGO stockpile. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: This option is no longer viable because PLP is not proposing an LGO stockpile. ***Why Dismissed*** – The Proposed Action no longer has an LGO stockpile and therefore the option is not reasonable.	☐ Proposed ☐ Alternative ☑ Dismissed
Storage Method– Separate WRF Storage	PAG-003	***Origination*** – This storage method was evaluated by PLP when developing the proposed project design. ***Description*** – This option would involve the construction of a separate permanent facility for waste rock. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Separate waste rock facilities are common at mines and this is a reasonable option to consider. 3. Practicable Test: This option requires the construction of a separate facility and water management and access infrastructure. The facility would be exposed to	☐ Proposed ☐ Alternative ☑ Dismissed

PAG Waste Rock			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		the air and hence would generate ARD and ML that would need to be collected and treated. Additional collection and treatment facilities and infrastructure would be needed. 4. Environmental Impacts Test: Construction of the associated infrastructure would increase wetland impacts for no environmental benefit. ***Why Dismissed*** – This option would increase overall adverse impacts associated with construction of a separate facility and PAG waste rock would likely generate acid rock drainage over time.	

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Water Treatment and Air			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
Water Treatment	WTP-001	***Origination*** – PLP Proposed Action ***Description*** – This option is part of the Proposed Action which involves water treatment technology to meet the Alaska water quality discharge standards. To meet the water quality standards in receiving body per *Alaska Water Quality Criteria Manual*, and to meet the mine plan requirements, two water treatment plants (WTPs) would be required. WTP #1 near the Open Pit and WTP#2 near the Main WMP. WTP #1 would use chemical precipitation and filtration for metals removal. WTP#2 would use chemical precipitation followed by Reverse Osmosis (RO) for meeting total dissolved solids (TDS)/sulfate limits, and biological selenium removal.	☑ Proposed ☐ Alternative ☐ Dismissed
Enhanced Water Treatment	WTP-002	***Origination*** – Evaluation of an option that treats water for discharge to meet the water quality of the natural receiving waters was suggested during scoping. ***Description*** –This option would require the water quality of all discharged water to be the same as receiving water. Additional water treatment steps would likely be required to achieve this. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It appears this suggestion was made without an understanding of the regulations that apply to water discharges. PLP would be required and has committed to achieving applicable water quality standards at the end of pipe (i.e., no mixing zones). The standards are developed by ADEC to be protective of aquatic life; therefore, the enhanced treatment makes this option not reasonable. ***Why Dismissed*** – PLP would be required and has committed to achieving applicable water quality standards at the end of pipe (i.e., no mixing zones). The	☐ Proposed ☐ Alternative ☑ Dismissed

Water Treatment and Air			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		standards are developed by ADEC to be protective of aquatic life; therefore, there is no benefit of additional treatment of the water making this option not reasonable.	
Enhanced Water Treatment – Zero Metal Discharge	WTP-003	***Origination*** – Evaluation of an option that would result in zero discharges of metals into the watershed was suggested during scoping. ***Description*** – This option would require there to be zero metal content in discharged water. In order to meet zero metal content, chemical precipitation followed by RO, and an additional ion exchange (IX) step would be required to completely remove the metals. The treatment system would essentially generate ultrapure water for discharge by providing a treatment that is well beyond what is required to meet the water quality standards, thereby resulting in "over treatment." This water is expected to have very low TDS or mineral content, and is likely to be "too clean" for discharge (i.e., some constituents have minimum standards). In order to address potential toxicity associated with this flow, addition of certain constituents is likely required to make it amenable for discharge resulting in some metal content. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: It appears this suggestion was made without an understanding of the regulations that apply to water discharges. PLP would be required and has committed to achieving applicable water quality standards at the end of pipe (i.e., no mixing zones). The standards are developed by ADEC to be protective of aquatic life; therefore, the additional treatment that would be required makes this option not reasonable. ***Why Dismissed*** –PLP would be required and has committed to achieving applicable water quality standards at the end of pipe (i.e., no mixing zones). The standards are developed by ADEC to be protective of aquatic life; therefore, there is	☐ Proposed ☐ Alternative ☑ Dismissed

Water Treatment and Air			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		no benefit of treating the water to make it cleaner than required making this option not reasonable.	
Enhanced Water Treatment – Reverse Osmosis	WTP-004	***Origination*** – Evaluation of an option that would require reverse osmosis for all water treatment was suggested during scoping. ***Description*** –This option would utilize chemical precipitation followed by Reverse Osmosis (RO) processing for water treatment at both water treatment plants (WTP#1 and WTP#2). ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: PLP would be required and has committed to achieving applicable water quality standards at the end of pipe (i.e., no mixing zones). The standards are developed by ADEC to be protective of aquatic life; therefore, the additional treatment that would be required makes this option is not reasonable. ***Why Dismissed*** – RO-based treatment is primarily required for TDS and sulfate removal. Because both TDS and sulfate are below the discharge limits in the influent water to WTP#1, RO is not required. Chemical precipitation followed by filtration would be sufficient to meet the discharge limits for WTP#1, and RO based treatment can be limited to just WTP#2. The option of using RO at both WTPs is not reasonable and would unnecessarily increase the carbon footprint, facility size, and the residual solids disposal requirements.	☐ Proposed ☐ Alternative ☑ Dismissed
Airtight Structure for Emissions Collection	AIR-001	***Origination*** – Evaluation of an option that covers the development with an airtight structure in order to contain ARD from getting into the air was suggested during scoping.	☐ Proposed ☐ Alternative ☑ Dismissed

AMERICAN OVERSIGHT

Table B-1: Preliminary List of Project Options Being Considered

Water Treatment and Air			
Option	**Option #**	**Option Details and Screening** ❖ Option Details: Origination, Description ❖ Screening Criteria: 1. Purpose and Need Test, 2. Reasonable Test, 3. Practicable Test, 4. Environmental Impacts Test ❖ Why Dismissed (as applicable)	**Status**
		Description – This option calls for the development and construction of an airtight structure that covers the Mine Site. Any fumes or gasses would be cleaned before the air can be re-released into the atmosphere. ***Screening*** – 1. Purpose and Need Test: Meets the purpose and need. 2. Reasonable Test: Design for this type of structure is not reasonable, as there is no air quality concern with emissions from ARD. An airtight structure would be the largest structure in the world. ***Why Dismissed*** – This option is dismissed because it is not reasonable and the suggestion is based on a misunderstanding of potential acid rock drainage impacts.

All,
As we gear up to get into the workshops and revisions to the dEIS Chapters 3 and 4, I would like to share a list of information request topics that have been generated to date. Not all of the RFIs are relevant to your areas of expertise or jurisdiction by law, but as your teams begin their preparation for the development of the analysis, it may be helpful for them to know what the Corps has asked for from the applicant. We will be posting the RFIs to the public website, but if there are specific RFIs not on the site that may assist your team, please send an email and we will get you the responses/requests as we can. This should reduce the number of redundant requests and help inform future information needs.

Thank you and your teams in assisting in the development of the analysis.

Shane McCoy
Program Manager

Subject: Pebble Cooperating Agency Meeting
Attachments: 20181024 Cooperating Agency Meeting.pdf
Location: Atwood Conference Center Room 106, 550 W 7th Avenue, Anchorage

Start: 10/24/2018 8:30:00 PM
End: 10/25/2018 12:30:00 AM
Show Time As: Tentative

Recurrence: (none)

Attached are slides for today's cooperating agency meeting.

Shane will be providing additional information on the meeting next week but asked that I send the teleconference and WebEx information. Additional materials/handouts will be distributed before the meeting for those calling in.

Draft Agenda:
1. Review of alternatives to be analyzed in detail
2. Format and level of detail for Chapter 2
3. Update on Appendix B (addressing USACE/CA comments, next version will be Draft EIS)
4. Review of select alternatives:

a. Filtered tailings (dry stack)
c. Other mine locations
d. Underground mining

Public Notice of Application for Permit

PUBLIC NOTICE DATE: January 5, 2018

REFERENCE NUMBER: POA-2017-271

WATERWAY: Multiple

An application has been received in this office from Pebble Limited Partnership (applicant) to discharge fill material into and perform work within waters of the United States. The project site is located in Southwest Alaska near Iliamna Lake, primarily within the Lake and Peninsula Borough with a portion of the supporting infrastructure in the Kenai Peninsula Borough. The project consists of four primary project elements: a mine site, a port at Amakdedori, transportation corridor, and natural gas pipeline. The submitted application is available on the Corps website at www.poa.usace.army.mil/Missions/Regulatory/Permitting-Section-Homepage/Department of the Army Permit Application POA-2017-271 submitted by Pebble Limited Partnership.

The Corps has determined and notified the applicant that an environmental impact statement level of analysis will be required for the review of the Department of the Army Permit application. As such, the Corps will conduct public scoping after publishing a Notice of Intent to develop an EIS in the federal register. The Notice of Intent will include a list of public scoping locations. Times and dates for these locations will subsequently be advertised via Corps Public Notice and website as well as local media outlets.

Please contact Sheila Newman, Regulatory Division Program Manager at (907) 753-2712, toll free from within Alaska at (800) 478-2712, by fax at (907) 753-5567, or by email at poaspecialprojects@usace.army.mil if further information is desired concerning this notice.

Scoping for Department of the Army Permit Application 2017-271-Pebble Limited Partnership, Environmental Impact Statement

JOINT BASE ELMENDORF-RICHARDSON – The U.S. Army Corps of Engineers – Alaska District requests public input regarding the scope of the environmental impact statement level of analysis for Department of the Army permit application POA-2017-271 submitted by Pebble Limited Partnership.

The Pebble Project has been in the public eye for many years and there have been multiple public input and comment opportunities from other agencies. This public body of information has helped to inform the Corps' preliminary scope for the environmental impact analysis.

The Corps is now asking the public for any additional information to help inform the scope of analysis as it specifically relates to the Pebble Limited Partnership's submitted permit application to include potentially affected resources, alternative options, analytical methodology, and potential mitigation measures.

Since Jan.5, the permit application has been publically available on the Alaska District's website. On Jan.12, the application was mailed via CD to 35 federally recognized Alaska Native Tribes alongside invitations for government-to-government consultation throughout the entire evaluation process including the EIS. The Corps maintains the application as well as additional scoping information at www.pebbleprojecteis.com.

Scoping input can be submitted by mail to:

U.S. Army Corps of Engineers, Alaska District
Program Manager, Regulatory Division
ATTN: DA Permit Application 2017-271, Pebble Limited Partnership
P.O. Box 6898
Joint Base Elmendorf-Richardson, Alaska, 99506-0898

Beginning April 1, scoping input can be entered directly into the project website at www.pebbeprojecteis.com.

Also, scoping input can be submitted in person at public meetings via directly into the provided computers, handing in written comments, or speaking to a court reporter.

AMERICAN OVERSIGHT

Please note that public scoping meetings are not public hearings. The Corps has chosen to arrange meetings to provide the public with an easy forum to provide input. All information received will become part of the public record upon receipt.

Meeting locations and times are indicated below. A video explaining major project components will be available for viewing. The Corps will have representatives available to answer questions regarding the Department of the Army permit application review process. Individuals may come in at any time during open hours and to provide scoping input. A Yupik translator will be available at the meetings.

NEWS RELEASE

U.S. ARMY CORPS OF ENGINEERS **BUILDING STRONG®**

For Immediate Release:
April 6, 2018
Release No. 18-007

Contact:
John Budnik, 907-753-2615
Public.affairs3@usace.army.mil

Corps extends public scoping period for Department of Army permit application 2017-271 Pebble Limited Partnership, Environmental Impact Statement

JOINT BASE ELMENDORF-RICHARDSON – The U.S. Army Corps of Engineers – Alaska District has allotted more time for the public scoping period for the environmental impact statement level of analysis for Department of Army permit application 2017-271 submitted by Pebble Limited Partnership.

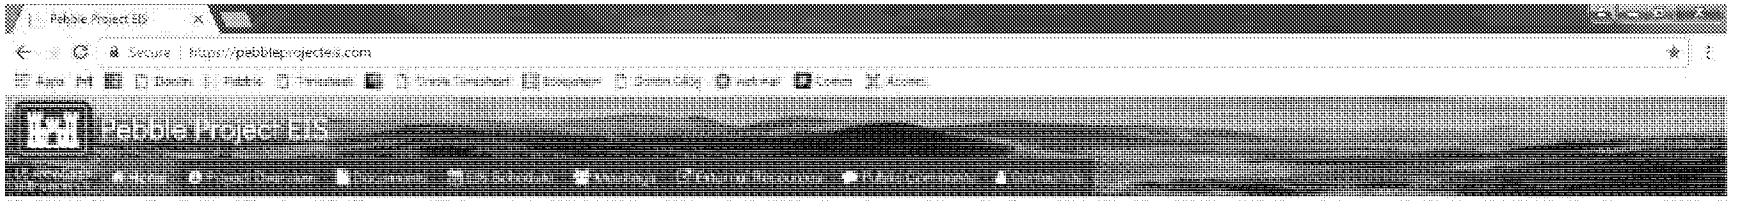
An additional 60 days has been added to the original 30-day public scoping period that began on April 1. Therefore, interested parties that would like to provide scoping input have until June 29 to submit.

The Corps is asking the public for any additional information to help inform the scope of analysis as it specifically relates to the Pebble Limited Partnership's submitted permit application to include potentially affected resources, alternative options, analytical methodology, and potential mitigation measures. The permit application is available on the project website at www.pebbleprojecteis.com.

Scoping input can be submitted by mail to:

U.S. Army Corps of Engineers, Alaska District
Program Manager, Regulatory Division
ATTN: DA Permit Application 2017-271, Pebble Limited Partnership
P.O. Box 6898
Joint Base Elmendorf-Richardson, Alaska 99506-0898

Scoping input can be entered directly into the project website at www.pebbleprojecteis.com.



Also, scoping input can be submitted in person at public meetings via directly into the provided computers, handing in written comments, or speaking to a court reporter. Please note that public scoping meetings are not public hearings. The Corps has chosen to arrange meetings to provide the public with an easy forum to provide input. All information received will become part of the public record upon receipt.

To learn more about the Corps' Regulatory Division and its program, visit http://www.poa.usace.army.mil/Missions/Regulatory/.

###

AMERICAN OVERSIGHT

Welcome

The U.S. Army Corps of Engineers invites you to participate in the Pebble Project Environmental Impact Statement (EIS) process. Pebble Limited Partnership proposes to develop the Pebble copper-gold-molybdenum porphyry deposit (Pebble Deposit) as an open-pit mine, with associated infrastructure, in southwest Alaska, approximately 17 miles west/northwest of the villages of Iliamna, Newhalen, and Nondalton. A 188-mile natural gas pipeline from the Kenai Peninsula across Cook Inlet to the Kime Site is proposed as the energy source for the mine. The Transportation Corridor includes an 18-mile crossing of Lake Iliamna and an Amakdedori Port facility on the western shore of Cook Inlet.

The proposed mine requires many federal and state permits. The EIS provides the basis for the U.S. Army Corps of Engineers and other federal agencies to evaluate federal permit applications.

Your input can make a real difference in understanding:

- Issues and concerns that should be addressed in the EIS
- The way in which land and resources might be affected by the project
- Ideas on alternatives and ways to minimize impacts

We hope this website will answer your questions and make it easy for you to participate. Please add your name to our mailing list if you would like to be mailed our newsletters. If you have any questions that are not answered on the website, please contact us.

This site is being continually updated. Check back often for updates.

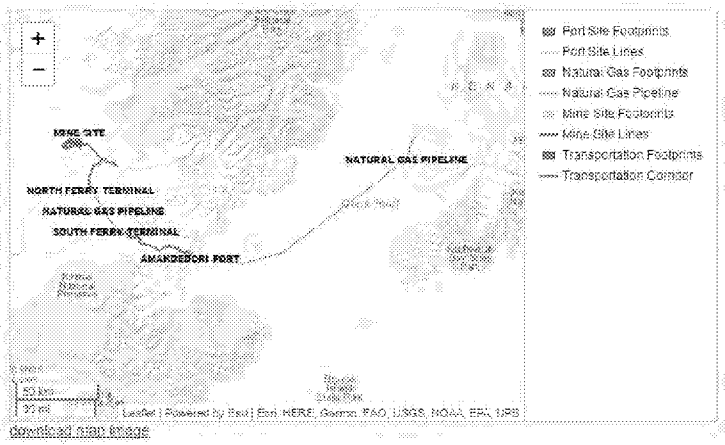
Pebble Project EIS

Pebble Project EIS

Project Overview | Mine Site | Transportation Corridor | Amakdedori Port | Natural Gas Pipeline | Applicant Video

Project Overview

Pebble Limited Partnership (Applicant) has applied for permits to develop the Pebble copper-gold-molybdenum porphyry deposit (Pebble Deposit) as an open-pit mine, with associated infrastructure. The Pebble Deposit is located under rolling, permafrost-free terrain in the Iliamna region of southwest Alaska, approximately 200 miles southwest of Anchorage and 60 miles west of Cook Inlet. The closest communities are the villages of Iliamna, Newhalen, and Nondalton, each approximately 17 miles from the Pebble Deposit. In addition to the Mine Site, the project would have three other major components: Transportation Corridor, Amakdedori Port, and Natural Gas Pipeline.



The Pebble Deposit lies within a 417-square-mile claim block held by subsidiaries of the applicant and by a subsidiary of the applicant's parent company, Northern Dynasty. Neither the applicant nor Northern Dynasty currently owns surface rights associated with these mineral claims. All lands within the claim block are owned by the State of Alaska. Rights to develop on State of Alaska land may be acquired when necessary locations for mine development have been determined and permits awarded. The Transportation Corridor crosses both state land and land patented under the Alaska Native Claims Settlement Act.

The proposed project would have a mine life of approximately 20 years. During that time, there would be:

- a total of 1.2 billion tons of material mined over the life of the project;
- mining rate up to 90 million tons per year;
- milling rate up to 58 million tons per year;
- annual copper-gold concentrate production of 600,000 tons; and
- annual molybdenum concentrate production of 15,000 tons.

The project would have an operating schedule of two 12-hour shifts per day for 365 days per year, and employ approximately 2,000 personnel for construction and 850 for operations.

A more detailed project description from the applicant to the U.S. Army Corps of Engineers can be found here.

Documents

To download a document, click on its title below. Before you download a file, please be aware of your connection speed and note the size of the file you want. Some files are very large and may take a long time to download, depending on the speed of your internet connection.

For example, at a minimal dial-up modem speed of 56 Kbps, a 2 MB document will take about 5 minutes to download; a 25 MB file will take about an hour. With a high speed connection of 10 Mbps, files of both these example sizes would download in less than 30 seconds.

⚠ Documents not produced by the U.S. Army Corps of Engineers may not be in compliance with the Americans with Disabilities Act Section 508, and documents that are produced by the U.S. Army Corps of Engineers may not be fully compliant. Please contact us if you require assistance and we will try to accommodate your needs. This may include providing the information to you in an alternative format.

Scoping Meeting Schedule

The U.S. Army Corps of Engineers hosted public meetings in nine communities to give a presentation on USACE's role in permitting for the Project and the Environmental Impact Statement (EIS) process. The purpose was to inform communities about the EIS and gather comments from the public about concerns. Full transcripts are located here. You can view all comments as they are submitted here.

Community	Date & Time	Location
Naknek	Monday, April 9, 2018 3:30 PM - 7:30 PM	Naknek School
Kokhanok	Tuesday, April 10, 2018 3:30 PM - 7:30 PM	Community Hall
Homer	Wednesday, April 11, 2018 5:00 PM - 9:00 PM	Homer High School
Newhalen	Thursday, April 12, 2018 3:30 PM - 7:30 PM	Newhalen School

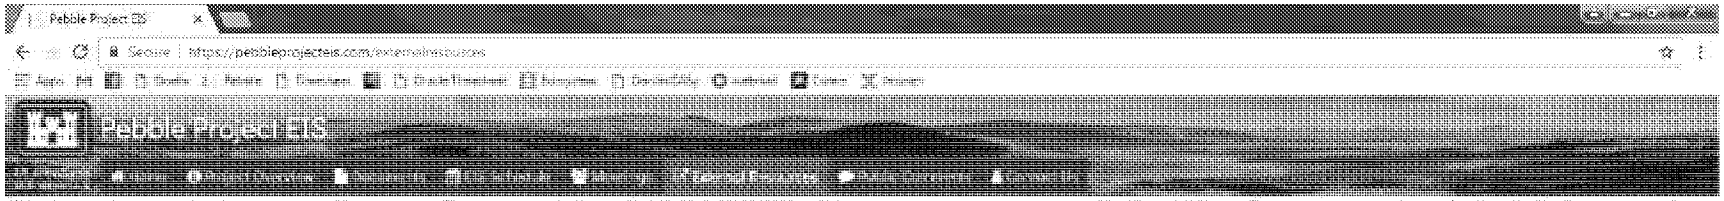
Nondalton	Monday, April 16, 2018 3:30 PM - 7:30 PM	Tribal Center
Dillingham	Tuesday, April 17, 2018 5:00 PM - 9:00 PM	Middle School
Igiugig	Wednesday, April 18, 2018 3:30 PM - 7:30 PM	Community Building
Anchorage	Thursday, April 19, 2018 11:00 AM - 5:00 PM	Denali'ina Center

Providing ample opportunities for the public to submit scoping comments on the Pebble Project EIS is of utmost importance to the USACE. Public comments during this scoping phase will be accepted during the scoping period, scheduled to run from April 1, 2018 to June 29, 2018.



Submit your comment

There will be an additional public comment period in January 2019 when the Draft EIS is released.

Public Scoping for the Pebble Project EIS

The US Army Corps of Engineers (USACE) is preparing an Environmental Impact Statement (EIS) to analyze the impacts of issuing permits for an open pit, copper-gold-molybdenum porphyry deposit, with associated infrastructure, as proposed by the Pebble Limited Partnership. The EIS scoping period begins April 1, 2018 and ends June 29, 2018.

At the beginning of developing an EIS, USACE reaches out through scoping to involve members of the public. The scoping period provides opportunities for people who could be affected by the proposed action to express their views and concerns, and to offer suggestions on the scope of analysis. Public input may include ideas for alternatives to the proposed action that could have lesser environmental impacts.

The EIS will identify potential impacts on the physical, biological, and social environment from all phases of the proposed project, including construction, mine operation, closure, and post-closure. The EIS will also look at mitigation methods—ways in which potential negative impacts could be avoided or lessened.

Public meetings will tentatively be held during the scoping period of April 1st to June 29th, 2018, in the following communities:

- Anchorage*
- Dillingham*
- Homer*
- Igiugig
- Kokhanok
- Naknek
- Newhalen
- New Stuyahok
- Nondalton

* To avoid long wait times, an open public testimony format will not be used.

Please check our website for the current meeting schedule.

During the scoping period, USACE will work with the public to identify issues and concerns to thoroughly analyze the potential effects of the proposed project. USACE will use the scientific literature, alongside traditional knowledge and observations provided by the public.

We welcome your comments and information on the resources that are important to you. For example, many communities will be concerned about potential impacts to fish, subsistence resources, and traditional land uses during project construction, operations, and closure.

To Participate...

Providing ample opportunities for the public to submit scoping comments on the Pebble Project EIS is of utmost importance to the USACE. A good way to get involved is to come to a scoping meeting and give your comment orally to a dedicated court reporter, or electronically submit using one of a number of dedicated laptop computers. You can also bring written comments to a meeting, use the comment form on the project website (www.PebbleProjectEIS.com), or send them to:

Program Manager, Regulatory Division
US Army Corps of Engineers
PO Box 6898
Joint Base Elmendorf Richardson
AK 99506-0898

Let us know what aspects of the proposed project are important to you!

Scoping comments can be submitted through June 29, 2018.

* Comments received/postmarked after June 29 will be considered but may not be included in the scoping report. Comments will be reviewed and incorporated into the Draft EIS.

AMERICAN OVERSIGHT

PEBBLE PROJECT DESCRIPTION

Pebble Limited Partnership (PLP), proposes to develop the Pebble copper-gold-molybdenum porphyry deposit (Pebble Deposit) as an open-pit mine, with associated infrastructure, in southwest Alaska. The Pebble Deposit is located approximately 200 miles southwest of Anchorage and 60 miles west of Cook Inlet. The closest communities are the villages of Iliamna, Newhalen, and Nondalton, each approximately 17 miles from the Pebble Deposit, and Kokhanok, which is located 3 miles to the northeast of the proposed road from the port site to the south ferry terminal on Lake Iliamna (see Figure 1).

PEBBLE PROJECT COMPONENTS

The Pebble Project as proposed consists of four facility and operations components:

Mine Site and Associated Facilities (see Figure 2)

- **Open pit mine**, developed in stages, with each stage expanding the area and deepening the previous stage. Final dimensions of the open pit would be approximately 6,500 feet long and 5,500 feet wide, with depths between 1,330 and 1,750 feet.
- **Mine site mineral processing facilities** include a crushing plant, coarse ore stockpile, grinding plant, froth flotation circuits to produce concentrates, and concentrate filters to remove moisture before shipment.
- **Copper-gold concentrate** would be loaded into covered bulk shipping containers and transported by truck to the Amakdedori Port. **Molybdenum concentrate** would be bagged and containerized before shipping to Amakdedori Port.
- **Tailings Storage Facility** located within the North Fork Koktuli watershed:
  - 1.1 billion tons storage volume.
  - separate cells for bulk and pyritic (lined) tailings.
  - four embankments: main (600 feet high), south (350 feet high), and east (60 feet high) perimeter embankments and an internal embankment (420 feet high) separating the bulk and pyritic tailings cells.
- **Low Grade Ore Stockpile** up to 330 million tons of mineralized material, segregated by relative value, and PAG waste rock, placed on an engineered liner to control seepage losses through the stockpile.
- **Waste rock** – Non-potentially acid generating (NPAG) waste rock would be used to construct various mine site structures, including the TSF embankments and mine site roads. PAG waste rock would be stored within the LGO stockpile until mine closure, and then back-hauled into the open pit.
- **Overburden Stockpile** segregated to the southwest of the open pit, and surrounded by a berm of non-mineralized rock to contain the material and increase stability.
- **Water Supply, Management and Treatment** consists of five components:
  - potable water well field and treatment plant.
  - two water management ponds (open pit and LGO/main).
  - sediment ponds.
  - three seepage ponds (south, west, and main embankment).
  - two water treatment plant/three discharge locations (north, south and east).

AMERICAN OVERSIGHT

- **Personnel camps** include a main construction camp to accommodate 1,700 workers, later refurbished for 850 rooms for operations.
- **Power generation** capacity and distribution infrastructure: 230 megawatt delivery capacity fired by natural gas and a 69-kilovolt distribution system.

Amakdedori Port Site (See Figure 3)

- **Ore carrier vessels** up to 40,000 dead weight tons and 700 feet in length, up to **25 Handysize ships will be required annually** to transport concentrate.
- Up to **30 marine line-haul barge loads of supplies and consumables** will be required annually. **Two ice-breaking tug boats** will be used to support marine facility operations.
- **2000 foot earthen access causeway** extending out to a marine jetty located in 15 feet of natural water depth.
- **Access channel and turning basin,** dredged to 50 foot depth.
- **Shore-based facilities** to receive and store containers and fuel, two, 2-MW natural gas power generators with an emergency diesel generator, a natural gas compressor station, maintenance facilities, employee accommodations, and offices.
- **Fuel storage** consisting of four 1.25 million gallon tanks inside a lined and bermed area

Transportation Corridor (see Figure 3)

Road System Connecting Amakdedori Port to the Mine Site

- **Private, double-lane road extending 30 miles south from the Mine Site to North ferry terminal** on the north shore of Iliamna Lake.
- **Private, double-lane road extending 35 miles southeast from the South Ferry Terminal to the Amakdedori Port** on Cook Inlet.
- **Eight bridges**, six of which would be single-span, two-lane bridges that range in length from approximately 90 to 170 feet. There would be one large (550 feet) multi-span, two-lane bridge across the Newhalen River and one large (455 feet) multi-span, two-lane bridge across the Gibraltar River.
- Daily transportation of concentrate, fuel, reagents and consumables would require **up to 35 truck round trips per day for each leg of the road**, including three loads of fuel per day.
- **Village surface road connections** from the Transportation Corridor to Iliamna, Newhalen, and Kokhanok.

Ferry Service and Terminals on Lake Iliamna

- **18 mile ferry crossing of Lake Iliamna.**
- **All-season icebreaking ferry** with 12 crew members.
- **Inbound supplies from the Amakdedori Port to the Mine Site** and **outbound copper-gold and molybdenum concentrates, backhauled waste, and empty containers.**
- **Average of one round trip ferry per day.**
- **Two ferry terminals** with 40 foot rock/aggregate causeway, container handling and storage facilities, office and maintenance buildings, and local power supply.

AMERICAN OVERSIGHT

Natural Gas Pipeline System (see Figure 1)

- **188 mile 10-12 inch diameter natural gas pipeline**, buried 3 feet deep onshore, in five segments:
  - starts on the eastern shore of Cook Inlet at Happy Valley near Anchor Point along the Sterling Highway.
  - 94 mile subsea pipeline crosses Cook Inlet to the Amakdedori Port Site.
  - 35 mile buried pipeline adjacent to the road from port site to south ferry terminal.
  - 18 mile pipeline across Lake Iliamna.
  - 30 mile buried pipeline adjacent to the road from north ferry terminal to Mine Site.
- **Two gas fired compression stations**, one on the eastern end at Anchor Point, and one at the Amakdedori Port.
- **Buried fiber optic cable** adjacent to pipeline.

PROJECT CONSTRUCTION

- **The project would take approximately four years to construct,** on four main project components – Mine Site, Amakdedori Port, Transportation Corridor, and Pipeline.
- **Transportation infrastructure to access the site is the first step**, along with Pre-production Phase environmental protection systems and temporary facilities that support construction crews (camps at port site, mine site, ferry terminals).
- **Initial access to the mine site within one year,** followed by earthworks, plant facilities, tailings storage embankments, stockpile foundations/liners, and water treatment facilities.
- **Natural gas line installation** will occur during the second and third construction years.
- **Completion of Pre-production Open Pit, power plant and processing facilities** in year 4.
- **Construction employment** estimated at 2,000 workers.

PROJECT OPERATIONS

- **Project operating life of 20 years**, **three mining phases** – pre-production, production and stockpile reclaim.
- **Conventional open pit mine** – drill, blast, truck and shovel operation.
- **Blasting events** – once to twice a day.
- **Tailings Storage Facility water management** – Control, collection, and recovery of tailings water for recycling or treatment prior to discharge; seepage collection system below impoundment structures; freeboard to contain inflow design flood.
- **Total material mined** – 1.2 billion tons over the life of the project.
- **Mining rate** up to 90 million tons per year, **milling rate** up to 58 million tons per year.
- **Annual concentrate production** – 600,000 tons copper gold, 15,000 tons molybdenum.
- **Operations employment** estimated at 850 workers, two shifts per day, 365 days/year.

AMERICAN OVERSIGHT

PROJECT CLOSURE

- **Reclamation and closure jurisdiction** – Alaska Department of Natural Resources Division of Mining, Land, and Water, and Alaska Department of Environmental Conservation.
- **Design for Closure** – early consideration of requirements for Closure and post-Closure site management.
- **Segregation of the bulk and pyritic tailings storage cells** to facilitate Tailings Storage Facility closure.
- **Potentially Acid Generating waste rock** backhauled to mine pit for subaqueous storage.
- **Comprehensive water management plan** that strategically discharges surplus treated water to downgradient streams in a manner that reduces the effect of flow changes on stream flow and fish habitat.
- **Removal of mill and other infrastructure** not required for closure and reclamation.
- **Reclamation of disturbed areas** through grading, use of top soil as need and revegetated.
- **Road system retained** as needed for post-Closure activities and monitoring.
- **Pit lake water quality will be monitored;** water will be treated and discharged before levels approach elevation where groundwater flows outward from the open pit.

For more details, see Attachment D Project Description, Department of Army Application for Permit (POA-2017-271) on www.PebbleProjectEIS.com.

How Alternatives will be Developed for the Pebble Project Environmental Impact Statement (EIS)

1. Identify need to which the United States Army Corps of Engineers (USACE) – Alaska District is responding and identify the overall project purpose. State the applicant's objectives for the project.
2. Compile a range of alternatives to be considered that meet the overall project purpose with consideration of the applicant's objectives. The alternatives compilation will include the no action alternative, any alternatives considered by the applicant, and alternatives suggested during the scoping process.
3. Determine whether identified alternatives are reasonable in accordance with the National Environmental Policy Act.
    a. Reasonable is based on the consideration of the overall project purpose including stated objectives as well as technology, economics, and common sense.
    b. Determine whether an alternative meets the overall project purpose inclusive of objectives.
        i. Alternatives that do not meet the overall project purpose will be eliminated at this stage.
        ii. Alternatives that meet the overall purpose will move forward.
    c. Alternatives that meet the overall project purpose will be reviewed to determine whether the alternative was available to the applicant during project planning (past 10 years).
        i. Alternatives identified as reasonable but were not available to the applicant will be removed at this time.
        ii. Alternatives that were available will move forward.
    d. Alternatives will be reviewed for technical feasibility (can these alternatives be accomplished using existing technology and equipment?).
        i. Alternatives determined to not be technically feasible will be removed at this stage.
        ii. Alternatives determined to be technically feasible will move forward.
    e. Alternatives will be reviewed for economic feasibility.
        i. Any alternative claimed to not be economically feasible by the applicant will require an economic analysis to support statement.
        ii. An alternative proven to not be economically feasible will be removed at this time.
        iii. Alternatives determined to be economically feasible will move forward.
    f. Alternatives will be reviewed using common sense.
        i. Alternatives that increase adverse environmental impacts will be removed at this time.
        ii. Alternatives will also be reviewed for logistical feasibility. Alternatives that are not logistically feasible will be removed at this time.

Identified REASONABLE ALTERNATIVES with significantly LESSER impacts will be evaluated in the EIS along with the NO ACTION alternative and the applicant's PROPOSED alternative.

AMERICAN OVERSIGHT

How Alternatives are Screened for Practicability

Due to the USACE specific authorities, alternatives must also be screened for practicability. The practicability determination is described below. Ultimately, the USACE must identify the **least environmentally damaging practicable alternative (LEDPA)** in the Record of Decision prior to making a decision under Section 404 of the Clean Water Act.

1. From the identified reasonable alternatives, further identify practicable alternatives in accordance with Clean Water Act Section 404(b)(1) of the Clean Water Act (the Guidelines). The Guidelines state practicable means the project is available and capable of being done after taking into consideration **cost**, **existing technology** and/or **logistics** in light of the overall project purpose including the applicant's objectives. Logistics and existing technology have at this point been screened in our determination of reasonable alternatives and are included below only for completeness and explanatory purposes. *An alternative needs to fail only one practicability factor to be determined not practicable*.
    a. Costs – Cost is analyzed in the context of the overall scope/cost of the project and whether it is unreasonably expensive. This determination is typically made in relation to comparable costs for similar actions in the region or analogous markets. Cost is to be based on an objective, industry-neutral inquiry that does not consider an individual applicant's financial standing. The data used for any cost must be current with respect to the time of the alternatives analysis. Because one alternative costs more than another does not mean that the more expensive alternative is impracticable. It is important to note that in the context of this definition, cost does not include economics.
    b. Existing Technology – The alternatives examined should consider the limitations of existing technology yet incorporate the most efficient/least-impacting construction methods currently available.
    c. Logistics – The alternatives evaluated may incorporate an examination of various logistics associated with the project (e.g., placement of facilities within a specified distance to major thoroughfares, utilization of existing storage or staging areas, and/or safety concerns that cannot be overcome).
    d. Availability – The Guidelines state that if an alternative is otherwise practicable, an area not presently owned by the applicant that could reasonably be obtained, utilized, expanded, or managed in order to fulfill the overall purpose of the proposed activity can still be considered a practicable alternative. In other words, the fact that an applicant does not own an alternative parcel, does not preclude that parcel from being considered as a practicable alternative. This factor is normally a consideration as a logistics and possibly cost limitation.
    e. Two tests are specified in the Guidelines for alternatives when the basic purpose of a project does not require siting within special aquatic sites such as wetlands. The basic purpose of this project is mining. The type of mining proposed (transitional metal-copper, gold, molybdenum) does not require siting within special aquatic sites. Therefore:
        i. It is presumed that alternatives that do not affect special aquatic sites such as wetlands are available

AMERICAN OVERSIGHT

ii. It is presumed that alternatives in sites that are not special aquatic sites will have a LESSER ADVERSE impact on the aquatic ecosystem

Once an otherwise practicable alternative has been identified, the applicant (Pebble Limited Partnership) will be required to clearly demonstrate to the USACE that both of these presumptions have been rebutted or the alternative will be considered in the determination of the LEDPA.

**All practicable alternatives are also reasonable alternatives.

2. The final step in developing alternatives is to construct detailed descriptions for the reasonable alternatives that have been retained and carried forward for evaluation in the EIS.

How the Public Can Provide Useful Guidance on Alternatives that should be Considered in the EIS

The purpose of scoping is to determine the alternatives that should be considered in the analysis and determine the extent and nature of issues by which each alternative should be evaluated.

Scoping is an important opportunity for all citizens to provide specific suggestions for alternatives that should be considered in preparing the EIS, and issues that should be addressed in that process. The following guidelines may be useful in submitting comments during the scoping period (*examples shown in italics*):

1. Keep in mind the reasonable alternative screening criteria described above – any suggestions should fulfill the overall project purpose in consideration of the applicant's objectives with a focus on reducing potential adverse environmental impacts.
2. You can suggest alternatives specific to components for developing the mine (*mining methods, water treatment, tailings management*), the port site, the transportation corridor and modes (*rail*), and the natural gas pipeline.
3. You can suggest changes in location of project components (*road, port site, mine components*).
4. You can suggest potential mitigation measures and conditions of development that may reduce environmental impacts.
5. Be as specific as possible and provide the reason for making your suggestions (*construction of a rail connection may eliminate truck traffic and reduce dust levels*).

The USACE will make the results of the scoping process publically available by publishing the Scoping Report on the project website (pebbleprojecteis.com) and will also communicate information for newsletters.

How Alternatives will be evaluated in this EIS

Once reasonable alternatives have been identified for evaluation as above, the USACE will evaluate each alternative in relation to the following:

- Conservation
- Economics
- Aesthetics

AMERICAN OVERSIGHT

- General environmental concerns
- Wetlands
- Historic properties (inclusive of sacred sites or areas of community and/or spiritual significance)
- Fish and wildlife values (inclusive of endangered species, marine mammals, fisheries and wildlife)
- Flood hazards
- Floodplain values
- Land use (inclusive of transportation corridors)
- Navigation
- Shore erosion and accretion
- Recreation
- Water supply and conservation
- Water quality
- Energy needs
- Safety
- Food and fiber production (this would include subsistence activities)
- Mineral needs
- Considerations of property ownership
- The needs and welfare of the people

In the EIS, we will develop a framework to analyze each of these issues with emphasis on issues that rise to the highest level of importance.

During scoping, we are also asking you to help us determine which of these factors are of highest concern to you, to provide information of specific concern regarding any factor listed, and to identify any other specific issues that are not listed. As with your comments related to alternatives, please be as specific as possible when identifying other issues or expanding on issues identified above. This will help us develop the analytical framework moving forward.

For alternatives identified as practicable, the USACE will ultimately make the following determinations:

1) Whether the alternative is the least environmentally damaging practicable alternative,

2) Whether the LEDPA will cause or contribute to the violation of applicable state or federal laws, such as water quality standards or the Endangered Species Act,

3) Whether the LEDPA will result in significant degradation of waters of the United States

4) Whether the LEDPA includes appropriate and practicable steps have been taken to minimize the adverse impacts of the project on wetlands and other waters.

AMERICAN OVERSIGHT

What Resources will be Analyzed in the EIS?

Using the analysis in the Environmental Impact Statement (EIS), The U.S. Army Corps of Engineers (USACE) will evaluate the environmental and related social and economic effects of the proposed project. The analysis will include direct and indirect impacts, cumulative effects, and potential spill and tailings dam failure scenarios. Comments received during the scoping period will likely result in additional resources to be considered in the analysis.

Social Environment

- Cultural Resources
- Historic Properties
- Land use and management
- Subsistence
- Transportation and Navigation
- Aesthetics
- Recreational and Commercial Fisheries
- Recreation
- Needs and Welfare of the People
- Environmental Justice
- Health and Safety

Physical Environment

- Geohazards
- Geology
- Soils
- Surface Water Hydrology including flood plains and flood hazards
- Groundwater Hydrology
- Water Quality
- Noise
- Air Quality
- Climate Change

Biological Environment

- Wetlands/Special Aquatic Sites
- Vegetation
- Birds
- Terrestrial Wildlife
- Fisheries and Aquatic Resources
- Marine Wildlife
- Threatened and Endangered Species

Direct impacts occur through direct interaction of an activity with an environmental, social, or economic component.
For example: pollutant discharge from a source could directly result in lowered water quality.

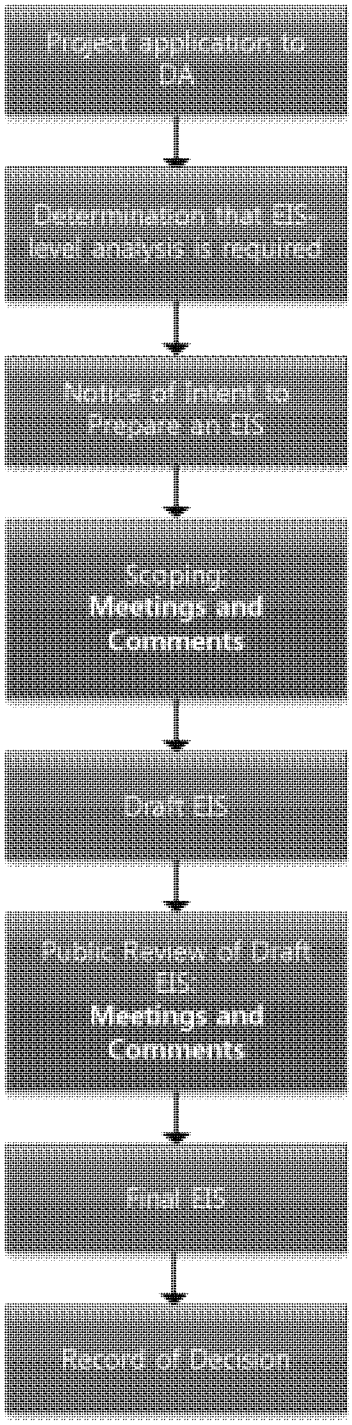
Indirect impacts on the environment are not a direct result of the project, but often a result of a complex impact pathway.
For example: pollutants in the air from a source could land on vegetation, indirectly causing acidic soils.

Cumulative impacts occur when the incremental impact of the project is combined with the effects of other past, present and reasonably foreseeable future projects.
For example: wetland fill from one project, combined with the wetland fill from a separate project.

AMERICAN OVERSIGHT

What is NEPA?

The national commitment to the environment was formalized through the passage of the National Environmental Policy Act (NEPA) of 1969. NEPA's goal is to help the federal government make decisions with full understanding of the potential environmental consequences associated with federal projects or authorizations. A thorough understanding of consequences allows us to identify potential actions that can be taken to protect, restore, or enhance the environment.



As the USACE prepares to review the submitted permit application, it must conduct a detailed study of:

- how the project will be built,
- the consequences of the project (good or bad) on the environment and for communities,
- alternative ways to develop the project that still meet the project's purpose and needs while better protecting people and the environment, and
- measures that can be taken to avoid or lessen any harmful impacts of the project.

Transparency

Before a decision is made and throughout its analysis, the federal government must ask citizens to voice concerns and suggest alternatives to ensure decisions on federal actions are well informed.

Steps in the EIS Process

AMERICAN OVERSIGHT

Roles and Responsibilities

When the Pebble Limited Partnership (Applicant) submitted an application on December 22, 2017, the US Army Corps of Engineers, Alaska District (USACE) was compelled to begin processing the permit application in accordance with 33 CFR 320. The USACE determined that review of the application would require an environmental impact statement (EIS) level of anlaysis in compliance with the National Environmental Policy Act. The USACE is the lead federal agency for developing the EIS

Role of the Corps

The USACE, as the lead agency, is responsible for reviewing the permit application submitted by the applicant, and analyzing the potential environmental impacts from the proposed project. As lead agency, the USACE is responsible for identifying, inviting, and assigning roles to cooperating agencies including agencies that also have permitting decisions to make for the proposed project. The USACE will lead the effort to take a hard look at reasonable and practicable alternatives and evaluate the impacts of the proposed project utilizing an interdisiplinary team. At the completion of the environmental impact analysis, the USACE, will issue a Record of Decision related to USACE's authorities under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act.

Role of the 3rd Party Contractor

AECOM (a consulting firm) has been hired to provide the interdisciplinary team that will develop a fact-based independent analysis of the Pebble Project as proposed and evaluate identified reasonable alternatives. AECOM will work solely under the direction of the USACE and will be the primary developers of the EIS. AECOM will also provide support to the USACE for scoping and public involvement, development of alternatives to the proposed action, assessment of potential impacts, developing the Draft and Final EIS, and distribution. The AECOM team is made up of specialists and scientists in the biological environment, the physical environment, and the social environment.

Role of the Applicant

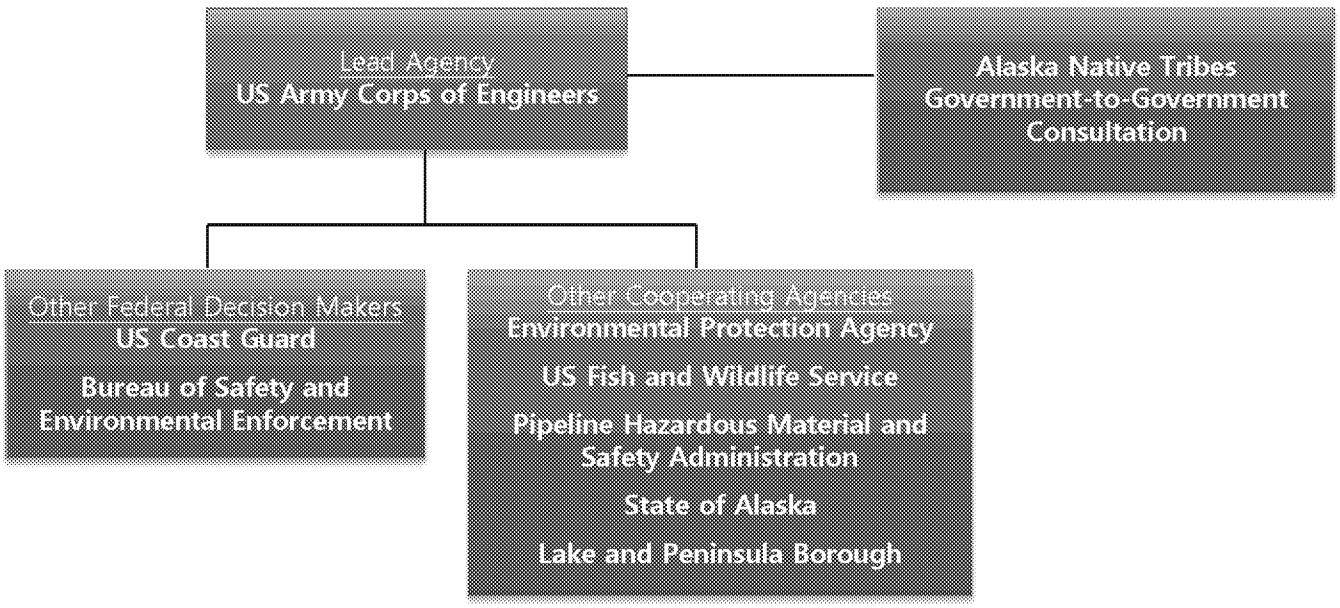
As the applicant is required to provide information to the USACE related to their proposed project. This includes:

- description of the proposed project,
- background material, completed research, and site information,
- data for the development of maps and figures, and
- other information that may be identified as necessary during preparation of the EIS.

The applicant will not be involved in the development of the EIS beyond this limited scope.

Role of Cooperating Agencies

Several cooperating agencies have been invited to provide technical support to the lead agency, the USACE. Cooperating agencies will be actively engaged in scoping and alternatives development and will then be assigned to technical teams based on the specific reasons they were invited to become cooperating agencies. Although cooperating agencies are involved in preparation and writing of certain portions of the EIS and cooperators may use the EIS for their own decisions, the USACE has final authority on the EIS content.



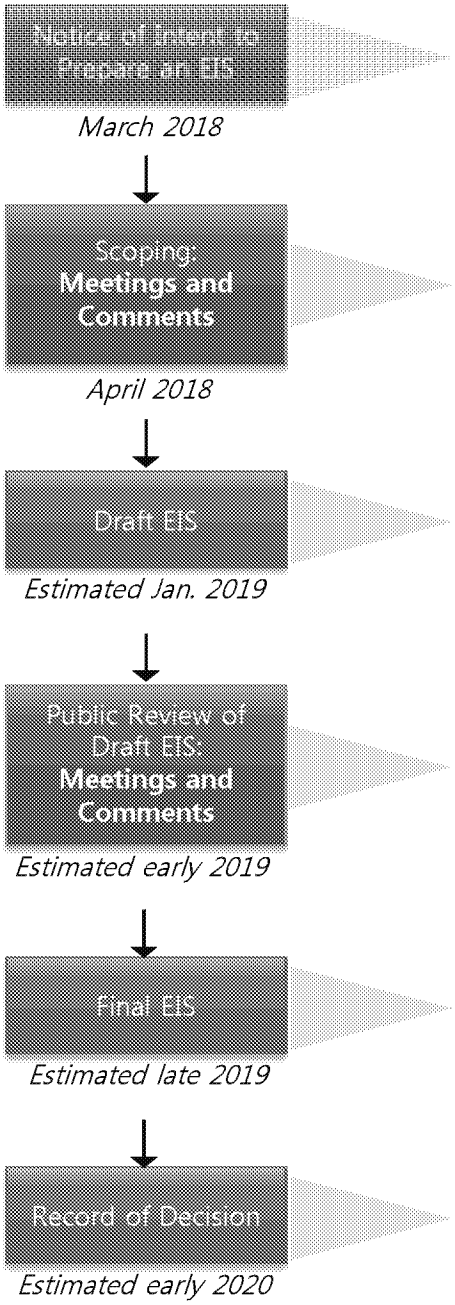
AMERICAN OVERSIGHT

Role of Alaska Native Tribes

The USACE has invited 35 federally recognized Alaska Native Tribes to consult throughout the entirity of the federal decision making process, including the development of the environmental impact statement. Federally recognized Alaska Native Tribes that the USACE has extended government-to-government consultation invitations to are:

- Aleknagik Traditional Council
- Chignik Bay Tribal Council
- Chignik Lagoon Village Council
- Chignik Lake Traditional Council
- Clarks Point Village Council
- Curyung Tribal Council
- Egegik Village Council
- Ekuk Village Council
- Ekwok Village Council
- Igiugig Village Council
- Iliamna Village Council
- Ivanof Bay Tribal Council
- King Salmon Tribal Council
- Kokhanok Village Council
- Levelock Village Council
- Manokotak Village Council
- Naknek Village Council
- Nanwalek IRA Council
- Native Tribe of Kanatak
- Native Village of Perryville
- New Koliganek Village Council
- New Stuyahok Traditional Council
- Newhalen Tribal Council
- Ninilchik Traditional Council
- Nondalton Tribal Council
- Pedro Bay Village Council
- Pilot Point Tribal Council
- Port Graham Tribal Council
- Port Heiden Village Council
- Portage Creek Village Council
- Seldovia Village Tribal Council
- South Naknek Vilage Council
- Traditional Council of Togiak
- Twin Hills Village Council
- Ugashik Traditional Council

Lead and Cooperating Agencies



AMERICAN OVERSIGHT

EIS Schedule

Preparation of the Pebble Project Environmental Impact Statement (EIS) level of analysis began in December 2017, when the US Army Corps of Engineers (USACE) received a permit application from the Pebble Limited Partnership (Applicant). The EIS process will take several months to complete a Draft EIS for public review, with a Final EIS expected within 24 months. The estimated schedule for the EIS is below.

Steps in the EIS Process

The USACE released a Notice of Intent to the United States Federal Register in March 2018. This initiated the process to prepare an EIS and began the scoping process.

The 30 day scoping process kicks off on April 1, 2018. Public meetings will be held at specific locations within the Bristol Bay region, and in Homer and Anchorage in April. Scoping offers a chance for the public to comment on the proposed project and alternatives.

Determining the alternatives to analyze, and then preparing the Draft EIS will happen immediately following the scoping period. The Draft EIS is anticipated to be released for public review and comment in 2019.

After the Draft EIS is released, the public will have a minimum of 45 days to submit comments. During that time, the USACE will plan public meetings, in the same locations that occurred during scoping, estimated for 2019.

The USACE will assess all public comments submitted on the Draft EIS, and incorporate changes into the Final EIS before release in 2019.

The Record of Decision will lay out USACE's decision on the application submitted by the Applicant. Three decisions are possible: issue a permit, issue a permit with conditions, or denial of the application. This is estimated to be released in 2020.

AMERICAN OVERSIGHT

EIS Outline

How the Draft and Final EIS will be Organized

The Environmental Impact Statement (EIS) will analyze the potential impacts to the biological, physical, and social environments. The EIS will be organized into chapters to address the specific requirements in the National Environmental Policy Act (NEPA). By understanding the layout of the document ahead of time, readers can more easily find the specific sections they may be interested in reviewing and providing comments.

Executive Summary – Provides overview of the Draft and Final EIS, summarizes draft findings of potential impacts, and serves as a guide for where to find details.

The purpose and need of a project is essential in establishing a basis for developing the range of reasonable alternatives required in an EIS and identifying and selecting a preferred alternative.

Chapter 1. Purpose and Need – Describes the purpose of the proposed project to inform the range of alternatives analyzed in the EIS.

Chapter 2. Alternatives – Describes alternatives to be analyzed, including a No Action Alternative, the Proposed Action (as designed by the Pebble Limited Partnership), and reasonable and practicable alternatives to address issues raised during scoping and the EIS process, such as, but not limited to, tailings and mine water management, alternate pipeline routes, surface access to the mine site and vehicle traffic levels, and port/ferry facilities, location, and traffic levels.

Chapter 3. Affected Environment – Describes the baseline conditions of key resource topics in the proposed project environment (such as fish and wildlife, water quality, economics, food production, commercial fishing, and recreation).

Chapter 4. Environmental Consiquences of Action – Analyzes the potential direct, indirect, and cumulative impacts, as well as potential mitigation measures relevant to each of the resources from the proposed action and each alternative.

Chapter 5. List of Preparers – Presents the list of contributors to the preparation of the EIS, including their affiliation, project role, educational background, and years of experience. Cooperating agency roles and responsibilities are also described in Chapter 5.

Chapter 6. List of Agencies, Organizations, and Persons to Whom Copies of the Statement Have Been Sent – Describes the distribution of the Draft and Final EIS documents for informational purposes and to identify public locations where the document is available.

Chapter 7. References – Presents the references used in preparing the EIS.

Chapter 8. Appendices – Presents the in-depth analyses, comments/response to comments, coordination, consultations, mailing lists and other information used in the analysis of the applicant's project.

AMERICAN OVERSIGHT

How to Comment

Public participation is an important part of developing an Environmental Impact Statement (EIS) under the National Environmental Policy Act (NEPA). Submitting substantive and concise comments during the scoping period is an important role the public plays in the NEPA process, and can influence the scope of analysis for the EIS.

General recommendations

- **Become familiar with the proposed project** — Review the project or agency website, read the project description, monitor local newspapers, and attend public meetings. The website for the Pebble Project EIS is www.PebbleProjectEIS.com.
- **Learn about the steps in the NEPA process** and opportunities for submitting to the U.S. Army Corps of Engineers (USACE). Public comment periods are during scoping, and at the draft EIS.
- **Keep your comments focused and as specific as possible** on the proposed project under consideration, what you think the EIS analysis needs to address and why.
- **Submit your comments within the timeframes announced** to ensure that your concerns are considered and addressed during the drafting of the EIS; the Scoping Comment period is from April 1 through April 30.

Comments on the project are not counted as votes; they are used to determine the appropriate scope of issues analyzed and contents of the EIS and to ensure that the impacts are adequately disclosed before the USACE makes a final decision on the permit application. Avoid simply agreeing or disagreeing with the proposed project. It is more important to identify specific relevant issues, alternatives, mitigation measures/conditions of permitting, and analytic tools so they can be used to inform the EIS analysis. The more clear, concise, and relevant your comments are, the more effective they will be in shaping the development of the EIS. For a citizen's guide to NEPA, visit https://ceq.doe.gov/get-involved/citizens_guide_to_nepa.html.

Tips for Writing Effective Comments

- **Be specific**. For example, if you are concerned about wildlife, focus on a particular problem or issue, such as a species that you feel should be analyzed, instead of making a broad statement such as "I am concerned about the impacts to wildlife."
- **Support your statements** with explanations, facts, and references, as appropriate.
- **Make suggestions,** including resources that should be analyzed, new data or analytic tools that should be used, and substantially different alternatives that should be evaluated in the EIS.

AMERICAN OVERSIGHT

Pebble Project EIS Comment Form

You can submit comments using the form on the website (www.PebbleProjectEIS.com), to a court reporter at a public scoping meeting, or in writing (using computers available at a meeting or by mail). We will not be taking public testimony at large meetings in Anchorage, Homer, and Dillingham. If you'd like to mail your comments or submit them at a meeting, please feel free to use this form and attach additional sheets as needed. Write your comments, questions, and suggestions below, then fold this page in thirds so that the mailing address is visible. Remember to affix first-class postage before putting it in the mail, postmarked by the comment deadline of June 29, 2018.

The following questions may help:

- What are your specific concerns about this project and how should they be addressed in the EIS?
- Are there particular fish and wildlife resources, subsistence activities/use areas, or other places that you use and how might they be affected by the project?
- Are there alternative ways of developing any of the components of the Pebble Project that should be considered in preparing the EIS?

Please note that all public comments, including names and addesses of of individuals and organizations, are publically available as part of documenting public involvement in preparing the EIS. The US Army Corps of Engineers intends to place public comments received during scoping on the project website.

Frequently Asked Questions

What is the U.S. Army Corps of Engineers' relationship with the applicant?

The U.S. Army Corps of Engineers (USACE) has no relationship with the applicant and is neither for or against the project. The USACE has a responsibility to review the applicant's proposed project with the same objectivity as it would any permit application and make a permit decision under the USACE statutory authorities.

Is the Pebble Project already approved and going to be built?

No.

What is the USACE's role in reviewing this project?

The applicant has applied for authorization under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. It is the USACE's responsibility to evaluate their application and ultimately make permit decisions (approval or denial) under the USACE's Clean Water Act and Rivers and Harbors authorities.

Why is the USACE conducting an EIS for this project?

The National Environmental Policy Act (NEPA) mandates an EIS-level of analysis should be conducted for review of any potential federal authorizations that could "significantly affect the quality of the human environment." The USACE has reviewed the permit application and has determined that the proposed project could "significantly affect the quality of the human environment."

Are any other federal decisions required based on the applicant's submittal of the permit application?

Two additional federal agencies have federal decision making authority: the U.S. Department of the Interior Bureau of Safety and Environmental Enforcement, and the U.S. Coast Guard.

Will the USACE seriously consider the No Action Alternative and what factors might lead to its selection?

The USACE cannot be pre-decisional, therefore, the process will be required to analyze and consider the No Action Alternative. In the context of USACE's evaluation, the No Action Alternative constitutes an action that would not include the discharge of fill material into waters of the United States.

What is the role of cooperating agencies that do not have federal decisions to make?

The role of cooperators invited due to specific expertise is to support the lead agency in developing the environmental analysis and providing technical assistance at the request of the lead agency.

AMERICAN OVERSIGHT

What is the role of federally recognized Alaska Native Tribes in the EIS process?

Thirty five federally recognized Alaska Native Tribes have been asked to consult directly with the USACE as lead agency throughout the entire decision making process to include the development of the environmental impact statement.

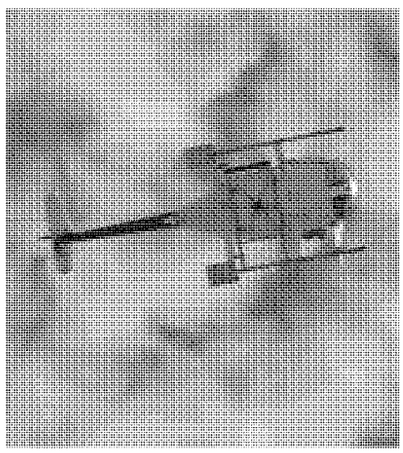
When and how will my comments be considered in preparing the EIS?

Public comments can be submitted at any time during the preparation of an EIS. Formal requests for comment occur during two important phases of an EIS:

- During the Scoping Period, the public is asked to comment on the issues and potential impacts that should be addressed in the EIS. The public is also asked to suggest alternatives to the proposed action that should be considered for evaluation in the EIS.
- Once the Draft EIS is released for public review and comment, the public is given the opportunity to submit comments in written form via the project website and orally at public meetings on the Draft EIS.
- All comments submitted will be put into the record, analyzed, and considered in determining the scope and potential impacts within the EIS and in making changes to the Draft EIS during the preparation of the Final EIS.
- The USACE is required to prepare responses to comments submitted on the Draft EIS; comments submitted and response will be included in the Final EIS.

AMERICAN OVERSIGHT

Pebble Project EIS



NEWSLETTER 1 | April 2018 | www.PebbleProjectEIS.com

US Army Corps of Engineers

Scoping Notice

The U.S. Army Corps of Engineers (USACE) Alaska District is conducting an Environmental Impact Statement (EIS) level of analysis to evaluate Department of the Army permit application POA-2017-271 submitted by Pebble Limited Partnership (PLP). PLP's application states the purpose of discharges of dredged and/or fill material into jurisdictional waters of the United States is for the purpose of developing a copper-gold-molybdenum porphyry deposit as an open-pit mine, with associated infrastructure, in southwest Alaska. The EIS scoping period begins April 1 and ends April 30, 2018.

The scoping period provides opportunities for any person interested in the proposed project to share information that can help shape the scope of analysis of the EIS. This may include ideas for alternatives to the applicant's proposed action as identified in the permit application (publically available at pebbleprojecteis.com) that could have lesser environmental impacts and identifying areas and/or issues of particular concern.

SCOPING PROCESS BEGINS

About PLP's Permit Application

PLP is proposing to develop the Pebble Deposit which is located under rolling, permafrost-free terrain in the Iliamna region of southwest Alaska, approximately 200 miles southwest of Anchorage and 60 miles west of Cook Inlet. The closest communities are the villages of Iliamna, Newhalen, and Nondalton, each approximately 17 miles from the Pebble Deposit. Portions of the proposed project lie within the Lake and Peninsula and Kenai Peninsula boroughs. Development of the Pebble Deposit would require federal permits from the USACE, The United States Coast Guard, and the Bureau of Safety and Environmental Enforcement for various aspects of the major project components. These three federal agencies are required to comply with the National Environmental Policy Act and thus will be using the EIS to inform their respective federal decisions. The major project components are briefly described here followed by an overview of the EIS process.

Major Project Components

Mine Site. The fully developed Mine Site would include the open pit mine, a tailings storage facility, a low grade ore stockpile, overburden stockpiles, material sites, water management ponds, milling and processing facilities, and supporting infrastructure such as a power plant, water treatment plants, camp facilities, and fuel and material storage facilities.

Transportation Corridor. The Transportation Corridor would connect the Mine Site to the Amakdedori Port on the west side of Cook Inlet. It has three main components:

1. A private, double-lane road extending 30 miles south from the Mine Site to a ferry terminal on the north shore of Iliamna Lake.

2. An ice-breaking ferry to transport materials, equipment, and ore concentrates 18 miles across Iliamna Lake between ferry terminals on the north and south shores of the lake.

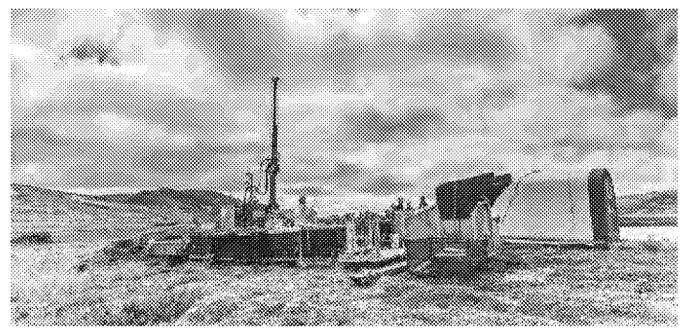
3. A private, double-lane road extending 35 miles southeast from the South Ferry Terminal near the community of Kokhanok, to the Amakdedori Port on the west side of Cook Inlet.

Amakdedori Port. The Amakdedori Port would be located near Amakdedori Creek on the western shore of Cook Inlet, approximately 190 miles southwest of Anchorage and approximately 95 miles southwest of Homer. It would include shore-based and marine facilities for the shipment of ore concentrates, freight, and fuel for the project. A 1300-foot earthen causeway with a 700-foot wharf would connect the port site with the docking facility. A 50-foot deep turning basin would be dredged adjacent to the docking facility, along with a 50-foot deep access channel. Other facilities would include fuel storage and transfer facilities, power generation and distribution facilities, maintenance facilities, employee accommodations, and offices.

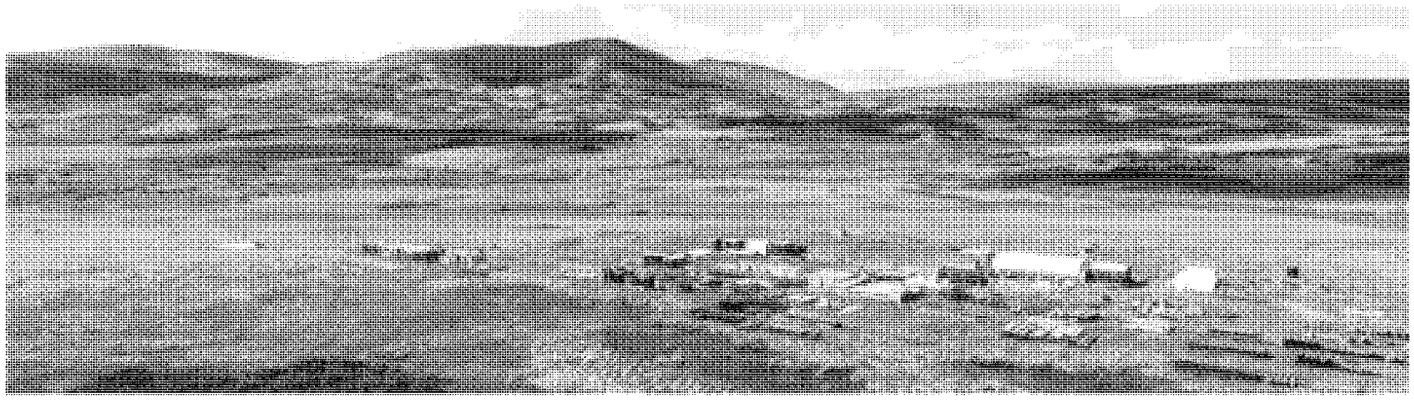
AMERICAN OVERSIGHT

EPA-0135-0002183

Natural Gas Pipeline. Natural gas, sourced from the existing natural gas supply infrastructure for the Cook Inlet area, would supply power generation for the Pebble Project, and would require the construction of a 188-mile pipe. The gas pipeline alignment would connect to existing infrastructure near Happy Valley on the Kenai Peninsula and travel south, paralleling the Sterling Highway for 9 miles to a compressor station near Anchor Point. From the compressor station, the pipeline would head southwest across Cook Inlet for 60 miles, before turning west for 35 miles to a landfall at the Amakdedori Port. A second compressor station and offtake point would be located at the port site. The pipeline would then follow the transportation corridor from the port to the mine site, including crossing Iliamna Lake on the lakebed.



ABOUT THE EIS



The USACE is serving as the lead federal agency for this EIS. The Bureau of Safety and Environment Enforcement and the United States Coast Guard have federal decision-making authority over portions of the applicant's proposed project and will serve as cooperating agencies. The U.S. Fish and Wildlife Service, Advisory Council on Historic Preservation, the State of Alaska (multiple divisions), the Lake and Peninsula Borough, the Pipeline and Hazardous Materials and Safety Administration, and the U.S. Environmental Protection Agency will serve as cooperating agencies to provide technical assistance for specifically identified special expertise. Thirty-five federally recognized tribal governments have been invited to participate directly through government-to-government consultation.

The EIS will identify potential impacts and potential benefits of the proposed project and reasonable altenatives on the physical, biological, and social environment from all phases of the project, including construction, operations, and post-closure. The EIS will also look at mitigation methods—ways in which potential negative impacts could be lessened. The USACE will use available scientific literature and subsequent data collected, alongside traditional knowledge and observations provided by the public.

We welcome your comments and information on the resources that are important to you. For example, many communities will be concerned about potential impacts to subsistence resources and land uses during project construction, operations, and closure. The EIS will address long-term cumulative effects, consider a reasonable range of alternatives, and analyze a range of practical mitigation and monitoring measures for protecting public health, water quality, wildlife, and subsistence resources.

AMERICAN OVERSIGHT
EPA-0135-0002184

Participate!

All interested parties are invited to participate in the EIS process. The goals of the public scoping process are to:

- Gather comments and suggestions from interested parties to help determine issues and concerns that are relevant to the analysis of potential impacts
- Help define a reasonable range of alternatives to evaluate in the EIS
- Capture information that will lead to the development of good mitigation and monitoring measures

Public Scoping Meetings

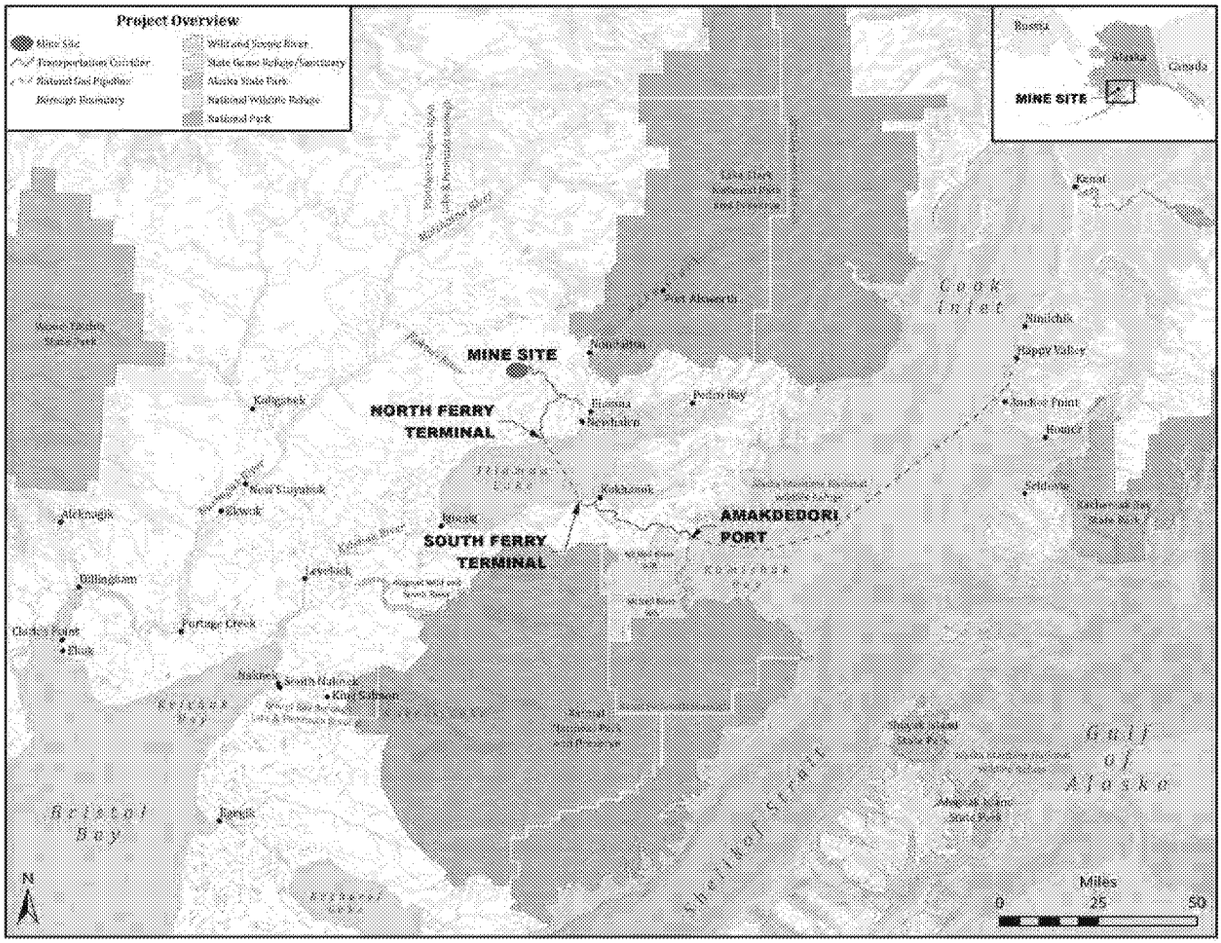
USACE has chosen to conduct scoping in multiple ways including scoping meetings in addition to our newsletters, website, and other communication methods. The scoping schedule includes meetings across the project area, as well as in Anchorage and Homer. The public meeting schedule is listed below.

COMMUNITY	DATE AND TIME	LOCATION
Naknek	April 9, 2018, 3:30 pm	Naknek School
Kokhanok	April 10, 2018, 3:30 pm	Tribal Hall
Homer*	April 11, 2018, 5:30 pm	High School
Newhalen	April 12, 2018, 3:30 pm	Newhalen School
Nondalton	April 16, 2018, 3:30 pm	Tribal Center
Dillingham*	April 17, 2018, 5:00 pm	Middle School
Iguigig	April 18, 2018, 3:30 pm	Community Building
Anchorage*	April 19, 2018, 5:00 pm	Dena'ina Center

**To avoid long wait times, a hot mic format will not be used.*

TO PARTICIPATE...

Providing ample opportunities for the public to submit scoping comments on the Pebble Project EIS is of utmost importance to the USACE. Come to scoping meetings and share your thoughts regarding project impacts and benefits and ideas for alternatives. Give your comment orally to a dedicated court reporter, or electronically submit using one of a number of dedicated laptop computers. You can also bring written comments to a meeting, use the comment form on the project website (www.PebbleProjectEIS.com), or send them to:



Program Manager, Regulatory Division
US Army Corps of Engineers
PO Box 6898
Joint Base Elmendorf Richardson,
AK 99506-0898

Let us know what aspects of the proposed project are important to you!

Written scoping comments can be submitted through April 30, 2018.
Comments received/postmarked after April 30 will be considered, but may not be included in the scoping report.
Comments will be reviewed and incorporated into the Draft EIS, as appropriate

Pebble Project EIS – Notice of Public Meetings

The Alaska District, U.S. Army Corps of Engineers (USACE) invites the public to attend public scoping meetings for the Environmental Impact Statement (EIS) analysis for the proposed Pebble Project, which would be located 17 miles west/northwest of the villages of Iliamna, Newhalen, and Nondalton, Alaska.

The EIS will analyze potential impacts from the proposed mine that would produce copper, gold, and molybdenum from the Pebble porphyry deposit. The proposed project also includes a 188-mile natural gas pipeline from the Kenai Peninsula across Cook Inlet to the Mine Site, an Amakdedori Port facility on the western shore of Cook Inlet, and an 83 mile transportation corridor that includes an 18-mile ferry crossing of Lake Iliamna.

These meetings are an opportunity for members of the public to provide comments and suggestions to help determine important issues and help define a reasonable range of alternatives to evaluate in the EIS. Please note that public scoping meetings are not public hearings. Scoping input can be submitted in person at public meetings via directly into the provided computers, handing in written comments, or speaking to a court reporter.

THE PEBBLE PROJECT

1 OVERVIEW

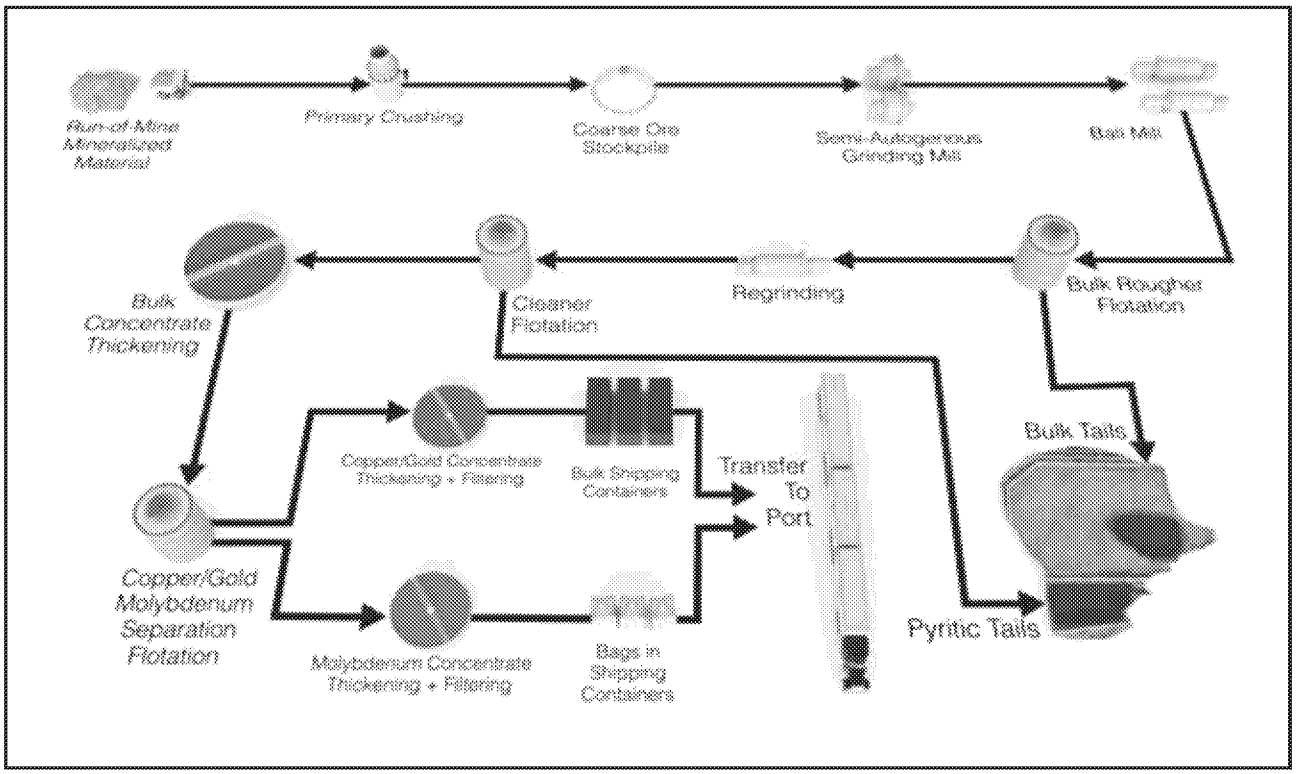
Pebble Limited Partnership (PLP) is proposing to develop the Pebble copper-gold-molybdenum porphyry deposit (Pebble Deposit) in southwest Alaska as an open-pit mine, with associated infrastructure.

PROJECT DESCRIPTION DETAILS

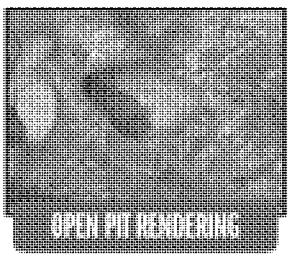
SUMMARY INFORMATION

- Located on state of Alaska land
- Project operating life of 20 years
- Employment of 2,000 people for construction and 850 for operation
- Gas pipeline from Anchor Point and gas-fired power plant at site
- Road and lake ferry to Cook Inlet
- Segregated storage of bulk and pyritic tailings

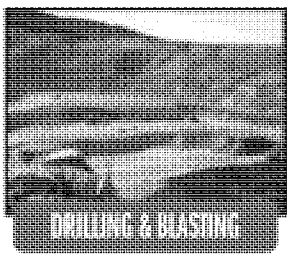
THE pebble PARTNERSHIP



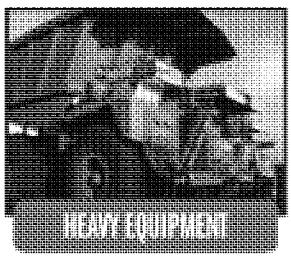
AMERICAN OVERSIGHT



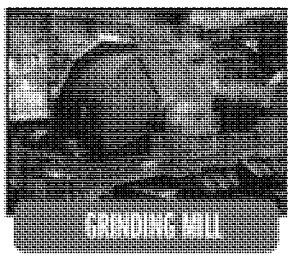
MINING & PROCESSING



2 MINING



The Project will mine approximately 1.1 billion tons of mineralized material throughout the 20-year mine life.



AN OVERVIEW OF MINERAL PROCESSING

OPEN PIT RENDERING

DRILLING & BLASTING

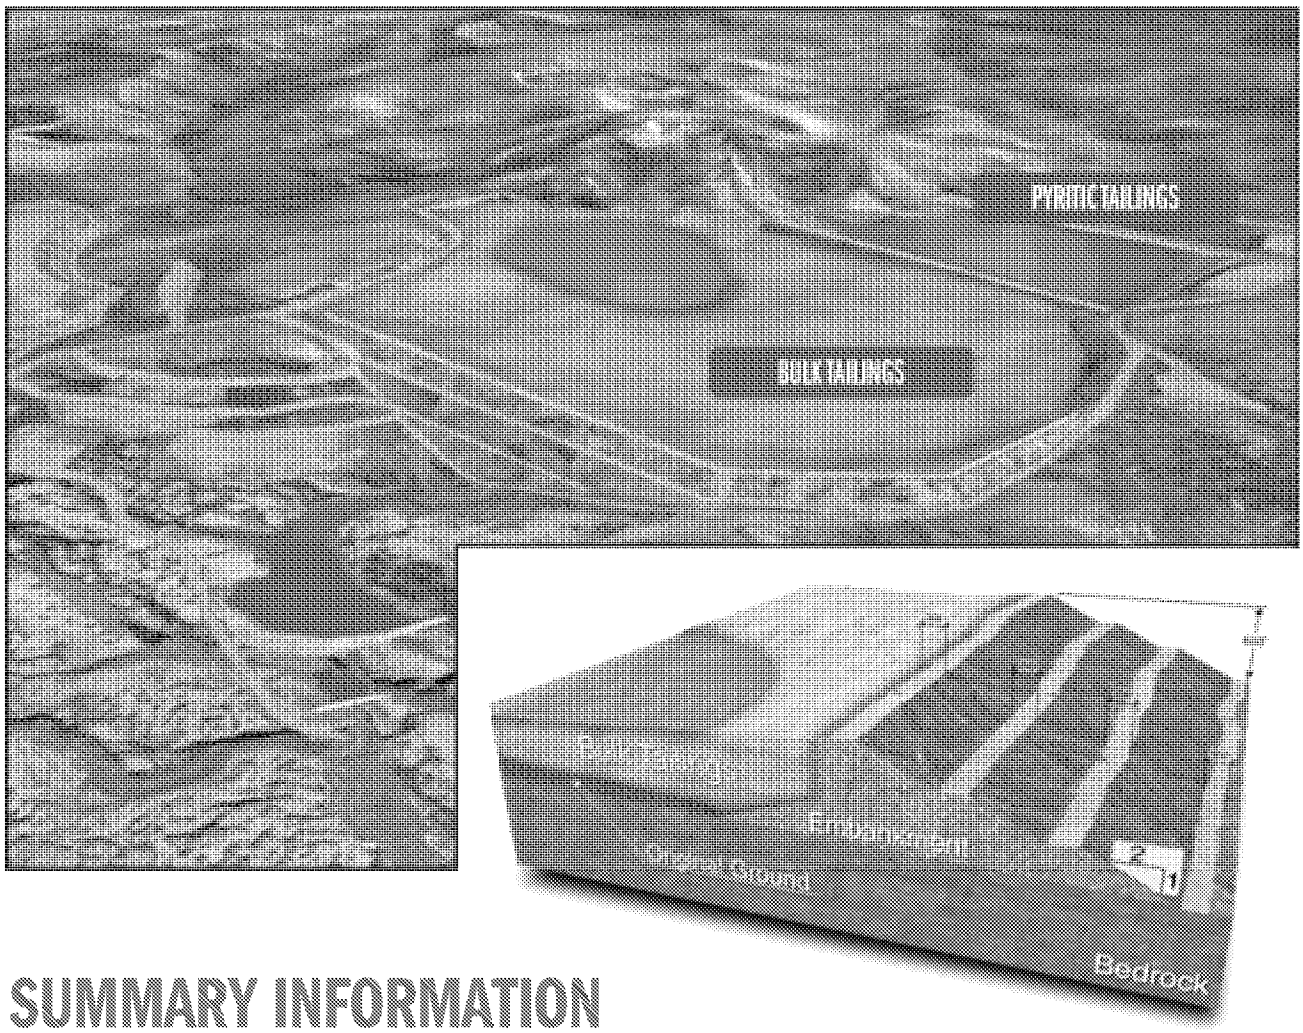
HEAVY EQUIPMENT

GRINDING MILL

SUMMARY INFORMATION

- Mining rate up to 90 million tons per year
- Milling rate up to 58 million tons per year
- Annual copper/gold concentrate production of 600,000 tons
- Annual molybdenum concentrate production of 15,000 tons

THE pebble PARTNERSHIP



AMERICAN OVERSIGHT

TAILINGS STORAGE

③ TAILINGS

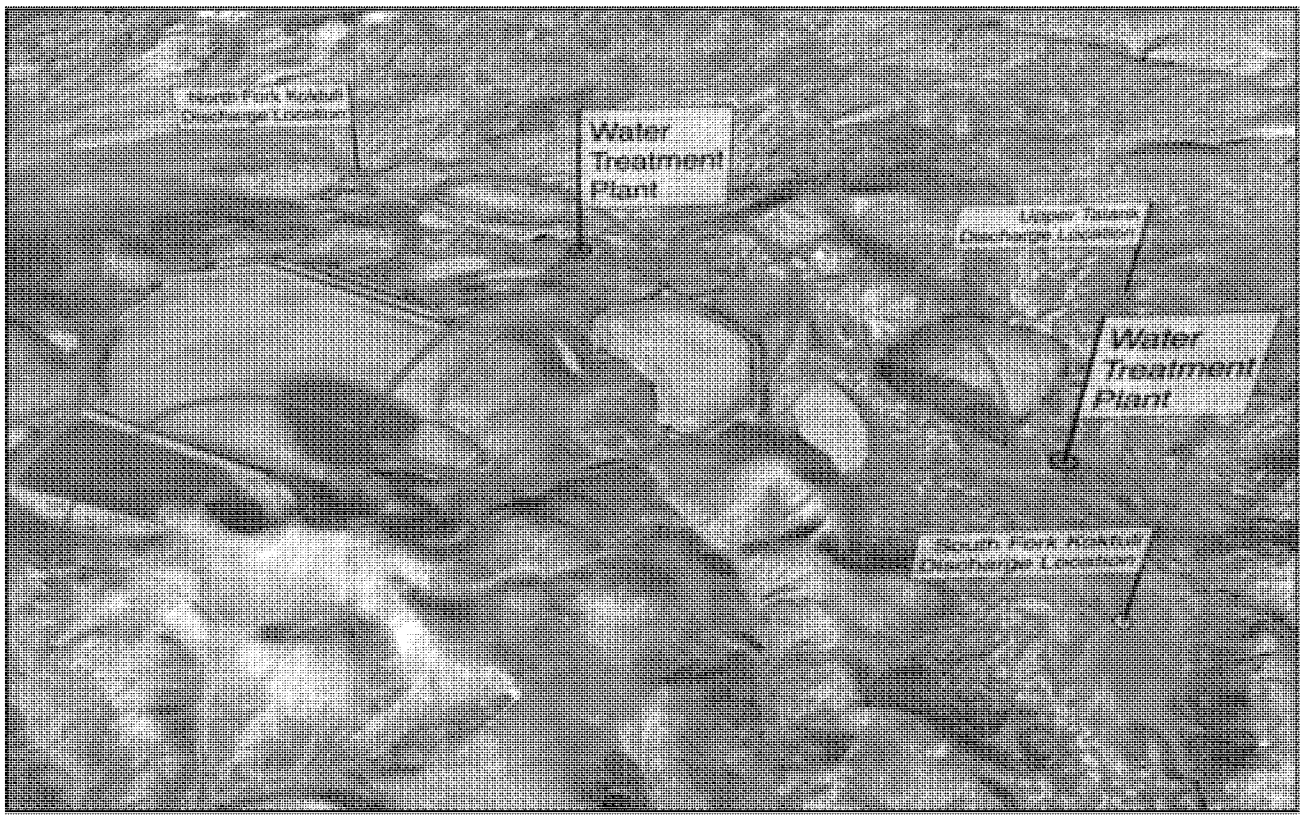
Pebble Limited Partnership (PLP) conducted a multiyear, multidisciplinary evaluation to select a Tailings Storage Facility (TSF) location that meets all engineering and environmental goals. It will store ground-up material after minerals have been extracted.

TAILINGS STORAGE FACILITY

SUMMARY INFORMATION

- Designed to meet Alaska Dam Safety Program standards
- Separate cells for bulk and pyritic tailings
- Minimize water storage in bulk tailings to keep water away from embankment
- Fully-lined cell for pyritic tailings with water cover
- Rock-filled embankments (600' high at main embankment)
- Seepage collection facilities for all embankments

THE pebble PARTNERSHIP



AMERICAN OVERSIGHT

WATER MANAGEMENT

4 WATER

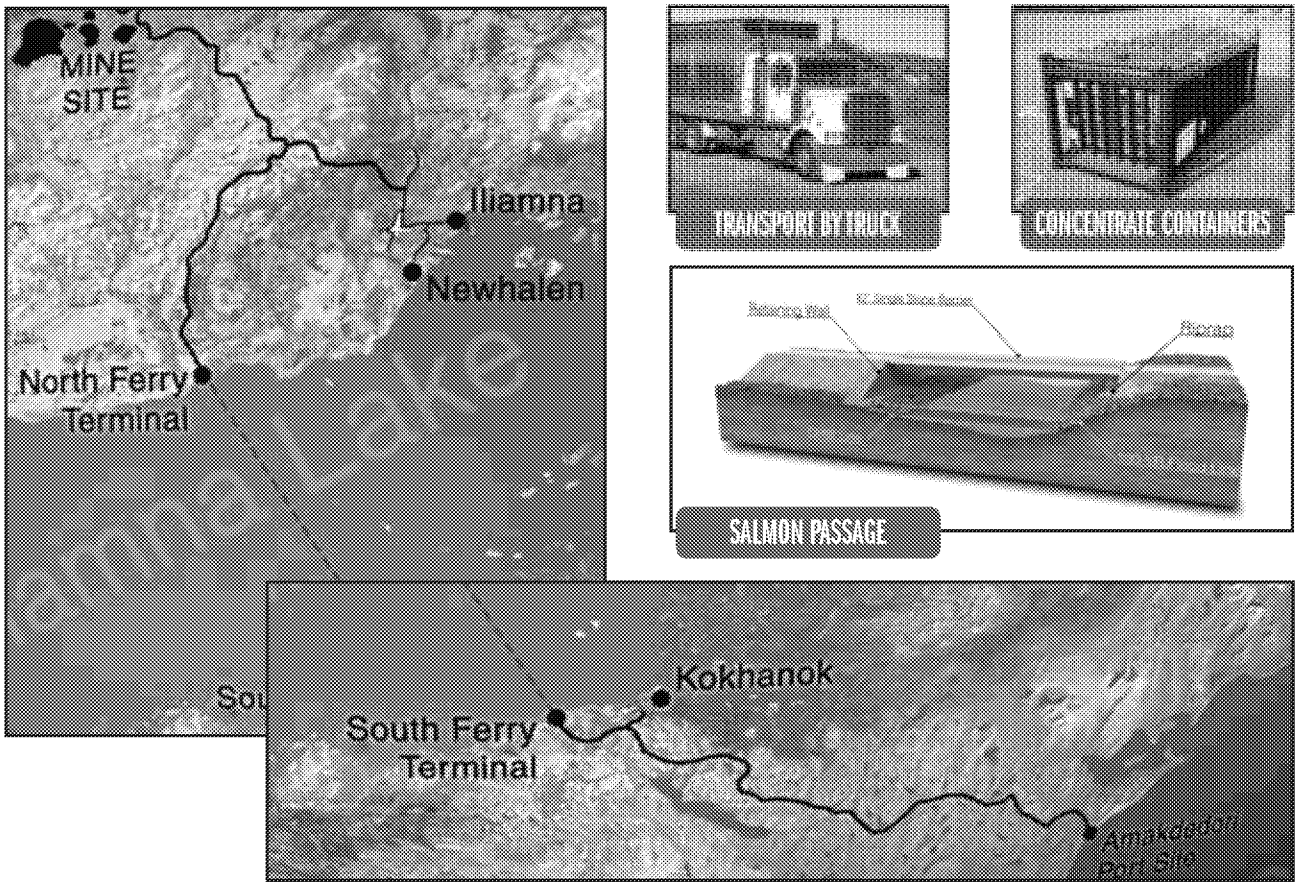
Pebble Limited Partnership (PLP) has designed the water management plan to minimize the volume of water diverted from natural flows and to treat and condition all water to meet quality standards before discharge.

MONITORING AND TREATMENT

SUMMARY INFORMATION

- All water is tracked and managed from rainfall to discharge
- One water treatment plant for pit-related water
- One water treatment plant for tailings, stockpile, and process contact water
- All water treated and conditioned to meet quality standards before release
- Discharge locations in each of three drainages
- No mixing zones will be required
- Discharge managed based on downstream habitat needs

THE pebble PARTNERSHIP



AMERICAN OVERSIGHT

ROADS & TRANSPORT

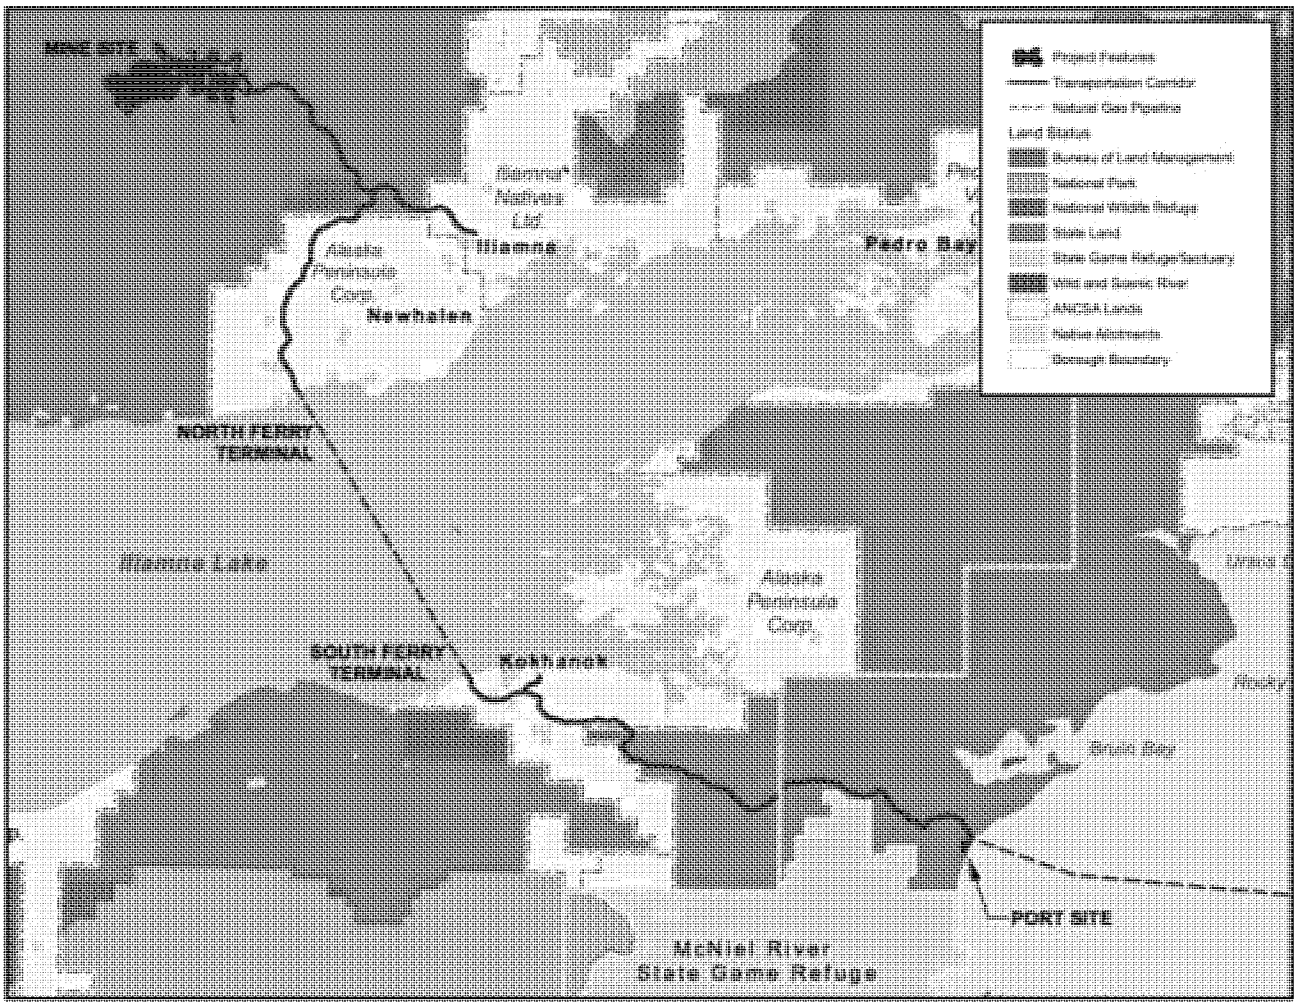
5 ROADS

An 83-mile transportation corridor runs from the mine site to a port site on Cook Inlet. The route was selected to minimize impact on wetlands, minimize stream crossings, and avoid area of known subsistence and recreational use.

NORTH & SOUTH ROAD SEGMENTS

SUMMARY INFORMATION

- Personnel flown to Iliamna Airport and driven to mine site
- 30-mile (north segment) and 35-mile (south segment) private roads
- Spur roads connecting to the villages of Iliamna, Newhalen, and Kokhanok
- Stream crossings designed to state of Alaska standards
- Up to 35 round trips by truck each day (one by ferry)
- Concentrate hauled in bulk containers with locking lids
- Fuel hauled in 6350-gallon sealed tank containers



THE pebble PARTNERSHIP

AMERICAN OVERSIGHT

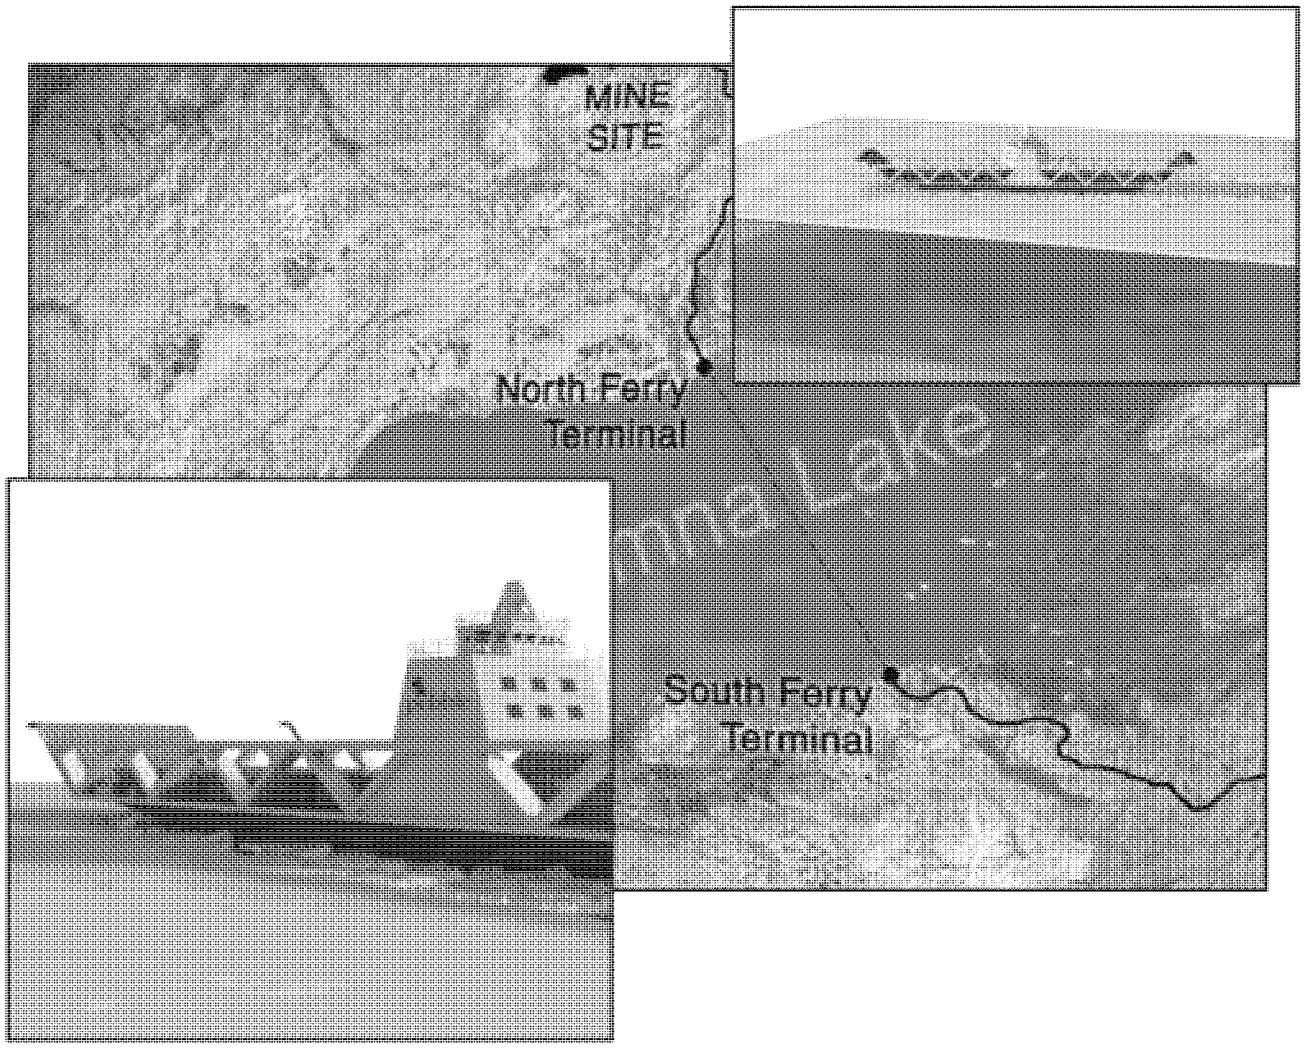
LAND STATUS

The mine site — including the pit, tailings storage, and all primary facilities — is located on state of Alaska land. The transportation corridor includes state of Alaska and ANCSA land.

MINE SITE & CORRIDOR LAND OWNERSHIP

SUMMARY INFORMATION

- Access Road = 65% state of Alaska + 35% Alaska Peninsula Corporation
- Iliamna Airport Spur = 55% state of Alaska + 45% Iliamna Natives Limited
- Iliamna Lake Crossing = 100% state of Alaska
- Kokhanok Airport Spur = 100% Alaska Peninsula Corporation



THE pebble PARTNERSHIP

AMERICAN OVERSIGHT

FERRY & TERMINALS

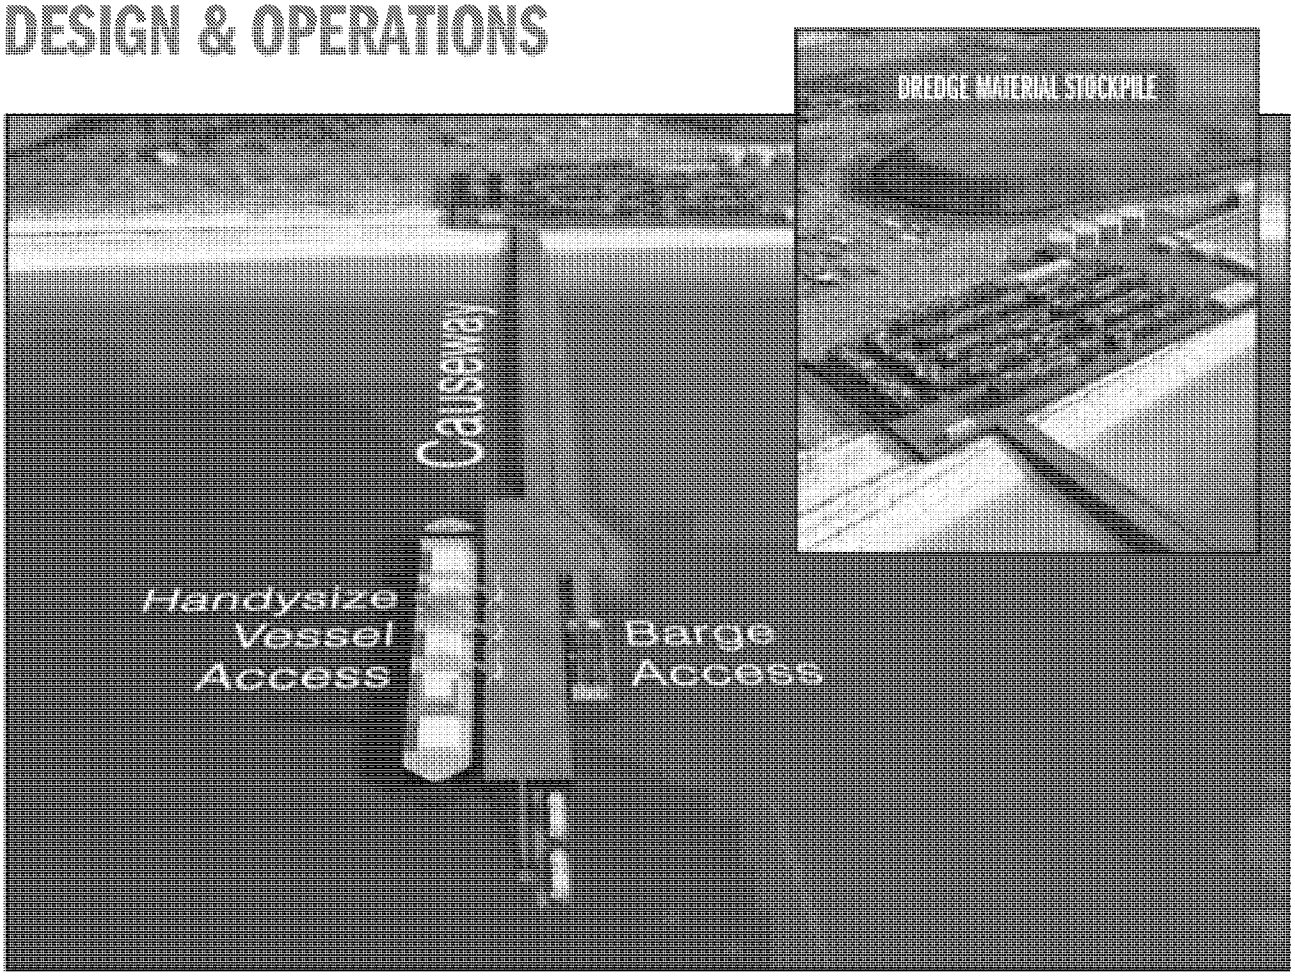
A custom-built ice breaking ferry will transit Iliamna Lake year round, carrying inbound supplies from the Amakdedori Port to the mine site and returning with copper-gold and molybdenum concentrates.

ILIAMNA LAKE CROSSING

SUMMARY INFORMATION

- The one-way ferry trip across Iliamna Lake is about 18 miles
- An average of one round trip per day will be required
- Vessel is designed to operate year-round, in all ice conditions
- Symmetrical forward and aft with two ice-breaking bows
- 12 crew members may be accommodated on the ferry

THE pebble PARTNERSHIP



AMERICAN OVERSIGHT

AMAKDEDORI PORT

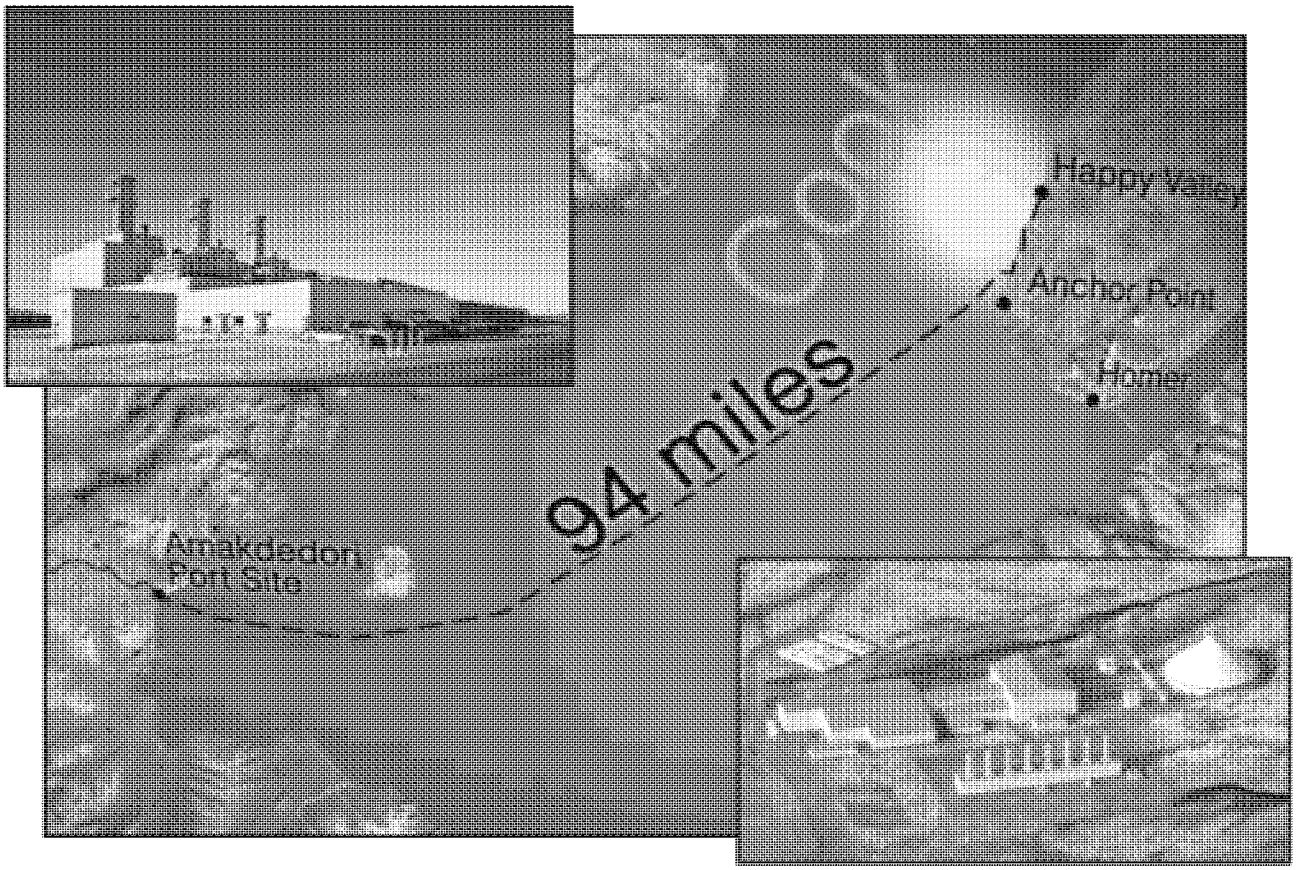
PORT

Incoming supplies such as equipment, reagents, and fuel will be barged to the Amakdedori Port and then transported by truck to the mine site.

DESIGN & OPERATIONS

SUMMARY INFORMATION

- 50-foot deep channel dredged to provide access for Handysize bulk carriers
- Mineral concentrate will be direct-loaded from the containers onto the vessels
- Equipment and supplies delivered by barge
- Shore-based facilities will receive and store containers and fuel
- Up to 25 concentrate shipments annually
- Up to 30 marine barge loads annually



THE pebble PARTNERSHIP

AMERICAN OVERSIGHT

POWER GENERATION

The power plant will be sized to meet the anticipated load of 230 megawatts using high-efficiency turbine or reciprocating engine generators operating in a combined-cycle configuration.

NATURAL GAS PIPELINE + POWER PLANT

SUMMARY INFORMATION

- Pipeline will connect to existing gas supply infrastructure near Happy Valley
- Buried pipe will transport gas to a compressor station near Anchor Point
- 94-mile subsea pipeline across Cook Inlet will come ashore near port site, follow road to site, and cross the bed of Iliamna Lake
- Gross flow rate of 50 million standard cubic feet per day
- 10" pipeline on land, 12" pipeline for water crossings
- Emergency backup power provided by diesel generators

THE pebble PARTNERSHIP

AMERICAN OVERSIGHT

CLOSURE & RECLAMATION

10 CLOSURE

Pebble Limited Partnership (PLP) is committed to conducting all mining operations, including reclamation and closure, in accordance with all local, state, and federal regulations.

PEBBLE: DESIGNED FOR CLOSURE

RECLAMATION

AFTER...

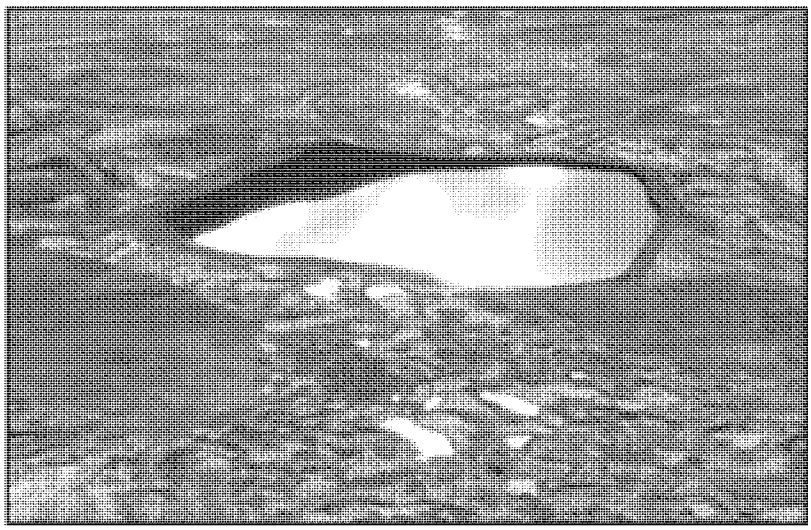
5 YEARS

Most buildings removed

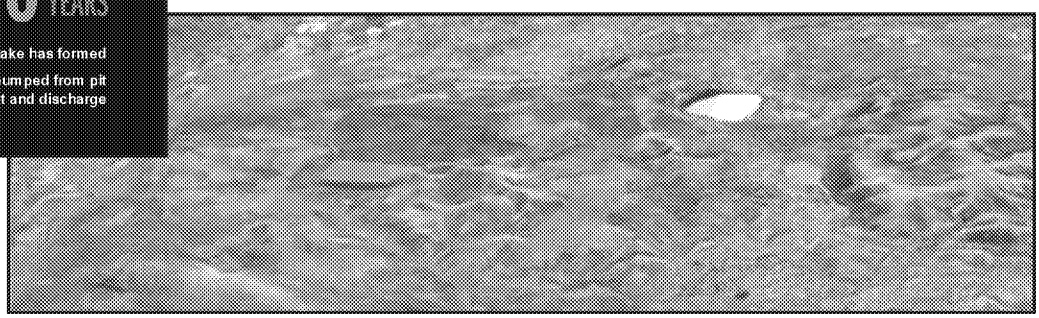
Terrain resculpted

Native plants resown

20 YEARS



Vegetation well-established in reclaimed areas



Pit continues to fill with water

30 YEARS

Pit lake has formed

Water is pumped from pit for treatment and discharge

SUMMARY INFORMATION

- Removal of mill and other facilities not used after closure
- Hauling of PAG waste rock into the open pit for under water storage
- Recontouring and placement of overburden for revegetation
- Plan and infrastructure for long term water management and treatment
- Financial assurance for closure and long term site management is required before construction

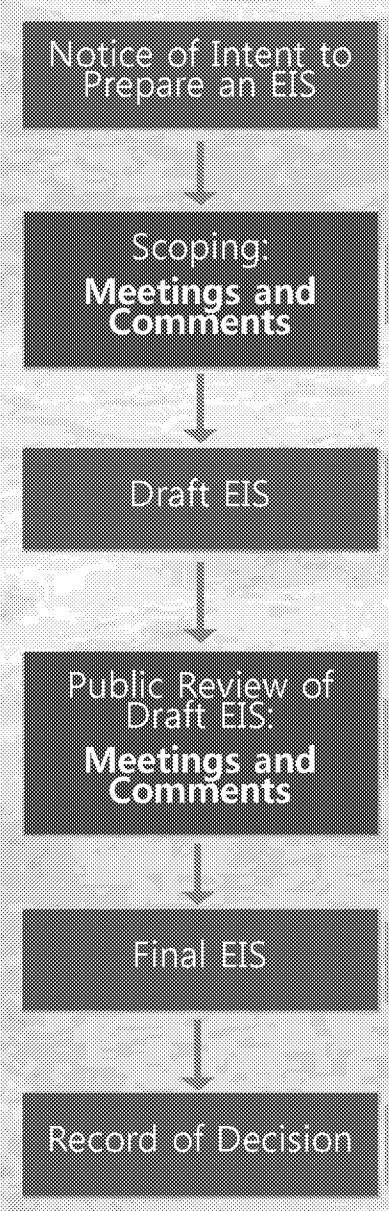
THE pebble PARTNERSHIP

AMERICAN OVERSIGHT

Tips for Writing Effective Comments

Public participation is an important part of developing an Environmental Impact Statement (EIS) under the National Environmental Policy Act (NEPA). Submitting substantive and concise comments during the scoping period is an important role the public plays in the NEPA process, and can influence the scope of analysis for the EIS.

- **Become familiar with the proposed project** — Review the project or agency website, read the project description, monitor local newspapers, and attend public meetings.
- **Learn about the steps in the NEPA process** and opportunities for submitting comments to the U.S. Army Corps of Engineers.
- **Keep your comments focused and as specific as possible** on the proposed project under consideration, what you think the EIS analysis needs to address and why.
- **Submit your comments within the timeframes announced** to ensure that your concerns are considered and addressed during the drafting of the EIS; the Scoping Comment period is from April 1 through June 29.
- **Be specific**. For example, if you are concerned about wildlife, focus on a particular problem or issue, such as a species that you feel should be analyzed, instead of making a broad statement such as "I am concerned about the impacts to wildlife."
- **Make suggestions,** including resources that should be analyzed, new data or analytic tools that should be used, and substantially different alternatives that should be evaluated in the EIS.



Comments on the project are not counted as votes; they are used to determine the appropriate scope of issues analyzed and contents of the EIS and to ensure that the impacts are adequately disclosed. Avoid simply agreeing or disagreeing with the proposed project. It is more important to identify specific relevant issues, alternatives, mitigation measures/conditions of permitting, and analytic tools so they can be used to inform the EIS analysis. The more clear, concise, and relevant your comments are, the more effective they will be in shaping the development of the EIS.

AMERICAN OVERSIGHT

The National Environmental Policy Act

Preparation of the Pebble Project Environmental Impact Statement (EIS) level of analysis began when the US Army Corps of Engineers (USACE) received a permit application from the Pebble Limited Partnership. The EIS process will take several months to complete a Draft EIS for public review, and several months to incorporate public comments into the draft to develop the Final EIS.

Steps in the EIS Process

The USACE released a Notice of Intent to the United States Federal Register. This initiated the process to prepare an EIS and began the scoping process.

The scoping process kicks off on April 1, 2018. Scoping offers a chance for the public to comment on the proposed project and alternatives.

Determining the alternatives to analyze, and then preparing the Draft EIS will happen immediately following the scoping period.

After the Draft EIS is released, the public will have a chance to submit comments. During that time, the USACE will plan public meetings to collect comments.

The USACE will assess all public comments submitted on the Draft EIS, and incorporate changes into the Final EIS before release.

The Record of Decision will lay out USACE's decision on the application submitted by the Applicant. Three decisions are possible: issue a permit, issue a permit with conditions, or denial of the application.

AMERICAN OVERSIGHT

How the Draft and Final EIS will be Organized

The Environmental Impact Statement (EIS) will analyze the potential impacts to the biological, physical, and social environments. By understanding the layout of the document ahead of time, readers can more easily find the specific sections they may be interested in reviewing and commenting on.

Executive Summary – Provides overview of the Draft and Final EIS, summarizes draft findings of potential impacts, and serves as a guide for where to find details.

Chapter 1. Purpose and Need – Describes the purpose of the proposed project to inform the range of alternatives analyzed in the EIS.

Chapter 2. Alternatives – Describes alternatives to be analyzed, including a No Action Alternative, the Proposed Action (as designed by the Pebble Limited Partnership), and reasonable and practicable alternatives to address issues raised during scoping and the EIS process, such as, but not limited to, tailings and mine water management, alternate pipeline routes, surface access to the mine site and vehicle traffic levels, and port/ferry facilities, location, and traffic levels.

The purpose and need of a project is essential in establishing a basis for developing the range of reasonable alternatives required in an EIS and identifying and selecting a preferred alternative.

Chapter 3. Affected Environment – Describes the baseline conditions of key resource topics in the proposed project environment (such as fish and wildlife, water quality, economics, food production, commercial fishing, and recreation).

Chapter 4. Environmental Consequences of Action – Analyzes the potential direct, indirect, and cumulative impacts, as well as potential mitigation measures relevant to each of the resources from the proposed action and each alternative.

Chapter 5. List of Preparers – Presents the list of contributors to the preparation of the EIS, including their affiliation, project role, educational background, and years of experience. Cooperating agency roles and responsibilities are also described in Chapter 5.

Chapter 6. List of Agencies, Organizations, and Persons to Whom copies of the Statement Have Been Sent – Describes the distribution of the Draft and Final EIS documents for informational purposes and to identify public locations where the document is available.

Chapter 7. References – Presents the references used in preparing the EIS.

Chapter 8. Appendices – Presents the in-depth analyses, comments/response to comments, coordination, consultations, mailing lists and other information used in the analysis of the applicant's project.

AMERICAN OVERSIGHT

What Resources will be Analyzed in the EIS?

Using the analysis in the Environmental Impact Statement (EIS), The U.S. Army Corps of Engineers (USACE) will evaluate the environmental and related social and economic effects of the proposed project. The analysis will include direct and indirect impacts, cumulative effects, and potential spill and tailings dam failure scenarios. Comments received during the scoping period will likely result in additional resources to be considered in the analysis.

Social Environment

- Cultural Resources
- Historic Properties
- Land use and management
- Subsistence
- Transportation and Navigation
- Aesthetics
- Recreational and Commercial Fisheries
- Recreation
- Needs and Welfare of the People
- Environmental Justice
- Health and Safety

Physical Environment

- Geohazards
- Geology
- Soils
- Surface Water Hydrology including flood plains and flood hazards
- Groundwater Hydrology
- Water Quality
- Noise
- Air Quality
- Climate Change

Biological Environment

- Wetlands/Special Aquatic Sites
- Vegetation
- Birds
- Terrestrial Wildlife
- Fisheries and Aquatic Resources
- Marine Wildlife
- Threatened and Endangered Species

Direct impacts occur through direct interaction of an activity with an environmental, social, or economic component.

For example: pollutant discharge from a source could directly result in lowered water quality.

Indirect impacts on the environment are not a direct result of the project, but often a result of a complex impact pathway.

For example: pollutants in the air from a source could land on vegetation, indirectly causing acidic soils.

Cumulative impacts occur when the incremental impact of the project is combined with the effects of other past, present and reasonably foreseeable future projects. For example: wetland fill from one projects.

For example: wetland fill from one project, combined with the wetland fill from a separate project.

AMERICAN OVERSIGHT

Roles and Responsibilities

When the Pebble Limited Partnership (Applicant) submitted an application on December 22, 2017, the US Army Corps of Engineers, Alaska District (USACE) was compelled to begin processing the permit application in accordance with 33 CFR 320. The USACE determined that review of the application would require an environmental impact statement (EIS) level of analysis in compliance with the National Environmental Policy Act. The USACE is the lead federal agency for developing the EIS.

Role of the Corps

The USACE, as the lead agency, is responsible for reviewing the permit application submitted by the applicant, and analyzing the potential environmental impacts from the proposed project. The USACE will lead the effort to take a hard look at reasonable and practicable alternatives and evaluate the impacts of the proposed project utilizing an interdisciplinary team. At the completion of the environmental impact analysis, the USACE, will issue a Record of Decision related to USACE's authorities under Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act.

Role of the 3rd Party Contractor

AECOM (a consulting firm) has been hired to provide an interdisciplinary team to develop a fact-based independent analysis of the Pebble Project as proposed and evaluate identified reasonable alternatives. AECOM will work solely under the direction of the USACE and will be the primary developers of the EIS. AECOM will also provide support to the USACE for scoping and public involvement, development of alternatives to the proposed action, assessment of potential impacts, and distribution. The AECOM team is made up of specialists and scientists in the biological environment, the physical environment, and the social environment.

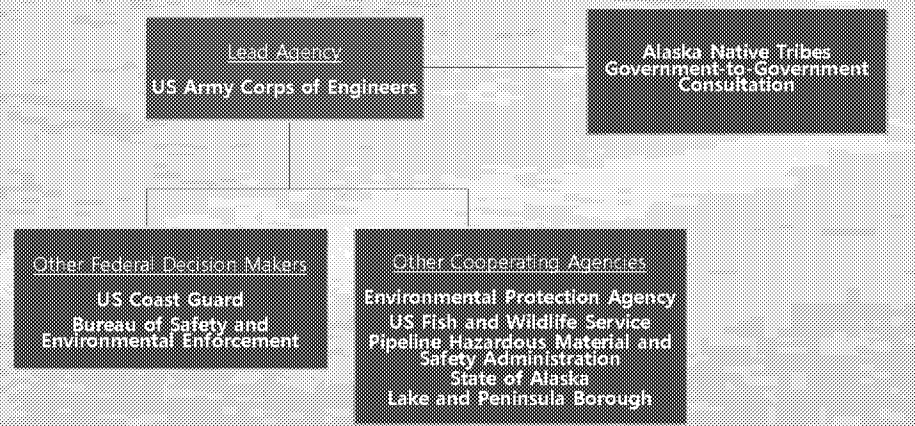
Role of Alaska Native Tribes

The USACE has invited 35 federally recognized Alaska Native Tribes to consult throughout the entirety of the federal decision making process, including the development of the environmental impact statement. Federally recognized Alaska Native Tribes that the USACE has extended government-to-government consultation invitations to are:

- Aleknagik Traditional Council
- Chignik Bay Tribal Council
- Chignik Lagoon Village Council
- Chignik Lake Traditional Council
- Clarks Point Village Council
- Curyung Tribal Council
- Egegik Village Council
- Ekuk Village Council
- Ekwok Village Council
- Igiugig Village Council
- Iliamna Village Council
- Ivanof Bay Tribal Council
- King Salmon Tribal Council
- Kokhanok Village Council
- Levelock Village Council
- Manokotak Village Council
- Naknek Village Council
- Nanwalek IRA Council
- Native Tribe of Kanatak
- Native Village of Perryville
- New Koliganek Village Council
- New Stuyahok Traditional Council
- Newhalen Tribal Council
- Ninilchik Traditional Council
- Nondalton Tribal Council
- Pedro Bay Village Council
- Pilot Point Tribal Council
- Port Graham Tribal Council
- Port Heiden Village Council
- Portage Creek Village Council
- Seldovia Village Tribal Council
- South Naknek Vilage Council
- Traditional Council of Togiak
- Twin Hills Village Council
- Ugashik Traditional Council

Role of the Applicant

As the applicant is required to provide information to the USACE related to their proposed project. This includes:



- description of the proposed project,
- background material, completed research, and site information,
- data for the development of maps and figures, and
- other information that may be identified as necessary during preparation of the EIS.

The applicant will not be involved in the development of the EIS beyond this limited scope.

Role of Cooperating Agencies

Several cooperating agencies have been invited to provide technical support to the lead agency, the USACE. Cooperating agencies will be actively engaged in scoping and alternatives development and will then be assigned to technical teams based on the specific reasons they were invited to become cooperating agencies. Although cooperating agencies are involved in preparation and writing of certain portions of the EIS and cooperators may use the EIS for their own decisions, the USACE has final authority on the EIS content.

Lead and Cooperating Agencies

AMERICAN OVERSIGHT

Public Scoping for the Pebble Project EIS

The US Army Corps of Engineers (USACE) is preparing an Environmental Impact Statement (EIS) to analyze the impacts of issuing permits for an open pit, copper-gold-molybdenum porphyry deposit, with associated infrastructure, as proposed by the Pebble Limited Partnership. The EIS scoping period begins April 1, 2018 and ends June 29, 2018.

At the beginning of developing an EIS, USACE reaches out through scoping to involve members of the public. The scoping period provides opportunities for people who could be affected by the proposed action that could have lesser environmental impacts.

In addition to Anchorage, Public meetings were held in April in the following communities:

- Naknek
- Kokhanok
- Homer
- Newhalen
- New Stuyahok
- Nondalton
- Dillingham
- Igiugig

The EIS will identify potential impacts on the physical, biological, and social environment from all phases of the proposed project, including construction, mine operation, closure, and post-closure. The EIS will also look at mitigation methods-ways in which potential negative impacts could be avoided or lessened.

During the scoping period, USACE will work with the public to identify issues and concerns to thoroughly analyze the potential effects of the proposed project. USACE will use the scientific literature, alongside traditional knowledge and observations provided by the public.

We welcome your comments and information on the resources that are important to you. For example, many communities will be concerned about potential impacts to fish, subsistence resources, and traditional land uses during project construction, operations, and closure.

To Participate...

Let us know what aspects of the proposed project are important to you!

Providing ample opportunities for the public to submit scoping comments on the Pebble Project EIS is of utmost importance to the USACE. A good way to get involved is to give your comment orally to a dedicated court reporter or electronically submit using one of the dedicated laptop computers. You can also submit hand-written comments, use the comment form on the project website (www.PebbleProjectEIS.com), or send them to:

Program Manager, Regulatory Division
US Army Corps of Engineers
PO Box 6898
Joint Base Elmendorf Richardson
AK 99506-0898

Scoping comments can be submitted through June 29, 2018.

AMERICAN OVERSIGHT

Pebble Project EIS Comment Form

You can submit comments using the form on the website (www.PebbleProjectEIS.com), to a court reporter at a public scoping meeting, or in writing (using computers available at a meeting or by mail). We will not be taking public testimony at large meetings in Anchorage, Homer, and Dillingham. If you'd like to mail your comments or submit them at a meeting, please feel free to use this form and attach additional sheets as needed. Write your comments, questions, and suggestions below, then fold this page in thirds so that the mailing address is visible. Remember to affix first-class postage before putting it in the mail, postmarked by the comment deadline of June 29.

The following questions may help:

- What are your specific concerns about this project and how should they be addressed in the EIS?
- Are there particular fish and wildlife resources, subsistence activities/use areas, or other places that you use and how might they be affected by the project?
- Are there alternative ways of developing any of the components of the Pebble Project that should be considered in preparing the EIS?

Please note that all public comments, including names and addesses of of individuals and organizations, are publicaly available as part of documenting public involvement in preparing the EIS. The US Army Corps of Engineers intends to place public comments received during scoping on the project website.

FACT SHEET

Pebble Limited Partnership Project Proposed Natural Gas Pipeline

Background

The Bureau of Safety and Environmental Enforcement (BSEE) is a cooperating agency on the Environmental Impact Statement that the United States Army Corps of Engineers, Alaska District, is preparing for the Pebble Limited Partnership project.

The Pebble Limited Partnership is proposing to develop the Pebble copper-gold-molybdenum porphyry deposit as an open-pit mine, with associated infrastructure, in southwest Alaska. The proposed project infrastructure will include an approximately 230-megawatt power plant that will be fueled using natural gas. Natural gas would be supplied to the site using a roughly 190-mile pipeline that would connect to the project site from a tie-in on the Kenai Peninsula near Happy Valley.

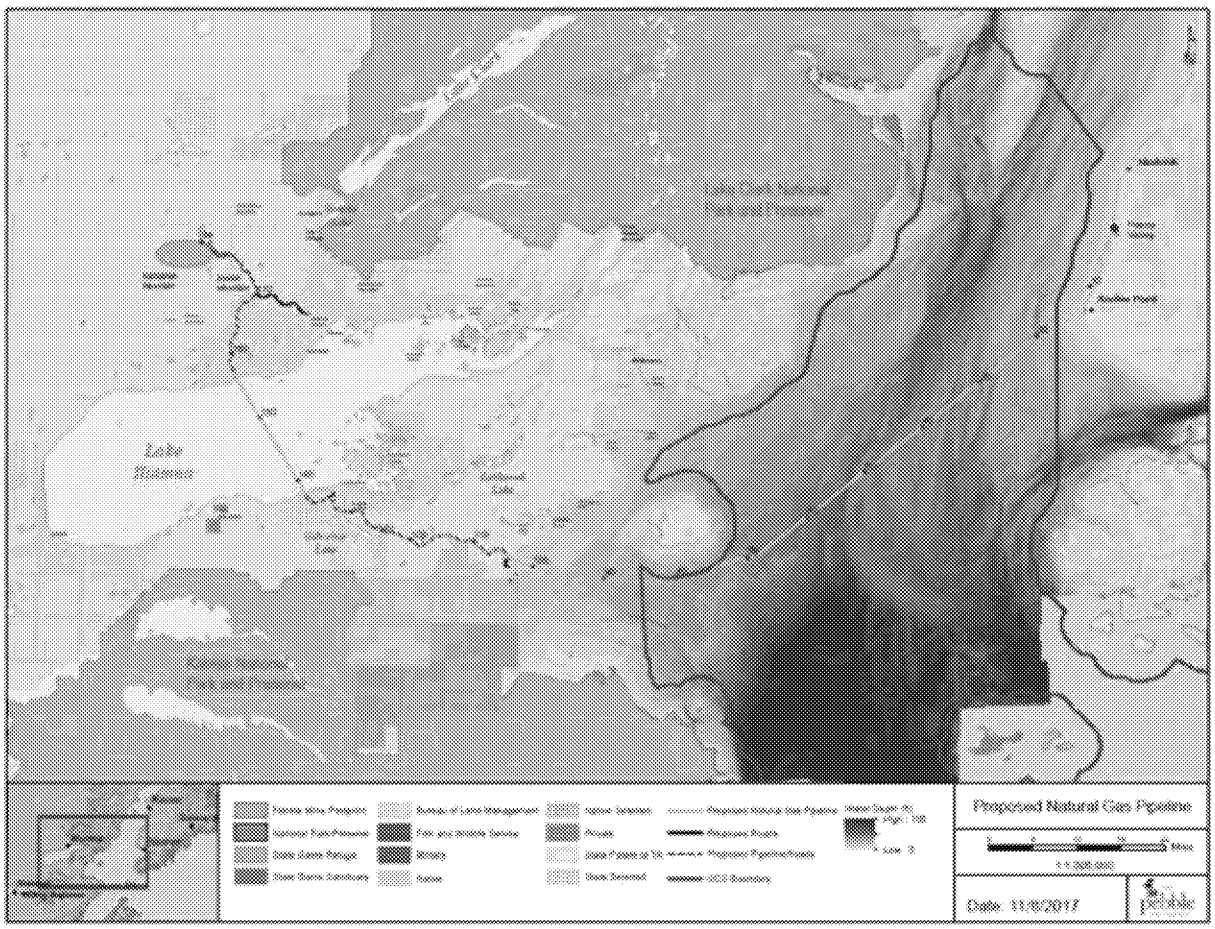
While BSEE has no regulatory oversight of onshore mining, our role will include a Pipeline Right-of-Way grant approval process for the proposed pipeline crossing federal waters of the Outer Continental Shelf in Cook Inlet.

Proposed Pipeline

The gas pipeline alignment, as currently proposed, would start near Happy Valley on the Kenai Peninsula and travel south paralleling the Sterling Highway for approximately 9 miles to a compressor station. From the compressor station, the pipeline heads southwest across Cook Inlet for 60 miles, before turning west for 35 miles to a landfall at the proposed Pebble port site near the mouth of Amakdedori Creek. A second compressor station and offtake point is located at the port site. The pipeline then follows the proposed road alignment from the port to the mine site, including crossing Iliamna Lake on the lake bed for approximately 18 miles. BSEE's jurisdiction for the proposed pipeline will likely only cover 63 miles, the portion that crosses federal waters of Cook Inlet.

The pipeline, as currently proposed, would be constructed of steel and designed to have a gross flow rate of 50 million standard cubic feet of natural gas per day. The onshore portions of the pipeline would be 10-inch diameter, while the offshore portion would be constructed using heavy wall 12-inch diameter pipe with negative buoyancy. All appropriate federal regulations would be followed in the design, construction, and operation of the pipeline.

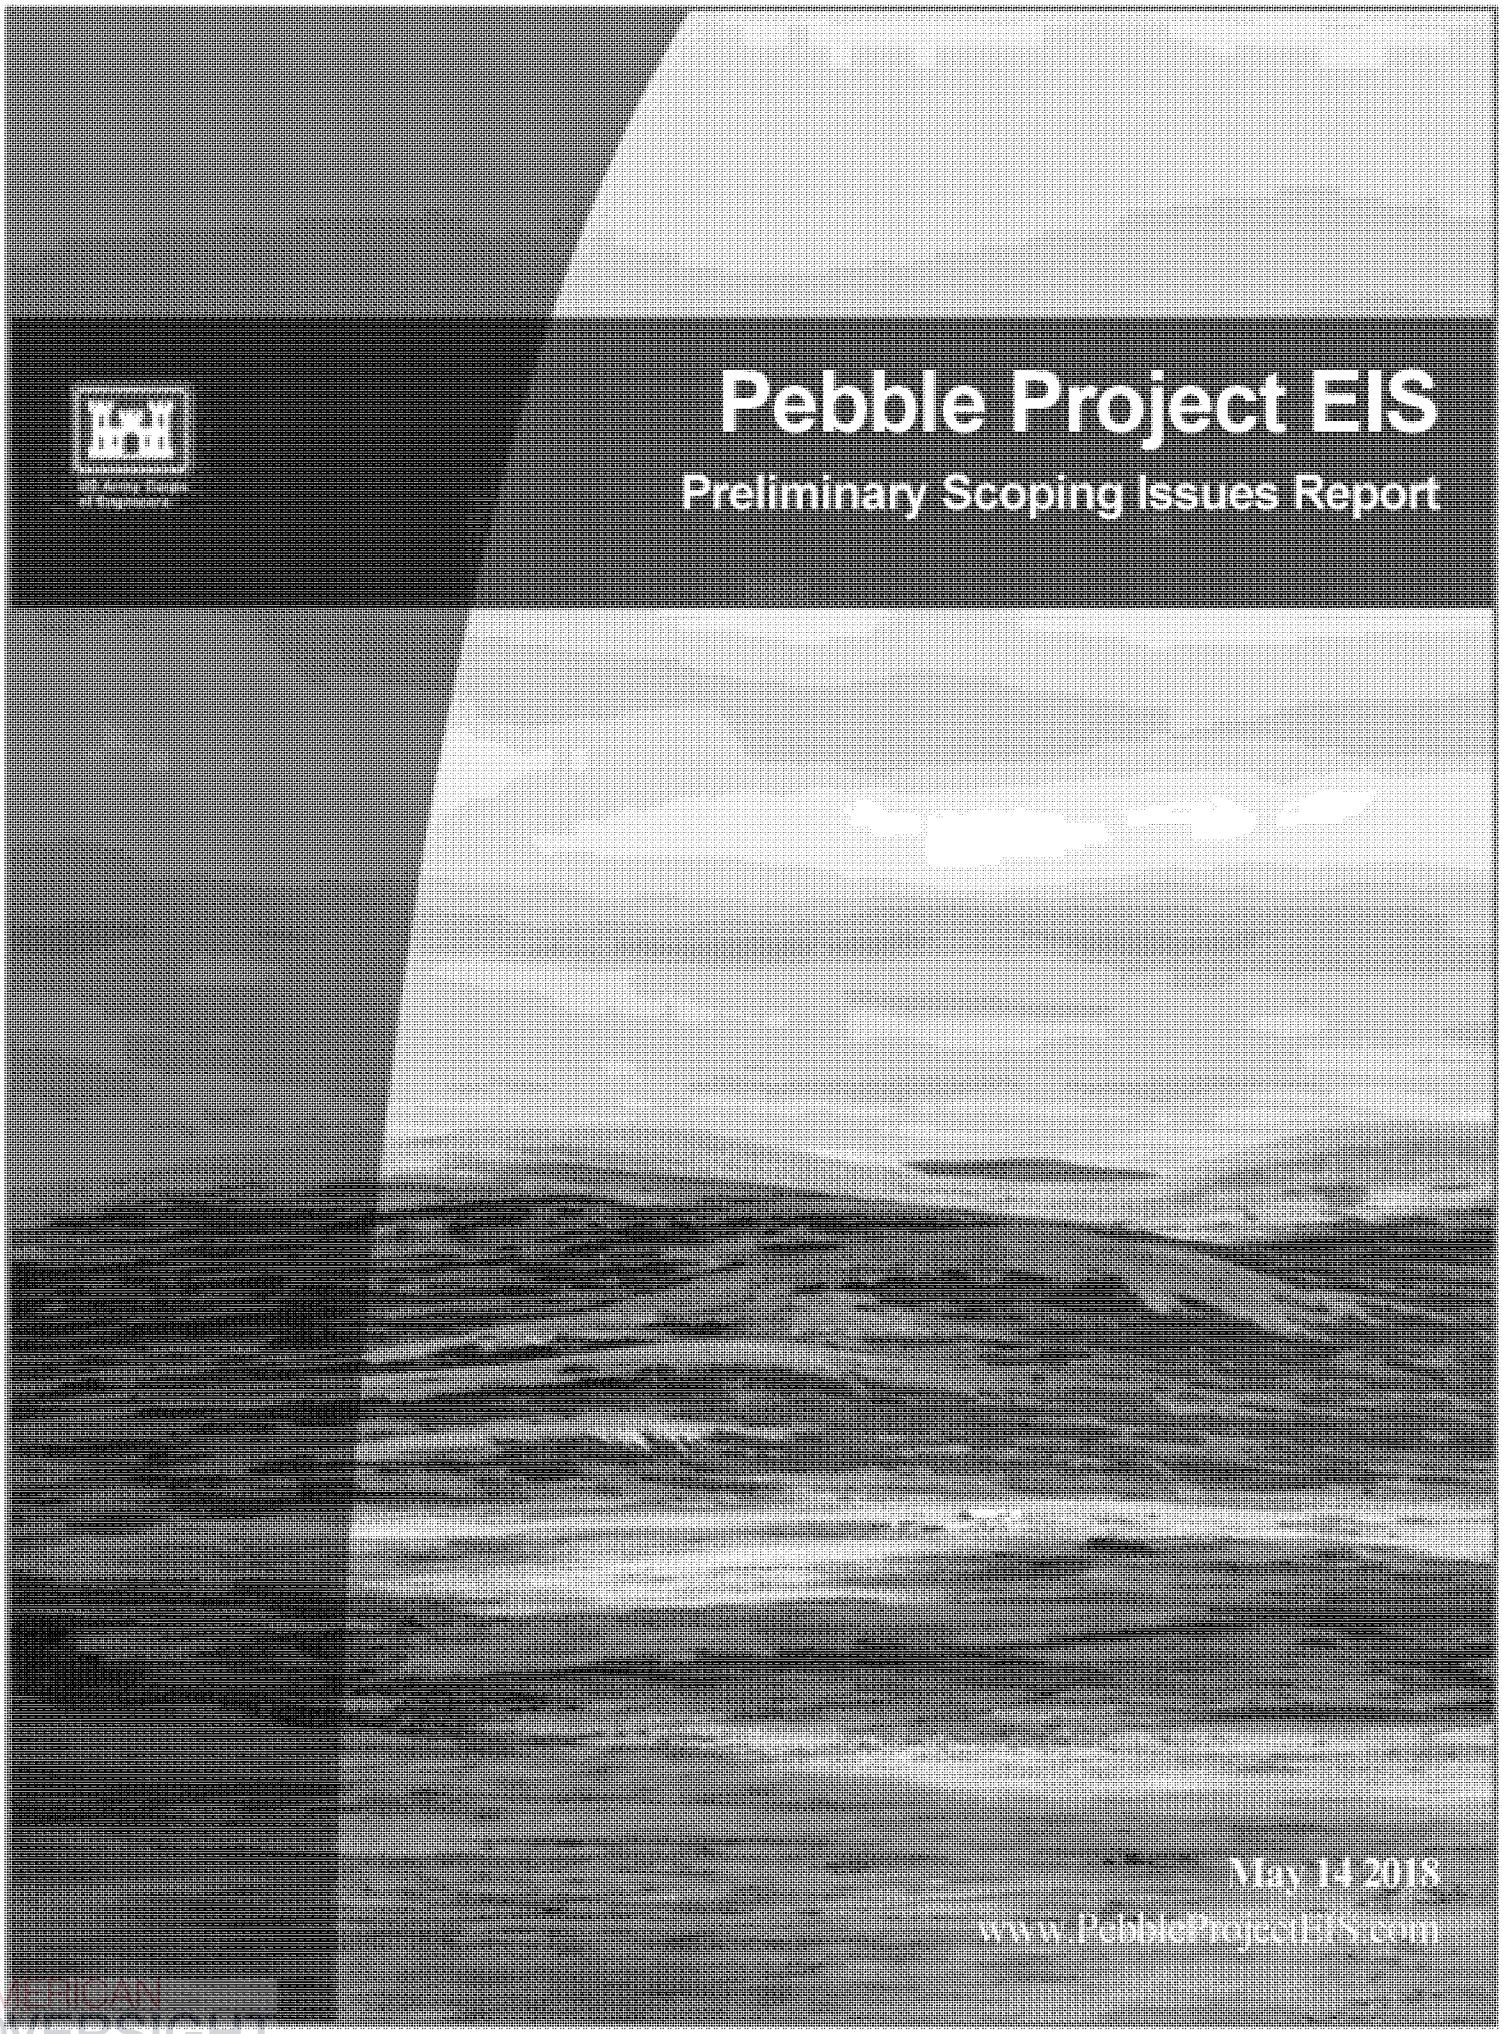
Right-of-Way Decision Process



Pipeline right-of-way requirements for permitting are detailed in the 30 Federal Code of Regulations Part 250—Oil And Gas And Sulphur Operations In The Outer Continental Shelf Subpart J—Pipelines and Pipeline Rights-of-Way.

AMERICAN OVERSIGHT

Applications for permits must be submitted to the BSEE Regional Supervisor and will include detailed information about the right of way, including consideration of effects from water currents, storm or ice scouring, soft bottoms, mudslides, earthquakes, permafrost, and other relevant environmental factors.



While the pipeline in this case will ultimately be regulated by the U.S. Department of Transportation, Pipeline and Hazardous Materials Safety Administration, BSEE's interest is to have the requisite level of information that enables a well-informed right-of-way decision process, with the knowledge that environmental and safety factors have been considered and addressed.

Pebble Project Proposed Natural Gas Pipeline

1.0 INTRODUCTION

This Preliminary Scoping Issues Report has been developed as an interim product, intended for the U.S. Army Corps of Engineers (USACE) to share the types of issues that have been received thus far in the scoping period with cooperating agencies. The final comprehensive product, the Scoping Report, will be developed at the conclusion of the scoping period.

2.0 PROJECT OVERVIEW AND SCOPING PROCESS

2.1 BACKGROUND

The Alaska District, USACE intends to prepare a Draft Environmental Impact Statement (EIS) to assess the potential social, economic, and environmental impacts associated with the proposed Pebble Project. The EIS will assess potential effects of a range of alternatives.

Pebble Limited Partnership (PLP) is proposing to develop the Pebble copper gold-molybdenum porphyry deposit as an open-pit mine, with associated infrastructure, in southwest Alaska, north of Iliamna Lake. The proposed project would require approximately four years to construct, with a projected mine life of 20 years. The proposed project would include excavation of an open pit that ultimately would be approximately 6,500 feet long by 5,500 feet wide, with depths between 1,330 and 1,750 feet; a tailings impoundment with 1.1 billion tons storage volume; a low grade ore stockpile with the capacity to store up to 330 million tons; an open pit overburden stockpile; a mill facility processing approximately 160,000 tons of ore per day; a natural gas-fired power plant with a total connected load of 230 megawatts (MW), supplied by a 188-mile, 10 to 12-inch diameter, natural gas pipeline across Cook Inlet and Iliamna Lake to the Mine Site; and transportation infrastructure including a 30-mile road from the mine site to a ferry terminal on the north shore of Iliamna Lake, an 18-mile crossing with an ice-breaking ferry to a terminal on the south shore of Iliamna Lake, and a 35-mile road to the proposed Amakdedori Port on Cook Inlet. The proposed mine and related facilities would have a total footprint of approximately 5.9 square miles.

The pipeline route would originate on the Kenai Peninsula, connecting to the existing gas pipeline infrastructure near Happy Valley. A metering station would be constructed at the off-take point. The pipeline would follow the Sterling Highway south for 9 miles to a gas-fired compressor station north of Anchor Point. The compressor station would feed a 94-mile subsea pipeline from the east shore of Cook Inlet to Amakdedori Port on the west shore. A second gas-fired compressor station would be located at the port site. The pipeline route would then follow the mine access road to the south shore of Iliamna Lake, where the pipeline would enter Iliamna Lake for approximately 18 miles. The pipeline would come ashore at on the north shore of the lake, where it would follow the mine access road to the mine site.

2.2 NOTICE OF INTENT

An application for a Department of the Army permit was submitted by PLP pursuant to Section 404 of the Clean Water Act (CWA) (33 U.S.C. 1344) and Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. 403) on December 22, 2017, and was advertised in a Public Notice, POA–2017–271, on January 5, 2018. On March 29, 2018, USACE issued a Notice of Intent in the Federal Register to prepare an EIS for the proposed project. The Notice of Intent is included in Appendix A and the Public Notice is included in Appendix B.

AMERICAN OVERSIGHT

2.3 SCOPING PROCESS

2.3.1 Scoping Process Overview

The scoping period began on April 1, 2018. On March 30, 2018, the USACE issued a press release to announce the opening of the 30-day comment period and to provide information for how to submit comments. On April 6, 2018, their second press release extended the scoping period by 60 days to continue through June 29, 2018. See Appendix B for both press releases.

Scoping is conducted to assist in determining the scope of analysis, significant issues, and alternatives to be analyzed in depth in the Draft EIS. The Council on Environmental Quality (CEQ) defines scoping as an "early and open process for determining the scope of issues to be addressed and for identifying the significant issues related to a proposed action" (40 CFR 1501.7). The scoping process provides an opportunity for people potentially affected by the project to express their views and concerns and to contribute to the completeness of the EIS.

This Preliminary Scoping Issues Report includes the initial results of the scoping comment analysis as well as appendices with pertinent documents (e.g., the Notice of Intent, sign-in sheets, and other scoping materials).

2.3.2 Public Notice, Press Releases, and Other Media

Prior to the scoping period start, the USACE began organizing public meetings and developing materials.

The project website (www.PebbleProjectEIS.com) went live on March 19, 2018. The website includes information about the project and EIS process. The USACE will use the website to disseminate important information to the public, such as the public meeting schedule. The website also provides an online form for the public to submit scoping comments. Comments that have been submitted are available to view in as close to real time as possible. Screen shots of the website (dated May 7, 2018) are in Appendix B.

On March 20, 2018, the USACE mailed hard copies of a Scoping Package to 35 identified Tribes in the Project Area. The complete Scoping Package (in Appendix B) includes:

- Information about the scoping process;
- A description of the project;
- The process for developing alternatives;
- A list of resources to be analyzed in the EIS;
- Information on the National Environmental Policy Act (NEPA);
- Roles of the various participating organizations;
- An EIS schedule and outline; and
- Information on submitting comments and a comment form.

To advertise the scoping period, the USACE began mailing the project's Newsletter #1 on March 29, 2018. The newsletter provided details on the public meeting schedule as well as information on how to submit comments. It was sent to every post office box in 33 communities, as well as 140 other organizations and individuals on a mailing list; a total of 3,670 newsletters were mailed. The USACE also ran announcements in the Bristol Bay Times, the Homer News, and the Anchorage Daily News. Finally, a flyer was emailed to communities for distribution on April 6, 2018. Newsletter #1, newspaper affidavits, and the flyer can be found in Appendix B.

AMERICAN OVERSIGHT

2.4 PUBLIC SCOPING MEETINGS

Public meetings were held in nine communities, including Anchorage. A total of 914 participants signed in to the public meetings (see Appendix C for sign-in sheets). The primary purpose of the public meetings was to give the public a forum for submitting comments, and an opportunity to talk to the USACE about the EIS and the Department of the Army permit application. Table 1 shows the meeting locations and the number of people who signed in.

Table 1: Scoping Meetings

Date	Community	Location and Time	Number Signed In
April 9, 2018	Naknek	Naknek School, 3:30-7:30 PM	45
April 10, 2018	Kokhanok	Community Hall, 3:30-7:30 PM	68
April 11, 2018	Homer	Homer High School, 5:00-9:00 PM	223
April 12, 2018	Newhalen	Newhalen School, 3:30-7:30 PM	47
April 13, 2018	New Stuyahok	Community Building, 1:00-4:30 PM	65
April 16, 2018	Nondalton	Tribal Center, 3:30-7:30 PM	46
April 17, 2018	Dillingham	Middle School, 5:00-9:00 PM	88
April 18, 2018	Igiugig	Community Building, 3:30-7:30 PM	47
April 19, 2018	Anchorage	Dena'ina Center, 11:00am-9:00 PM	285

2.4.1 Meeting Description

The format of the public meetings varied depending on the location. In general, a brief introduction by the USACE was given. A 17-minute video describing the project was shown (or available to be watched), and the public was given multiple ways to comment. Time was allotted for members of the public to speak directly with USACE staff, State of Alaska staff, or in some locations, other cooperating agency staff. AECOM (the third party NEPA contractor) staff were also present.

In Naknek, Kokhanok, Newhalen, New Stuyahok, Nondalton, and Igiugig, the USACE provided a microphone ("hot mic") where participants could speak their comments out loud in front of other meeting attendees. Comments were transcribed by a court reporter, either during the hot mic session or individually after the session. In Homer, Dillingham, and Anchorage, two court reporters were available to take comments one-on-one; no hot mic was provided.

At all meetings, laptop computers were provided for the public to submit comments electronically to the project website. The online comment form included an interactive map; commenters could mark a point on the map that corresponds to their comment. Paper comment forms were available for handwritten or typed comments, which could be submitted to the USACE at a meeting or mailed later.

2.4.2 Meeting Materials Description

The USACE requested that the PLP create a video that described their proposed project and mining process. The resulting 17-minute video gives an introduction to the surrounding environment, project components and footprint, water management and mining process, and reclamation. At some meetings this video was shown after the USACE introduction, and at others it was shown on a repeating loop.

AMERICAN OVERSIGHT

Ten posters prepared by the PLP to describe the project, the mining process, and reclamation were displayed. The USACE displayed posters describing both the NEPA process, and how to write effective comments. The Anchorage meeting also included posters on the scoping process, the EIS outline, resources to be discussed in the EIS, and roles of cooperating agencies.

The USACE also provided the Scoping Package, paper comment forms, and a handout from the Bureau of Safety and Environmental Enforcement, a cooperating agency. A screenshot of the video, as well as all posters and handouts are in Appendix D.

2.4.3 Additional Agency Involvement

[Note: Agency involvement will be summarized after the scoping period has ended.]

2.4.4 Government-to-Government Consultation

[Note: Specific government-to-government activities will be summarized after the scoping period has ended.]

2.4.5 Next Steps in the NEPA Process

Scoping is the first opportunity for public involvement under the NEPA process. An additional opportunity for public comment will follow the release of the Draft EIS. A Notice of Availability will be published in the Federal Register informing stakeholders and other members of the public that the Draft EIS is available for comment in early 2019. The Draft EIS comment period will include public hearings.

Public comments shape the NEPA process by identifying project-related questions and issues of concern. Typically questions are in reference to the project, existing environment, extent of temporal and spatial impacts, or potential consequences to the human environment from the proposed action. Substantive questions and issues of concern are grouped by subject matter in this scoping report. This information is used in the alternatives development process, the study of the affected environment, and in the process to analyze environmental consequences (or impacts).

AMERICAN OVERSIGHT

3.0 SCOPING COMMENT SUMMARY

This section contains a description of the scoping comment analysis process and a summary of the public scoping comments received to date. The public comment summary includes the following:

- Description of the scoping comment analysis process (description of the comment database, development of the coding structure, identification and coding of comments, comment summary process); and
- A summary of issues identified to date, categorized by physical environment, biological environment, social environment, or NEPA process.

3.1 SCOPING CONTENT ANALYSIS PROCESS

Public and agency comments were analyzed and categorized using a process called "content analysis." The analysis process included:

1. Importing and organizing all submission content into a comment database;
2. Developing a coding structure;
3. Review of submissions to assign codes to relevant comments; and
4. Preparation of a narrative report of analysis results.

The goals of the content analysis are to:

1. Ensure that every submission (every received set of comments, submitted by any means, is defined as a "submission") is considered;
2. Identify the concerns raised by commenters;
3. Represent the breadth and depth of the public's viewpoints and concerns as fairly as possible; and
4. Present those concerns in a way that facilitates consideration of comments.

All comments were treated equally. Emphasis was on the content of a comment, rather than who wrote it or the number of submitters who agreed with it.

3.1.1 Scoping Comment Database

Names, contact information, and comment text for commenters who submitted comments were entered into an electronic database. The majority of the comments were submitted to the USACE in electronic format through the project website comment form. Some comments were received by the USACE via email or postal service. As comments were received they were made available to the public to view on the project website. Hard-copy comments, including those delivered by postal service or submitted in person at public meetings, were scanned and entered into the database and also posted to the project website.

The content of the comments was filtered using various database queries and identifying potential form letters (see form letter discussion below). Any submission identified as having the same commenter information and content, regardless of delivery format (e.g., hard-copy letter, email) or date, was counted as one submission.

AMERICAN OVERSIGHT

3.1.2 Form Letters

Form letters are defined as any submissions with the same content. Electronic comments were pre-screened in the database, using various queries to identify similar content and thus potential form letters. If consistent content was identified, a form letter record with that content was created in the database and additional submissions with the same content were placed into that form letter category.

3.1.3 Coding Structure Development

Submission content was sorted into categories to represent commenters' concerns and rationale through a coding structure. Codes provide an efficient and accurate grouping of similar comments; coded concerns are referred to as "comments" in this report.

The aim of the coding structure is to identify applicable project elements, environmental resources, and planning processes in submissions. An initial coding structure was developed based on expected issues and concerns; this structure will continue to be developed as more submissions are received to identify any additional concerns.

3.1.4 Comment Identification and Coding

Submissions were reviewed to identify substantive comments that will be used to formulate the issues and analysis conducted in the EIS process. Individual statements within the submission are identified as a comment and then assigned to a category/topic by an automated system. Submissions may contain more than one comment, each coded separately based on the issue and the specific rationale. This form of analysis allows for specific comments to be captured and then grouped under the umbrella of a general resource issue.

3.2 PUBLIC COMMENT SUBMITTAL SUMMARY

3.2.1 Submittals Received

In total, XXX comments were received up to June 29, 2018. XXX form letters were received.

[Note: Comment statistics will be summarized after the comment period is complete.]

3.3 COMMENT SUMMARY PROCESS

[Note: Comment content will be summarized into a final narrative summary for the final version of this report.]

The intent of the narrative summary is to provide representative summaries that capture, with a minimum of repetition, major topic areas or concerns expressed during the public scoping period. The topic areas or concerns contained in the summary of public comment will be used to develop the issues, alternatives, and mitigation strategies that will be analyzed in the EIS process.

During the summary writing process, comment analysts review coded comments to understand the overall content of the comment and to identify topic areas or concerns in similar comments from different respondents. Similar comments are summarized into concise narrative statements and organized by the theme categories.

Comments are organized in two broad categories below:

- Summary of Public Comment – Resource Topics. This section provides issues identified in scoping comments organized by resource topic (e.g., air quality,

AMERICAN OVERSIGHT

socioeconomics, and fish). This section summarizes resource-specific comments, such as comments concerning fish and wildlife habitat loss, loss of recreational access, and dust and emissions along the access roads and at the mine site.

- Summary of Public Comment – NEPA Process and Regulatory Compliance. This section provides a summary of public comments on the NEPA process and alternatives. Topics include the public involvement process, project purpose and need, other laws and regulations, tribal consultation, cooperating agencies, and the no action alternative. Public comment suggestions for proposed action alternatives and mitigation measures are also included.

3.4 SUMMARY OF PUBLIC COMMENT – RESOURCE TOPICS

3.4.1 General Resources

A variety of general comments were received indicating that the EIS should analyze the direct, indirect, and cumulative impacts on resources in the Project Area.

3.4.2 Physical Resources

Comments indicated that the EIS should analyze the direct, indirect, and cumulative impacts on specific physical resources, including:

- Air quality;
- Climate change;
- Geology and seismic activity;
- Surface and groundwater hydrology impacts;
- Noise impacts;
- Fuel spill risks and releases;
- Hazardous materials stored and transported to and from the mine site;
- Natural gas supply and pipeline safety;
- Tailings dam; and
- Water resources – quality and quantity.

3.4.2.1 Air Quality

Comments were received regarding impacts to air quality from construction, fugitive dust emissions, vehicle equipment emissions and mining activities. These include:

- Dust pollution from the mine and roads, and what chemicals may be used to control dust.
- Impacts to air quality including impacts from transporting ore and materials, or loading and shipping ore and concentrate.
- Emissions from the power plant.
- Impacts related to fugitive dust.
- Prevailing winds creating waves on the pyritic tailings facility which could allow oxidation of the tailings resulting in acid generation.
- Impacts from air pollutants emitted during mine operations and contribution to greenhouse gas emissions from the power plant.
- Greenhouse gas emissions as a result of the proposed project and all alternatives.

AMERICAN OVERSIGHT

3.4.2.2 Climate Change

Comments were received about the impacts of climate change to the environment and how climate change trends may interact with effects of the proposed project.

3.4.2.3 Geology and Seismic Activity

Comments were received regarding impacts to the geology of the project area, including concerns that major faults occur in the proposed Project Area.

- Describe how the proposed project facilities would withstand earthquakes, particularly the tailings storage facility.
- Include detailed information about seismically active areas, geological faults and tectonic activity, and corresponding design features.
- Analyze impacts to bedrock, surface geology, gravel resources, paleontological resources, and landforms from all proposed project components.
- Analyze impacts from volcanic activity, especially at Amakdedori.

3.4.2.4 Surface and Groundwater Hydrology

Comments were received on impacts to groundwater systems and aquifers from tailings, transportation of groundwater, and how it moves underground. A thorough understanding of the groundwater and surface water hydrology and how they relate to each other should be demonstrated.

- Analyze impacts from the mining process lowering the groundwater table and what that will do to surface water hydrology in nearby streams.
- Address earthquake impacts on hydrology characteristics.
- Explain the water balance model of the project.

3.4.2.5 Noise

Comments were received on impacts of noise pollution as a result of project construction and mining operations.

- Discuss noise impacts of blasting in the project area, and describe the blasting methods that would be used.

3.4.2.6 Fuel Spill Risks and Releases

Comments were received about the potential for fuel and oil spills or accidental releases, including adequate response capacity to clean up spills in various conditions, and potential impacts to natural resources or environment from spills or release.

- Analyze impacts of spills of diesel and natural gas to every resource discussed in the EIS.
- An earthquake could rupture the gas pipeline under the lake when salmon are migrating and kill the fish.
- Explain who is responsible for spill response on Cook Inlet and Iliamna Lake. Response plans should be developed for all parts of the project.

AMERICAN OVERSIGHT

3.4.2.7 Hazardous Materials

Comments were received about the potential for hazardous material storage, spills, and impacts to resources or the environment and, in particular, address chemicals associated with mine process and storage of materials (arsenic, acids).

- The revised mine plan calls for no cyanide to be brought in to the region.
- Address impacts of hazardous and solid waste generated from the proposed project. A hazardous and solid waste material handling, storage, management, and disposal plan should be developed and evaluated into the Draft EIS.
- Describe how blasting agents will be transported and managed.
- During the copper extraction process an alcohol is added during the flotation along with a collector chemical called potassium amyl xanthate (or the potassium salt of an alkyl dithiocarbonate), which can be toxic.

3.4.2.8 Natural Gas: Pipeline and Gas Supply

Comments were received on the impacts of the proposed project on the supply, demand and cost of natural gas in the proposed Project Area and Cook Inlet.

- Lower costs of fuel in rural Alaska as result of potential new gas supply and spur/distribution systems.
- The supply of available natural gas in Cook Inlet may not be sufficient to provide power to the proposed project.
- Alternative energy sources should be examined. Many of the minerals to be mined will go into solar panels, wind turbines, and hydro turbines. The PLP could support the industries they will be supplying by utilizing alternative, renewable energy sources.
- Explain if the use of natural gas by PLP would affect existing railbelt supply and users.

Comments were received on the design, route, construction, and safety and reliability of the natural gas pipeline.

- That part of Alaska has exceptionally high tides – routinely greater than 20 feet. Please consider this when analyzing an underwater gas pipeline.
- There are safe and secure methods to construct a pipeline that would cross existing submarine cables. The pipeline owner/operators should enter into a cable crossing agreement to ensure the safety and security of both the fiber cables and the gas pipeline.
- There are no pipelines in Cook Inlet this long. In Nikiski, it is surprising how rapidly the seabed can change. This can cause unforeseen problems in maintenance. While lower Cook Inlet and Kamishak Bay do not have ice or currents to the same extent as the upper Cook Inlet, Lower Cook Inlet is not nearly as protected as the waters of upper Cook Inlet, and Kamishak Bay has probably the worst winter sea conditions of anywhere this side of the Bering Sea.
- At Iliamna Lake, maintenance could be difficult when the lake is frozen.
- The route for this pipeline means that it will be sitting at the base of Augustine Volcano.

AMERICAN OVERSIGHT

3.4.2.9 Tailings Dam

Comments were received regarding concern for the stability of the tailings dam, potential for tailings dam failure, and impacts of such a failure.

- Describe the impacts of dam failure and recognize the public concern of the stability of the tailings dam. Specifically, the USACE should consider the impacts to biological and social environments of a dam failure as a result of an earthquake.
- Analyze impacts of a tailings dam failure to every resource discussed in the EIS.
- Look at examples of other tailings dam failures (in Spain, Canada, Australia, and others in the United States). Some dams have failed because of engineering, some because of earthquakes.
- Analyze impacts from tailings leaks and leaching, not just failures.
- Tailings dam engineering has improved considerably over the decades. Pebble's tailings dam design will have to be approved to adequately protect the environment before the project will be permitted.
- Analyze impacts from rainfall causing overtopping of the tailings dam.

3.4.2.10 Water Quality and Quantity

Comments were received concerning a detailed analysis and discussion of the physical and chemical impacts on all water resources.

- Analyze impacts to water quality and quantity from construction and operation.
- Analyze pit water and tailings dam management.
- The mine site water balance should be estimated for each phase of the mine development.
- The proposed pit will be contaminated during closure like the Berkeley Pit in Montana and be forever toxic to wildlife and waterfowl.
- Analyze erosion, turbidity, temperature changes.
- Ferry crossing concerns, including changes in shoreline erosion and turbidity, and pollution from the proposed ferry.
- Composition of the (potential) contaminants from all project sources, including blasting.
- Prevailing winds will create waves on the pyritic tailings facility which will allow oxidation of the tailings.
- Risks associated with acid rock drainage from mine project components, including the waste rock facility, leaching, and pathways for acid rock drainage. Acid rock drainage was noted as a potential source of impact on many resources, such as water quality, wetlands, fish, and subsistence food resources.
- Describe how acid rock drainage, the tailings, and metals leaching would be managed and treated post-closure.
- Analyze the potential for wastewater to enter streams and rivers.

3.4.3 Biological Resources

Comments indicated that the EIS should analyze the direct, indirect and cumulative impacts on specific biological resources, including:

- Vegetation and ecosystems;

AMERICAN OVERSIGHT

- Fish and aquatic resources;
- Wetlands and special aquatic sites;
- Wildlife and non-Threatened and Endangered Species (TES) birds and mammals; and
- Threatened and Endangered Species.

3.4.3.1 Vegetation and Ecosystems

Comments were received concerning potential for disturbance from project construction and operations, and on invasive species. Comments were also received concerning terrestrial, lake, and marine habitat impacts from project construction and operations.

- Analyze impacts to rare and sensitive plants (including removal).
- Address how fugitive dust would affect vegetation within the project area and beyond.
- Address risk for invasive (non-native) species introduction by marine barges and the ferry; include ballast water management.
- Analyze ecosystems as unique in the Bristol Bay area, in the degree to which they remain unaffected by commercial development and other human technologies. Evaluate how the proposed project could alter the biological and human ecosystems and landscape.
- Analyze the potential direct, indirect, and cumulative effects of all components and all phases (including reclamation and restoration) of the proposed project on terrestrial, marine, and freshwater ecosystems.
- Analyze impacts that habitat fragmentation from Amakdedori Port and the mine access road would have on bear movements.

3.4.3.2 Fish and Aquatic Resources

Comments were received related to potential impacts to fish (King Salmon, Sockeye Salmon, Silver Salmon, Pink Salmon, Chum Salmon, Dolly Varden/Arctic char, Rainbow Trout, and Grayling) populations, abundance, diversity, migratory patterns, contamination, and potential for displacement from project components.

- Address effects of ferry traffic on resident and migrating fish in Iliamna Lake: the potential for the ferry to cause erosion of the lake shoreline and the effect of that on fish; the effect of the ferry on salmon spawning and rearing habitat; the effect of increased noise on salmon productivity; the potential for increased turbidity and its effect on salmon; the potential for ferry traffic to cause wave action that could harm the fry on their way to the ocean; the potential for ferry propellers to entrain fish and cause mortality, and the potential for fish to avoid the area around the ferry and not come back to the area.
- Address effects of gravel pits on stream hydrology and fisheries.
- Iliamna Lake creatures are poorly studied and additional baseline studies are needed.
- Water withdrawal and capture, storage, treatment and release of wastewater associated with the mine could impair the fish habitat functions of streams, wetlands, and aquatic resources.
- Address the potential for fish to become contaminated from mining chemicals or fuel spills.

AMERICAN OVERSIGHT

- Evaluate how the proposed project road to Iliamna Lake would impact fish species as road traffic will create of dust that may contain copper and other heavy metals that could enter the watershed and affect resident aquatic organisms including salmon.

Comments were received regarding the impacts of the mine access road crossing streams and anadromous waters, and the impacts of those stream crossings on fish.

- Current plans will impact more than 5 miles of anadromous streams.
- The construction process would build an 80-mile road system with 200 stream crossings.
- Analyze bridge and culvert impacts to fish, including fish passage and habitat condition change.
- Proposed road corridor has been designed to minimize impact on wetlands, minimize stream crossings and avoid areas of known for subsistence and recreational use.

Comments were received regarding the impacts to aquatic resources, including introduction of invasive species.

- Shipping from foreign ports may result in ballast water transporting invasive species such as green crab, which would have a devastating impact on the ecosystem and commercial shellfishery.
- Require a shellfish population (scallops, razor clams, and hardshell clams) baseline assessment and impact assessment regarding the dredging project prior to any dredging work at Amakdedori Port. Base recommendations on the impacts this dredging will have on the shellfish populations of Western Cook Inlet. The proposed channel dredging could affect the sedimentation deposition rate on adjacent beaches and nearshore shellfish habitat.

3.4.3.3 Wetlands and Special Aquatic Sites

Comments were received on filling of wetlands and alternations of wetlands habitat, fragmentation, and loss of wetland habitat as a result of project activities.

- Include delineation of all wetlands that could be affected by the proposed project.
- Estimated mine site to fill 3,190 acres of wetlands and water bodies, nearly three times the maximum set by the EPA for Bristol Bay in 2014.
- Impacts to wetlands dewatering and hydrological changes, pollution to wetlands, impacts on wetlands functions, clearing and removal of wetland vegetation, degrading wetland vegetation from all proposed Pebble project components and during construction, operation, and closure phases.
- Given the extent of streams, wetlands, lakes and ponds both overlying the Pebble deposit and within adjacent watersheds, excavation of a massive mine pit and construction of large tailing impoundments and waste rock piles would result in discharge of dredged or fill material into these waters.

3.4.3.4 Wildlife and non-TES Birds and Mammals

Comments were received related to potential impacts to wildlife (including terrestrial and marine mammals), and on potential impacts to migratory birds and waterfowl populations; abundance, diversity, migratory patterns and potential for displacement; and attraction of birds to tailing ponds.

AMERICAN OVERSIGHT

- Describe how the project construction, operation, and closure would change wildlife patterns and behavior. Noise from mining, the mine access roads, ferry traffic could all impact behavior.
- Assess how wildlife can acclimate to construction and operation impacts.
- Analyze how noise levels from construction or large vessel traffic may deter bears from coming to McNeil River Falls, or could affect bear behavior and change or end the use of McNeil River by bears.
- Examine how increased contact between bears that use the McNeil River and humans could result in food conditioning of bears or direct bear mortality by humans.
- The proposed ferry could strike marine mammals (seals) in Iliamna Lake, which would congregate in the open water created by the icebreaking ferry.
- Ferries could impact the migration pattern of wildlife.
- Take advantage of traditional knowledge on freshwater seals in Iliamna Lake, there is a Freshwater Seal Commission.
- The transportation of mining materials across Cook Inlet has potentially negative effects for local marine mammals, particularly underwater noise pollution that impacts the use of sonar in marine mammals such as whales, dolphins, and seals, and about the speed of the cargo ships carrying materials.
- Consider noise in the water created by the proposed ice-breaker ferry and the impacts to fish and wildlife.
- The Bristol Bay watershed is unique in that it provides habitat for more than 190 birds. Additionally, there are more than 40 species of water birds here and confirmed breeding sites for more than 22 species.
- Describe what steps the developers propose to keep tailings ponds/lakes free from pollutants or physically restrict birds from trying to land on them.
- Analyze impacts from noise, blasting, and other human interference to birds.
- Blast control can mitigate noise impacts to birds, like they do with birds at the airport.
- Address effects of the project on birds and migratory waterfowl that are used for subsistence.

3.4.3.5 Threatened and Endangered Species

- The proposed port site is designated Critical Habitat for the Cook Inlet Beluga Whale and the Northern Sea Otter, both listed as endangered; and Iliamna Lake is home to freshwater seals that have been considered in the past for Endangered Species Act status.

3.4.4 Social Resources

Comments indicated that the EIS should analyze the direct, indirect and cumulative impacts on specific social resources, including:

- Socioeconomics;
- Subsistence;
- Traditional way of life;
- Archaeological and cultural resources;
- Land ownership, management, and use;
- Transportation and navigation;

AMERICAN OVERSIGHT

- Recreation;
- Environmental justice;
- Public health and safety;
- Visual resources; and
- Wilderness characteristics.

3.4.4.1 Socioeconomic Impacts

Comments were received regarding the economic impacts to local communities, regional economy, and national economy.

- PLP should give the USACE an independently prepared economic feasibility analysis, which is usually done for other mines like Donlin. Without the economic feasibility analysis, the USACE could be analyzing and the public could be commenting on a mine that will never be built due to a lack of funds.
- The impact of the use of Iliamna Lake and the proposed transportation corridors/pipelines on sport fishing and the sport fishing-related economy should be evaluated.
- Consider the socioeconomic impacts to Bristol Bay's recreational fisheries. More than 37,000 angling trips are taken to Bristol Bay each year, which supports dozens of businesses, and a $91 million annual economy.
- The project could destroy the Bristol Bay commercial sockeye salmon fishery.
- The project could damage the Bristol Bay wild salmon brand because the watershed would contain a mining district and no longer be pristine.
- Consider that the project would create a boom and bust economic cycle that would ultimately leave people without jobs.
- The mining company will bring their own workers and not train local people to work at the mine.
- The Pebble Mine would bring much needed economic opportunity to a region by creating jobs during construction and operation.
- Residents are moving closer to much larger metropolitan regions to seek opportunities that do not currently exist near their homes in the region.
- Consider that the Kennicott Copper Mine was located in the watershed of the Copper River which did not affect the value of the salmon fishery in that region.
- The population would increase during construction and heavily impact local communities.
- EIS should look at the long term social impacts, such as trapping and life style change impacts.
- The commercial salmon fishing economy sustains 20,000 jobs; 20,000 jobs will be lost if this mine goes forward.
- People need jobs and fish.
- Analyze impacts on the bear viewing industry near the proposed Amakdedori Port.
- There were inquiries about if there would be compensation to commercial fishermen if there is a disaster and fish prices go down like was done with Exxon Valdez.
- The project will kill the hearts and souls of the people; our way of life has no value.
- Consider that fish taxes are important to the finances of the Bristol Bay Borough.

AMERICAN OVERSIGHT

- Review social benefits like education opportunities, and potential reduction in the high cost of living in the region due to transportation improvements.
- PLP should consider using regional Native corporations that are already in the pipeline construction and maintenance industry.

3.4.4.2 Food and Fiber Production – Subsistence

Comments were received related to potential impacts to food and fiber production (subsistence) and subsistence resources like harvest, sharing, and traditional use areas. Comments were also received on contamination concerns and/or avoidance of subsistence resources.

- Consider that impacts to any subsistence resource (e.g., fish, wildlife, vegetation) would impact subsistence as well.
- Consider the importance of the salmon fishery to subsistence and the heavy reliance on fish for all users in the area.
- Analyze impacts on subsistence resources including wildlife migration, habitat for growing food, traditional use areas, fisheries, berries and other edible plants, and the cumulative effects from other mining activity.
- Analyze impacts of potential contaminants entering into the air or water and affecting subsistence resources, including effects on subsistence resources due to potential accidental spills, and bioaccumulation of toxins in subsistence resources, and effects
- Impacts to the residents along Iliamna Lake who rely on access to small islands for the harvest of bird eggs in the spring.
- We are in fear for our subsistence way of life. Leave our dinner table alone!
- Helicopter traffic during exploration displaced caribou from the project area and this would also occur during construction and operations of the mine. Also address Koktuli.
- Helicopter traffic impacts on spring waterfowl hunting, geese. Operations air traffic could be significant, there should be no fly zones, and address caribou hunting impacts.
- Helicopter traffic during exploration disrupted subsistence activities and this would occur during construction and operations of the mine.
- Many species of fish are used for subsistence harvest, not just salmon.
- Analyze potential beneficial impacts to subsistence as cash income earned from jobs could support subsistence activities. Cash income could be available to fund the boats, motors, fuel, and nets necessary to maintain subsistence activities.
- A sudden influx of noise, people, and heavy equipment over ancestral hunting and fishing lands would have a devastating effect on the intangible riches the sustainable Dena'ina subsistence culture has to offer.

Comments were received on impacts to important locations for subsistence activity from the project, including:

- The proposed road in the Talarik watershed is an important moose hunting area.
- The road corridor would go through our winter moose hunting area.
- Helicopter traffic during exploration at Pebble displaced caribou from the project area and this would also occur during construction and operations of the mine.
- We depend on king salmon from the Koktuli River.

AMERICAN OVERSIGHT

- The Amakdedori area has been historically used for early subsistence activities, including salmon harvest.
- The mountain behind Nondalton is traditional subsistence area.
- The Frying Pan Lake area is important to Nondalton people and shared with other neighboring people.

3.4.4.3 Traditional Culture and Way of Life

Comments were received related to potential cultural impacts and the desire to maintain traditional practices. Includes comments related to traditional land use areas (cultural continuity), and traditional ecological knowledge.

- Fully disclose the potential impacts of project-related activities on local Alaska Native traditional ways of life. Local culture and environment has already changed from what it was historically, and this may affect the ability to pass values on to future generations.
- Traditional ecological knowledge should be studied and incorporated into the Draft EIS. Individual tribal members engage in traditional subsistence activities and have knowledge and experience with their land, wildlife, wetlands, fish, birds, plants, and other resources of the region.

3.4.4.4 Archeological and Cultural Resources

Concerns were expressed about impacts to archaeological and cultural resources subject to Section 106 of the National Historic Preservation Act.

- Review any traditional native or cultural sites within the mine and utility corridors, and provide mitigation for same.
- There are ancestral burial grounds at/near the proposed Amakdedori port.
- Amakdedori has been used as a site for a cultural camp.
- Analyze impacts to irreplaceable Native Alaskan rock art sites. This region of Alaska contains several recorded rock art (petroglyph) sites. No doubt more such sites remain to be discovered. Many of the rock art panels are on shorelines and only visible during low tide; thus, it is easy for archaeological surveys to miss these important cultural resources.
- Analyze impacts to cultural resources (historical and pre-historical sites) and direct destruction of cultural resources from all project components.

3.4.4.5 Land Ownership, Management and Use

Comments were received about land status (ownership), land management, and land use for the project areas.

- The proposed mine site and many project components including the port site and a majority of the transportation corridor are proposed on state-owned lands. Mine construction, operation, and closure would limit any access to these lands and transportation corridor to private entities only.
- A pattern of land use change would occur in the region long-term with additional mining deposits explored for development.
- Review any trails that could be impacted by the project.

AMERICAN OVERSIGHT

- The Pebble Mine will be built on state land set aside decades ago in Western Alaska specifically for mining.
- Ensure that activities are consistent with land use plans and goals of all landowners, including the State of Alaska, and Alaska Native corporations.
- Analyze the effect of project components on the public use of the surrounding area with regards to trails and waterfront usage.
- Explain the security status of the ferry terminals, the mine access road, and Amakdedori Port, including when and how the public may or may not access or cross project facilities.
- Explain if local Tribal governments have included the mine access road in their Indian Reservation Roads Program that would make it public, versus private roads as stated by PLP.

3.4.4.6 Transportation and Navigation

Comments were received regarding the impacts to transportation systems, including airports, roads, rivers, and trails as a result of the project.

- Evaluate the potential impacts resulting from navigational challenges, traffic, and user conflicts at Iliamna Lake, Kamishak Bay, and Cook Inlet. The Draft EIS should evaluate how the ferry crossing and vessel traffic could disrupt schedules, local access and local boaters.
- An ice-breaking ferry across Iliamna Lake would create difficulties and hazardous situations for people travelling across the ferry route on snowmachines.
- Analyze impacts from increased air traffic during all project phases.
- Concerns about traffic on the Sterling Highway.
- The wind has pushed ice on the north shore of Iliamna Lake in piles as high as 50 feet and could damage the proposed ferry terminal.
- The east winds on Iliamna Lake are strong and generate large waves that would make the proposed ferry unreliable and dangerous; winds can reach 100 mph.
- A disabled ferry could be blown by the wind onto the shoreline such as at Eagle Bluffs.
- The Amakdedori Port location experiences very strong onshore winds that could be hazardous.
- Consider the impact of travel restrictions from road and ferry and who is benefiting.
- It will be difficult to maintain the Amakdedori Port dredged channel due to sediment transport in that area.

3.4.4.7 Recreation

Comments were received on impacts to recreation and tourism; recreational hunting and fishing; usage near the mine, along river systems, and in transportation/pipeline corridor during construction and operation. This includes comments on disruption of recreational experiences (bear viewing, sport fishing).

- Consider the effects of project components on recreational hunting and existing guided hunting operations (e.g., changes to access, disturbance of wildlife from helicopters or vehicle traffic).

AMERICAN OVERSIGHT

- Concerns about impacts to fish, and how impacts to species could be detrimental to the sport fishing community and businesses.
- The proposed project would bring an influx of the number of people in the Iliamna area that would want to recreate, sport fish and hunt, including mine employees and support industry personnel.
- Displacement of wildlife would impact the experience of people.

3.4.4.8 Environmental Justice

Comments were received relating to disproportionate, adverse impacts to low income and minority communities as result of the proposed project.

- Analyze impacts related to environmental justice include food security and subsistence resources, health impacts from pollution and exposure to increased industrial activities and noises, increased risk of injury and exposure to hazardous materials, increased exposure to outsiders and the cascading social and psychological problems that brings.
- The economic benefits will not be for the people of the region but the impacts will.
- The environmental justice risk outweighs the benefits.

3.4.4.9 Public Health

Comments were received on impacts to local communities' public health and infrastructure as a result of the project (disease, contaminants, lifestyle changes, behavioral health, and physical health).

- Analyze public health concerns related to development and infrastructure development in rural communities.
- The short and long-term impacts from all stages of the project include increased risks of accidents and injuries, exposure to hazardous materials, negative impacts on food, nutrition, and subsistence, increased potential for infectious diseases, and risks to health and human services from population-stressed infrastructure and services
- Consider the social and psychological impacts the stress this project has already put on people and the communities who live in the project area. It is important for the EIS to consider stress, social and psychological impacts.
- Evaluate the potential impacts of development on indigenous women, and increased rate of violence as a result.
- Fully discuss the potential that the proposed project could be associated with behavioral health impacts, such as increased use of drugs and alcohol. More disposable income in communities may increase the use of alcohol and drugs.
- An influx of people could bring diseases to an area with minimal healthcare available that may not be able to handle large capacities of patients.

3.4.4.10 Visual Resources and Aesthetics

Comments were received on visual impacts.

- Evaluate the impacts to visual resources with the potential to diminish the visual experience of visitors and local residents.
- Consider visual impacts to recreation, and secondary industries like flightseeing operators and wildlife viewing guides.

AMERICAN OVERSIGHT

- The project will have permanent and significant impacts on the appearance of the landscape as viewed from key observation points, planes, etc. and will in turn impact use and enjoyment of the area by many.
- Measures should be implemented to minimize the aesthetic impacts as much as is reasonably possible.

3.4.4.11 Wilderness Characteristics

Comments were received related to wilderness characteristics and values.

- This area has wilderness characteristics, and is adjacent to a National Park.
- The potential impact on the Koktuli, Nushagak and its tributaries, Upper/Lower Talarik Creeks, the Gibraltar River, the Kvichak River, and other tributaries of Iliamna Lake have an undeniable wilderness quality that could be impacted by the proposed project. The impact of the loss of pristine wilderness, specifically in the Gibraltar, Talarik, and Koktuli drainages should be considered and, when possible, quantified.

3.4.5 NEPA Process and Regulatory Compliance

Comments were received on the NEPA process and need for compliance with regulations including:

- The general NEPA process;
- The purpose and need of the proposed project;
- Cumulative effects analysis;
- Government to government consultation;
- The proposed action and project alternatives;
- Mitigation measures;
- Monitoring and adaptive management;
- Bonding and reclamation;
- Data and available information; and
- Research and evaluation needs.

Comments were received about the overall NEPA and EIS process, the permit application to the USACE, due process, and the scoping meetings. These types of comments generally do not inform preparation of the EIS as to the project purpose and need, resources/level of impacts to be analyzed, or alternative to the proposed action that should be considered in the EIS. A summary of the general NEPA process comments includes the following:

- The Pebble Mine application is incomplete. The USACE should suspend its NEPA process/ not release a Draft EIS without more information from PLP. Foundational information for major parts of Pebble's proposal, including the proposed transportation corridor, port or use of Iliamna Lake, are lacking from their application. The data PLP supplied is more than 10 years old and thus is not reliable for analyzing project impacts.
- The Pebble Mine application is not incomplete. The Pebble Mine plan and application has recently been revised to satisfy EPA guidelines.
- There should be opportunities at each public hearing for oral comments in an open public forum. Everyone should have the opportunity to hear the comments of fellow concerned citizens. Open oral comments provide new information and learning opportunities not only for USACE and their contractors, but for all attendees. Please

AMERICAN OVERSIGHT

change your scoping format for future meeting to include an opportunity to express concerns through an open oral comment period.

- The limited number of scoping hearings and failure to host scoping hearings in communities within the Nushugak and Kvichak River drainages means that the opinions and voices of local populations have not been accounted for.
- Extend the scoping period beyond 30 days. Tribes in Bristol Bay are requesting at least 120 days for this scoping period.
- A 30 day scoping process is sufficient. Few projects have been talked about for as long and with such passion as the Pebble Mine and at this point, no new information about possible adverse effects will come to light.
- The USACE should compare PLP's plans to the EPA's analysis before moving forward with permitting.
- The USACE needs to acknowledge that the current permit application could be the initial phase in a much broader mine development plan. Reviewing just phase one of the project unlawfully segments environmental review, shortchanges the public interest, and risks untold impacts to the Bristol Bay region's world-class fisheries. The EIS scope should include looking at the impacts of the potential of creating a mining district in the area.
- PLP should get a fair permitting process.
- The EIS process is being rushed; the USACE took more time to prepare the Donlin Gold EIS.

Comments were received that the USACE should initiate formal consultation and coordination with tribal governments. This includes comments on formal consultation and coordination under EO 13175.

Coordination with other agencies is an important part of the NEPA process. Comments were received on how the USACE should seek and promote full and broad-scope participation by federal and state resource agencies and tribal government entities as cooperating agencies, and undergo comprehensive formal consultation with appropriate entities. Comments were also received on how the USACE should extend cooperating agency invitations to interested tribal governments, as well as local, state, and federal agencies with special expertise and involve cooperating agencies on the full scope of the proposed Pebble Project.

3.4.5.1 Purpose and Need of the Action and USACE Permits

Comments were received regarding the purpose and need of the action, and the public interest of the project for the purpose of USACE permitting.

- Explain how an EIS process can proceed without more commitment from financial backers.
- PLP says their project would help with mineral independence but they will export all of the mined minerals.
- The USACE should accept the purpose and need statement contained in the permit application from PLP.
- The Pebble EIS should present a clear and concise statement of the underlying purpose and need for the proposed project consistent with the implementing regulations for NEPA (40 CFR 1502.13). This statement should be framed broadly enough as to allow for the analysis of a range of reasonable alternatives.

AMERICAN OVERSIGHT

- The Draft EIS should reflect not only the purpose and need of the project proponent, and the USACE, but also the broader public interest and need based on the scoping comments.

3.4.5.2 Cumulative Effects Analysis Process

Comments were received on how the cumulative effects analysis should be thorough, well-defined, and complete.

- Describe how the Draft EIS process considers cumulative effects, and identify the geographic scope and timeframe for the cumulative effects analysis.
- Consider the cumulative impacts of fully mining the entire 11 billion-ton deposit. Pebble Limited Partnership has repeatedly said, as recently as September 2017, their project is, "a multi-generational opportunity. Its size and scale will lead to a very, very long life mine." Based on statements such as this, and official records indicating they plan to mine up to 11 billion tons of ore, it is reasonably foreseeable that Pebble intends to expand its mine far beyond what is currently proposed.
- There are 20 large-scale active mining claims in the Bristol Bay watershed that this project could encourage by providing the transportation and power infrastructure.
- The EIS scope should include looking at the impacts of the potential of creating a mining district in the area.
- Needs a cumulative effects analysis on culture.

3.4.5.3 Proposed Action and Alternatives

Comments requested more detailed information on the project plans, such as the water management plan, transportation plans, and spill response plans.

- The design and operational plans for the proposed project and alternatives should be evaluated. Alternatives to the proposed project were suggested.
- All of the pyritic tailings should be removed and not stored on the land in perpetuity.
- There is no need to dredge the proposed port to -50 feet; a shallower depth should be evaluated.
- A port at Diamond Point in Iliamna Bay should be evaluated against the proposed Amakdedori Port.
- The USACE should consider finding an alternative location to take the rocks for processing.
- As an alternative to a tailings ponds dam for waste storage, all waste should be trucked to Canada and stored in Canada, since the company is Canadian.
- The USACE must look at a range of alternatives beyond Pebble's mine site and include alternatives for mining copper and gold somewhere other than Bristol Bay.
- The USACE does not need to explore alternatives to Pebble's proposed mine site as being somewhere other than Bristol Bay because it already 100 miles from the bay and should be deemed a reasonable distance.
- The previous plan involved a road along the northeastern side of Iliamna Lake, and was justifiably criticized for the devastation that it would have brought to the village of Pedro Bay and the many salmon-bearing streams that it would have crossed. Now the proposed project includes roads and a ferry across Iliamna Lake. This would place a different part of the basin at great risk, and requires continual barge traffic across this large and windy lake. This is very likely to prove disastrous, and then the

AMERICAN OVERSIGHT

operators of the mine will compel the state as a whole and the residents of this basin to accept some other plan such as a road around the lake in the eastern or western end. These will be equally bad ideas.

- The USACE should consider alternatives to permit 50 percent or 100 percent of the current known resources to be mined. A larger and longer mine plan more fully benefits economic development in the state of Alaska and the USA.
- The road system would cross numerous anadromous streams. It would be best to require bridges at all of these crossings. Oregon and Washington states have been working for many years to bring back their salmon runs. Recreating salmon habitat including headwaters has proven to be extremely hard.
- Apply a realistic scope to assess mine impacts. The time frame of analysis is small at 20 years; the applicant's website notes that the mine can operate for 200 years and could have 11 billion tons of ore. Examine the full extent of mining the deposit.
- More alternatives should be considered, including a combination of simultaneous open pit and underground mining, a larger open pit mine, or a longer lived open pit mine. It may be possible to mine with open pits for the shallower portions, and mine by underground mining the deeper or eastern portions of the Pebble deposit.

3.4.5.4 Mitigation Measures

Comments were received related to the need for project mitigation, and suggestions for mitigation measures.

- PLP has not given any mitigation plans for sociocultural impacts.
- The mine may go into production without enough safeguards, or conditions to mitigate, and then go bankrupt and impact the environment.
- Tribes and the public should be involved in the mitigation planning, and monitoring of the proposed project.
- The sociocultural impacts cannot be mitigated.
- Review any traditional native or cultural sites within the mine and utility corridors, and provide mitigation for same.
- Consider and recognize the extensive mitigation measures that Pebble has built into the new proposed plan to address environmental and stakeholder concerns.
- Water takes the path of least resistance, so rainfall will attempt to make its way to the river bodies, but this can be mitigated with runoff ponds and filtrated release.
- Take measures to decrease whale strikes by ships.
- Measures should be implemented to minimize the aesthetic impacts as much as is reasonably possible.

3.4.5.5 Monitoring and Adaptive Management

Comments were received in regards to the need for monitoring plans during operations and after closure of the mine.

- The history of multiple open pit mining sites has shown that the open reservoirs put in place to hold contaminated water and processing liquids have routinely been compromised by leaking and / or by drastic failure of containment levees. While they highlight the measures taken to put these toxins in containment, they fail to address the long term maintenance and mitigation of the toxins to make them inert.

AMERICAN OVERSIGHT

- Explain what oversight and monitoring would be applied to meet minimum detrimental environmental conditions, by whom, and under what authority.
- Explain if there would be a fund for additional environmental monitoring while the project is ongoing.

3.4.5.6 Bonding and Reclamation

Comments were received related to reclamation activities, bonding, and setting up escrow fund for restoration. Mechanisms for treatment in perpetuity post closure (i.e., plan for permanent water treatment, the entity that would pay post closure costs – secure financing in perpetuity).

- Local communities would be hooked up to the gas line, as well as a maintenance crew watching over the hazardous tailing piles and dams. Describe bonding to cover these costs if something happens to PLP.
- It appears PLP has organized and financed the project so that there is no ongoing substantial entity to bear the costs of any environmental cleanup caused by the mine, its operation, or eventual closure. Explain what provision has been made for them to post say a $500 million bond to cover such damage.
- The reclamation bond the company would agree to would never be enough.

3.4.5.7 Data and Available Information

Comments were received that suggested specific, documents, articles, or other information that should be utilized when developing the Draft EIS.

- Review research on fiber optics cable placement on tundra by Rorik Peterson at the University of Alaska Fairbanks. In addition, the USACE should review mapping provided by GCI regarding fiber optic cable placement of the TERRA-SW and KKFL cable crossings in Cook Inlet and Iliamna Lake that would intersect with the proposed natural gas pipeline.
- Regarding impacts to shellfish populations, review the following:
    - Alaska Department of Environmental Conservation (ADEC): CISCP sensitive areas section - https://dec.alaska.gov/spar/ppr/plans/scp_ci/CISCP_DSensitive_Areas_Jan2017.pdf, page D40-41.
    - Collapsed or recovering shellfish fisheries in the state of Alaska IR.1J.2002.06.pdf Preliminary Report to the Alaska Board of Fisheries COLLAPSED OR RECOVERING SHELLFISH FISHERIES IN THE STATE OF ALASKA, ALASKA DEPARTMENT OF FISH AND GAME, Division of Commercial Fisheries, Regional Information Report 1 1J02-06, OCTOBER 1999.
- Acknowledge how Traditional Ecological Knowledge information may be used and how to ensure that sensitive information is protected and follow a set of protocols for use of this information.
- Review spills in Cook Inlet. In a study by the Cook Inlet Regional Citizen's Advisory Council, 70 of the 88 were caused by structural or mechanical failures.
- Alaska Department of Fish and Game (ADF&G), Division of Commercial Fisheries news release: 2018 Bristol Bay Sockeye Salmon Forecast.

AMERICAN OVERSIGHT

- The Economic Importance of the Bristol Bay Salmon Industry. Prepared for the Bristol Bay Regional Seafood Development Association by Gunnar Knapp Mouhcine Guettabi Scott Goldsmith. April 2013.
- There is a recent text book edited by Dr. Carol Anne Woody that should be a resource for the EIS.

3.4.5.8 Research and Evaluation Needs

Comments were received regarding the lack of baseline research, monitoring, and evaluation needs, or data gaps for the project.

- The USACE should suspend its NEPA process until the PLP presents sufficient environmental baseline and economic data about its proposal so as to reasonably inform the NEPA process.
- No new baseline documents or data were submitted with PLP's application to the USACE in December 2017. The only publicly available baseline documents compiled by PLP are now more than a decade old, with data collected from 2004 to 2008. Those baseline studies failed to include newly proposed project components such as the transportation corridor, Iliamna Lake, and the proposed port site.
- Baseline data for the proposed Amakdedori Port and Kamishak Bay may be lacking in terms of what is known about water currents, shifting sands/silts and ice and how these physical conditions may affect trenching.
- ADF&G lacks assessment tools for the shellfish that live in Cook Inlet. Current baseline studies for these species do not exist. In light of the possible increase in sediment deposition rate resulting from dredging in the area of the Pebble Project, the USACE should require a shellfish population baseline assessment and impact statement regarding the dredging project prior to any dredging work beginning in Amakdedori Bay.
- No baseline data exists for the proposed port and use of Iliamna Lake, or the 83-mile transportation corridor making it impossible to analyze the potential impacts these activities would have on sensitive salmon habitat, tributaries, and adjacent wetlands.
- An extensive and thorough baseline study on bear populations including numbers, movement, diet, and feeding areas should be done.
- There is a lack of baseline studies on newly added mine components for an informed permit process, such as wastewater discharges to Frying Pan Lake.

3.4.6 Non Substantive Comment

Submissions without substantive comment that are not specific to a particular issue are considered non-substantive. These include comments in support of or in opposition to the applicant's proposed project.

Subject: request for review of Draft EIS Sections, SUSPENSE 31 OCT 2018, (UNCLASSIFIED)
Attachments: Sec4.5_Recreation__reviewdraft_2018.10.16.docx; AppK3.1_TEK_reviewdraft_2018.10.16.docx; Sec3.1_IntroAE_reviewdraft_2018.10.16.docx; Sec3.5_Recreation_reviewdraft_2018.10.16.docx; Sec4.1_IntroEC_reviewdraft_2018.10.16.docx

CLASSIFICATION: UNCLASSIFIED

All,
USACE and our third party contractors have been diligently trying to provide as much review time for DEIS sections as possible. For the first round of review of the preliminary draft chapters, USACE asked agencies to provide a high level review of the specific sections that directly addressed your special expertise as identified by USACE; we asked your teams to review for, "did we miss something and did we get it on the correct path for analysis".

In addition to the sections which USACE requested cooperating agencies' assistance, some cooperating agencies requested to review other portions of Chapters 3 and 4 in order to inform their review. Therefore, USACE intends to distribute the current version of all draft sections to all CAs, as they become available. When revising the draft EIS prior to public comment, USACE will consider those comments which are related to the CA's identified area of special expertise. Other comments related to the DEIS will be considered at the same time as the public's comments, after the Notice of Availability for the dEIS.

USACE intends to have all sections distributed to the CAs by 11/09/2018 and intends to request comments back by 11/21/2018. USACE has received general requests to extend the CA comment period. At this time, we do not anticipate extending the comment period.

This email initiates reviews of sections of the DEIS in more detail. We are providing the following sections for your review. We request comments from the agencies listed below, as these sections relate to areas that USACE has identified as within their special expertise.

Sec3.5-Recreation, 4.5-Recreation (CAs listed as EPA, NPS, USFWS, State of Alaska). There are no figures associated with these two sections.

Sec3.1-Intro to AE, K3.1 (tech appendix on TEK for Sec3.1), Sec 4.1-Intro to EC (CAs listed as EPA, USACE, State of Alaska). Section 3.1 has one figure listed in the TOC (watersheds map) that will be included in the DEIS version.

Please provide your comments on agency letterhead, either by mail or email, to poaspecialprojects@usace.amy.mil.

Respectfully,

Shane McCoy
Program Manager

AMERICAN OVERSIGHT

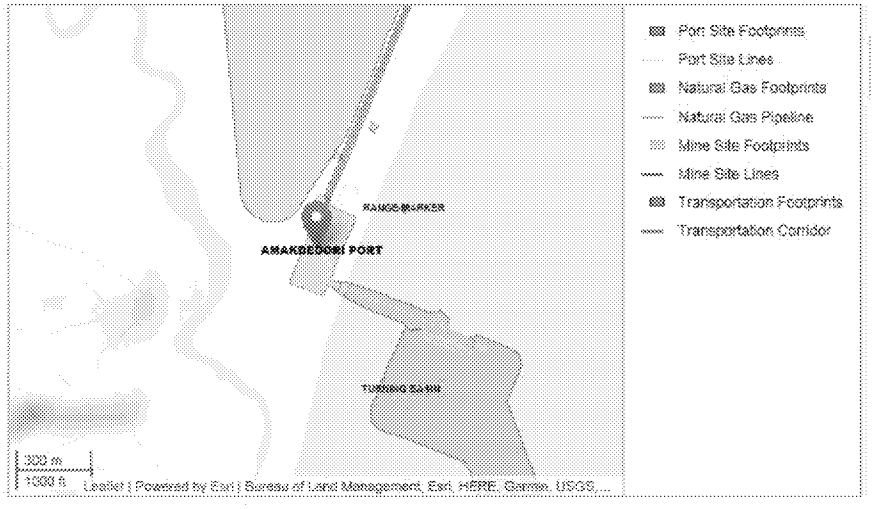
K3.1 INTRODUCTION TO AFFECTED ENVIRONMENT - TRADITIONAL ECOLOGICAL KNOWLEDGE

Information about traditional ecological knowledge (TEK) and the approach taken by the US Army Corps of Engineers (USACE) to collect TEK is outlined in Section 3.1. The information collected is below.

K3.1.1 Scoping Comments

Scoping comments were pulled from the Scoping Report (Appendix A). Comments received that pertain to the topics listed in Section 3.1, Introduction to Affected Environment, are listed below.

- Fish
  - The area that makes up the headwaters is full of underwater streams in which small fry/fingerlings swim as they emerge. They sometimes swim into lakes and ponds of the region and often get too big to get out; they are called landlocked salmon.
  - Many species of fish are used for subsistence harvest, not just salmon.
  - The people in Seldovia have a long tradition of subsistence fishing for herring in Kamishak Bay. The herring also support other animals that we subsist on.
  - The placement of the tailings impoundment facility located on the North Fork of the Koktuli River is prime king salmon habitat.
- Wildlife
  - Exploration activities at the site have caused caribou to avoid the area.
  - Helicopter traffic during exploration disrupted subsistence activities. Particularly, helicopter traffic impacts spring waterfowl hunting (geese), displaces caribou, and impacts the Koktuli River.
- Birds
  - Kamishak Bay is home to a large seabird nesting colony.
  - Bald eagles nest and feed along the coast and along all of the major salmon spawning rivers in the Bristol Bay and Cook Inlet regions, with a relatively high number of golden eagles also found here.
- Marine Mammals
  - Incorporate traditional knowledge on freshwater seals in Iliamna Lake, and be aware that there is a Freshwater Seal Commission.
  - The proposed ferry could strike seals in Iliamna Lake, which would congregate in the open water created by the icebreaking ferry.
- Vegetation
  - Over 80 edible and medicinal plants grow and are harvested in the project area including several species of berries, wild peas, wild onions, ferns, cow parsnip, rosehips, and many others.
- Subsistence activity
  - Be sure to include Kodiak Island to your analysis, as it has important subsistence areas that could be impacted by the project.
  - The road corridor would go through winter moose hunting area in the Talarik Creek watershed.

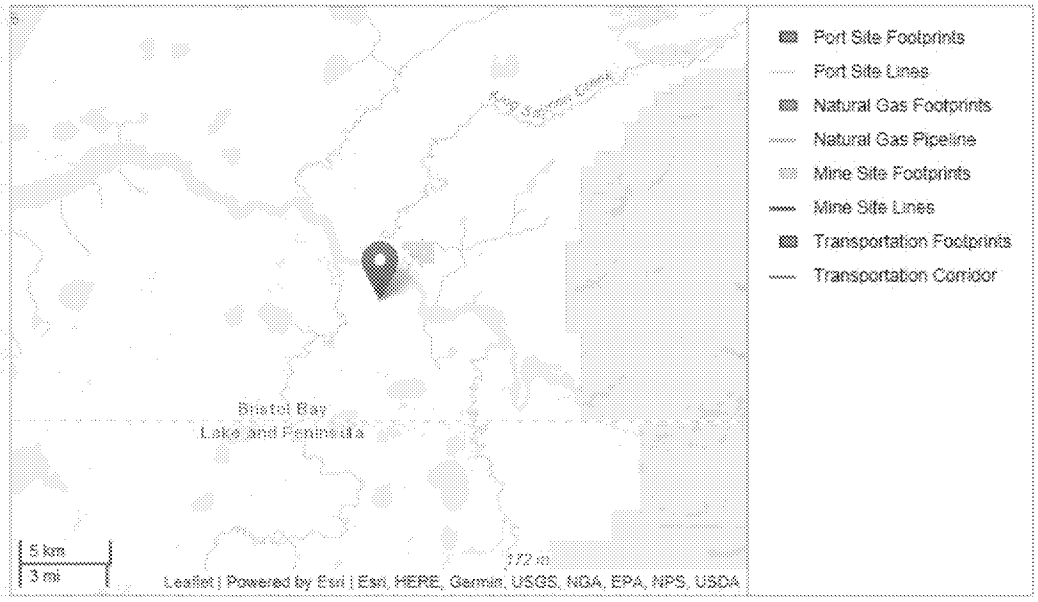


AMERICAN OVERSIGHT

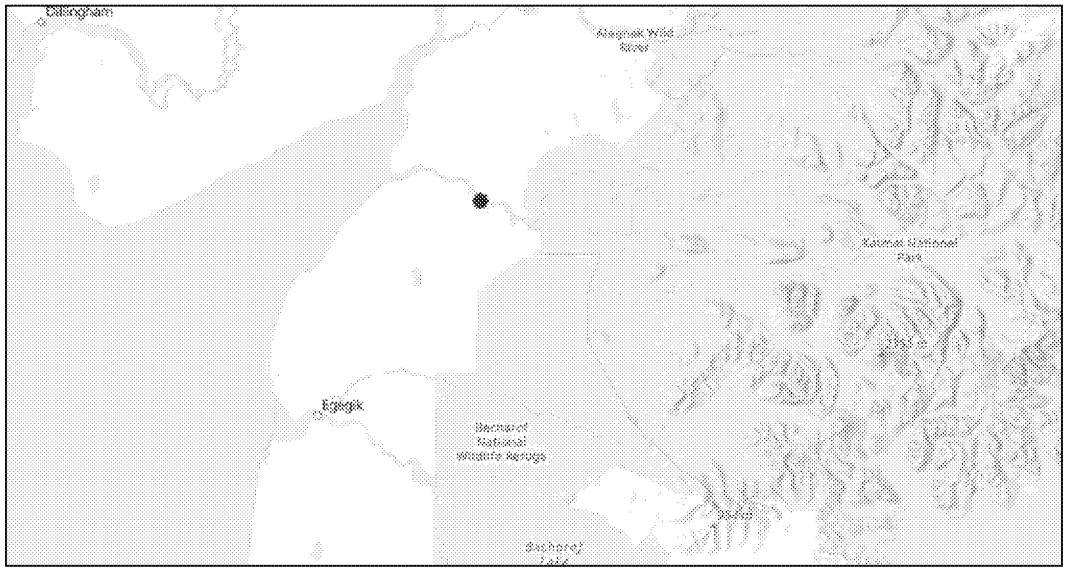
  - The Nushugak, Mulchatna, and Koktuli watersheds are the hunting and fishing areas for people of New Stuyahok.
  - The Amakdedori area has been historically used for early subsistence activities, including salmon harvest.
  - The mountain behind Nondalton is traditional subsistence area.
  - The Frying Pan Lake area is important to Nondalton people and shared with other neighboring people.
  - The people in Seldovia have a long tradition of subsistence fishing for herring in Kamishak Bay. The herring also support other animals that we subsist on.
  - The residents along Iliamna Lake rely on access to small islands for the harvest of bird eggs in the spring.
  - A chart on the Bristol Bay seasonal subsistence gathering cycle was submitted.
- Culturally important areas
  - The Amakdedori port area has been used as a site for a cultural camp, subsistence use areas, and school field trips.
  - There are ancestral burial grounds at/near the proposed Amakdedori port, along the road route on the south side of Iliamna Lake, and on the road route to the south ferry dock.
  - This region of Alaska contains several recorded rock art (petroglyph) sites. No doubt more such sites remain to be discovered. Many of the rock art panels are on shorelines and only visible during low tide; thus, it is easy for archaeological surveys to miss these important cultural resources.
- Navigation
  - While lower Cook Inlet and Kamishak Bay do not have ice or currents to the same extent as the upper Cook Inlet, Lower Cook Inlet is not nearly as protected as the waters of upper Cook Inlet, and Kamishak Bay experiences challenging winter sea conditions.
  - No depths are recorded on navigation charts for Iliamna Lake. Some rocks on the chart do not exist; others are not where the charts show them to be. Some are not on the charts at all. There are places where the depth goes from 400 feet to 30 feet.
  - The wind has pushed ice on the north shore of Iliamna Lake in piles as high as 50 feet and could damage the proposed ferry terminal.
  - The east winds on Iliamna Lake are strong and generate large waves that would make the proposed ferry unreliable and dangerous; winds can reach 100 miles per hour.
  - A disabled ferry could be blown by the wind onto the shoreline such as at Eagle Bluffs.

Scoping comments that referenced a geographic location via the online comment form web mapping feature are below.

AMERICAN OVERSIGHT



- Culturally important areas

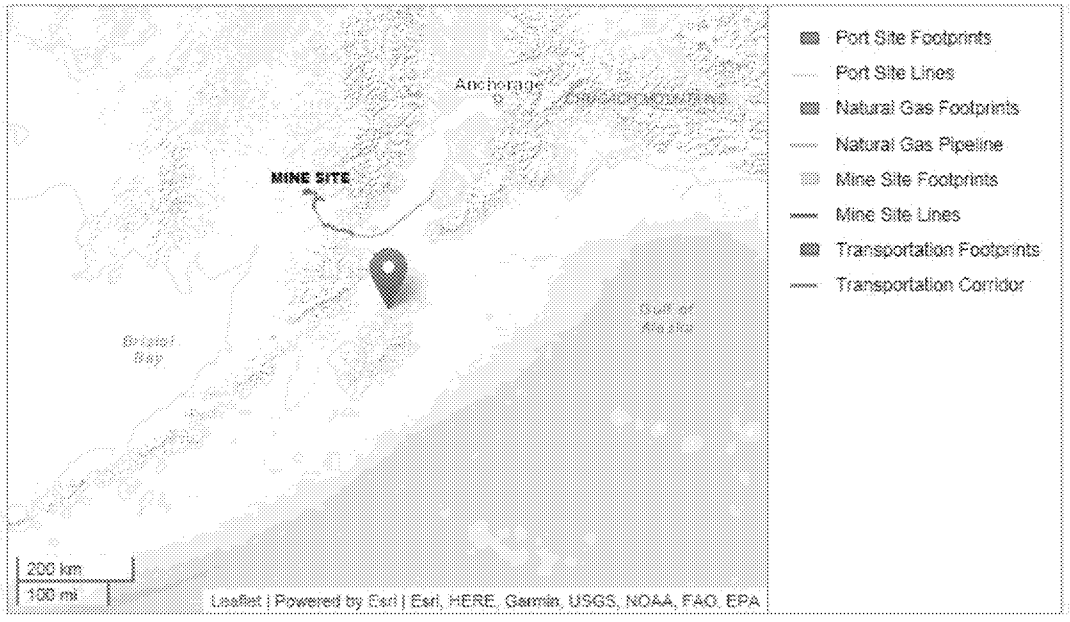


Applicable Comment
The proposed dredge storage and port site on this map is overlaid on the Amakdedori Native Village. This is also the site of cultural learning camps, subsistence use areas, and school field trips. … Survey work needs to include consultation with local tribal governments to apply religious and culturally appropriate research methods. Any alternatives will need to address meaningful mitigation to the loss of access to historical cultural resource sites and to living cultural resource sites. Loss of access and location changes to the traditional learning camps and school field trips to the Amakdedori Native Village will need to be made in consultation with the Kokhanok school and parents. Alternative locations for these teachings would need to include other cultural sites of the Kachemak Tradition. … 

AMERICAN OVERSIGHT

- Subsistence Activity

Applicable Comment
It worries me that the mine could impact animals, fish and berries that my friends and I gather for subsistence. A lot of us depend on the land and water for food. It offsets the high cost of living and shipping food into the area. We rely on moose, caribou, bear, many berries etc. …



AMERICAN OVERSIGHT

- Subsistence Activity

Applicable Comment
My husband and I have a setnet site on Raspberry Island. We are especially concerned about transport plans across Lake Clark and Cook Inlet. We learned during the Exxon oil spill the spills in one place can impact fisheries and habitats along a wide swath. Although the spill was in Prince William Sound we found oil on our beaches in the Kodiak District and our fisheries was shut down.

K3.1.2Existing Documents

K3.1.2.1 Environmental Baseline Document

The Environmental Baseline Document Chapter 23, Subsistence, contains the detailed results of a study done by Steven R. Braund & Associates in coordination with the Alaska Department of Fish and Game (SRBA 2011b). Two major elements of this study were to survey residents, and then follow up with interviews. The data (tables, charts, and maps) used to determine the environmental baseline for Section 3.9, Subsistence in this EIS reflect the findings of this study. In this way, TEK regarding areas of subsistence use and harvest data are incorporated, and would be reflected in pertinent EIS chapters.

K3.1.2.2 EPA Watershed Study

Appendix D in Volume 2 of the EPA Assessment of Potential mining Impacts on Salmon Ecosystems of Bristol Bay, Alaska is a study of TEK and cultural characterization in the Nushagak and Kvichak watersheds, conducted by Boraas and Knott (Boraas et al. 2013). The study was based on interviews in the region. Information from this study that would be considered TEK and pertains to the topics presented in listed in Section 3.1 is listed below.

- Fish
  - That is spring water [at Kijik]. It does not freeze. That is why you can go over there and get a sockeye salmon in March; it might have a green head, and it is red, but it is still a sockeye salmon. You can go over there on New Year's Day and get a fresh sockeye salmon.

AMERICAN OVERSIGHT

- But, I think, when they are spawning, that is where they hit the spring waters, where it does not freeze. It is always open, even in the dead of the winter. It is always open; you got to be careful there. Especially up in Lake Clark, around Kijik. It is, man, 30 below zero, and still open water.
- They are sensitive, very sensitive. If you put something bad in the water the fish will sense it. They will probably not go up the river, they will go somewhere else. If they spawn here and they notice something different they will move to another spot. The fish are very sensitive.
- For quite a few years there when we were building up the king salmon run we did not even fish in June. It was just to build up those runs. It is kind of ironic that the kings we built up are on the Koktuli River where that mine is going to go. It is almost a whole decade that we sacrificed to build up that run. We built it up and now it might go away.
- You do not see Bristol Bay having troubles because our ecosystem is whole and not damaged. We are very appreciative of what we have. In relationship to the mine the place I work up here is the Bristol Bay Economic Development Corporation and… one of the companies we bought is Ocean Beauty Seafoods which is one of the largest salmon producers in Alaska. We put up 161 million pounds of commercially caught goods in a year. So I talk to the people and if there is a mine that goes in like pebble and we have copper coming out and affecting our fish, are you interested in buying our fish? These are customers we sell 300-400 thousand pound lots to. No, we are not interested….We don't want ourselves and our kids to eat contaminated foods.
- They [Salmon] would not go there [where water is contaminated] They are also very sensitive to temperature. They have a really keen sensory acuity, not only them, but all the critters, all the birds. …They are so sensitive in every aspect of that word.

- Wildlife
  - You cannot even get meat like you used to; you cannot even go out hunting for moose or caribou. Nothing is here anymore; everything is disappearing. I know, you know [name] could verify too. There used to be so much caribou, we would see them all over the road, all over the lake, everything.
  - Since the Pebble Mine started their exploration, I speak for everyone around here that we have not had the big caribou herds that come through here anymore.
  - The drill wells are making all the noise. We were over there, my wife and I were over there last spring, and when we went over there to check out the Pebble, there [we] saw three other helicopters right in the same area, and that is lots of traffic. We have not had caribou meat around here ever since. Have not had caribou meat caught here in probably the last 6 years.
- Vegetation
  - What they used to say, was the first time, when they first moved down to fish camps, then this wild celery, I do not know if you know what that is, but we eat those. They go up on the mountainside and pick lots of that, and then they peel it, they peel the peelings off and we eat the inside part.
- Subsistence activity areas
  - In Easter they went up to Koliganek the next village up. He said people up there caught white fish and pikes. He said the water is good upriver, it is not like down

AMERICAN OVERSIGHT

here. I think it is the water that is coming down from up Mulchatna. He thinks it's from them working on that pebble up there [Pebble Mine].

- Culturally important areas
  - There are 10,000 cache pits [at the Kijik archaeological site on Lake Clark] and they are still counting; over 200 houses, which are huge. So it was pretty big.
- Weather and climate
  - There is open water all over. They got drilling rigs that are sitting on open water. You cannot walk up there with knee boots you got to have hip boots there is so much water this year. The ground is saturated.

K3.1.3 Cooperating Agencies

Cooperating agencies review and comment on draft sections of the EIS during development. During that process, some information was presented that would qualify as TEK. Information received pertaining to the topics listed in Section 3.1 is listed below.

- Cultural Resources
  - The village site at Amakdedori, cabins and trails, have significant personal and cultural value to a number of individuals in the borough. The old cabins, trails, and village have personal meaning to many who reside in the borough.

K3.1.4 Tribal Consultation

Information was also collected during government-to-government consultation meetings between the USACE and Tribes. Comments received that pertain to the topics in Section 3.1 are listed below.

- Wildlife
  - Participants stated that the bears move widely across the region from Amakdedori to the mine site and beyond.
  - The road would cross caribou migration paths. Caribou are coming back to the area, the lichen crop is robust.
  - Belugas are changing their diets because their food is not available for them anymore.
- Weather and climate
  - The mine site is in bowl, in right wind conditions, can hear noise from the mine.
- Subsistence Use Areas
  - Razor clams on the east side of Cook Inlet are declining so a lot of people dig razor clams on the west side, at Amakdedori. Aquatic resources like clams, crab, herring and shrimp have declined on the east side of Cook Inlet.

3.0 AFFECTED ENVIRONMENT

3.1 INTRODUCTION

Chapter 3, Affected Environment, describes the existing environment that would be affected by the proposed project and alternatives under consideration in this Environmental Impact Statement (EIS). This chapter is intended to help the lay reader and agency decision maker find the information they need to evaluate the affected environment and understand the impacts and consequences discussed in Chapter 4, Environmental Consequences.

Each resource section in Chapter 3 (Section 3.2 through Section 3.26) discusses:

- The overall existing condition of the resource, including the natural and physical environment
- The types of potential impacts typically associated with the proposed project for that resource
- The area of analysis (see "project area" definitions below)
- Applicable regulations in the context of the resource.

3.1.1 Project Components

The project is discussed in Chapter 3 and Chapter 4 by its four major components. These include:

Mine Site: Includes the footprint at the mine site (minus milepost 24-29 of the mine access road, which is included in the transportation corridor).

Transportation Corridor: Includes the footprint of access roads (including milepost 25-29, which overlaps with the mine site footprint), spur roads, ferry terminals, ferry route, and all associated infrastructure.

Amakdedori Port: Includes the footprint of the port, dock, all associated infrastructure, and lightering locations.

Natural Gas Pipeline Corridor: Includes the pipeline route and all associated infrastructure from the Kenai Peninsula across Cook Inlet to the mine site.

3.1.2 Project Area

Project area terms are applied in Chapter 3 and Chapter 4 and refer to specific areas. These include:

Project area: Refers to the exact proposed project footprint.

Mapping area: Refers to a specific area in which wetland and vegetation surveys were conducted in the field and subsequently mapped (generally only applied in Section 3.22 or 4.22, Wetlands, and Section 3.26 or 4.26, Vegetation.

EIS analysis area: Refers to the entire area of resource analysis, which is specific to each of the resource sections and may differ by resource.

3.1.3 Resource Interrelationships

Although resources are described in Chapter 3 and analyzed in Chapter 4 in discrete sections, these subjects are dynamic and interrelated. A change in one resource can have cascading or

AMERICAN OVERSIGHT

synergistic impacts to other resources. The site of the proposed project and the nature of open-pit mining activity would lead to a complex interaction between groundwater, surface water, and a number of water-related resources. The proposed project would also lead to a complex interaction between water-related resources and fish and aquatic resources. Impacts to water, fish, and wildlife resources would in turn have impacts on subsistence resources; for example, water quality may affect fish populations, which in turn may influence subsistence harvests, which can have implications for other human outcomes such as health and socioeconomics. As a result, there is some overlap among the resource sections in Chapter 3, and the impacts described in Chapter 4. Impacts described in one section may depend on the analysis from another section. During the writing process, subject-level authors and cooperators collaborated by sharing data and discussing interrelated aspects of the analyses to better capture the interrelated nature of environmental resources in both Chapter 3 and Chapter 4.

Two interrelated multiple-resource topics were identified for analysis in the EIS that span various resource sections in Chapter 3 and Chapter 4. The framework for description and analysis of these topics is provided below.

3.1.3.1 Traditional Ecological Knowledge

In recent decades, Native Alaskans have effectively advocated for recognition of their complex bodies of knowledge and understanding about climate change, flooding and erosion, surface/groundwater hydrology, landscapes, fish and wildlife life histories and migratory patterns, and seasonal distributions/utilization of subsistence resources. This traditional ecological knowledge (TEK) is just as important as modern means of transportation and hunting technology in supporting safe and efficient subsistence harvest activities.

The U.S. Army Corps of Engineers (USACE) has taken the following approach to incorporating TEK into this EIS:

- Reviewing scoping comments to determine what relevant TEK was provided
- Reviewing pertinent sections of the Environmental Protection Agency (EPA) watershed assessment (EPA 2014), and Environmental Baseline Document Chapter 23, Subsistence (SRBA 2011b) to identify any relevant material that can be considered TEK and attributed to an individual or organization
- Inquiring about relevant TEK during all government-to-government meetings, as appropriate.

Specific topics that the USACE considered for inclusion as TEK include:

- Information on surface/groundwater hydrology and water quality in the project area. This would include areas of high water table, variations in stream flow and underlying causes, when breakup and freeze-up typically occurs, and areas where water quality might be affected by natural and human made causes
- Information on location, frequency, and trends with regard to natural hazards such as flooding, erosion, river and lake ice, avalanches, and rock slides
- Observations of trends, patterns, or changes in weather and climate, including storms, rainfall, and snowpack
- Information on fish, wildlife, birds, and marine mammals in the project area. This would include distribution and seasonal presence, population trends, migration patterns, habitat areas, behavior, and changes over time
- Information on the vegetation in the project area, including species used for subsistence, areas of occurrence, and changes over time

AMERICAN OVERSIGHT

- Important areas and seasons of subsistence activity, utilization and sharing of subsistence resources, and changes over time
- Culturally important areas from a historic and contemporary perspective
- Areas being used by guides and commercial operators for sport fishing, hunting, and wildlife viewing, and changes over time
- Information important to navigation in the project area
- Information on where residents are collecting surface water for residential use.

TEK has been incorporated into relevant resource sections. TEK information collected is found in Appendix K3.1.

3.1.3.2 Climate Change

Climate change may be addressed in three ways in an EIS. These include:

1. Effects of the project on climate change. This category addresses the effect of the proposed action on climate change as indicated by greenhouse gas (GHG) emissions, per the Council on Environmental Quality (CEQ) 2014 Revised Draft Guidance on Consideration of Greenhouse Gas Emissions and Climate Change in National Environmental Policy Act (NEPA) Reviews (CEQ 2014), per rescission of the 2016 Final Guidance on Greenhouse Gases and Climate Change.
2. Effects of climate change on the project area. This category addresses the implications of climate change for the environmental effects of the proposed action; or in other words, examines the impacts of climate change on a proposed action that could affect sensitive populations or environmental resources (CEQ 2014). Climate change as a cumulative effect is considered under this category, per CEQ 1997 Considering Cumulative Effects under the NEPA (CEQ 1997) and CEQ 2014.
3. Effects of climate change on proposed project infrastructure. This category addresses the effects on the proposed project infrastructure from climate change, and considers accounting for potential climate change effects on a proposed action over the course of its anticipated useful life, especially in areas that may be vulnerable to specific effects of climate change, per CEQ 2014.

This EIS addresses the three categories in the following locations and ways:

1. Project-caused GHG emissions are discussed and analyzed in Section 4.20, Air Quality.
2. Climate change trends are integrated into discussion if appropriate to the resource in Section 3.2 through Section 3.26. Climate change as a cumulative effect is discussed in a subsection if appropriate to the resource in Section 4.2 through Section 4.27.
3. Climate change effects on proposed project infrastructure are addressed if appropriate to the resource in Section 4.2 through Section 4.27.

3.1.4 Project Physical Setting

3.1.4.1 Location

The proposed Pebble Project location is primarily in the Bristol Bay watershed (see Figure 3.1-1) in southwest Alaska, a rolling, permafrost-free terrain, approximately 200 miles southwest of Anchorage and 60 miles west of Cook Inlet. The closest communities are Iliamna, Newhalen, and Nondalton, each approximately 17 miles from the Pebble Project mine site.

AMERICAN OVERSIGHT

The Bristol Bay watershed encompasses approximately 41,900 square miles and is defined by the Aleutian Range to the east and southeast, the Kuskokwim Mountains to the west, and a range of hills to the north that separate it from the Kuskokwim River watershed. The largest rivers that drain into Bristol Bay are the Nushagak and Kvichak rivers, which together drain 49 percent of the Bristol Bay watershed, or approximately 20,000 square miles. A portion of the project is located in the Cook Inlet watershed, which encompasses the city of Anchorage and various communities on the Kenai Peninsula and around the Cook Inlet coastal shoreline.

3.1.4.2 Climate & Meteorology

The climate in the mine site area is transitional. Winters are characterized by a continental climate as frozen waterbodies and sea ice in Bristol Bay create a land-like mass, while summers have a maritime climate due to the influence of the open water of Iliamna Lake and, to a lesser extent, the Bering Sea, Bristol Bay, and Cook Inlet.

Mean monthly temperatures range from about 55 degrees Fahrenheit (°F) in summer to 2°F in winter. Precipitation in the North Fork Koktuli (NFK) River drainage averages approximately 57 inches per year, and 51 inches per year in the South Fork Koktuli River (SFK). About one-third of this precipitation falls as snow. The wettest months are August through October. White-out conditions and wind storms or periods of poor light/visibility occur in winter.

Winter weather systems, consisting of cool to cold saturated air, typically travel into the region from the Bering Sea (west), along the Aleutian Island chain (southwest) and the Gulf of Alaska (south), resulting in frequent clouds, rain, and snow. Less frequent incursions of frigid, stable arctic air masses produce shorter periods of clear, but very cold conditions. During summer, warm air masses from Interior Alaska can cause atmospheric instability, which results in cumulus clouds and thunderstorm activity. No permafrost has been identified to date in the project area.

3.1.4.3 Topography

The area consists of low, rolling hills separated by wide, shallow valleys. Elevations range from approximately 775 feet in the SFK valley up to 2,760 feet on Kaskanak Mountain. Glacial and fluvial sediment of varying thickness covers most of the area at elevations below approximately 1,400 feet, while ridges and hills above 1,400 feet generally exhibit exposed bedrock or have thin veneers of surficial material. Hills are generally moderately sloped with rounded tops, and valley bottoms are generally flat.

The port site is located just north of the mouth of Amakdedori Creek on the shore of Cook Inlet in the northern part of the Aleutian Range physiographic division. Topography is generally flat with dunes located closer to the gravel beach shoreline of Cook Inlet.

The terrain includes a range of types, from flat to moderately undulating near the mine site, gently sloping and colluvial terrain along the transportation corridor in the vicinity of the north shore of Iliamna Lake, and mountainside slopes to narrow valley bottoms through the Aleutian Range. The transportation corridor spans the Nushagak watershed at the mine site and traverses the Kvichak watershed, both in the greater Bristol Bay watershed. The corridor continues through the Tuxedni-Kamishak Bay's watershed of the greater Cook Inlet watershed.

The first portion of the natural gas pipeline corridor is located on the Kenai Peninsula, and crosses Cook Inlet. The remaining portion overlaps the transportation corridor.

AMERICAN OVERSIGHT

3.1.4.4 Land Cover

The mine site area is ecologically diverse, with rivers, tundra, marshy lowlands, and ponds. Much of the land is covered by alpine tundra, shrubs, wetland and scrub communities, or areas of mixed broad-leaf and spruce trees, depending on elevation and location.

Around the port area, the western shorelines from Kamishak Bay north to Iniskin Bay are comprised of diverse habitats, including steep rocky cliffs, cobble or pebble beaches, and extensive sand/mud flats. Eelgrass is found at a number of locations and habitats; eelgrass, along with macroalgae, is an important substrate for spawning Pacific herring. Much of the land is well-drained and covered by dwarf shrub communities with inclusions of alder shrub and grass-herb communities. Wetland habitats consisting of wet meadows and shrub communities are limited to the northwestern extent of the port site where groundwater discharge occurs, as well as areas in the floodplain of Amakdedori Creek.

Vegetation communities in the transportation corridor north of Iliamna Lake primarily consist of dwarf shrub, spruce woodland, mixed broad-leaf and spruce forest, and shrubs. Wetland habitats dominated by willow shrub communities are common on floodplains of streams, while wet meadows and mixed shrub wetlands are common at toe slopes where groundwater discharge occurs. The transportation corridor crosses numerous streams in the Bristol Bay and Cook Inlet watersheds. Much of the land at lower elevations south of Iliamna Lake is covered by dwarf shrub and broad-leaf forest communities. At higher elevations where shallow bedrock occurs, dwarf shrub and alder shrub communities are prevalent. Wetland habitats are common in depressional areas, valley bottoms, and on slope benches and include wet meadows and scrub-shrub communities.

In the eastern portion of the natural gas pipeline corridor, the Cook Inlet region is comprised of marine, coastal, and estuarine habitats. Pelagic waters in Cook Inlet are influenced by riverine and marine inputs resulting in salinity gradients and horizontal mixing throughout the inlet. Deeper waters of Cook Inlet are characterized by unconsolidated sediments on a smooth bottom and strong tidal currents. The variety of habitats in the region support lower trophic organisms, fish, shellfish, marine mammals, and birds. Fish and shellfish are important components of the Cook Inlet food web, as they feed on lower trophic organisms such as plankton, and serve as prey for other fish, birds, and marine mammals.

3.1.4.5 Hydrology

The Pebble Deposit straddles the upper reaches of the SFK and Upper Talarik Creek (UTC) drainages. The headwaters of the NFK are immediately north of the Pebble Deposit. The SFK drains south from the Pebble Deposit area, and then west and northwest, where it joins the NFK, which flows west from the Pebble Deposit area. At the confluence, these streams form the Koktuli River, which flows into the Mulchatna River, a tributary to the Nushagak River. The Nushagak River flows into Bristol Bay near the city of Dillingham. UTC flows south from the Pebble Deposit area and then southwest into Iliamna Lake, which is the source of the Kvichak River.

The NFK and SFK are two of 24 tributaries of similar or larger size in the 315-mile long Nushagak River system. The north and south forks of the Koktuli River flow for 36 and 40 miles, respectively, to the main stem Koktuli River. The Koktuli River flows for approximately 39 miles before entering the Mulchatna River, which flows another 44 miles before entering the Nushagak River. The Nushagak River flows about 110 miles before it empties into Bristol Bay southwest of Dillingham. The total distances from the NFK and SFK headwaters to Bristol Bay are 228 miles and 232 miles, respectively.

AMERICAN OVERSIGHT

The UTC drainage is in the 225-mile long Kvichak River system. The headwaters of the Kvichak River system are approximately 109 miles northeast of the Pebble Deposit at the source of the Tlikakila River at Lake Clark Pass. UTC flows approximately 39 miles to Iliamna Lake. The lake empties into the Kvichak River, which flows approximately 70 miles to Bristol Bay. The total distance from the headwaters of UTC across Iliamna Lake to Bristol Bay is approximately 140 miles.

The Cook Inlet basin is an expansive watershed surrounding the 180-mile long Cook Inlet waterbody. Covering more than 38,000 square miles of southern Alaska, it receives water from six major watersheds and many smaller ones. More than 10 percent of the basin is covered by glaciers where suspended sediment loading in glacier fed rivers without lakes is significant, leading to a high suspended sediment load in portions of Cook Inlet. Lower Cook Inlet is connected to the Pacific Ocean southwest through Shelikof Strait and southeast by the Gulf of Alaska; it demonstrates complex circulation on variable timescales. The region has the fourth largest tidal range in the world; tidal fluctuations in Kamishak Bay average 13 feet. When the tide drops from mean high to mean low water, the inlet loses almost 10 percent of its volume, and exposes approximately eight percent of its surface area. Most of these tidally exposed areas are in the arms at the north end of Cook Inlet and along the west side of the waterbody.

AMERICAN OVERSIGHT

3.5 RECREATION

For the purposes of this section, the region around the project site is defined as the area from Lake Clark National Park and Preserve south to Katmai National Park and Preserve and from the Nushagak River east to the western Kenai Peninsula. Refer to Figure 3.2-1 for generalized land status. The region around the project area is, for the most part, remote and undeveloped. These lands and waters support a wide variety of dispersed recreation activities including sport and trophy hunting, hiking, camping, and snowmachining. Due to the economic importance of fishing in this region, recreational and commercial fishing are discussed in a separate section. See Section 3.6, Commercial and Recreational Fishing, for more information. See Section 3.9, Subsistence, for information on subsistence hunting and fishing and refer to Figure 3.2-1 for area locations.

3.5.1 Recreation Management

3.5.1.1 Federal Lands

National Park Service

The following section provides information on the management of the three National Park Service (NPS) units in the regional recreation area of the project. Commercial use of all three units is subject to commercial use authorizations (CUAs), which authorize appropriate commercial services to park visitors (NPS 2018a). CUAs may not exceed 2 years per term and provide for incidental use of the park by commercial service operators where services originate and terminate outside of the park boundary (NPS 2018a). Concession contracts are commonly issued for 10 years and are issued on a competitive basis. Commercial services are authorized under the National Parks Omnibus Management Act of 1998, Public Law 105-391 (NPS 2018a).

Lake Clark National Park and Preserve

Lake Clark National Park and Preserve is about 15 miles northeast of the mine site and is not accessible by road. The park covers the eastern two-thirds of the park unit and the preserve is a north-to-south strip of land adjacent to the western side of the national park. Most of the park is designated Wilderness and it is the sixth largest park unit in the nation. In the general park/preserve boundary, there are private inholdings (privately owned or selected by Alaska Native Claims Settlement Act [ANCSA] village or regional corporations) around the southwest third of Lake Clark, including the community of Port Alsworth around Lower Tazimina Lake and near the Cook Inlet coast (Kevin Waring and Associates 2011b).

Lake Clark National Park and Preserve is managed according to the 1984 General Management Plan for the park and a 2014 amendment to this plan. The 1984 General Management Plan contains a management concept for visitor access, recreation, and use within the park unit, including development, access, commercial use, visitor use, visitor information, and interpretive materials (NPS 1984). The 2014 amendment expanded visitor activities and interpretive services. The amendment included designating some existing cabins for public use, designating an informal water route on Lake Clark, providing a few improved visitor facilities, and providing limited new commercial services (NPS 2014).

The most current Superintendent's Compendium includes the designations, closures, permit requirements, and other restrictions that have been adopted under the superintendent's discretionary authority (NPS 2017a).

AMERICAN OVERSIGHT

There are approximately 90 visitor service providers (CUA holders and concessioners) in this NPS unit for the following activities: air taxi, water taxi, backpacking/overnight camping, boating trips, bear viewing, group camping, hiking/walking tours, big game transport, incidental hunt transport, kayak tours, mountaineering, paddleboarding, photography, sport fishing, sport hunting, skiing, and snowshoeing (NPS 2018a).

Katmai National Park and Preserve

The Katmai National Park and Preserve boundary is located approximately 7 miles south of the transportation corridor at its nearest point. This NPS unit is primarily national park, with the preserve located adjacent to the western part of the northern boundary of the park. Most of the park is designated Wilderness and it is the fifth largest park unit in the nation. There are also over 20,000 acres of privately owned lands in the unit (Kevin Waring and Associates 2011b).

Katmai National Park and Preserve is managed under a variety of management plans. The 1986 General Management Plan discusses management of park access and circulation, visitor use and services, and potential development in the park unit (NPS 1986). The 2009 Long Range Interpretive Plan describes desired visitor experiences, existing interpretive resources, and includes recommendations to achieve the desired future interpretive program as well as implementation priorities (NPS 2009a). The 2014-2018 Strategic Plan includes 5 year goals and strategies for management of three NPS units (NPS 2013). Similar to Lake Clark National Park and Preserve, the most current Superintendent's Compendium lists the designations, restrictions, closures, and permit requirements adopted under the superintendent's discretionary authority. The 2017 Compendium for Katmai National Park and Preserve also covers the Aniakchak National Monument and Preserve and Alagnak Wild River (NPS 2017b).

There are approximately 125 visitor service providers (CUA holders and concessioners) in this NPS unit for the following activities: air taxi, backpacking/overnight camping, boating trips, bear viewing, charter boat service, group camping, hiking/walking tours, big game transport, incidental hunt transport, kayak tours, lodging and food service, photography, sport fishing, and sport hunting (NPS 2018a).

Alagnak Wild River

The Alagnak River is designated a Wild River in the Wild and Scenic Rivers System and consists of 67 miles of river corridor that is mostly (93 percent) federally owned, with some privately owned Native allotments and other private inholdings within the river corridor. The Wild River begins downstream of Kukaklek Lake and flows westward, though the last 12 miles of the Alagnak River are outside the designated corridor. The river was designated a Wild River in 1980, and there is no road access to it (Kevin Waring and Associates 2011b). It would be approximately 50 miles south of the transportation corridor at its nearest point.

There are several management plans that discuss recreation in the Alagnak Wild River. The 1983 Management Plan contains management objectives for visitor use and interpretation including access, accommodating hunting, and encouraging activities compatible with the natural environment (NPS 1983). The 2009 Long Range Interpretive Plan and 2014-2018 Strategic Plan described above under Katmai National Park and Preserve also apply to the Alagnak Wild River (NPS 2009a, NPS 2013).

There are approximately 20 visitor service providers (CUA holders and concessioners) in this NPS unit for the following activities: air taxi, backpacking/overnight camping, boating trips, bear viewing, group camping, hiking/walking tours, photography, and sport fishing (NPS 2018a).

AMERICAN OVERSIGHT

US Fish and Wildlife Service

Alaska Maritime National Wildlife Refuge

The Alaska Maritime National Wildlife Refuge (NWR) includes 3.4 million acres (USFWS 2013a) from Forrester Island in southeastern Alaska, to the tip of the Aleutian chain, and almost to Utqiaġvik on the Arctic Ocean (USFWS 2011a). In the project area, several islands in Cook Inlet are in this NWR; the nearest point would be approximately 15 miles from Amakdedori Port.

The Alaska Maritime NWR is managed by a comprehensive plan (USFWS 1988). The five purposes of the refuge (i.e., conservation, treaty obligations, subsistence use, scientific research, and water quality/quantity) protect the wildlife resources that attract recreational visitors. As stated in the Land Protection Plan for the NWR, "the Alaska Maritime Refuge is managed to conserve native fish and wildlife populations and their habitats, while providing opportunities for subsistence, compatible types of recreation, and research" (USFWS 2011a). Some uses of the NWR, including commercial guides and outfitters, transporters such as water and air taxis and charters, cabins, and long-term tent camps require a special use permit from the US Fish and Wildlife Service (USFWS). General public use of the NWR for hunting, wildlife viewing, photography, interpretation/environmental education, hiking, and camping do not require a special use permit (USFWS 2014a).

Bureau of Land Management

Bureau of Land Management (BLM) lands in the region are under the management of the Anchorage Field Office and are part of the Iliamna East planning block under the Bay Resource Management Plan (RMP) (BLM 2008a, BLM 2008b). Only one BLM tract in the Iliamna East area is unencumbered; the remainder of the BLM parcels are selected by the state, ANCSA corporations, or both (BLM 2008b). The BLM manages these parcels until they are conveyed and is required to seek and consider comments from the relevant Native corporation for any authorization to use Native-selected lands (Kevin Waring and Associates 2011b). RMP recommendations for management of ANCSA-selected lands would be implemented by BLM only if the land selections were relinquished to the federal government. The small unencumbered tract is located west of Lake Clark, 25 miles northeast of the mine site (Kevin Waring and Associates 2011b).

Pertinent recreation management direction in the RMP includes:

- management of all unencumbered and selected lands (until they are conveyed) as semi-primitive motorized;
- opportunities for commercial recreation would be provided consistent with area objectives for recreation management;
- lands would be managed for dispersed recreational use and no facilities would be developed; and
- camping associated with commercial activities would be prohibited without BLM's written authorization, though short-term camping not associated with commercial activities would be allowed for less than 14 days in one location (BLM 2008a).

3.5.1.2 State Lands

A variety of general uses are allowed on state lands without a permit from the Division of Mining, Land and Water. Such uses include hiking, backpacking, skiing, horseback riding, using a vehicle (below a certain weight depending on the type of vehicle), landing an aircraft, using

AMERICAN OVERSIGHT

watercraft, hunting, fishing, trapping, harvesting plants, recreational gold panning, hard-rock mineral prospecting or mining, and non-commercial camping (ADNR 2011).

Alaska Department of Fish and Game

McNeil River State Game Refuge and Sanctuary

The McNeil River State Game Sanctuary and Refuge is located immediately north and east of Katmai National Park and Preserve, south of Iliamna Lake, and inland of Kamishak Bay. The refuge portion is located north of McNeil Falls and camp, adjacent to Katmai National Preserve, while the sanctuary portion includes visitor facilities for brown bear viewing at McNeil Falls and camp, adjacent to Katmai National Park and Preserve. The boundary of the refuge portion would be within 1 mile of the transportation corridor.

The 2008 Management Plan for the McNeil River State Game Refuge and Sanctuary includes statutory goals for the sanctuary and refuge, as well as policies regarding recreational topics such as access, information and education, recreation activities, camping, structures, boat storage, and trails (ADFG 2008a). Under Alaska Statute (AS) 16.20.162, access permits are required for entry into the McNeil River State Game Sanctuary. Permits are required for bear viewing, special access to the sanctuary (e.g., for scientific, educational and media purposes), transporters, and activities in the sanctuary other than viewing bears (non-viewing permits) (ADFG 2018e).

Alaska Department of Natural Resources

Bristol Bay Area Plan

The Bristol Bay Area Plan covers state lands just inland of Cook Inlet west to Bristol Bay. The plan includes chapters on the goals and management guidelines for public recreation and tourism as well as public access. The project area is in regions 6, 8, 9 and 10 of the plan area. In Region 6, the project area (specifically the mine site and a portion of the transportation corridor) would be in units 23 and 24. Both of these units are designated Minerals, a designation that is given to areas associated with significant resources that may experience mineral exploration or development. Permanent facilities related to commercial recreation are prohibited in Unit 23 (ADNR 2013a).

In Region 9, the transportation corridor would be in units 7 and 7A. Unit 7 is designated General Use and is to be managed for a variety of uses, including dispersed recreation. General Use areas are not intended for intensive forms of development other than occasional use at specific sites, usually associated with mining, oil and gas exploration, or recreation. Unit 7A is designated as Habitat for protection of moose wintering habitat. The plan notes that development is not appropriate in this unit, other than utility, communication, road/bridge, or other public service-related development (ADNR 2013a).

In Region 10, the transportation corridor would be in units 1 and 2. Unit 1 is designated General Use and is to be managed for a variety of uses including public recreation and tourism. Unit 2 is designated Minerals and Habitat. The plan specifically notes that the "general resource management intent for the Pebble Copper area is to consider mineral exploration and development, while ensuring the protection of important habitat areas." Specifically, Upper Talarik Creek, in both units 1 and 2, is to be protected for its recreation, habitat, and water resource values. Permanent, commercial recreation-related facilities are prohibited in Unit 2. The plan also notes that impacts to dispersed recreation along Talarik Creek should be avoided in Unit 2 (ADNR 2013a).

AMERICAN OVERSIGHT

The Nushagak River and the Mulchatna River headwaters and lands that provide the waters for these rivers (e.g., Koktuli River) include the mine site lands, and are managed by the Alaska Department of Natural Resources under the Nushagak and Mulchatna Rivers Recreation Management Plan (ADNR 2005). More information is provided in Section 3.2, Land Ownership, Management, and Use.

Lower Talarik Creek Special Use Area

The Lower Talarik Creek Special Use Area was established in 1999 and in this area the state has limited commercial recreation activities to day use only with registration. From August through October, camping for personal non-commercial use in this area is allowed for no more than 5 days, only in a designated area adjacent to the Alaska Department of Fish and Game (ADF&G) cabin (ADNR 2013a).

Kenai Area Plan

The Kenai Area Plan covers state lands on the Kenai Peninsula and the west side of Cook Inlet. The plan documents the land management intent for the applicable lands and includes chapters on the goals and management guidelines for public recreation and tourism as well as trails and access. The project area is in regions 7 and Region 12 of the plan area. In Region 12, the project area is in Unit 592, which is designated Habitat and will remain in state ownership. There is no discussion of recreational use of this area. The project would also pass near Augustine Island. The island itself is under an Interagency Land Management Assignment to the University of Alaska for research and is managed for scientific and education purposes. The plan states that any authorized recreational uses of the island should minimize impacts on research opportunities and natural processes on the island. Immediately south of the island, state lands are in Unit 522A. The plan designates this unit as Public Recreation and Tourism and notes that these areas attract recreationists that range throughout the area and may have a high potential for dispersed recreation because of desirable recreation conditions (ADNR 2001).

On the Kenai Peninsula, there are two state park-managed recreation areas. One is a 60-acre state recreation site (Stariski) located five miles north of Anchor Point, and the other is the larger Anchor River State Recreation Area, at the mouth of the Anchor River. Both sites are accessible via the Sterling Highway.

3.5.1.3 Private Land

Land owned by Native corporations and Native allotments are considered to be private property and therefore are not open for public recreational use. Permission and/or permits for access and seasonal recreational use of these lands must be obtained from the landowner.

3.5.2 Regional Recreation

The region around the project site is generally inaccessible by road, except for the Kenai Peninsula area near the east end of the gas pipeline. There is a limited road system that connects Iliamna with Newhalen and supports sport fishing activities and lodges. The few developed public recreation facilities that are present in the area are generally accessed via air or water.

3.5.2.1 Recreation Opportunities

The following subsections describe the main recreation opportunities and activities that occur in the region surrounding the project.

AMERICAN OVERSIGHT

Sport Fishing

Sport fishing is the primary major recreational activity that occurs in the EIS analysis area. Rivers like the Nushagak, Mulchatna, Newhalen, Gibraltar, Kvichak, and Upper Talarik Creek, as well as Iliamna Lake support recreational fishing for species of salmon, rainbow trout, and other freshwater fish. Sport fishing use is increasing in the area; much public use is guided, with operators flying their clients to a place for the day from nearby lodges or base use out of camps established nearby. Sport fishing is managed by the ADF&G through a permit system, using numerous tools like effort, catch, harvest information, and abundance. Near Iliamna, sport fishing has decreased in the past decades along the Newhalen River. For more information on sport fishing, as well as recreational lodges and guiding operations in the area, see Section 3.6, Commercial and Recreational Fisheries.

Sport Hunting and Trapping

Hunting, primarily for moose, caribou, and bear, is a major recreation activity in the region (Kevin Waring and Associates 2011b). Much of the region is open to hunting, except Lake Clark National Park, Katmai National Park, and McNeil River State Game Sanctuary. However, hunting and trapping are allowed in the Lake Clark National Preserve, Katmai National Preserve, and McNeil River State Game Refuge (ADFG 2018e, NPS 2017g, NPS 2018a). Hunting and trapping are also allowed in the Alagnak Wild River and on certain islands in the Alaska Maritime NWR (NPS 2016a, USFWS 2014a). BLM lands are open to hunting, as are state-owned lands unless otherwise restricted by the ADF&G, which manages hunting in Alaska. Hunting on private property, including on village corporation lands and Native allotments, requires landowner permission.

The NPS and State of Alaska cooperatively manage wildlife resources in the three regional NPS units (Lake Clark, Katmai, Alagnak Wild River), and hunters in these units must follow current state and federal hunting regulations and must have all required licenses and permits (NPS 2018a, NPS 2017g, NPS 2016a). The Lake Clark National Preserve is divided into three authorized hunting guide areas and there are currently two concessioners authorized to guide sport hunters in these areas (NPS 2017g). There are also two concessioners authorized to guide sport hunters at Katmai National Preserve (NPS 2018a). The McNeil River State Game Refuge is open to hunting and trapping of species except brown bears (ADFG 2018e).

As noted in the BLM Bay Proposed RMP/Final EIS, "the BLM-managed portion of the upper Iliamna Lake region has world class recreational values, primary sport fishing and hunting". Commercial guides under permit with the BLM frequent this area (BLM 2007).

The region is in Game Management Units (GMUs) 9 (most of the region) and 15C (Kenai Peninsula). The project area is specifically in GMUs 9B and 15C. The species hunted in GMU 9 include brown/grizzly bear, caribou, Dall sheep, moose, wolf, and wolverine. Species hunted in GMU 15 include black bear, brown/grizzly bear, caribou, Dall sheep, moose, mountain goat, wolf, and wolverine. In these two GMUs, non-resident sport hunters need a licensed hunting guide or hunt with an Alaska resident who is a close relative for brown bear, mountain goat, and Dall sheep.

Hunting seasons for the species available in these two GMUs vary. Table 3.5-1 lists the hunting seasons for each species by GMU.

AMERICAN OVERSIGHT

Table 3.5-1: General Hunting Season for Game Management Units 9B and 15C

Species	General Hunting Season*	
	GMU 9B	GMU 15C
Black bear	No closed season	No closed season
Brown/Grizzly bear	May 10 to 25 in even years and October 7 to 21 in odd years	September 1 to May 31
Caribou	August 1 to March 31	No open season
Mountain goat	N/A	August 10 to October 15 and November 1 to14
Moose	Resident: September 1 to September 20 Nonresident: September 5 to September 15	August 25 to September 30
Dall sheep	August 10 to September 20	August 1 to August 5, August 10 to September 20
Wolf	August 10 to June 30	August 10 to April 30
Wolverine	September 1 to March 31	September 1 to March 31

Source: ADF&G 2017
*These are general seasons; specific seasons by sex/age/location are not presented here. The dates listed in the table change periodically based on Board of Game decisions.
N/A = not available

Water-Related Recreation (Boating)

Various forms of boating, including canoeing, kayaking, rafting, and power boating, are popular in most recreation areas in the region. River kayaking and rafting opportunities abound in Lake Clark and Katmai national parks. The three Wild Rivers in Lake Clark National Park and Preserve (Chilikadrotna, Mulchatna, and Tlikakila rivers) are popular for rafting (NPS 2016e). The 80-mile Savonoski Loop out of Brooks Camp is a popular canoeing and kayaking route in Katmai National Park and Preserve (NPS 2018a). This park also has several popular rafting waterways. Both whitewater and non-whitewater river boating opportunities are available in both park units.

On Alagnak Wild River, whitewater and non-whitewater boating opportunities are also available. Trips often begin at Nonvianuk or Kukaklek Lakes with several take-outs available along the lower 30 miles of river (NPS 2015a).

Boating occurs on the Mulchatna River all the way to its confluence with the Nushagak River. The Koktuli River is also floated to its confluence with the Mulchatna River, both by individuals and as guided float trips.

River-based boating opportunities vary based on season, amount of rainfall, and temperatures. Generally, river levels are lowest in early spring and increase throughout spring and early summer as spring rains fall and snow melt occurs, with river levels generally peaking in July and then declining into the fall (NPS 2015a).

Due to lack of road access to the region, and because many visitors travel to the area by small plane, boating equipment that can be brought to the region by visitors is limited. Guided trips are available through approved concessioners and CUA operators in the national parks, and via other companies in and around the region.

Lake boating opportunities occur during the ice free season, and are available on several lakes in both Lake Clark and Katmai national parks and preserves. Motorboating opportunities are

AMERICAN OVERSIGHT

available at Lake Clark and Crescent Lake in Lake Clark National Park and Preserve, and Naknek Lake in Katmai National Park and Preserve (NPS 2017h, NPS 2018a). All three lakes are popular destinations for visitors. In 2017, there were 10 companies authorized to provide boating trips in Lake Clark National Park and Preserve, three companies authorized for kayak tours, one company authorized for paddleboarding, and one company authorized as a water taxi (NPS 2018a). The Lake Camp area at Naknek Lake in Katmai National Park and Preserve is accessible via the road from King Salmon and contains a boat ramp, parking area, picnic area, and restrooms (NPS 2018a). In Katmai National Park and Preserve in 2017, there were 11 companies authorized to provide boating trips, six companies to provide charter boat services, and three companies authorized to provide kayak tours (NPS 2018a).

McNeil State Game Refuge is open to boating (ADFG 2018e).

Powerboating, canoeing, and kayaking opportunities are available in Cook Inlet, and particularly along the inlet edges such as along the Lake Clark National Park and Preserve boundary where there are also bear viewing opportunities.

Boating opportunities are also available at Iliamna Lake, Alaska's largest body of freshwater (Van Lanen 2012), though most use of the lake is for sport fishing. Access is available from Iliamna and Newhalen.

Kayaking and boating opportunities are also available on the east side of Cook Inlet near the terminus of the gas pipeline at the Anchor River State Recreation Area. Tractor-assisted boat launching is available at this location. Such activities primarily occur during the summer months.

Wildlife and Nature Viewing

The region surrounding the project area offers highly valued opportunities for wildlife and nature viewing. The most popular wildlife viewing activity in the region is brown bear viewing, both inland and along Cook Inlet, with the best opportunities provided at food-rich locations, such as major salmon rivers and the Cook Inlet shoreline. Bear viewing is especially popular at Lake Clark and Katmai national parks, and McNeil State Game Refuge and Sanctuary. Popular locations for bear viewing at Lake Clark National Park and Preserve include Chinitna Bay, Crescent Lake, Silver Salmon Creek, Shelter Creek, and Tuxedni Bay (NPS 2017c). Katmai has many food-rich areas where bears tend to congregate, such as Brooks Camp, in the preserve, and along the Cook Inlet coast. Bears can be found in the Katmai backcountry, and can also be found feeding on sedges, clams, and salmon (NPS 2018a).

McNeil State Game Refuge and Sanctuary was designated a wildlife sanctuary in 1967 to protect the world's largest concentration of wild brown bears. McNeil River Falls are located about a mile from the mouth of McNeil River; the falls slow the movement of salmon heading upstream to spawning grounds, causing salmon to congregate. Large numbers of brown bears can be seen at McNeil State Game Refuge and Sanctuary in early July through mid-August (ADFG 2018b).

Notable bird watching opportunities are also available at most recreation areas in the region. Raptors, waterfowl, seabirds, shorebirds, songbirds, and upland birds can be found throughout the region. For instance, 187 species of birds have been documented at Lake Clark National Park and Preserve (NPS 2017d) and millions of sea birds, endemics, and birds from Asia can be found in the Alaska Maritime NWR (USFWS 2016a).

Though bear viewing opportunities are world-class within the region, opportunities for viewing other wildlife species are also available at all of the recreation areas within the region. For instance at McNeil State Game Refuge and Sanctuary, harbor seals, moose, caribou, wolves, wolverines, red foxes, and arctic ground squirrels can also be seen (ADFG 2018b). There are

AMERICAN OVERSIGHT

also wildlife viewing opportunities at Iliamna Lake, which contains a population of freshwater seals (Van Lanen 2012, ADNR 2013a).

Other nature- and wildlife-related opportunities available in the region include nature photography, beach combing, clam digging, and berrypicking (LPB 2018). Often these activities are combined with activities such as bear viewing, sightseeing, backpacking, hiking, and camping during the summer and fall.

Flightseeing/Sightseeing

Due to the lack of road access in the region and the heavy use of small planes and floatplanes for transportation, there are many opportunities for flightseeing in the region. Flightseeing (i.e., sightseeing by plane) is an effective way to see the broader landscapes of the region and even see wildlife and bird species, particularly in the two national park units. Flightseeing occurs primarily during the summer months from June through September. There were 32 and 39 authorized air taxi CUA holders in 2017 that offered flightseeing opportunities in Lake Clark and Katmai national parks, respectively, with most operators originating out of Anchorage, Homer, King Salmon, Kodiak, and Soldotna (NPS 2018a). Many air taxis also provide flightseeing tours (NPS 2016c).

Camping/Backpacking/Hiking

Due to the relative lack of developed facilities or trails and large expanses of wilderness, backcountry recreation activities such as camping, backpacking, and wilderness hiking are popular in the two national park units. There are also developed camping opportunities at both national parks. Between the two parks, there are very few developed trail opportunities, with less than 5 miles of trail in Katmai National Park, and 6.8 miles of trail in Lake Clark National Park (NPS 2016b, NPS Undated LC). In 2017, there were 29 authorized CUA holders that provided guided hiking or overnight backpacking services in Katmai National Park, and 22 in Lake Clark National Park (NPS 2018c, NPS 2018d).

Primitive camping opportunities are also provided in the Alagnak Wild River (NPS 2015a). Developed, though low impact, camping and hiking opportunities are available in the McNeil State Game Refuge and Sanctuary (ADFG 2018c).

Camping is allowed on most of the Alaska Maritime NWR, though no developed campgrounds exist in the NWR (USFWS 2014a). Camping related to commercial activities is prohibited on BLM lands without written authorization from the BLM. Short-term camping (i.e., less than 14 days in one location) not associated with commercial use is allowed. On state land, access, travel, improvements and structures, and other miscellaneous uses are generally allowed and managed by the Division of Mining, Land, and Water. Camping is also available on the east side of the Cook Inlet near the terminus of the gas pipeline at the Stariski State Recreational Site and Anchor River State Recreation Area, which also offers hiking opportunities.

Due to harsh winter weather conditions in the region, camping, backpacking, and hiking activities generally occur during the summer months, from June through September.

Other Opportunities

Biking on ice using fat tire bikes is a new winter use in Lake Clark National Park and Preserve. There is currently no restriction on bike use in the park (NPS 2016d). Other winter activities include cross-country skiing, snowshoeing, trekking, and riding snowmachines. There is recreational use of Roadhouse Mountain to the northeast of Iliamna, as well as some all-terrain

AMERICAN OVERSIGHT

vehicle (ATV) use on trails around the Iliamna area, which are used for transportation, subsistence, and recreation.

3.5.2.2 Recreation Facilities

Commercial Lodges

Commercial lodges are the main form of lodging in the region due to the lack of consistent visitation to support hotels and motels. In 2012, there were 38 lodges in the area with active business licenses (Kevin Waring and Associates 2015d). There are clusters of commercial lodges at Port Alsworth, King Salmon, Naknek, Iliamna/Newhalen, Homer, Pedro Bay, and Kokhanok, as well as along the Kvichak, Mulchatna, and Alagnak rivers (ADNR 2013). There are also commercial lodges scattered around the region on private inholdings in Lake Clark and Katmai national parks (NPS 2017f, NPS 2015a). Commercial lodges often also provide guide services for hunting, fishing, and other recreation activities on private property, Native corporation land, and/or public lands. Therefore, commercial lodges provide a home base for many recreationists, as well as a starting point for trips onto public lands. See Section 3.6, Commercial and Recreational Fisheries, for more details on the commercial lodges present in the region.

Public Recreation Facilities

Public recreation facilities in the region include lodges, campgrounds, cabins, a primitive camping area, trails, and visitor centers. The only public lodge facilities within the region are located at Katmai National Park. There are two lodges in the park, Brooks Lodge and Grosvenor Lodge, both operated by a concessioner. In addition to a lodge, Brooks Camp includes a campground for 60 people, a visitor center, ranger station, and an auditorium with daily ranger-led programs. Facilities at Brooks Camp are available from June 1 to September 18. There is also a six-person public use cabin, Fures Cabin, on the Bay of Islands on Naknek Lake in Katmai National Park that is available from June 1 to September 17. There are 5 miles of trail in the national park and one scenic overlook. The Lake Camp area at Naknek Lake in Katmai National Park and Preserve contains a boat ramp, parking area, picnic area, and restrooms (NPS 2018a).

Developed facilities at Lake Clark National Park include a cabin and primitive camping area. The Priest Rock Public Use Cabin is a historic log cabin for six people on the north shore of Lake Clark and is accessible by float plane or boat (NPS 2017i). The Hope Creek Primitive Camping Area is located at Upper Twin Lake near the Proenneke Historic Site and does not provide any services (NPS 2017f). The maintained trails in the park are the Tanalian Trails that begin in Port Alsworth and continue to Tanalian Falls or Tanalian Mountain (NPS 2017e).

McNeil Camp at McNeil State Game Sanctuary provides 14 camp sites, a public use cook cabin for food storage and cooking, restrooms, a wash house, and staff facilities (ADFG 2018c).

The two state park units on the Kenai Peninsula near the terminus of the gas pipeline both include camping and picnicking facilities. There are 13 camp sites and some picnic sites at Stariski State Recreational Site, and 186 campsites total in five separate campgrounds at Anchor River State Recreation Area, along with 20 picnic sites and a boat launch.

There are no developed facilities in the Alagnak Wild River, but the US Fish and Wildlife Service has a visitor center nearby in King Salmon. The Alaska Maritime NWR does not include any recreation facilities in the region other than a visitor center in Homer (USFWS 2014a). There are no developed facilities on BLM lands (unencumbered or selected).

AMERICAN OVERSIGHT

3.5.2.3 Recreation Access

Overland Access

Road access to or in the public recreation areas in the region is limited to outside of and in Katmai National Park, in the vicinity of Iliamna/Newhalen, and from the Sterling Highway between Soldotna and Homer on the east side of the region. There are unpaved and paved roads between the town of Naknek (located west of the park) and Lake Camp on Naknek Lake in the park. These roads allow access from nearby towns to the boat ramp facility in the park on Naknek Lake. There is also an unpaved road from Brooks Camp to the Valley of Ten Thousand Smokes viewpoint at the Three Forks Overlook (NPS Undated 1). Daily bus tours are provided by the concessioner from Brooks Camp to the overlook when the camp is open (June 1 to September 18)(NPS 2018a).

On the east side of the region, the Sterling Highway provides road access to the Stariski State Recreational Site and Anchor River State Recreation Area on the Kenai Peninsula.

Locally in the project area, skiffs, ATVs, and trucks are the primary modes of local surface transportation around Iliamna Lake (ADNR 2013).

Water-Based Access

Inland of Cook Inlet, water-based access to public recreation areas occurs on major rivers and lakes. Small boats can travel up the Naknek River to Lake Camp in Katmai National Park and boats can travel the Alagnak Wild River as well (Kevin Waring and Associates 2011b; NPS 2015a). Lake Clark and Naknek Lake provide water-based access to portions of Lake Clark and Katmai national parks, respectively. Water-based access can also be provided at Iliamna and Nondalton. In and along the shoreline of Cook Inlet, water-based access is essential to reaching public recreation destinations such as the eastern portions of Lake Clark and Katmai national parks and the Alaska Maritime NWR. Commercial boat operators need to be authorized to operate in the three NPS units and Alaska Maritime NWR (NPS 2018a, USFWS 2014a).

Air-based Access

Air-based travel via small plane is the main form of access to recreation areas in the region, primarily from Anchorage, Homer, Iliamna, King Salmon, Port Alsworth, Kodiak, Dillingham, and Soldotna. Airport facilities located near the project area include Iliamna, Igiugig, Levelock, Big Mountain, Koggiung, Kvichak-Diamond J, Kokhanok, and Pedro Bay (ADNR 2013a). Only certain air-based operators are allowed to operate in the three NPS units, McNeil State Game Refuge and Sanctuary, and Alaska Maritime NWR (NPS 2018a, USFWS 2014a, ADFG 2018f). Different operators can land on different surfaces depending on the landing gear of the plane (e.g., floats/amphibious gear, wheels, skis/wheeled skis) and therefore have various seasons and conditions in which they can operate.

3.5.2.4 Recreation Settings

Apart from a few developed sites previously described, the regional public recreation areas generally provide a primitive, remote recreation setting where solitude is common and there are no lights or sounds from human development. In popular areas (primarily popular bear viewing locations), the few developed sites such as Lake Camp and Brooks Camp, and areas closer to villages/towns, the recreation setting may include views of limited human development and other visitors, though the setting is still primarily remote and primitive.

AMERICAN OVERSIGHT

3.5.2.5 Regional Recreational Use and Users

Given the lack of easy access and limited, dispersed development in the region, overall recreational use is estimated to be relatively low for all public recreation areas in the region compared to other parts of the state. The Bristol Bay Area Plan notes that southwest Alaska shows among the lowest level of tourism compared to other areas of the state in general, with only 17 percent of visitors to Alaska traveling to southwest Alaska, and only three percent traveling to southwest Alaska as their sole destination, with the majority of these visits to Katmai National Park and Wood-Tikchik State Park (ADNR 2013a). However, there are areas in the region that receive moderate to high use relative to the region. These areas tend to be the more accessible locations with public recreational use facilities such as the national parks and the McNeil State Game Sanctuary, or areas on the Kenai Peninsula that are accessible by road.

Between 2008 and 2017, Katmai National Park and Preserve averaged 36,825 visitors per year. During the same period, Lake Clark National Park and Preserve averaged 13,402 visitors per year. Visitor use at Lake Clark National Park and Preserve has been increasing over the last 10 years to almost 17,000 visitor use days, with the number of visitor use days increasing dramatically for bear viewing, sport fishing, and photography, while participation in other activities has stayed fairly constant (NPS 2018d) Over the same time period, visitor use at Katmai National Park and Preserve has generally fluctuated between 25,000 and 30,000 visitor use days (NPS 2018c). According to monthly visitation data, peak use of these two areas is from June to September. This is when the majority of annual use occurs, especially at Katmai National Park and Preserve, with 97 to 100 percent of the park's visitation occurring during these months. In the last 6 years, about 80 percent or more of visitation to Lake Clark National Park and Preserve has been during the peak season (June to September). The Long Range Interpretive Plan for Katmai National Park and Preserve notes that most of the park's visitors participate in two primary activities: bear viewing and sport fishing; there are virtually no drop-in visitors due to the effort needed to reach the park (NPS 2009a).

The number of bear-viewing visitors at McNeil River Camp was an average of 178 people per year between 2008 and 2017. The number of bear-viewing visitors at McNeil River Camp is capped at 257 visitors per year. In 2017, there were 1,092 user days (i.e., the participation in a recreational activity at a given resource during a 24-hour period by one person) associated with the bear-viewing program at McNeil River Camp in McNeil State Game Refuge and Sanctuary, and another 513 user days reported by guides or the public using the Kamishak River and Chenik Creek areas of the refuge and sanctuary, primarily for fishing and bear viewing (ADFG 2018a). The annual visitation to the Kamishak River and Chenik Lake areas likely varies due to the number of commercial transporter permits issued and used at each of these areas each year. There are no visitation estimates available for the Alagnak Wild River, Alaska Maritime NWR, BLM lands, or state lands/park sites.

Overall, due to the remoteness and lack of easy access and lodging facilities, it is expensive to visit the recreation areas in the region. As stated in the Alaska Maritime NWR Land Protection Plan, "recreational use is limited by the difficult logistics and expense of visiting remote islands. However, it is possible that the demand for visitor services will increase in the future as adventure travel becomes increasingly popular" (USFWS 2011). This may be true for other areas as well.

AMERICAN OVERSIGHT

3.5.2.6 Recreational Use at Project Components

Mine Site

Recreational use at the mine site consists of some sport hunting and fishing, as well as occasional snowmachine use. Flights taking recreationists to various destinations in the region and the state may also pass over the mine site. Though there is no existing estimate of recreational use at the mine site, given the remoteness of the mine site and relative closeness of Lake Clark National Park and Preserve and other more well-known and accessible fishing and hunting destinations, recreational use at the mine site is likely low.

Alternative 1 Transportation Corridor

Within the transportation corridor there is recreational use of Roadhouse Mountain to the northeast of Iliamna, as well as use of some ATV trails around the Iliamna area for transportation, subsistence, and recreation. There are no visible ATV trails along the access road corridor nearing the mine site or along the access road nearing Amakdedori Port.

There are also recreational use opportunities (primarily fishing) of extremely high quality in the general transportation corridor area, particularly along the Newhalen River and Upper Talarik Creek by the north access road, and in the Gibraltar River and Gibraltar Lake portions of the south access road corridor, which some local lodges advertise as offering guided fishing, hunting, and sightseeing trip options (Haugen, Bush and Rice 2003). Recreational sport hunting and snowmachine use may occur occasionally within the road corridors.

At Iliamna Lake, both motorized and non-motorized boating take place (AELO 2018), both as an activity in itself and as a means of accessing other recreation opportunities, primarily fishing, which is the main recreation opportunity at Iliamna Lake. Snowmachine use occurs on the lake in the winter; however, most of this use is likely for transportation and subsistence and minimally for recreation.

Due to its current inaccessibility and location of nearby high quality recreation opportunities, recreational use of the north and south mine access road corridors, the Kokhanok Airport spur road, and the Iliamna spur road is likely low though there is no existing recreational use estimate for the transportation corridor.

Amakdedori Port

The Amakdedori Port site is located on state lands designated for habitat use by the Kenai Area Plan (ADNR 2001). The Kenai Area Plan does not discuss recreational use, although there may be recreational boating, overflights, hunting, fishing and incidental wildlife viewing near the port site. There is no existing estimate of recreational use at the port site, though there is some boating use on the Cook Inlet. Due to the large size of the inlet and other nearby locations with known fishing, hunting, and wildlife viewing opportunities, there is likely little to no use of the port site itself for recreation.

Alternative 1 Natural Gas Pipeline Corridor

Existing recreational use along the pipeline alignment in Cook Inlet and on the Kenai Peninsula consists of boating on Cook Inlet and recreational use at the state park sites on the Kenai Peninsula. Boating on Cook Inlet is both an activity in itself and a means of accessing other recreation opportunities such as fishing, wildlife viewing, birdwatching, and beachcombing, as well as access to the recreation areas on the west side of the Cook Inlet like the Lake Clark and Katmai national parks and preserves. The Stariski State Recreational Site, located near the

AMERICAN OVERSIGHT

proposed compressor station, offers camping, picnicking, and hiking opportunities. The Anchor River State Recreation Area offers boating, camping, picnicking, and hiking opportunities. There is no existing estimate of recreational use for the Cook Inlet or either state park unit site.

Alternatives 2 and 3 Transportation Corridor

As stated above, there are also recreational use opportunities along the Newhalen River and at Iliamna Lake, as well as on Iliamna River. Fishing is the primary recreational opportunity in these areas, including guided sport fishing opportunities from lodges in the northern Iliamna Lake area, particularly around Pedro Bay. One lodge in the northern lake area offers guided kayaking trips on Iliamna Lake (AELO 2018). Recreational sport hunting use may also occur in the transportation corridor. There is no existing estimate of recreational use, including Iliamna Lake, though given the presence of ledges and communities around northern Iliamna Lake, there is likely more recreational use in the Alternative 2 and 3 transportation corridors than the Alternative 1 transportation corridor.

Diamond Point Port

The Diamond Point Port site would be located at the junction of Iliamna Bay and Cottonwood Bay. There is known commercial fishing use of this area (ADNR 2001) and likely recreational fishing opportunities as well. There are also opportunities for wildlife viewing in Iliamna Bay as there are large colonies of seabirds at the mouth of the bay as well as brown bears, moose, and shorebirds in the area (ADNR 2001). Therefore, there may also be opportunities for hunting. There is no existing estimate of recreational use at the port site, though given the known fishing and hunting use of Iliamna Bay and Ursus Cove, there may be more recreational opportunities at the Diamond Point Port site than the Amakdedori Port site.

Though there may be opportunities for recreational boating in the bays, there is one concentrated boat traffic effort in Iliamna Bay every year. In early June, around 60 boats make the trek from Homer to Bristol Bay via Iliamna Lake and the Kvichak River. The boats cross the Cook Inlet and head to Williamsport to be transported on the road from Williamsport to Pile Bay (Dischner 2015b). The boats that make this trek are primarily commercial fishing boats, but may include some recreational fishing boats. The boats also make the return trip from Bristol Bay back to Homer at the end of the summer (Dischner 2015a).

Alternatives 2 and 3 Natural Gas Pipeline Corridor

Under Alternatives 2 and 3, the natural gas pipeline would come into Ursus Cove and then cross land north to reach Cottonwood Bay and the Diamond Point Port site. Ursus Cove is a known bear hunting location (H&H Alaskan Outfitters 2018) and both Ursus Cove and Cottonwood Bay are known commercial fishing locations (ADNR 2001). Both Ursus Cove and Cottonwood Bay may also be used for other hunting activities, recreational fishing, and wildlife viewing given the large seabird colonies at the mouth of Iliamna Bay as well as the presence of moose and shorebirds around Iliamna Bay (ADNR 2001). There is no existing estimate of recreational use in Ursus Cove or Iliamna Bay.

AMERICAN OVERSIGHT

4.0 ENVIRONMENTAL CONSEQUENCES

4.1 INTRODUCTION

Chapter 4, Environmental Consequences, describes the potential impacts on the environmental resources addressed in Chapter 3, Affected Environment, that would occur under the No Action Alternative, the Applicant's Proposed Alternative, and other action alternatives.

Each of the resource sections in Chapter 4 (Section 4.2 through Section 4.26) discusses:

- Direct and indirect impacts characterized by four factors of analysis (see "Types of Effects Considered" and "Impact Characterization [Four Factors]" sections below) of each alternative, for each resource described in Chapter 3, Section 3.2 to Section 3.26.
- Cumulative effects to each resource for each alternative.

A discussion of other resources or topics that are not specifically addressed in Section 4.2 through Section 4.26 is included below in the "Other Resources or Topics" section. Chapter 4 also includes Section 4.27, Spill Risk, which analyzes diesel, concentrate, reagent, and tailings spill scenarios.

In this document, the terms "effect" and "impact" have the same meaning and are used interchangeably.

4.1.1 Impact Characterization (Four Factors)

Adverse and beneficial effects of the project were evaluated and described for each of the resources. Each resource section provides context for analyzing impacts by considering them generally in relation to four dimensions:

Magnitude: The intensity of the impact.

Duration: How long the impact would be expected to occur or last.

Geographic extent: Where the impact would be expected to occur.

Potential: How likely the impact is to occur.

Not every resource considers every dimension. The level of quantified or qualified information presented is appropriate to the context of the resource. In each of the resource subsections, the methods applied for analysis are described.

Project component values, such as road lengths and pad acreage, are approximations based on best available data. Due to differences in data processing systems (e.g., Geographic Information System [GIS]) and methodologies (e.g., number rounding), the values presented in the Environmental Impact Statement (EIS) may differ slightly from values presented in other project-related documents, such as permit drawings. These differences have been reviewed, and were determined to be unimportant to the analysis, as well as to the overall permitting process.

See Section 3.1, Introduction to Affected Environment, for a description of project components and project area terms.

AMERICAN OVERSIGHT

4.1.2 Time Periods (Phases)

Impacts on some resources may vary depending on the phase of the proposed project. Accordingly, the impact assessment was divided into three time periods:

Construction phase: The period of construction of mine infrastructure prior to operations.

Operations phase: The 20-year period of mine operations.

Closure or post-closure phase: Any activity occurring after mine operations cease.

Division of analysis into these three time periods works well for some resources, but is less relevant for others, such as socioeconomics or recreation.

4.1.3 Types of Effects Considered

The National Environmental Policy Act (NEPA) requires three types of impacts to be evaluated. These include direct, indirect, and cumulative impacts as defined below.

Direct Effects: Effects caused by the action and occurring at the same time and place (40 Code of Federal Regulations [CFR] 1508.8). Limited to the proposed action and alternatives.

Indirect Effects: Effects that are "caused by an action and are later in time or farther removed, but are still reasonably likely. Indirect impacts may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems" (40 CFR 1508.8). Indirect effects are caused by the project, but do not occur at the same time or place as the direct effects. Limited to the proposed action and alternatives.

Cumulative Effects: Additive or interactive effects that would result from the incremental impact of the proposed action when added to other past, present, and reasonably foreseeable future actions (RFFAs) regardless of what agency (federal or non-federal) or person undertakes such other actions (40 CFR 1508.7). This includes incremental impacts of the proposed action and alternatives when added to other past, present, and RFFAs. Interactive effects may be either greater or less than the sum of the individual effects; therefore, the action's contribution to the cumulative case could increase or decrease the net effects. Assessing the cumulative impacts from multiple projects/activities requires considering the impacts of their combined potential area of effects and associated actions. It also requires a logical nexus with the potential effects of the proposed action.

Past actions include activities that may have been initiated in the past, but could also involve present operations such as infrastructure development and non-mining related actions. They may have lingering effects in degrading the environment or may influence trends in the physical, biological, or social environment.

Present actions include mining projects and related activities that may have just come online or are currently underway and are causing impacts. They may also include other non-mining related projects, such as transportation, oil and gas development, or community development that are currently in progress.

For this analysis, RFFAs are existing plans, permit applications, and fiscal appropriations that are external to the proposed action, and likely (or reasonably certain) to occur. See Table 4.1-1 for a comprehensive list of potential RFFAs that were examined for this project. Actions are considered reasonably foreseeable if they are proximate to the project area and are anticipated to enter the permitting process in the next 5 years, are identified in planning documents as scheduled for development, or if significant resources have been committed to the proposed

AMERICAN OVERSIGHT

action. Proximity is based on natural geographic boundaries of potentially affected resources and the period of time that the project's impacts would persist.

Direct, indirect, and cumulative impacts are analyzed in each of the resource sections in Chapter 4. Cumulative effects are described in a separate subsection in each resource section for the proposed action and, if applicable, other action alternatives, based on applicable RFFAs listed in Table 4.1-1 that were evaluated as being "reasonably foreseeable."

4.1.3.1 Past and Present Actions

Past and present actions that have either lingering effects or influence trends in the environment with a nexus to the project are relatively limited, and are described below.

Commercial and Subsistence Harvest of Fish and Wildlife. Past and present harvest of fish and wildlife for commercial and subsistence purposes put some degree of pressure on those resources. While commercial fishing in the Bristol Watershed started in the 1880s, the period from the turn of that century through the adoption of Alaska Limited Entry Act by the State of Alaska in 1972, saw incremental changes in both fishing technology and the understanding of the salmon fishery resource. It was likely that there were historic instances of overharvest, with implications for the overall salmon resource. Similarly, local residents have historically harvested fish and wildlife in pursuit of traditional subsistence activities. However, fish and wildlife resources are managed by the Alaska Department of Fish and Game (ADF&G) and federal land managers to maintain sustainable populations, and there are no long-term adverse effects or trends affecting the resource.

Commercial Recreation and Tourism. Southwest Alaska, including the Bristol Bay region and the area around the project, is renowned for sport fishing, hunting, boating, and wildlife viewing opportunities, and there is a long history of these activities in area. Similar to commercial fishing, the sport harvest of fish and game is managed by ADF&G and federal land managers to maintain sustainable populations, and there are no long-term adverse effects or trends affecting the resource. These activities take place primarily from late spring to early fall, and there may be small plane, helicopter, and boat traffic associated with access that can contribute to the disturbance of wildlife, as well as recreation and subsistence activity experience.

Mining Exploration Activities. There are a number of mineral claims and resources in the Bristol Bay watershed that have been subject to mineral exploration activities. Exploration activities have been intermittent, depending on the specific claim or resources, and there has been small plane, helicopter, and boat traffic associated with exploration that can contribute to the disturbance of wildlife, as well as recreation and subsistence activity experience. In the immediate area of the project, there has been no mineral production activity that has had lingering adverse effects on the environment.

Williamsport-Pile Bay Road. Construction of the Williamsport-Pile Bay Road in the 1930s provided access between Cook Inlet and the Bristol Bay via a 15.5 mile road to Iliamna Lake and down the Kvichak River. The road allows transportation of fishing vessels bound for Bristol Bay commercial fisheries, as well as some goods and supplies for lake and river communities, contributing to road and lake traffic during the summer season. The road is owned and maintained by the State of Alaska.

4.1.3.2 Reasonably Foreseeable Future Actions Considered

The following categories of reasonably foreseeable future activities were considered for the cumulative effects analysis:

- Mineral Exploration and Mining

AMERICAN OVERSIGHT

- Oil and Gas Exploration and Development
- Transportation and Infrastructure
- Energy and Utilities
- Commercial Fishing
- Subsistence
- Tourism, Recreation, Hunting and Fishing
- Scientific Research and Surveys
- Contaminated Sites and Industrial Pollutants

With regard to mineral and oil and gas resources, a distinction was made between exploration and development activities. Many of the mineral projects assessed are on lands open to mineral entry and have been the subject of exploration activities for over 30 years, but have not been developed. Similarly, oil and gas lease sales have been held in waters of Cook Inlet for over 50 years, but not all exploration activities have led to oil and gas development. The decision to take resources from exploration to development depends on many factors.

Activities associated with commercial and subsistence harvest, viewing, and scientific study of fish and wildlife have the potential to contribute to cumulative effects of developing the project. Effects can include mortality and injury on an individual and population level, and disturbance and changes in distribution and migration, which can affect availability to various users.

Events such as large oil spills, chronic pollution, and historic contaminated sites can contribute to cumulative effects in several ways. Effects can include mortality and injury to fish on an individual and population level, avoidance and changes in distribution and migration, and contamination with regard to human consumption by subsistence, commercial, and recreational harvesters.

Finally, climate change and other changes in the natural environment can contribute to cumulative effects through past, present, and RFFAs. The way in which this EIS addresses climate change is discussed in Section 3.1, Introduction to Affected Environment.

The following parameters are used to identify potential reasonably foreseeable future activities for the cumulative effects analysis:

- Geographic timeframe. Typically only projects with dedicated funding, currently in or scheduled to undergo federal, state, or local permitting, and with a medium to high probability of occurring, are included. However, the USACE has determined that expansion of the Pebble Project to develop 55 percent of its reserves over a 78 year period, as outlined in the Wardrop 2011 Preliminary Assessment Technical Report, will be analyzed under the cumulative effects analysis (see Table 4.1-1 for further discussion). Therefore, other reasonably foreseeable future activities that may occur in the 78 year time period will also be considered. However, in order to be considered reasonably foreseeable within this time frame, potential RFFAs need to meet the subsequent criteria.
- Projects located on lands open to mineral entry or development. When lands are classified as open to mineral development, it facilitates obtaining permits and other approvals for exploration and development activities. However, in order to be considered reasonably foreseeable for development within this time frame, potential reasonably foreseeable future actions need to meet the subsequent criteria.
- Projects with dedicated funding, currently in the permitting process, undergoing a state or federal environmental assessment, or listed in a planning document with a specific time frame for development. Projects may be considered reasonably

AMERICAN OVERSIGHT

foreseeable for development if they have dedicated funding and a schedule for development; have federal, state, or local permit applications under review or approved; are currently being evaluated through a federal NEPA compliance effort of State Best Interest Finding Effort; or are identified in a planning document (such as scheduled lease sales) with a specific project description and time frame for development. However, potential projects on land open to mineral entry or classified to allow mining are not considered reasonably foreseeable without meeting additional criteria described in this section.

- Information to support the feasibility of development has been documented. The project has conducted extensive exploratory drilling and analysis in order to compile information on mineral reserves in terms of measured, indicated, and inferred resources, along with characterization of the grades of ore in the deposit (Wardrop 2011). Estimated costs associated with developing the deposit were also prepared for three development scenarios, although that information was based on a different project configuration and is several years old. The potential feasibility for development of other projects is evaluated based on the published information on result of drilling and delineation of measured, indicated, inferred, and grade of reserves. To the extent they are available, estimated costs associated with development are also assessed.
- Proximity to the project infrastructure and factors affecting co-use by other parties. The question of whether development of the project would facilitate development of other nearby mineral deposits depends in part on proximity to the project and ability to use project infrastructure. Construction of access to project transportation infrastructure is expensive and also depends on land ownership access and sensitivity of environmental resources along the access route. Project infrastructure would be privately funded and co-use of mining and port facilities dependent on permission from Pebble Limited Partnership (PLP). While the access road would be privately funded on State land, the State of Alaska would likely require allowing access to other mineral deposit owners if an agreement could be reached with PLP regarding operation and maintenance costs, based on the precedent set in state permit conditions for granting Pogo Mine Access (S. Buckley, personal communication 2018).
- Geographic nexus with the direct and indirect effects of project development on specific resources evaluated in the EIS. Along with the factors previously described, there would need to be interactive and synergistic effects of an RFFA on resources directly and indirectly affected by development of the project in a specific geographic range that varies by resource.

AMERICAN OVERSIGHT

Table 4.1-1: Potential RFFAs Evaluated for Cumulative Effects

Potential Mineral Deposits in Southwest and Southcentral Alaska				
Prospect, Project, or Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
Pebble Project – develop 55% of delineated resources over a 78-year period	Expansion of the Pebble Project to develop 55% of its reserves over a 78-year period, as outlined in the Wardrop 2011 Preliminary Assessment Technical Report. It would likely use the same transportation facilities, power plant, and natural gas pipeline facilities, but would need additional tailing storage and possibly processing facilities. It is not part of the proposed action and would require additional permits and separate NEPA compliance.	Potential project expansion. Expansion identified as option in Wardrop 2011 report and analyzed in the Environmental Protection Agency (EPA) Watershed Assessment (EPA 2014) on the basis of lands being classified as open for mineral exploration and development and assuming access to Pebble Project infrastructure.	Wardrop 2011	Yes - for continued exploration and development. The Pebble Project has conducted extensive exploratory drilling and analysis in order to compile a feasibility assessment level on information on mineral reserves in terms of measured, indicated, and inferred resources, along with characterization of the grades component ore in the deposit (Wardrop 2011). If permitted, the project processing and transportation infrastructure would be in place, and development of 55% of the Pebble Project resources is considered reasonably foreseeable in the 78-year time frame outlined in Wardrop 2011.
Pebble South	A 142 square kilometer (km^2) porphyry copper deposit/claim ~15 kilometers (km) southwest of Pebble Deposit. Prospect is part of the PLP/Northern Dynasty Minerals (NDM) Limited (Ltd.) claim block and includes the 38 and 308 zone prospects. Primary additional development would include the mine pit, mineral processing, tailings storage and waste rock areas, and a new transportation corridor to existing Pebble Project transportation system, power supply, and natural gas infrastructure.	Potential project expansion. Expansion identified as option in Wardrop 2011 report and analyzed in for cumulative effects in the EPA Watershed Assessment based on land classification of the deposit and assuming access to Pebble Project infrastructure.	EPA 2014	Yes - for further exploration. No - for development. Resource delineation has not progressed sufficiently to forecast development, is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable within the 78-year time frame. Note: Because claims are currently owned by NDM Ltd., if future drilling and resource delineation indicate that it is feasible to develop the project, it is possible that construction and operations could access and utilize the Pebble Project transportation system.

Table 4.1-1: Potential RFFAs Evaluated for Cumulative Effects

Potential Mineral Deposits in Southwest and Southcentral Alaska				
Prospect, Project, or Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
Big Chunk South	A 119 km² porphyry copper deposit/claim ~20 km north of the Pebble project area. The claim block is entirely in the Chulitna River drainage, which flows into Lake Clark National Park and Preserve. Potential development includes Tailings Storage Facilities (TSFs), mill, and other facilities for mining. Multiple build-out scenarios.	Undergone some airborne surveys and limited drilling to delineate the resource. Claims transferred to NDM Ltd. in 2014. Analyzed for cumulative effects in the EPA Watershed Assessment (EPA 2014) based on land classification of the deposit and assuming access to Pebble Project infrastructure.	EPA 2014	Yes - for further exploration. No - for development. Resource delineation has not progressed sufficiently to forecast development is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable in the 78-year time frame. Note: Because claims are currently owned by NDM Ltd., if future drilling and resource delineation indicate that it is feasible to develop the project, it is possible that construction and operations could access and use the Pebble Project transportation system.
Big Chunk North	Porphyry copper deposit ~34 km northwest of the Pebble project area. The claim block straddles the drainage divide between the Nushagak and Kvichak River watersheds. Potential development would include TSFs, mill, and other facilities for mining.	Claims transferred to NDM Ltd. in 2014. Analyzed for cumulative effects in the EPA Watershed Assessment based on land classification of the deposit and assuming access to Pebble Project infrastructure.	EPA 2014	Yes - for further exploration. No - for development. Resource delineation has not progressed sufficiently to forecast development, is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable in the 78-year time frame. Note: Because claims are currently owned by NDM Ltd., if future drilling and resource delineation indicate that it is feasible to develop the project, it is possible that construction and operations could access and utilize the Pebble Project transportation system.
Fog Lake	Gold, copper in volcanic rocks	As of 2008, exploration	EPA 2014	Yes - for further exploration.

AMERICAN OVERSIGHT

	southwest of the Pebble Project area. Potential development includes TSFs, mill and other facilities for mining.	and assuming access to Pebble Project infrastructure.		website and no longer appears to be active. It is not considered reasonably foreseeable in the 78-year time frame.
Iliamna	183 km² porphyry copper claim block ~90 km southwest of the Pebble project area in the Kvichak River watershed.	Millrock Resources began exploration in 2012. Analyzed for cumulative effects in the EPA Watershed Assessment (EPA 2014) based on land classification of the deposit and assuming access to Pebble Project infrastructure.	EPA 2014 Bristol Exploration Co., Inc. 2011	No - for further exploration. No - for development. This project has been removed from the Millrock Resources and TNR Gold Corp websites and no longer appears to be active. It is not considered reasonably foreseeable in the 78-year time frame.
Kamishak	Porphyry copper in a breccia pipe roughly 80 km southeast of the Pebble Project area.	There were 18 holes drilled between 1990 and 1991, and an additional 5 holes were drilled in 2006. As of 2008, reserves had not been identified.	AERI 2008	No - for further exploration. No - for development. Resource delineation has not progressed sufficiently to forecast development, is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable in the 78-year time frame
Shotgun	Quartz-feldspar porphyry deposit with gold as the primary interest, located roughly 160 km northwest of the Pebble Project, 90% owned by TNR Gold Corporation. If developed, Shotgun could access tide water via barge transport from Dillingham (150 km away) up the Nushagak River to Koliganek, New Stuyahok, or Ekwok (80, 110, and 120 km away, respectively). It would not be practicable to connect to Pebble	There have been extensive drilling programs since the late 1980s through 2012, and as of 2013, inferred mineral resources were estimated at 20.7 million tons, with a grade of 1.06 gram of gold per ton, with a cut-off grade of 0.50 gram per ton of gold.	TNR Gold Corp. 2011, 2012, 2018 ADNR 2012	Yes - for further exploration. Yes - for development. Mineral exploration has delineated inferred mineral resources, but it is unclear to what extent they are measured or indicated. The prospect is not currently subject to development permitting or in a planning document. However, given the extent of delineated resources, for the purposes of this analysis, the

AMERICAN OVERSIGHT

	Project infrastructure.			Shotgun prospect is considered reasonably foreseeable in the 78-year time frame.
Johnson Tract	Gold rich poly-metallic deposit located roughly 80 miles east of the Pebble Project, owned by Cook Inlet Region, Incorporation (CIRI) and subject to an exploration agreement with Constantine Metals Resources Ltd. CIRI has access rights through Lake Clark National Park and Preserve to a port site at Tuxedni Bay on Cook Inlet.	Discovered by Anaconda in 1982, 90 holes have been drilled but no exploration has occurred in more than 20 years. Constantine Metals has agreed to resume exploration and take the project to the point of evaluating feasibility of developing the mine.		Yes - for further exploration. No - for development. Resource delineation has not progressed sufficiently, is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable in the 78-year time frame.
Copper Joe	Porphyry copper located significantly north of the Pebble Project, in close proximity to the Whistler Deposit.	Kiska Metals / First Quantum Minerals Ltd. conducted exploration work in 2016.		Yes - for further exploration. No - for development. Resource delineation has not progressed sufficiently, is not subject to development permitting or in a planning document, and is not considered reasonably foreseeable in the 78-year time frame. In addition, there is no geographic nexus with the Pebble Project.
Proposed Mining and Mineral Projects in Southwestern and Southcentral Alaska				
Donlin Gold	Open pit hard rock mine in the Kuskokwim River watershed, 277 miles west of Anchorage. The proposed mine would have a total footprint of approximately 16,300 acres. Includes a 312-mile long pipeline to carry natural gas from Cook Inlet to the mine site.	Final EIS issued in April 2018. USACE and Bureau of Land Management (BLM) have issued a Joint Record of Decision (JROD) granting major federal permits.	USACE 2018	Yes – for further exploration. Yes - for development. Final EIS on the project has been completed and the JROD was signed in August 2018. The project is considered reasonably foreseeable in the 78-year time frame.
Diamond Point Rock Quarry	Proposed granite quarry project near the convergence of Cottonwood and	An application for development of a rock	USACE 2010	Yes – for development. Reserves of quarry rock have been

	Iliamna bays on the west side of Cook Inlet. Project involves modification of shoreline to construct a staging area and dock facility. Dredging would be required in Iliamna Bay	quarry at Diamond Point was submitted to the USACE in 2009. The site is currently undeveloped. Proposed coastal infrastructure includes constructing a 20 acre fill for staging equipment, stockpiling aggregate, and barge loading facilities.		estimated and a permit application was filed for development. The project is considered reasonably foreseeable in the 78-year time frame.
Potential Oil and Gas Exploration and Development				
Project/Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
Alaska Stand Alone Pipeline Project	Proposed 737-mile natural gas pipeline from Prudhoe Bay to Point McKenzie, Alaska. The project involves the construction of a liquefied matural gas (LNG) extraction plant on the western side of Cook Inlet at Point McKenzie.	A Final EIS was completed in 2018. A ROD is expected soon.	Alaska Stand Alone Pipeline (ASAP) 2018	Yes – for development. The project is considered reasonably foreseeable in the 78-year time frame. However, it would not be built if the Alaska LNG project is funded for development.
Alaska Liquefied Natural Gas Project (Alaska LNG)	Proposed 800-mile natural gas line from Prudhoe Bay to Nikiski, where the gas will be liquefied and shipped to foreign markets. Involves a natural gas pipeline crossing Cook Inlet and will result in increased marine traffic in Cook Inlet.	Federal Regulatory Energy Commission (FERC) application filed. A Draft EIS is under development for release in 2019; a Final EIS would be released in 2020. Construction would begin after 2020. The project does not have funding to proceed.	Alaska LNG 2018	Yes – for development. While funding for development is not currently available, the project is considered reasonably foreseeable in the 78-year time frame.
Drift River Oil Pipeline Transportation Project	Proposes to repurpose an existing natural gas pipeline crossing Cook Inlet to an oil pipeline. Involves the installation of 9 miles of new cross-inlet pipeline between Beluga and	Project is in the permitting phase. Decommissioning of the Drift River Terminal was initiated in 2017.	KDLL, Public Radio for Central Kenai, 2018	Yes – for development. The project is in the permitting phase and scheduled for execution. It is considered reasonably foreseeable in the 78-year time

AMERICAN OVERSIGHT

Potential Mineral Deposits in Southwest and Southcentral Alaska				
Prospect, Project, or Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
	Nikiski.			frame.
Cook Inlet Oil and Gas Lease Sales	In 2015, the Alaska Oil and Gas Association estimated there were 600 million barrels of recoverable oil and 19 trillion cubic feet of recoverable natural gas in Cook Inlet. There are a total of 16 platforms with 8 operators as of 2016. Exploration activities continue with future development anticipated. The Bureau of Ocean and Energy Management is responsible for leasing oil and gas in federal waters, and ADNR has the same responsibility for state waters.	In 2017, Federal Lease 244 resulted in bids for 14 tracts in Cook Inlet. Federal Lease Sale 258 for Cook Inlet is scheduled for 2021. ADNR released a preliminary Best Interest Finding on the Cook Inlet Area-wide Oil and Gas Lease Sale in June 2018. Oil and gas exploration and development activities in Cook Inlet are ongoing and likely to continue.	BOEM 2018	Yes – for exploration. Yes – for development.
Hydrocarbon Exploration Licensing and Leasing Program	ADNR, Lake and Peninsula Borough (LPB), Bristol Bay Borough, and Aleutians East Borough have signed a Memorandum of Understanding (MOU) in support of oil and gas lease sales and licensing on state land in the analysis area. Similar MOUs exist between ADNR and the Aleut Regional Native Corporation and Bristol Bay Native Corporation.	Exploration underway.	Bristol Bay Area Plan for State Lands 2015	Yes – for exploration. No – for development. Exploration activities are underway, but given the lack of previous oil and development in the region, development and production are not reasonably foreseeable in the 78-year time frame.
Transportation and Infrastructure				
LPB Transportation Projects	Several road improvement and new transportation corridors currently being studied. Studies include the Williamsport-Pile Bay road upgrade, Nondalton–Iliamna River Road Corridor and Bridge, Kaskanak Road /Cook Inlet to Bristol Bay (Igiugig).	Ongoing.	LPB Comprehensive Plan 2017	Yes – for development. These projects are considered reasonably foreseeable in the 78-year time frame.

AMERICAN OVERSIGHT

Potential Mineral Deposits in Southwest and Southcentral Alaska				
Prospect, Project, or Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
LPB Community Development and Capital Improvement Projects	Village infrastructure development projects including power plant upgrades, sewer and water improvement projects, transmission upgrades and energy efficiency initiatives.	Ongoing. List of projects from LPB 2017 capital improvement projects.	LPB Comprehensive Plan 2017	Yes – for development. These projects are considered reasonably foreseeable in the 78-year time frame.
Rural Alaska Village Grant Program	US Department of Agriculture Rural Development program to improve rural sanitization. Grant money used to improve water and sanitation services.	Ongoing	USDA Rural Development 2018	Yes – for development These projects are considered small-scale community improvements.
Energy and Utilities				
Lake and Peninsula Borough and other regional Renewable Energy Initiatives	LPB and other communities and electrical generation cooperatives are studying renewable energy projects to help combat high fuel costs. Studies include wind, hydroelectric, river, and tidal energy alternatives. Igiugig has a permit for a removable in-river power generation facility in the Kvichak River.	Studies ongoing. Igiugig has been installing its pontoon-mounted power generator annually in the Kvichak River. The Tazimina Run of River Hydro Project upgrade has been completed, 12 miles northeast of the village of Iliamna The village of Kokhanok has received funding to refurbish its existing wind diesel power plant.	LPB Comprehensive Plan 2017	Yes – for development. These projects are considered reasonably foreseeable in the 78-year time frame.
Nushagak Electric Cooperative Village Intertie Project	The Nuyakuk Run of River Hydro Project would connect the communities of Dillingham, Levelok, New Stuyahok, Koliganek, Aleknagik, and Ekwok with power and fiber optics with operation projected for 2024.	Nushagak Cooperative has submitted a preliminary permit application to FERC for their hydro project on the Nuyakuk River in Wood Tikchik State Park. Pedro Bay is pursuing permitting for the Knutson	US Department of Energy FERC 2018 (83 FR 15826)	Yes - for development. This project is considered reasonably foreseeable in the 78-year time frame.

		Creek Run of River Hydroelectric Project.		
Commercial Fishing				
Bristol Bay - Nushagak and Naknek/Kvichak State Management Districts - Salmon Lower Cook Inlet Management Area - Salmon and Herring	Continued stock assessment and allocation decisions under existing management plans.	Ongoing. Anticipate a continuation of commercial fishing in the analysis area.	ADF&G Commercial Fishing Management Reports 2018	These actions will occur in response to annual stock assessments and direction from management plans.
Subsistence Activities				
Villages of Iliamna, Newhalen, Pedro Bay, Port Alsworth, Nondalton, Igiugig, Kokhanok, Koliganek, Levelock, New Stuyahok, King Salmon, Naknek, Aleknagik, Clarks Point, Manokotak, Dillingham, Ninilchik, and Seldovia	Past, present, and foreseeable subsistence activities are described in Section 3.9, Subsistence.	Ongoing. Anticipate a continuation of subsistence practices within the analysis area.	See Section 3.9, Subsistence.	Subsistence harvest of fish, wildlife, and plants will continue for the foreseeable future.
Tourism, Recreation, Hunting and Fishing				
National Parks and Preserves Wildlife Refuges State of Alaska Special Management Areas Alaska Native	Hiking, camping, wildlife viewing and photography. Sport fishing is the primary recreational activity that occurs in the EIS analysis area. Hunting, primarily for moose, caribou, and bear, is a major recreation activity in the region.	Activities are expected to continue in the EIS analysis area.		Tourism, recreation, hunting, and fishing will continue for the foreseeable future.

AMERICAN OVERSIGHT

Table 4.1-1: Potential RFFAs Evaluated for Cumulative Effects

Potential Mineral Deposits in Southwest and Southcentral Alaska				
Prospect, Project, or Activity	**Description**	**Status**	**References**	**Reasonably Foreseeable?**
Corporation Lands				
Industrial Pollutants and Contaminated Sites				
Communities in project area	Identified sites with low levels of contamination have been identified in many Alaskan communities. Communities with site entries in the immediate vicinity of the project include Nondalton, Iliamna, Pedro Bay, Newhalen, and New Stuyahok. Many of the sites are associated with fuel storage tanks/power generation	Many of the sites in the Alaska Department of Environmental Conservation database have been cleaned up. The primary potential nexus with activities proposed by the Pebble Project would be in communities where Pebble proposes construction and operations support activities.	ADEC 2018	There is a potential for interaction with contaminated sites in Iliamna.
Scientific Surveys and Research				
Federal, state, institutional, and private surveys and research	Scientific surveys and research conducted by government, institutional, and private parties have the potential to disturb wildlife, as well as interfere with subsistence and recreational activities and experience. Activities conducted by aircraft typically have created the most potential for conflict.	While some agencies and organizations conduct annual surveys, others are difficult to forecast.		There is a potential to disturb wildlife, and for interaction with subsistence and recreational activities and experience.

AMERICAN OVERSIGHT

4.1.4 Issues Selected for Analysis

The US Army Corps of Engineers (USACE) and cooperating agencies selected substantive impact topics for further analysis, and eliminated others from evaluation. Based on scoping comments, issues were selected for analysis, and are organized by social, physical, or biological environment.

These issues are briefly described in this section and documented as Statements of Concern in the Scoping Report (Appendix A). Comments indicated that the EIS should analyze impacts on:

Social Resources:

- Socioeconomics
- Subsistence
- Traditional way of life
- Archaeological and cultural resources
- Land ownership, management, and use
- Transportation and navigation
- Recreation
- Environmental justice
- Public health and safety
- Visual resources
- Wilderness characteristics
- Food and fiber

Physical Resources:

- Air quality
- Geology and seismic activity
- Surface and groundwater hydrology impacts
- Noise impacts
- Hazardous materials stored and transported to and from the mine site
- Natural gas supply and pipeline safety
- Tailings dam
- Water quality and quantity

Biological Resources:

- Vegetation and ecosystems
- Fish and aquatic resources
- Wetlands and special aquatic sites
- Wildlife, birds, and mammals
- ESA-listed threatened and endangered species

Other Concerns:

- Climate change
- Invasive species
- Fuel spill risks and releases

AMERICAN OVERSIGHT

4.1.5 Other Resources or Topics

This section provides a summary of analysis of other resources or topics that are not addressed specifically in Section 4.2 through Section 4.27.

4.1.5.1 Conservation (33 CFR 320.4[a], [m], [n])

Conservation is a broadly defined concept that typically includes the wise and efficient use, management, and protection of a natural resource; avoidance of wasteful or unnecessary use of the resource; and sustainability of the resource for future or alternate use. The conservation aspects of a large mineral resource extraction project are multi-faceted and complex. They involve the efficient extraction and use of copper, gold, and molybdenum minerals, temporary and permanent losses or gains in other affected resources, and a variable duration of impacts on those resources.

Overall, the project will result in adverse short-term impacts on natural resource conservation, and in variable (generally adverse to neutral) long-term effects on natural resource conservation; including mineral resources, fish and wildlife, water supply, wetlands, and energy. Supporting discussions regarding impacts on the conservation of each of these resources are provided in other appropriate sections of this EIS. Project-related impacts on the conservation of each of these resources will vary in intensity and duration; many of the effects will be temporary.

4.1.5.2 Energy Needs (33 CFR 320.4[n])

Energy conservation and development are major national objectives. The project is not an energy production facility, but will have effects on energy needs. There is no existing power infrastructure in the project vicinity. Due to the remote location and lack of current infrastructure, the project would be required to provide basic infrastructure in addition to support facilities typically associated with mining operations. The project will create new base load electric demand for ore extraction and processing. The peak electrical load for the project will be approximately 270 megawatts (MW). Project energy requirements represent additional base and peak load electrical demand. Various mine load centers would be serviced by a 69 kilovolt distribution system using a gas-insulated switchgear system located at the power plant. Waste heat from the power plant would be used to heat buildings and supply process heating to the water treatment plant.

Natural gas sourced through the existing natural gas supply infrastructure will be the primary energy source for the project. Natural gas pipeline infrastructure would include a compressor station on the Kenai Peninsula side, and a second compressor station located at a Cook Inlet port site. The port site would include two 2 MW natural gas power generators with an emergency diesel generator. Natural gas would be fed to the port site power station to be used for heating. A lake ferry would include generator engines. The mooring system design would allow engines to be turned off while parked.

4.1.5.3 Mineral Needs

Society has demands and uses for molybdenum, copper, and gold, and for the mining of these resources. PLP's stated purpose for the project is to provide for increased domestic copper, gold, and molybdenum production to meet world demand. PLP presented information demonstrating that these minerals are important precious metal used worldwide for electronics, jewelry, currency/bullion, and medical purposes. Direct mining products include copper concentrates, molybdenum concentrate, and gravity-recovered gold. The project will ultimately result in production of molybdenum, copper, and gold. These metals are highly conductive to

AMERICAN OVERSIGHT

electricity and are used in electrical wiring in some high-energy applications, circuitry, and other uses; they are more efficient than other metals for these applications.

The project represents a needed exploitation and use of these metals, but also represents an irretrievable and irreversible commitment of the use of copper, gold, and molybdenum ore resources. The project will result in a short-term, beneficial effect on mineral needs.

4.1.5.4 General Environmental Concerns (33 CFR 320.4[a][1] and 33 CFR 320.4[p])

During the formal scoping period, many issue-specific comments were received from the public as well as local, state, and federal agencies. Concerns addressed under "general environmental concerns" include those not addressed elsewhere. The USACE has identified climate change and traditional ecological knowledge (TEK) as matters of general environmental concern not addressed in a specific resource section. Discussion of both of these topics is integrated into the descriptions in Chapter 3, and the analysis in Chapter 4; see Section 3.1, Introduction to Affected Environment, for information on how these topics were discussed and analyzed.

[Provide summary of TEK and climate change analysis, as applicable, after completion of Chapters 3 and 4].

4.1.6 Unavoidable Adverse Effects

The Council on Environmental Quality (CE!Q) guidelines require agencies to evaluate "any adverse environmental effects which cannot be avoided should the proposal be implemented" (40 CFR 1502.16). Unavoidable adverse effects are those remaining after the project has complied with applicable stipulations and mitigation measures. A detailed discussion of beneficial and adverse effects is presented for each resource in Section 4.2 through Section 4.26. Unavoidable adverse impacts to resources in the EIS analysis area are described below.

4.1.7 Irreversible and Irretrievable Commitment of Resources

CEQ guidelines require an evaluation of "any irreversible or irretrievable commitments of resources which would be involved in the proposal should it be implemented" (40 CFR 1502.16). A commitment of resources is irreversible when the impacts of the proposed action or alternatives would limit the future options for use of the resource. This applies primarily to non-renewable resources or to processes or resources that are renewable over long periods of time. Irretrievable commitments apply to loss of production or use of renewable resources. These opportunities are foregone for the period of the proposed action, during which the resource cannot be used. These decisions are reversible, but the utilization opportunities foregone are irretrievable. Irreversible and irretrievable commitments of resources for the alternatives analyzed in this EIS include:

- Ground disturbance, particularly due to project construction and operations, would cause irreversible impacts including land to be permanently altered, soils and bedrock to be permanently displaced, vegetation to be permanently removed, and wetlands to be permanently altered or filled. Any inadvertent effects to cultural resources or historic property would also result in an irreversible commitment of resources.
- Incidental or induced mortality of fish and wildlife resulting from project construction and operations, as well as any reduction in habitat value, could result in localized irretrievable commitment of these resources during the life of the project. Subsistence harvesting and recreational activity in areas occupied by facilities would not be possible during the life of the project, resulting in an irretrievable commitment of related resources.

AMERICAN OVERSIGHT

- Funds and labor would be irretrievably committed for project permitting and development.
- Consumption of renewable and non-renewable resources would be required for infrastructure development, including metals, aggregate, cement, wood, and other materials.
- Non-renewable resources (e.g., gasoline, diesel, natural gas, and electrical power generated from these fuels) would be irreversibly committed for project construction, operations, and closure. Fuels would be required to operate aircraft, motor vehicles, barges, vessels, machinery, and mining equipment.
- Water would be irretrievably committed for milling and processing.

4.1.8 Financial Assurance and Bonding

The State of Alaska will require financial assurance to ensure completion of reclamation and closure activities, including long-term post-closure management requirements, and for management of wastes to prevent water pollution.

PLP would be required to fully bond the project upfront, and would meet financial assurance obligations as the trust is being funded to the amount approved by the Alaska Department of Environmental Conservation and Alaska Department of Natural Resources (ADNR) (e.g., through a letter of credit or surety bond).

Prior to commencing construction, the PLP would develop and submit for approval a Project Reclamation and Closure Plan. PLP would also have associated financial assurance mechanisms in place. The Reclamation and Closure Plan and financial assurance obligations would be updated on a 5-year cycle in accordance with regulatory requirements to address any changes in closure and post-closure requirements and cost obligations.

PLP would develop a detailed reclamation and closure cost model to address all costs required for both the physical closure of the project and the funding of long-term post closure monitoring, water treatment, and site maintenance. The estimate would include the costs of closure planning and design, and mobilization of third-party equipment to site; detailed estimates of equipment and labor requirements for physical closure; capital, sustaining capital, and operating costs for water treatment and other long-term post-closure operations; and appropriate indirect costs and contingencies developed following ADNR guidance.

AMERICAN OVERSIGHT

4.5 RECREATION

For the purposes of this section, the region around the project site is defined as the area from Lake Clark National Park and Preserve south to Katmai National Park and Preserve, and from the Nushagak River east to the western Kenai Peninsula. See Figure 3.2-1 for generalized land status. Potential impacts include:

- Adverse effects to recreation opportunities and experiences for recreationists participating in hunting, fishing, wildlife viewing, and boating activities
- Displacement of recreationists participating in hunting, fishing, wildlife viewing, boating activities, and snowmachine use
- Adverse effects to recreation experiences for visitors flying over the project area
- Changes to recreational settings.

4.5.1 No Action Alternative

Under the No Action Alternative, the Pebble Project would not be developed. No construction, operation, or closure activities would occur at the mine site or Amakdedori Port, or in the transportation corridor or the natural gas pipeline corridor. Therefore, no future direct or indirect effects on recreation resources would be expected. Exploration activities currently associated with the project may continue; however, helicopter traffic related to these exploration activities may decrease. Although recreational use at the mine site is minimal, such a decrease in helicopter traffic would be noticeable to recreation users of the Newhalen River and the northern shoreline of Iliamna Lake near Iliamna. The decrease in noise could benefit the quality of recreation opportunities in these areas.

4.5.2 Action Alternative 1 – Applicant's Proposed Alternative

The following sections describe anticipated recreational impacts from the project. For economic impacts related to commercial and recreational fishing, see Section 4.6, Commercial and Recreational Fisheries.

4.5.2.1 Mine Site

Recreational use at the mine site is likely minimal, consisting of some sport hunting, sport fishing, and occasional snowmachine use. Flights taking recreationists to various destinations in the region and the state may also pass over the mine site.

Construction, operations, and closure at the mine site may affect sport hunting and fishing on state lands surrounding the project area. Project-related activities, such as blasting and operation of heavy equipment and helicopters, would adversely affect the recreational experience for hunters and anglers by changing the setting from a quiet undisturbed landscape to a developed industrial area in visual and auditory distance of the mine site. The noise generated by these activities would also displace wildlife from the immediate mine site area, and likely from lands immediately surrounding the project area, thus reducing the likelihood of hunting success close to project components. Noise from construction and operations at the Mine Site could cause sleep disruption for hunters and other recreationists up to 3 to 3.5 miles away from the mine site and would be 10 decibels (dBA) higher than the ambient noise level up to 2.3 to 2.4 miles away from the mine site. An increase of 10 dBA would sound, based on human perception, "twice as loud." Therefore, hunters, anglers, or guides who currently use the immediate vicinity would likely stop using these areas and would be displaced to other areas during construction, operations, and closure activities.

AMERICAN OVERSIGHT

Given the low estimated use of the mine site and immediate surrounding area for sport hunting and fishing, project-related noise and activities at the mine site would result in minimal displacement of sport hunting and fishing use, likely to other state lands in the area with similar habitat. However, project-related noise and aircraft traffic that would be noticeable to recreation users on the Newhalen River, Upper Talarik Creek, and the upper north and south forks of the Koktuli River would detract from the quality of the recreation experience, potentially resulting in some displacement of activities to other areas. For further analysis, see Section 4.11, Aesthetics; Section 4.19, Noise; and Section 4.23, Wildlife Values.

Project construction, operations, and closure at the mine site would also physically remove acreage available for recreation. However, given the likely low use of the site for recreation, the loss of 8,129 acres (i.e., size of the mine site footprint) for recreation would likely result in minimal displacement of recreational use to other nearby state lands where similar recreation opportunities and settings exist.

The mine site would be approximately 15 miles from the border of Lake Clark National Park and Preserve, the nearest regional recreation destination and known recreational use area to the mine site. Project-related noise and activities would not be likely to affect recreational settings or activities in the preserve. As stated in Section 4.11, Aesthetics, the mine site would be visible from a small portion of this park unit (from high elevations in southwestern corner near Roadhouse Mountain); however, visibility from this distance would be weak. As described in Section 4.19, Noise, mine site construction and operations noise would not affect sensitive receptors there.

Activities at the mine site would be visible and potentially audible to visitors flying over the area to reach regional recreation destinations such as Lake Clark National Park and Preserve or nearby lodges, fishing at the Upper Talarik Creek, and accessing the North Fork and South Fork Koktuli rivers for recreational river floating purposes. The presence of the mine, a large industrial use in an otherwise generally primitive area, may adversely affect the recreational experience for visitors flying over the mine site by causing a change in the recreational setting. Because of the mine's location relative to nearby lodges and airstrips/airports, only a few flight paths would cross the mine site itself; thus, few visitors flying into the area would be affected by the presence of the project, but the intensity of the impact would be substantial. The recreational experience for visitors on these flights would be adversely affected during project construction, operations, and closure.

Recreation by construction and operations staff would be expected to occur outside of the mine site, because site rules would prohibit hunting, fishing, or gathering on site to minimize impacts on local subsistence resources. Since the mine would operate on a fly-in, fly-out basis, non-resident staff members would not likely contribute to an increase in recreational use, although some may occasionally stay in the area or visit for recreational trips to nearby destinations. As described in Section 4.3, Needs and Welfare of the People—Socioeconomics, operation of the mine is not expected to generate a large increase in the number of full-time residents.

4.5.2.2 Transportation Corridor

Near the transportation corridor there is recreational use of Roadhouse Mountain to the northeast of Iliamna, as well as use of some ATV trails around the Iliamna area for transportation, subsistence, and recreation. There are also recreational use opportunities of extremely high quality in the general transportation corridor area, particularly along the Newhalen River and Upper Talarik Creek by the north access road, and in the Gibraltar River and Gibraltar Lake portions of the south access road corridor, which some local lodges advertise as offering guided fishing, hunting, and sightseeing trip options (Haugen, Bush, and

AMERICAN OVERSIGHT

Rice 2003). Recreational sport hunting and snowmachine use may occur occasionally in these road corridors. At Iliamna Lake, some boating takes place (both motorized and non-motorized), both as an activity in itself and as a means of accessing other recreation opportunities, primarily fishing, which is the main recreation activity at Iliamna Lake. Due to its current inaccessibility and location of nearby high quality recreation opportunities, recreational use of the north and south mine access road corridors, the Kokhanok Airport spur road, and the Iliamna spur road is likely low.

Noise and activities along the transportation during project construction, operations, and closure would affect the quality of sport hunting, fishing, and other recreational activities on state lands and along creeks in and surrounding the project area by generating potential noise and visual impacts. Impacts on sport hunting and fishing opportunities and experiences would be similar to those described above for the mine site.

Project-related noise and activities would not affect recreational settings or activities in Lake Clark National Park and Preserve. As stated in Section 4.11, Aesthetics, the transportation corridor would be visible from a small portion of this this park unit (from high elevations in southwestern corner near Roadhouse Mountain); however, visibility from this distance would be weak, and construction and operational noise would not affect sensitive receptors there.

The road and ferry terminals would also physically remove acreage available for recreation during project construction, operations, and closure. However, given the likely low use of these portions of the corridor for recreation, the loss of 916 acres for recreation would likely result in minimal displacement of recreational use to other state lands in the general area with similar habitat.

As stated in Section 4.3, Needs and Welfare of the People—Socioeconomics, limited access to the roadways and ferry terminal would be available to local residents and businesses only. Therefore, the transportation corridor facilities would not induce recreation or expose previously inaccessible areas to public access and use (PLP 2018-RFI 027).

Activities in the transportation corridor may be visible and potentially audible to visitors flying over the corridor to reach regional recreation destinations such as Lake Clark National Park and Preserve, float trip destinations (on the Mulchatna, Gibraltar, and other rivers), or nearby lodges. The presence of roads, ferry terminals, and ferry in an otherwise generally primitive area may adversely affect the recreation experience for visitors flying over the corridor because of the change in the recreation setting from remote and primitive to more developed and seemingly accessible. Because of the narrow road corridor and vegetation along the roadways and the size of the ferry terminals, the corridor would likely be visible to most visitors only briefly. The recreation experience for visitors on these flights could be adversely affected.

The transportation corridor may be intermittently visible from the far northern edges of Katmai National Park and Preserve at high elevations; however, visibility from this distance would be weak. The transportation corridor would be visible in some portions of the McNeil River State Game Refuge, at higher elevations. See Appendix K4.11 for complete viewshed figures. There is minimal use of the northern borders of these two recreation areas; however, the construction, operations, and closure of the corridor could adversely affect the recreation experience for visitors along the northern border of both recreation areas from the change in recreation setting to a more developed and less remote and primitive area. Given the distance of the transportation corridor from these areas, intermittent visibility, and the likely low level of recreational use of the northern borders of both recreation areas, impacts to recreation experiences would be limited.

AMERICAN OVERSIGHT

The project may also affect incidental wildlife viewing along the transportation corridor; although the primary recreation use in these areas is likely from other activities, such as fishing. Movement and distribution of bears and other terrestrial mammals through the transportation corridor to the McNeil River State Game Refuge and Katmai National Park and Preserve may be disrupted; therefore, construction and operations activities in the south access corridor may have some adverse impacts on wildlife viewing in both of those recreation areas. See Section 4.23, Wildlife Values, for more information on impacts to bear movement and distribution.

Iliamna Lake provides opportunities for wildlife viewing, although there are no known opportunities specific to the proposed ferry terminal locations, ferry route, or pipeline route. Fishing is the primary recreational use of the lake, and extensive opportunities for fishing are available given the lake's size. The project would likely displace wildlife and fish from the locations of the ferry terminals and ferry route during all phases, thus reducing the likelihood of viewing any wildlife or catching fish in and immediately adjacent to the project area. Project noise would also change the recreation setting of the terminal sites from quiet and remote to developed and active. Therefore, all project phases would adversely affect wildlife viewing and fishing experiences and opportunities around the Iliamna Lake portions of the transportation corridor. Other locations around the lake would be available for displaced wildlife viewing and fishing use.

Project-related noise and activities during construction, operations, and closure could adversely affect boating on Iliamna Lake. Construction of the pipeline and ferry terminals and operation of the ferry would likely displace boaters from the area immediately surrounding the equipment, ferries, and facilities. Boaters would likely be displaced to other areas of the lake during construction, operations, and closure to avoid the noise and hazards presented by the equipment and activities. Project-related noise and equipment would particularly affect non-motorized boating use, which is generally a quieter activity that requires more time and effort to circumnavigate in-water obstructions. One ferry trip per day would occur during operations, which would not be expected to contribute considerably to boat traffic on the lake. Although recreational lake boat traffic may slow down and avoid the ferry, alternative open water would be available for boating use during ferry operations. The ferry terminals would be visible from portions of the lake (within about 3 to 5 miles of the terminal) and would change the recreation setting of these areas of the lake to a more developed setting, though there is extensive lake area and shoreline for any boaters that would prefer a less developed setting.

During the winter, there is heavy snowmachine use of the lake. Although most of this use is considered transportation use, there may be some recreational snowmachine use of the lake. Ferry traffic may displace snowmachine use in and adjacent to the ferry route across the lake; however, the remainder of the lake would be available for snowmachine use, although recreationists may need to take longer routes to avoid open water from the ice-breaking ferry. The Kokhanok east ferry terminal variant would result in similar impacts to those described above. The summer-only ferry operations variant would avoid impacts to snowmachine use of the lake. See Section 4.12, Transportation and Navigation, for impacts to non-recreational lake traffic.

4.5.2.3 Amakdedori Port

The Amakdedori Port site is located on state lands designated for habitat use by the Kenai Area Plan (ADNR 2001). The Kenai Area Plan does not discuss recreational use, although there may be recreational boating, overflights, hunting, fishing, and incidental wildlife viewing near the port site. Boat traffic to and from the port would be minimal: up to 27 concentrate vessels and 33 supply barges per year during operations. There would be a larger number of boats during construction; however, Cook Inlet is large and there is a long expanse of shoreline available

AMERICAN OVERSIGHT

nearby for any boaters displaced from the port site. Therefore, activities at Amakdedori Port would result in minimal adverse impacts on recreational boat traffic, and thus, on boating experiences and opportunities around the port site and in Cook Inlet. The visual impacts of the port would affect the recreational setting for boaters.

The project may affect incidental wildlife viewing, hunting, and fishing opportunities at the port site, to the extent that they occur. Noise and activities would displace wildlife and fish from the immediate area, thus adversely affecting wildlife viewing, hunting, and fishing opportunities and experiences by reducing the likelihood of seeing wildlife or catching fish.

In addition, project-related noise and activities during construction, operations, and closure at Amakdedori Port would adversely affect the recreational experiences of visitors within visual and auditory distance of the port site because of the change from a quiet, undeveloped area to a developed site with visible facilities, generators, and in-water facilities. The adverse effects would displace from this area those visitors who prefer a quiet, undisturbed recreation setting, or who participate in recreation opportunities such as wildlife viewing, hunting, and fishing, which typically require a quiet, undisturbed recreation setting.

Overall, because recreational use of the Amakdedori Port site is likely low, project-related wildlife and fish displacement, noise, and activities would result in minimal displacement of wildlife viewing and fishing uses to other nearby shoreline areas.

The port site, including construction, operations, and closure activities, would be visible from the Cook Inlet shoreline area further north of the port, but visibility would decrease with distance and would be weak at 10 miles. It may be visible from some portions of the McNeil River State Game Refuge, as well as from flights over the site to regional recreation destinations such as Katmai National Park and Preserve, or towns farther west such as King Salmon or Naknek. The port site may be visible from the Chenik Creek area of the McNeil River State Game Refuge (this site is within the viewshed of the port) and would affect views from this recreation area. However, the port would not be visible from McNeil Camp (see Appendix K4.11), the main recreation area in the McNeil River State Game Sanctuary, and would therefore not affect views from this recreation site, though vessel traffic may be evident and may intermittently affect the recreation setting at the camp. The port would not be visible from Augustine Island, but may affect views from Cook Inlet shoreline areas surrounding the port. Although recreational use of McNeil River State Game Refuge is limited by permit numbers, and the use of nearby shoreline areas is low, on-water sightseeing and/or wildlife viewing may occur in these locations. Construction, operations, and closure at Amakdedori Port could adversely affect the recreational experience for visitors participating in sightseeing or wildlife viewing opportunities in these surrounding areas, by causing a change in the recreational setting to a more developed and less remote, primitive area. However, given the distance of the port site from these areas, which would reduce the port's visibility, as well as the likely low level of recreation use at these nearby locations, impacts on recreation experiences would be limited.

The project would not result in changes in access to McNeil River State Game Refuge or Sanctuary. Visitors fly in to the sanctuary, where the main recreational use areas are located. McNeil Camp, the main access point to the sanctuary and refuge, is located 12 miles south of the Amakdedori Port site. The port would remove 25 acres from use for recreation opportunities.

4.5.2.4 Natural Gas Pipeline Corridor

Potential impacts on recreation have been described above for the transportation corridor where it shares a footprint with the natural gas pipeline. Existing recreational use along the pipeline alignment in Cook Inlet and on the Kenai Peninsula consists of boating in the inlet and recreational use on the peninsula. Boating in Cook Inlet is both an activity in itself and a means

AMERICAN OVERSIGHT

of accessing other recreation opportunities such as fishing, wildlife viewing, birdwatching, and beachcombing.

Equipment present in Cook Inlet during project construction and closure would be visible and audible to recreational boaters within a certain distance, and would likely temporarily displace any boating and fishing use from the area immediately surrounding the equipment and construction activity; however, alternate open water is available for use by displaced boaters or anglers. Recreation experiences for non-motorized boaters would also be temporarily adversely affected by noise and activity by equipment used during construction or closure, which would affect the recreation setting of the state recreation area for these users. Due to the distance of the land-based recreation facilities at the state recreation area from the compressor station and pipeline, impacts to land-based recreational experiences from noise and construction activities would be minimal.

Noise and activities during project construction and closure may also temporarily adversely affect recreation experiences for visitors to the Stariski State Recreation Site, which is located approximately 1.5 miles north of the proposed compressor station. Visitors participating in camping, picnicking, and hiking may also be adversely affected by the change in the recreation setting caused by the noise and project activities, thus adversely affecting their recreation experiences. Some visitors may be temporarily displaced from the site to other state parks or locally managed recreation sites along the Kenai Peninsula because of the change in recreational setting. There would be no impacts to recreation during operations.

The pipeline would be located south of Augustine Island in Cook Inlet. Although no recreation occurs on the island itself, some sightseeing of the island's volcano and wildlife occurs from the water. Therefore, equipment and noise associated with construction and closure may temporarily adversely affect sightseeing opportunities and experiences along the south side of the island. However, displaced boats would be able to view the island from other locations around the island that were not affected by project equipment and noise.

The pipeline would not be visible above ground and would not remove any acreage from use for recreation opportunities. Recreation experiences for on-water or state park unit visitors may be temporarily affected during pipeline operations because of the presence of boat traffic during pipeline maintenance.

4.5.3 Action Alternative 2 – North Road and Ferry

4.5.3.1 Mine Site

Impacts on recreation from the mine site would be the same as discussed under Action Alternative 1.

4.5.3.2 Transportation Corridor

There are likely opportunities for hunting bear and moose in and adjacent to the transportation corridor. Impacts on sport hunting opportunities and experiences from project-related noise and activities would be similar to those described above for the mine site under Alternative 1.

Similar to the mine site, project-related noise and activities along the Alternative 2 transportation corridor would not likely affect recreational settings or activities in Lake Clark National Park and Preserve. As noted in Section 4.11, Aesthetics, the transportation corridor would not be visible from this park unit except at high elevations on the southern border; and as described in Section 4.19, Noise, transportation corridor construction and operations noise would not affect sensitive receptors there.

AMERICAN OVERSIGHT

Activities in the ferry terminal portions of the transportation corridor would also physically remove 18 acres available for recreation during project construction, operations, and closure. Visitors would likely be displaced to other lands in the general area with similar habitat.

The transportation corridor facilities would not induce recreation or expose previously inaccessible areas to public access and use (PLP 2018-RFI 027) as stated in Section 4.3, Needs and Welfare of the People—Socioeconomics.

Impacts to visitors flying over the corridor would be the same as those described under the transportation corridor for Alternative 1. The north road would be visible from Roadhouse Mountain, where there is some known recreational use. Therefore, the project could alter the setting for recreationists on Roadhouse Mountain by decreasing the naturalness of the area and increasing visible human development of the area.

Northern Iliamna Lake and the surrounding area provide opportunities for wildlife viewing, although there are no known opportunities specific to the proposed ferry terminal locations, ferry route, or road corridor. However, the movement and distribution of bears and other marine and terrestrial mammals throughout the transportation corridor may be disrupted. Thus, construction and operations activities in the transportation corridor may have some adverse impacts on wildlife viewing, including viewing of the Iliamna Lake harbor seals. See Section 4.23, Wildlife Values, for more information on impacts to wildlife movement and distribution.

Impacts to fishing under Alternative 2 would be the same as those described under Alternative 1, but there are more guided fishing operations that could be impacted.

Impacts to boating and snowmachine use on Iliamna Lake would be the same as those discussed under Alternative 1. The summer-only ferry variant would avoid impacts to snowmachine use of the lake. See Section 4.12, Transportation and Navigation, for impacts to non-recreational lake traffic.

The transportation corridor would be located, in part, on the Williamsport-Pile Bay Road and the Pile Bay ferry terminal site would be located near the existing road ending at Pile Bay. Therefore, use of the transportation corridor and Pile Bay ferry terminal site may impact the annual transport of boats from Homer to Bristol Bay. Increased road and boat traffic and noise, as well as project-related activities on the transportation corridor and at the Pile Bay ferry terminal may adversely affect recreational experiences for anglers during their boat transport. However, few of those boats are recreational vessels.

Construction of the natural gas pipeline along the north road would result in similar impacts to those described below for Alternative 3 transportation corridor.

4.5.3.3 Diamond Point Port

Construction, operations, and closure noise and activities may displace wildlife and fish from the Diamond Point Port area, thus adversely affecting wildlife viewing, hunting, and fishing opportunities and experiences by reducing the likelihood of seeing wildlife or catching fish. However, there are already some industrial activities occurring in the area. Project-related noise and activities during construction, operations, and closure at Diamond Point Port would add to the adverse effects to recreational experiences of visitors within visual and auditory distance of the port site and existing activity. The adverse effects would displace from this area those visitors who prefer a quiet, undisturbed recreational setting, or who participate in recreational opportunities such as wildlife viewing, hunting and fishing, which typically require a quiet, undisturbed recreation setting.

AMERICAN OVERSIGHT

Impacts to boating from the Diamond Point Port would be similar to those described under Alternative 1 for the Amakdedori Port, except during the period of time when many commercial and some recreational fishing boats are transported from Willamsport to Pile Bay. During this transport, boats can get backed up in Iliamna Bay and project-related boat traffic, particularly during construction when more boats may be accessing the port site, would have a more noticeable effect on boat traffic during this time. However, Iliamna Bay is large and would provide enough space for all boat traffic.

Because there is a higher likelihood of recreational use of the Diamond Point Port site given the known hunting use of Ursus Cove nearby, commercial fishing use of Iliamna Bay, and known wildlife resources in the general area (ADNR 2001) compared to the Amakdedori Port site, the Diamond Point Port site would likely affect more recreationists than the Amakdedori Port site.

The Alaska Maritime National Wildlife Refuge is the only designated recreation area where the port site, including construction, operations, and closure activities, would be visible. The recreation setting from the affected areas of the refuge would change from views of natural, undeveloped areas with mostly fishing boat traffic, to a view with visible developed facilities and larger vessel traffic.

4.5.3.4 Natural Gas Pipeline

Impacts on recreation from construction of the natural gas pipeline through Cook Inlet (except near Ursus Cove) would be the same as discussed under Action Alternative 1, except that the pipeline would pass north of Augustine Island.

Under Alternative 2, the natural gas pipeline would come into Ursus Cove and then cross land north to reach Cottonwood Bay and the Diamond Point Port site. Ursus Cove is a known bear hunting location (H&H Alaskan Outfitters 2018) and both Ursus Cove and Cottonwood Bay are known commercial fishing locations (ADNR 2001). Both Ursus Cove and Cottonwood Bay may also be used for other hunting activities, recreational fishing, and wildlife viewing.

Noise and activities related to construction of the natural gas pipeline through Ursus Cove and up through Cottonwood Bay to the Diamond Point Port site would likely temporarily displace wildlife and fish from the Cove and Cottonwood Bay surrounding the construction area, thus reducing the likelihood of viewing or hunting any wildlife or catching fish in and immediately adjacent to the project area. Hunters, anglers, or guides who currently use these areas would likely stop using these areas and would be displaced to other areas during construction activities.

Similar to the pipeline under Alternative 1, the pipeline in Alternative 2 would not be visible above ground and would not remove any acreage from use for recreational opportunities. Impacts to boaters would be similar to those described for Alternative 1.

4.5.4 Action Alternative 3 – North Road only

Impacts on recreation would be the same as discussed under Action Alternative 2 for the mine site, Diamond Port, construction of the natural gas pipeline, and portions of the north road that overlap with the transportation corridor of Alternative 2.

Impacts on sport hunting opportunities and experiences from project-related noise and activities would be similar to those described above for the mine site under Alternative 1. Impacts to visitors flying over the corridor would be the same as those described under the transportation corridor for Alternative 1. Impacts to recreational settings or activities in Lake Clark National Park and Preserve would be the same as those described for Alternative 2.

AMERICAN OVERSIGHT

Activities in the transportation corridor would also physically remove 1,085 acres available for recreation during project construction, operations, and closure. Visitors would likely be displaced to other lands in the general area with similar habitat.

The transportation corridor facilities would not induce recreation or expose previously inaccessible areas to public access and use (PLP 2018-RFI 027).

The project may also affect incidental wildlife viewing along the transportation corridor; although most recreational use in the corridor is likely from other activities, such as fishing. Movement and distribution of bears and other terrestrial mammals through the corridor may be disrupted, thus construction and operations activities in the corridor may have some adverse impacts on wildlife viewing. See Section 4.23, Wildlife Values, for more information on impacts to bear movement and distribution.

There are fishing opportunities on the rivers and streams that cross the Alternative 3 transportation corridor, particularly along the Newhalen and Iliamna rivers due to the quality of the fishing on these rivers and the presence of lodges in the Pedro Bay area. Construction noise and activities would likely displace fish at river/stream crossings, which would particularly affect fishing at the road crossing on the Newhalen and Iliamna rivers. Project noise would also change the recreation setting of the road corridor from quiet and remote to developed and active. Therefore, all project phases would adversely affect fishing experiences and opportunities along the transportation corridor. Other portions of the streams crossed by the transportation corridor would be available for anglers that prefer a remote experience away from the roadway.

Impacts to the boat portaging on the Williamsport-Pile Bay Road would be similar to those described for Alternative 2, but would only affect the experience of anglers while transporting boats on the sections of the road that would also carry project traffic.

4.5.5 Summary of Key Impacts

See Table 4.5-1 for a summary of key issues.

Table 4.5-1: Summary of Key Issues for Recreation

Category	Alternative 1 (+ variants)	Alternative 2 (+ variants)	Alternative 3 (+ variants)
Recreation experience	Project-related noise and aircraft traffic may adversely affect recreation experiences for hunters and anglers by changing the recreation setting and displacing wildlife throughout the project area. Adverse effects on recreational experiences for visitors within visual and auditory distance and may displace visitors that prefer a quiet, undisturbed recreation setting	Same as Alternative 1	Same as Alternative 1
Recreation setting	Recreationists flying over project components would be adversely impacted, as the project would be visible	Impacts would be similar to Alternative 1, except it would not affect the McNeil River State Game Refuge	Same as Alternative 2 except there would be no ferry terminals.

AMERICAN OVERSIGHT

Table 4.5-1: Summary of Key Issues for Recreation

Category	Alternative 1 (+ variants)	Alternative 2 (+ variants)	Alternative 3 (+ variants)
	from planes. The recreational setting from Iliamna Lake would be impacted by ferry terminals. Vessel traffic may intermittently affect the recreation setting of McNeil Camp	but may affect views from portions of the Alaska Maritime National Wildlife Refuge and change the recreational setting for visitors to Roadhouse Mountain.	
Recreation activities	There would be adverse effects on wildlife viewing, hunting, and fishing opportunities and experiences by displacing wildlife. Boating and snowmachine use on Iliamna Lake could be displaced or altered.	Same as Alternative 1 except that more guided fishing opportunities would be impacted. There would also be adverse effects to activities in Ursus Cove and Cottonwood Bay during construction.	Same as Alternative 2 except with additional adverse effects on fishing opportunities and experiences at road river/stream crossings, particularly at Newhalen and Iliamna rivers. There would be no adverse effect to recreation on Iliamna Lake.

4.5.6 Cumulative Effects

The reasonably foreseeable future actions identified in Section 4.1 carried forward in this analysis include mining claims; oil and gas development within Cook Inlet; road improvement projects; and continuance of recreation activities in the greater regional area, as summarized below:

- Pebble Project buildout- develop 55% of the resource over 78 year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Johnson Tract*
- Copper Joe*
- Diamond Point Rock Quarry
- Alaska Stand Alone Pipeline Project
- Alaska LNG
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure and Energy Project
- National Parks and Preserves, Wildlife Refuges, State of Alaska Special Management Areas, Alaska Native Corporation Lands

*Indicates exploration activities only.

Reasonably foreseeable mineral development could contribute cumulatively to reducing the undeveloped nature of the region, and thereby reduce opportunities available for recreation activities like hunting, fishing, and wildlife viewing in remote areas. There would be additive effects to recreation experiences for visitors flying over the region, as the landscape as a whole is more visible from a higher elevation, and all development would be more noticeable.

AMERICAN OVERSIGHT

The Diamond Point Rock Quarry could contribute cumulatively to impacts to recreational opportunities and experiences, boat traffic, and changes to the recreation setting in Iliamna Bay. Oil and gas projects in Cook Inlet could contribute cumulatively to temporary adverse impacts to boating, fishing, and boat traffic in the inlet if construction periods overlapped. Transportation projects could contribute cumulatively to changes in the recreational setting of the region and decrease opportunities for recreation in remote areas.

The project would contribute to cumulative impacts to recreation and there would be a higher contribution to cumulative impacts for Alternatives 2 and 3 from activities in Iliamna Bay.

K3.16 SURFACE WATER HYDROLOGY

This appendix contains supplemental technical information on the following topics related to baseline surface water hydrology discussed in Section 3.16:

- Meteorological inputs to water balance models (operations and closure)
- Water balance calibration

K3.16.1 Meteorological Inputs to Water Balance Models

The surface water (watershed) balance model was initially calibrated using continuous streamflow records collected from 2004 to 2008 at 15 streamflow gaging stations (Schlumberger 2011a). The model was also used to validate site meteoric data and precipitation variability across the site. A meteorological data collection program was designed and implemented to provide data representative of the mine site analysis area. Meteorological data have been collected from eight monitoring stations (Figure K3.16-1) (SLR 2013). The stations are labeled Pebble 1, Pebble 3, Pebble 4, Pebble 5, Pebble 5A, Pebble 6, Pebble 8 in the general mine site analysis area, and the Iliamna Air Quality station in Iliamna, Alaska (Iliamna Airport). The closest long-term meteorological records are from Iliamna Airport.

To evaluate surface water and groundwater interaction in the Pebble study area, a month-to-month water balance approach was selected, which included a semi-distributed spreadsheet method (Schlumberger 2011a). The selected method allowed for adjacent sub-catchments (smaller watersheds or basis) to be chained together, including the interaction of surface water and groundwater components.

The development of the mine site water balance model included the following components (Schlumberger 2011a):

- The watersheds of the NFK and SFK rivers and the UTC were divided into sub-catchments; each sub-catchment is numbered and associated with a gaging station (Figure K3.16-2).
- Inputs to each sub-catchment included precipitation and inflow from up-gradient catchments.
- Precipitation distribution was accounted for in runoff, recharge, evapotranspiration, and sublimation.
- Groundwater recharge (combination of precipitation recharge and stream leakage) was accumulated in groundwater storage.
- Groundwater was discharged in and from each sub-catchment in proportion to the amount of groundwater in storage. A portion of this groundwater was transmitted down-gradient to the next sub-catchment according to Darcy's Law. The remainder of the groundwater was discharged in the sub-catchment as surface water.
- Snowmelt was accounted for when temperatures rose enough to melt accumulated snow and generate runoff.

AMERICAN OVERSIGHT

The input parameters to the water balance model were adjusted until modeled streamflows closely resembled measured streamflows. The following inputs were used to develop the water balance model (Schlumberger 2011a).

K3.16.1.1 Temperature

Monthly mean temperature data from the Iliamna Airport were used for developing a long-term dataset for the mine site water balance model. Temperature data selected for this purpose was from the period of record from 1942 to 2017. Data gaps in the temperature data were addressed using regional regression analysis to estimate missing data from the long-term dataset (Knight Piésold 2018m).

Scaling factors were then applied to transform the temperature record from Iliamna Airport into synthetic (estimated) series at the Pebble 1 station location. Scaling factors represent fundamental physical relationships and processes, which have been quantified by empirical calibration methods (Knight Piésold 2018a). The adiabatic[1] relationship between topographic elevation and air temperature is an example of a scaling factor considered for temperature. The standard adiabatic lapse rate relationship between elevation and temperature is -3.6 °F per 1,000 feet of elevation. The observed temperature difference between Iliamna Airport and Pebble 1 station is -4.7 °F, which equates to a lapse rate of -3.4 °F per 1,000 feet of elevation. Therefore, the observed temperature difference of -4.7 °F was adopted and applied to each month of the Iliamna Airport data to create the synthetic temperature dataset for the mine site at Pebble 1 station.

K3.16.1.2 Precipitation

Monthly precipitation data from Iliamna Airport for the same period of record (1942 to 2017) were used for developing a long-term precipitation dataset for the mine site water balance model. Data gaps in the precipitation data set were addressed using regional regression analysis to estimate missing data from the long-term dataset (Knight Piésold 2018m).

Scaling factors were then applied to transform the precipitation record from Iliamna Airport into synthetic (estimated) series at the Pebble 1 station location. Scaling factors were applied to the Iliamna Airport precipitation dataset to account for location and elevation. The calibrated scaling factors are shown in Table K3.16-1, and were based on the following:

- Group A: Factors that represent differences in measured precipitation between the Iliamna Airport and Pebble 1 meteorology stations; values for these factors were calibrated by comparison of concurrent measured records at the two stations for the period 2005 to 2009.
- Group B: Factors that represent differences between measured and estimated actual precipitation at the Pebble 1 station; values for these factors were calibrated by comparison of measured meteorology parameters at Pebble 1 station and measured streamflow at downstream gaging stations for the period 2005 to 2009.
- A combination of Group A and Group B factors were applied to the Iliamna precipitation data that were used as input to the Pebble watershed module, in order to achieve a good match between the flows measured in the field at numerous locations and the flows predicted by the watershed module for those same locations.

[1] The adiabatic relationship is the process of heat being reduced in the air with change in air pressure that occurs at increased elevations. Air expands and cools as it rises – thus resulting in cooler air at higher elevation.

AMERICAN OVERSIGHT

The combined scaling factors presented in Table K3.16-1 applied to each applicable monthly total precipitation value in the Iliamna Airport precipitation record to generate the synthetic monthly precipitation series for the Pebble 1 station location (Knight Piésold 2018m).

K3.16.1.3 Snowmelt

Annual maximum snow water-equivalent (SWE) values surveyed at the project snow courses and regional snow courses during the period of 2004 through 2008 are presented in Table K3.16-2 (Knight Piésold 2018g). Snow course locations are depicted on Figure K3.16-2.

K3.16.1.4 Other Meteorological Data

Other meteorological data collected include temperature, radiation, wind speed, relative humidity, evaporation, and sublimation. General site meteorology is discussed in Chapter 3.1, Introduction.

Table K3.16-2: Annual Maximum Snow Water Equivalent – Project and Regional Snow Courses

Snow Course	Elevation (feet)	Annual Maximum Snow Water Equivalent (inches)						
		2004	2005	2006	2007	2008	Average	Long-Term Average
Project Snow Courses								
Pebble Snow Course 1	2,000	10.5	15.5	9.7	5.8	19.4	12.2	12.5
Pebble Snow Course 1A	2,000	8.2	13.8	7.5	5.3	16.7	10.3	10.6
Pebble Snow Course 2	1,200	9.8	12.0	8.1	6.3	15.6	10.4	10.6
Regional Snow Courses								
Brooks Camp	150	1.8	-	1.5	-	0.8	1.4	2.4
Fishtrap Lake	1,800	8.6	11.7	-	4.9	9.5	8.7	9.4
Port Alsworth	270	5.1	2.5	2.2	1.9	-	2.9	3.4
Telaquana Lake	1,550	4.4	6.4	4.5	1.4	5.8	4.5	4.1
Three Forks	900	8.2	-	2.5	-	3.0	4.6	3.0
Upper Twin Lakes	2,000	6.5	6.8	4.0	4.0	7.2	6.1	6.1

Source: Knight Piésold 2018g, Table 5.1.

The annual maximum SWE was similar at both Snow Course 1A and Snow Course 2. The annual maximum SWE averaged around 10 inches at these two snow courses, and ranged from around 6 inches in 2007 (lowest snowpack were Fishtrap Lake, Telaquana Lake, and Upper Twin Lakes. These sites had mean annual maximum SWE values of around 5 to 9 inches during the 2004 to 2008 period, with the lowest values in 2007 and highest values in 2005 and 2008, indicating a general coherence in snowpack patterns throughout the region in this elevation range. The estimated long-term mean for each of the three project snow courses is an average of three estimates generated by the relationships between that project snow course and each of the three regional snow courses (Knight Piésold 2018g).

AMERICAN OVERSIGHT

K3.16.2 Water Balance Calibration

The watershed model was calibrated using meteorological and streamflow data for the period 2005 to 2009, and then was used to generate long-term synthetic series of monthly streamflow for each gaging station for the 1942 to 2017 period of record (Knight Piésold 2018g). Table K3.16-3 provides data to compare measured discharge and watershed module discharge estimates for the following periods of record:

- Stream Gage Period of Record: 2004 to 2015
- Recent climatic period: 1977 to 2017
- Full period of synthetic series: 1942 to 2017

Source: Knight Piésold 2018g, Table 6.5. Note: Shaded cells indicate that no data were collected during these periods.

Watershed module estimated discharges are generally similar to the stream gage values for the period of record 2004 to 2015, with average ratios ranging between 1.00 and 1.05. Watershed module discharge estimates for the longer-term periods are similar as well, with average ratios between the watershed module discharges and the gage records ranging from 1.02 to 1.08 (Knight Piésold 2018g).

The relationship between watershed module estimated discharge and measured streamflow for gaging stations NK100B, SK100G, and UT100D is shown in Figure K3.16-3, Figure K3.16-4, and Figure K3.16-5, respectively. These gaging stations were selected for presentation because of their proximity to the mine site.

3.16 SURFACE WATER HYDROLOGY

This section describes existing surface water conditions in the project area including the mine site, transportation corridor, port, and pipeline corridor. The area includes numerous streams, lakes (including Iliamna Lake), marine water (Cook Inlet), and wetlands (see Section 3.22, Wetlands/Special Aquatic Sites). The discussion below addresses potentially affected waterbodies, baseline water balance models, flood hazards, floodplain values, tides, and water use (both surface and groundwater). Drainage basins (synonymous in this document with catchment, watershed, sub-catchments), flow patterns, circulation, discharge/recharge, and interaction with groundwater are described. Section 3.17, Hydrogeology, provides more information regarding groundwater conditions. Section 3.18, Water and Sediment Quality, addresses quality of surface water, groundwater, and sediment/substrate in waterbodies.

Baseline surface water conditions have been characterized by studies conducted from 2004 through 2012 (Knight Piésold et al. 2011, 2015b). These studies also considered previous studies and data collected by the US Geological Survey (USGS) and US Department of Agriculture, Natural Resources Conservation Service. In particular, Knight Piésold et al. 2011 provides an overview of regional hydrology in the Bristol Bay drainages and hydrologic context for the mine study area and transportation and pipeline corridors. The baseline studies are summarized in this section and more details regarding meteorological inputs to water balance models and water balance calibration are provided in Appendix K3.16.

The combined Bristol Bay drainage area is approximately 41,900 square miles – an area bound by the Aleutian Range to the east and southeast, the Kuskokwim Mountains to the west, and the Kuskokwim River watershed boundary to the north (Figure 3.16-1). The largest rivers draining into Bristol Bay are the Nushagak and Kvichak rivers. These two rivers comprise 49 percent of the Bristol Bay drainages. The Koktuli River forms at the confluence of the North Fork Koktuli (NFK) and South Fork Koktuli (SFK) rivers, approximately 17 miles west of the mine site. The Koktuli River flows into the Mulchatna River, a tributary of the Nushagak River. The Pebble deposit straddles two regional watersheds, but nearly all the project mine site footprint is in the Nushagak River watershed (12,700 square miles). Most of the transportation and pipeline corridors from the mine site toward the east are within the Kvichak River watershed to the Cook Inlet watershed boundary defined by the Alaska Range. The remaining onshore transportation and pipeline corridors and port sites are in the Cook Inlet watershed.

Most of the mine site is hydrologically connected to Bristol Bay via the NFK and SFK rivers that join the Mulchatna River west of the mine site. The Mulchatna River flows to the confluence with the Nushagak River about 65 miles from its mouth at Bristol Bay.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

3.16.1 Alternative 1 – Applicant's Proposed Alternative

3.16.1.1 Mine Site

The mine site is within the upper portions of the NFK, SFK, and Upper Talarik Creek (UTC) watersheds (Figure 3.16-2 and Figure 3.16-3). Figure 3.16-4 and Figure 3.16-5 depict stream gaging stations in the mine study area and in the vicinity of the mine site, respectively. The majority of the mine site facilities would be in the NFK watershed. The open pit, as well as the overburden stockpile, open pit water management pond (WMP), and water treatment discharge – south, would be in the SFK watershed. Only the water treatment plant (WTP #1) discharge – east and a short portion of the mine access road would be in the UTC watershed under Alternative 1.

Drainage Basins

Drainage basin characteristics of the NFK and SFK rivers and the UTC are described in this section, and general features are listed in Table 3.16-1.

The topography of the drainage basins listed in Table 3.16-1 consists of low rolling hills and wide shallow valleys (Knight Piésold 2011). Section 3.13, Geology, addresses geologic units and geologic history and processes of the region and project area.

General characteristics common to the drainage basins listed in Table 3.16-1 include:

- Main streams occupy valley bottoms 0.5 to 2 miles wide.
- Tributaries to the main streams are incised into the hilly terrain and typically occupy narrow valleys with bottom widths of only 0.1 to 0.2 mile.
- The three main stream channels in the project area are highly sinuous and flow within floodplains containing wetlands and oxbow lakes.
- The upper parts of the three main basins are represented by flat, poorly drained terrain.
- Areas of glacial drift (sediment of glacial origin) deposits occur along lower hillslopes and near the headwaters of the main stream valleys, characterized by undulating terrain and numerous kettle lakes.

Table 3.16-1: Mine Site Area Drainage Basins

Drainage Basin	Drainage Area (mi^2)	Channel Length (mi)	Basin Relief (ft)	Mean Basin Elevation (ft amsl)
NFK River	113	36	580 to 3,074	1,300
SFK River	107	40	580 to 2,760	1,150
UTC	135	39	46 to 3,074	1,000

amsl = above mean sea level

mi2 = square miles

North Fork Koktuli River

The NFK River watershed extends northeast from the confluence with SFK River to Groundhog Mountain, approximately 7 miles northeast of the mine site (Figure 3.16-2). The NFK River drainage area topography is relatively gentle, with elevations ranging from around 600 feet amsl near the confluence with SFK River to roughly 3,000 ft amsl at Groundhog Mountain. Lakes and small ponds are common in the upper portions of the NFK watershed, including Big Wiggly Lake, Lilly Lake, and Black Lake. Fewer lakes and ponds exist in the middle and lower portions of the watershed.

South Fork Koktuli River

SFK River extends east and north from the NFK River confluence (Figure 3.16-2). The watershed topography is relatively gentle, with elevations ranging from approximately 600 feet amsl near the NFK/SFK confluence to 2,760 feet amsl on Kaskanak Mountain, a high point along the NFK/SFK watershed boundary. Lakes and small ponds are common in the upper and lower portions of the watershed, and are less common in the central portion. Frying Pan Lake, approximately 1.5 miles south of the open pit, is a shallow residual waterbody in the upper SFK River valley (Knight Piésold 2011). Frying Pan Lake is the largest lake in the project area, approximately 1 mile long and 0.5 mile wide, with a relatively uniform depth of approximately 3 feet.

Upper Talarik Creek

The UTC watershed extends north from the creek outlet at Iliamna Lake to the southern end of Groundhog Mountain (Figure 3.16-2). UTC flows south from its headwaters to Iliamna Lake, roughly 10 miles west of the Newhalen River outlet. The Iliamna Lake outlet is the Kvichak River, which flows into Bristol Bay. The watershed topography is relatively gentle, with elevations ranging from approximately 46 feet amsl at Iliamna Lake to 3,074 feet amsl on Groundhog Mountain. Lakes and small ponds exist throughout the watershed, in relatively flat, poorly drained terrain.

Streamflow

Streamflow in the Bristol Bay region is generated primarily from spring snowmelt runoff and runoff from autumn rain events. The mine site watersheds are undisturbed; therefore, baseline streamflow presented in this section is representative of existing natural conditions. The annual pattern of streamflow in the mine site watersheds is characterized by high flows in spring due to snowmelt; lower flows occur during early to mid-summer; and a high flow period during late summer and fall due to rain events (Knight Piésold et al. 2011). Baseline surface water quality conditions at the mine site are presented in Section 3.18, Water and Sediment Quality.

Groundwater/surface water interaction in the mine site watersheds is controlled by glacial and fluvial deposits of varying thicknesses that occur over most of the project area below elevations of approximately 1,400 feet amsl (see Section 3.13, Geology). Section 3.17, Hydrogeology, describes interaction, importance, and function of these deposits related to surface water runoff, groundwater storage, and exchange between surface water and groundwater.

Gaging Stations

Since 2004, streamflow monitoring has been conducted at gaging stations on the NFK and SFK rivers and the UTC, as well as tributary streams in each watershed. Figure 3.16-2 depicts all gaging station locations in the three watersheds and Figure 3.16-3 provides a focused view of gaging stations with regard to the mine site. Three gaging stations are operated by the USGS

AMERICAN OVERSIGHT

(NK100A, SK100B and UT100B), and the remaining 25 are operated by Pebble Limited Partnership (PLP). Table 3.16-2 lists stream gaging stations, organized by watershed, that collect continuous flow data during the open water season and the number of years in which data were collected at each station. Table 3.16-3 presents a summary of the early spring, low-flow discharge measurements collected at both continuous and non-continuous data collection sites in each watershed. The following summaries provide a description of streamflow at gaging stations closest to the mine site. The stations selected for discussion represent streamflow in the upper portion or at the mouth of each watershed near the mine site.

North Fork Koktuli River

NK 100C, Main Stem: There are six gaging stations along the main stem of the NFK River (Figure 3.16-4). Station NK100C is in the upper reaches of the NFK River, approximately 20 miles upstream of the SFK River confluence. NK100C is the gaging station closest to the mine site on the main stem of the NFK River, roughly 3.5 miles west of the NFK/SFK rivers watershed divide. At NK100C, the river drains an area of approximately 24 square miles, including a large complex of lakes and wetlands, and flows through a narrow valley cut through glacial outwash and drift deposits (see Section 3.13, Geology, for explanation of outwash and drift). The channel above NK100C is dominated by riffles and runs, and the streambed is composed primarily of coarse gravel. Flows at NK100C are buffered by upstream lakes and wetland storage (Knight Piésold et al. 2011). Based on 8 years of record, the long-term average annual discharge at NK100C is 48 cubic feet per second (cfs) (Table 3.16-4). The lowest average annual discharge recorded was 37 cfs and the highest average annual discharge recorded was 63 cfs. Streamflow measurements were recorded at NK100C during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge measurements ranged from 8 to 22 cfs during the 8-year period of record. Spring and fall instantaneous peak discharge measurements were obtained over a 5-year period (Table 3.16-5). The lowest instantaneous peak discharge recorded was 117 cubic feet per second during the fall of 2011. The highest annual instantaneous peak discharge recorded was 586 cubic feet per second, during the spring of 2009.

NK119A, Tributary: Station NK119A is in the western tributary of the NFK River (the tributary is designated in baseline studies as NK 1.190). The bulk tailings storage facility (TSF) would be in the NK 1.190 catchment (Figure 3.16-3). This tributary is a relatively steep, upland stream, with headwaters along the NFK/SFK rivers watershed divide. The drainage area above NK119A is approximately 8 square miles. The channel above NK119A is dominated by short rapids with irregular scour pools; the streambed is composed primarily of coarse gravels, some cobbles, and numerous boulders (Knight Piésold et al. 2011). Based on 8 years of record, the long-term average annual discharge at NK119A is 24 cfs (Table 3.16-4). The lowest average annual discharge recorded was 15 cfs and the highest average annual discharge recorded was 36 cfs. Streamflow measurements were recorded at NK119A during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge measurements ranged from 2 to 4 cfs during the 8-year period of record. Spring and fall instantaneous peak discharge measurements were obtained over an 8-year period (Table 3.16-5). The lowest instantaneous peak discharge recorded was 110 cfs, during the spring of 2007. The highest instantaneous peak discharge recorded was 690 cfs, during the fall of 2004.

Notes:

1 Gaging stations listed include main stem and tributaries.

2 Calendar years that stream stage data were collected.

3 Complete water years of record (measured) – Refers to the number of years that stream stage data were collected for at least 3 months and used to compute discharge.

AMERICAN OVERSIGHT

4 Station NK100A1 reported drainage area: Drainage area on Knight Piésold (2013) Table 7-2 is 85mi2; on Table 7-4, drainage area is 81.97 mi2

5 Station NK100B1 and NK100C1 were installed in 2011 for the purpose of verifying measured flows at NK100B and NK100C.

mi^2 = square miles

Source: Knight Piésold 2015b, Table 7-2

Note: Shaded rows are stations that represent streamflow in the upper portion or at the mouth of each watershed near the mine site and subject of more detailed discussion in the narrative.

South Fork Koktuli River

SF 100F, Main Stem: There are six gaging stations along the main stem of the SFK River (Figure 3.16-4). Station SK100F is in the upper reaches of SFK River, approximately 29 miles upstream of the NFK River confluence. SK100F is roughly 2.5 miles south of the mine site, just downstream from the outlet of Frying Pan Lake, and drains an area of approximately 12 square miles. The river at SK100F flows in a narrow valley between hillslopes of moraine deposits and weathered bedrock. The channel in this reach is characterized by riffles and runs, and a large pool. The streambed is composed primarily of very coarse angular gravels and some cobbles. Based on 8 years of record, the long-term average annual discharge at SK100F is 30 cfs (Table 3.16-4). The lowest average annual discharge recorded was 24 cfs and the highest average annual discharge recorded was 37 cfs. Streamflow measurements were recorded at SK100F during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge measurements ranged from 1 to 8 cfs during the 7-year period of record. Spring and fall instantaneous peak discharge measurements were obtained over a 3- and 4-year period, respectively (Table 3.16-5). The lowest instantaneous peak discharge recorded was 54 cfs, during the spring of 2007. The highest instantaneous peak discharge recorded was 249 cfs, during the spring of 2006.

SK 119A, Tributary: Station SK119A is in an SFK River tributary (designated in baseline studies as SK 1.190), approximately 3.5 miles south of Kaskanak Mountain, a high point along the NFK/SFK rivers watershed divide. SK 1.190 enters SFK River approximately 21 miles upstream of the NFK River confluence. The tributary at the gaging station drains approximately 11 square miles near the outlet of a relatively steep, narrow tributary valley. At the gaging station, the creek flows within a narrow alluvial plain bounded by low terraces and colluvial hillslopes. The channel in this reach is characterized by riffles and runs, and the streambed is composed primarily of coarse gravels and cobbles. Based on 8 years of record, the long-term average annual discharge at SK119A is 35 cfs (Table 3.16-4). The lowest average annual discharge recorded was 27 cfs and the highest average annual discharge recorded was 51 cfs. Streamflow measurements were recorded at SK119A during March and early April to characterize low flow conditions (Table 3.16-3). Low-flow discharge measurements ranged from 2 to 8 cfs during the 6-year period of record. Spring and fall instantaneous peak discharge measurements were obtained over a 6- and 9-year period, respectively. (Table 3.16-5). The lowest instantaneous peak discharge recorded was 158 cfs, during the spring of 2007. The highest instantaneous peak discharge recorded was 606 cfs, during the fall of 2005.

Upper Talarik Creek

UT 100D, main stem: There are nine gaging stations along the main stem of UTC (Figure 3.16-4). Station UT100D is in the upper reaches of UTC, approximately 26 miles upstream of the mouth at Iliamna Lake, and roughly 2.5 miles east of the mine site. The drainage area above the station is approximately 12 square miles, consisting of mostly low-gradient wetlands and some adjacent upland, including the general deposit location. UTC meanders through floodplains and associated low terraces within a glacio-lacustrine (former glacial lake) basin. The channel in this

AMERICAN OVERSIGHT

reach is characterized by riffles and pools, and the streambed is composed primarily of medium gravel. Based on 8 years of record, the long-term average annual discharge at UT100D is 28 cfs (Table 3.16-4). The lowest average annual discharge recorded was 24 cfs and the highest average annual discharge recorded was 32 cfs. Streamflow measurements were recorded at UT100D during March and early April to characterize low-flow conditions (Table 3.16-3). Low-flow discharge ranged from 6 to 11 cfs during the 8-year period of record. Spring and fall instantaneous peak discharge measurements were obtained at UT100D over a 1- and 8-year period, respectively (Table 3.16-5). The lowest instantaneous peak discharge recorded was 103 cfs, during the fall of 2009. The maximum instantaneous peak discharge recorded was 272 cfs, during the fall of 2007.

AMERICAN OVERSIGHT

Meteorological Inputs to Water Balance Modeling

The mine site analysis area is in a transitional climatic zone with strong maritime influence. Summer temperatures are moderated by the open waters of Iliamna Lake, the Bering Sea, and Cook Inlet. Winter temperatures are more continental because of the presence of ice on Iliamna Lake and sea ice in Bristol Bay during the coldest months. Winter weather systems typically travel into the region from the Bering Sea to the west, from along the Aleutian Island chain to the southwest, and from the Gulf of Alaska to the south (Hoefler 2010).

A mine site water management plan is essential to understanding fresh water and mine process water requirements in relation to natural runoff timing and pit dewatering requirements, to design water management and treatment systems, and to minimize the potential for an uncontrolled discharge of untreated contact or tailings water. As part of the water management plan, water balance models were developed for the mine site for operations and closure. The models are used to understand the movement of surface water and groundwater in the mine site analysis area (Schlumberger 2011; Knight Piésold 2018a, 2018d) and to predict conditions under various circumstances (e.g., seasonal precipitation). The groundwater balance model is discussed in Section 3.17, Hydrogeology. Appendix K3.16 provides more detail regarding meteorological input and calibration of the water balance models.

Flood Hazards

The NFK, SFK, and UTC watersheds are essentially undeveloped, therefore there are no pre-mine flood hazards, because the floodplains are in their natural state and serve to naturally moderate floods.

Floodplain Values

The stream channels in the NKF, SFK, and UTC watersheds are highly sinuous and flow within floodplains containing wetlands and oxbow lakes. Existing floodplain values are related to biologic and water resources. Biological resources related to wetlands in the mine study area are described in Section 3.22, Wetlands/Special Aquatic Sites. Water resources include those resources and functions of floodplains related to natural moderation of floods, water quality maintenance, and groundwater recharge.

Flood Magnitude and Frequency

Peak flow estimates for the mine site study area are listed in Table 3.16-6. USGS regional regression equations were used for estimating instantaneous peak flows for the mine site for return periods up to 10 years (Curran et al., 2016). Weighted peak flow estimates for USGS gaging stations were used as the basis for estimating peak flows with return periods greater than 10 years throughout the mine study area drainages. Index flood ratios were generated relating the weighted peak flow estimates for return periods of 25 years to 200 years to the 10-year peak flow value for the corresponding gaging station (Knight Piésold 2018b).

Table 3.16-6 Return Period Peak Flows in Mine Study Area

	UT100D	200	242	265	292	311	330	349

Notes:

QT refers to peak streamflow with average recurrence interval of "T" years.

Peak flows for return periods of 2 to 10 years were estimated based on the flood frequency analysis of local gaging records.

Peak flows for return periods of greater than 10 years were estimated based on the ratios of QT/Q10 from the regional equations.

cfs = cubic feet per second

3.16.1.2 Transportation Corridor

This section describes baseline surface water data across the transportation corridor in Alternative 1. The ferry route is addressed under natural gas pipeline corridor.

The road corridor spans multiple watersheds, from its starting point at the southeastern edge of the Nushagak watershed in the mine site, across the greater Kvichak watershed, including Iliamna Lake, to the Aleutian Range watershed divide, and finally entering the greater Cook Inlet watershed east of the divide.

The surface water hydrology in the watersheds surrounding the mine site is well characterized, as described above (e.g., HDR 2011; Knight Piésold 2011 and 2015b; SLR 2011). The northernmost segment of the transportation corridor (the northern half of the mine access road) is in the well-studied UTC watershed, for which abundant data are available. Limited data are available for the southern segment of the mine access road from the south ferry terminal to Amakdedori. No known surface water investigations have been conducted along the south access road.

Climatic factors influencing surface water across the corridor are the same or similar to those described above for the mine site; there are no glaciers in the road corridor watersheds. There is no known permafrost in the transportation corridor; however, permafrost has been observed in the general area (Detterman and Reed 1973) and may be present at depth in isolated zones, such as on north-facing slopes. Section 3.14, Soils, addresses the occurrence of permafrost.

AMERICAN OVERSIGHT

Drainage Basins

Mine Access Road

The maximum elevation of the transportation corridor is approximately 1,700 feet amsl among gently rounded hills and wide valleys. The northern half of the mine access road would roughly parallel the UTC watershed, using culverts to cross a number of small tributaries and a bridge to cross the main channel of the UTC.

Iliamna Spur Road

The Iliamna spur road corridor heads eastward out of the UTC drainage and enters the Newhalen River watershed. The Newhalen River is one of the larger rivers in the area, with a drainage area of 3,451 square miles at its mouth (Knight Piésold et al. 2011a). It drains glaciated mountainous headwaters, is the main outlet for the large glacial Lake Clark, and has a high suspended sediment load. The Newhalen River flows southward through poorly drained lowland/wetland areas with abundant kettle ponds. Numerous small tributaries feed into the river before it reaches its outlet into Iliamna Lake, 3 miles southwest of the village of Iliamna. A bridge would be constructed across the Newhalen River along the Iliamna spur road.

Just south of the intersection with the Iliamna spur road, the transportation corridor turns southwest, paralleling an unnamed drainage that flows southward and drains into Iliamna Lake just south of the north ferry terminal. The corridor drops in elevation southward as the terrain flattens out over glacial and fluvial deposits, with abundant kettle ponds and wetlands (Wahrhaftig 1965, 1994). The mine access road terminates at the north ferry terminal at an elevation of approximately 50 feet amsl.

South Access Road

The northern two-thirds of the south access road and the Kokhanok spur road are in the Kvichak watershed, west of the Aleutian Range divide. In the Aleutian Range physiographic province, the terrain consists of low, rounded ridges of exposed bedrock, and valley bottoms dominated by wetlands, streams, and abundant kettle ponds (Wahrhaftig 1965, 1994). Bedrock exposures are common, with less-abundant surficial deposits of ground moraine and alluvium (Detterman and Reed 1973; AECOM 2018h). Elevations range from 50 feet amsl at the shores of Iliamna Lake, to about 800 feet amsl near the divide. Streams flow north in sinuous patterns through the varied upland terrain, eventually meandering downgradient into Iliamna Lake.

This segment of the road would require four bridges, including the Gibraltar River bridge near Iliamna Lake, Bridge Lake bridge, and two unnamed creek bridges just west of the divide. The corridor passes within a mile of Gibraltar Lake, a prominent elongate lake approximately 7 miles long by 0.5 mile wide, of unknown depth. Gibraltar Lake is fed by small streams on the southern and western sides, including Dream Creek and Emerald Creek, and likely groundwater as well; the lake drains north into the Gibraltar River and then into Iliamna Lake.

East of the Aleutian Range divide, the final segment of the transportation corridor drops into the Tuxedni-Kamishak Bay watershed of the greater Cook Inlet watershed. The terrain east of the divide is rocky and undulating, with elevations close to 800 feet amsl at the divide, dropping down to more gentle slopes and wetlands nearing the coast at sea level. There are fewer kettle ponds east of the divide. Streams flow in sinuous patterns through the varied terrain, eventually draining south and east into Kamishak Bay. The road corridor here would include two bridges, including Bridge Lake bridge just east of the divide, and an Unnamed Creek bridge close to the port. The terminus of the road corridor is east of Amakdedori Creek at the Amakdedori port site.

AMERICAN OVERSIGHT

Amakdedori Creek is a meandering stream fed by a number of small lakes and tributaries, which drains east into Kamishak Bay.

Streamflow

Mine Access Road

The mine access road would cross multiple small tributaries in the UTC watershed; using culverts to cross small tributaries and a bridge to cross the main channel of the UTC. The UTC has a drainage area of 135.2 square miles, and a mean annual discharge of 225 cfs (Knight Piésold 2011). Flow in the UTC is generated by snowmelt, rainfall, and groundwater, and is fully described under the mine site discussion above. Smaller drainages and tributaries of the Kvichak watershed that drain into Iliamna Lake are also fed by snowmelt and rainfall, and likely have significant groundwater interaction.

Iliamna Spur Road

The Iliamna spur road would include a substantial bridge over the Newhalen River, which has a drainage area of 3,451 square miles at its mouth and is one of the largest rivers in the area (Knight Piésold et al. 2011a). A USGS gaging station was installed at the Newhalen River (ID 15300000) close to the village of Iliamna in 1951, and was active through 1986. PLP installed two new gaging stations in 2008: one at the same USGS site (NH100-APC3), and the other 8 miles downstream (NH100-APC2). Flow in the Newhalen River increases substantially in spring and early summer as a result of snow and glacial melt. Snowmelt runoff is stored in several large lakes upstream of the gaging station (ID 15300000), resulting in delayed peak flows during July and August, which are the highest annual flows. As with other local drainages, flow declines in late summer and autumn, with the lowest flows occurring in late winter (Knight Piésold et al. 2011). The Newhalen River has a mean annual unit runoff of 2.6 cubic feet per square mile (or approximately 35 inches of annual basin runoff depth) (Knight Piésold et al. 2011a).

South Access Road

Drainages in the project area south of Iliamna Lake have not been the focus of any known hydrologic studies to date. Streams and tributaries along the South Access Road corridor are likely fed by spring snowmelt, rainfall runoff, and groundwater. Groundwater contributes to streamflow east of the divide, in the Tuxedni-Kamishak watershed, particularly in the winter months (Glass 1999). There is no known stream gage data in proximity to the south access road corridor. The closest known stream gage data are from Williams Creek and an unnamed creek in locally named Y valley, about 30 miles northeast. Data from these streams are limited, and the watersheds are more mountainous and likely hydrologically different from the road corridor area.

Flood Magnitude and Frequency

The mine access road would require a bridge across the UTC east of the mine site. At the proposed bridge site, the UTC meanders within a floodplain containing wetlands, oxbow lakes, and associated low terraces. The Iliamna spur road would require construction of the Newhalen River bridge. Upstream of the bridge site, the Newhalen River flows within a wide floodplain containing wetlands, which narrows at the bridge site.

Along the south access road, the Gibraltar River meanders within a floodplain containing wetlands and oxbow lakes at the site of the proposed bridge. Limited information is available on

AMERICAN OVERSIGHT

floodplains and flood data for other streams that would require bridge and culvert crossings. The southernmost section of the south access road is listed as a mapped area in the Federal Emergency Management Agency (FEMA) Flood Mapping database (FEMA quadrants 0200125250A and 0200124875A), but no flooding data are available for this area (FEMA 2018 https://msc.fema.gov/portal/search).

Surface Water Extraction Sites during Construction

Figure 4.16-7 (in environmental consequences, Section 4.16, Surface Water Hydrology) depicts surface water extraction sites that would be used to support construction and maintenance of the access roads (PLP 2018-RFI 022).

AMERICAN OVERSIGHT

Stream Crossing Bank Erosion/Scour

Erosion of stream banks is generally caused by an increase in flow during flooding events. There are no known studies of baseline stream bank erosion along the transportation corridor.

Fish habitat field studies conducted in summer 2018 included collection of substrate composition (e.g., sand, silt, gravel) and water turbidity (PLP 2018-RFI 036). This information is discussed in Section 3.18, Water and Sediment Quality.

3.16.1.3 Amakdedori Port

Drainage Basins

Amakdedori port is in the Tuxedni-Kamishak Bay watershed of the greater Cook Inlet watershed. The Aleutian Range west of the port forms the divide between the Kvichak and Cook Inlet watersheds. The terrain is rocky and undulating with elevation of about 800 feet amsl at the divide, and drops down to more gentle slopes and wetlands around the port area. Streams flow generally south and eastward in the port area, draining into Kamishak Bay. No detailed hydrologic data is available for Amakdedori Creek.

Streamflow

No streamflow gaging stations are present in the port area (USGS 2018). The closest known stream gage data are from Williams Creek and an unnamed creek (Y valley) approximately 30 miles northeast of the port. Data from these streams are limited, and the watersheds are more mountainous and likely hydrologically different from the port area, and thus not comparable.

Flood Hazards

The port would be developed above the floodplain above Amakdedori Creek; therefore there are no flood hazards. The creek would remain in its natural state and serve to naturally moderate floods.

Flood Values

The stream channel in the vicinity of the port location, Amakdedori Creek, is sinuous and flows within its floodplain. Floodplain values are related to biologic and water resources. Biological resources related to wetlands within the mine study area are described in Section 3.22, Wetlands/Special Aquatic Sites. Water resources include those resources and functions of floodplains related to natural moderation of floods, water quality maintenance, and groundwater recharge. The area is not populated and there is currently no infrastructure in the area that would be within the floodplain.

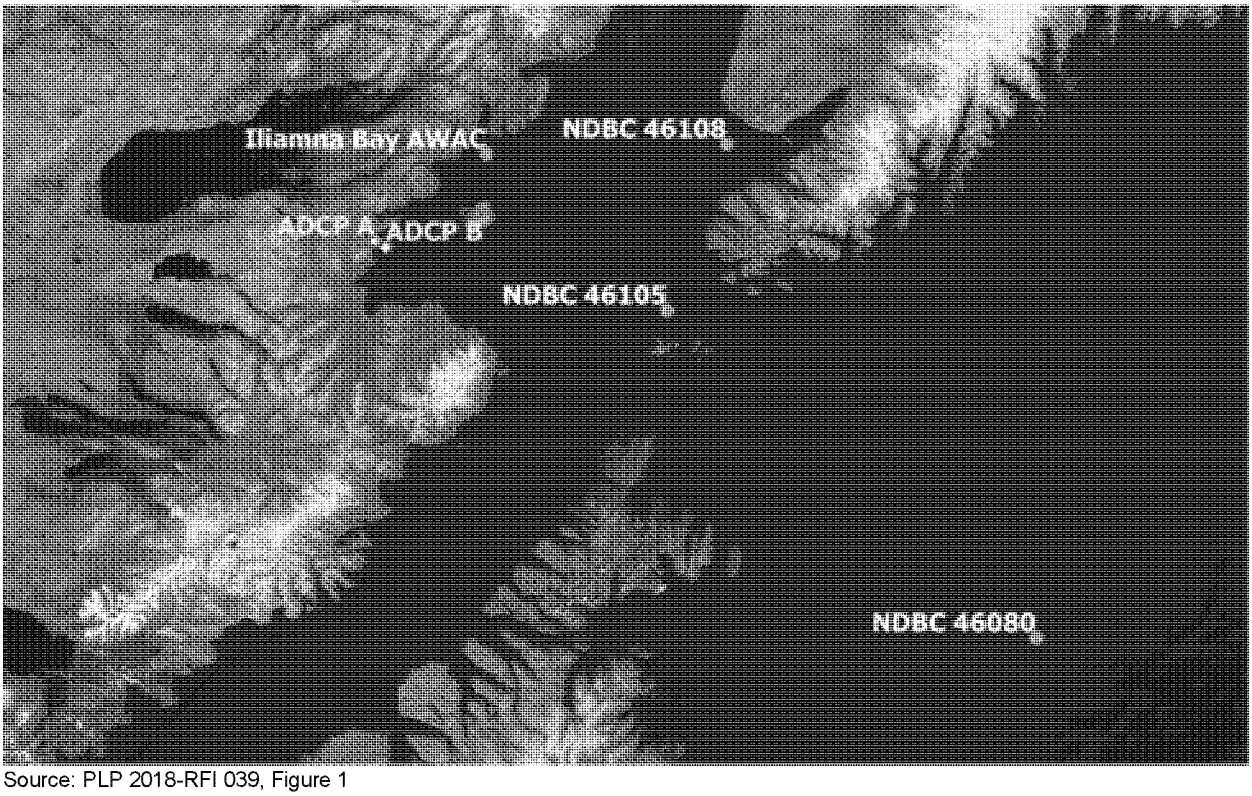
Flood Magnitude and Frequency

The port site area is listed as a mapped area in the FEMA Flood Mapping database (FEMA quadrant 0200125250A), but no flooding data are available for this area (FEMA 2018).

Surface Water Use

There is no known or documented surface water use at the proposed port site. The mouth of Amakdedori Creek is just south of the proposed port. The creek has been advertised as a destination for recreational fishing, but its use has not been documented.

AMERICAN OVERSIGHT



Marine Water – Western Marine Landfall of Natural Gas Pipeline

Available Information

Environmental baseline data for the proposed western landfall of the natural gas pipeline were collected in the Iliamna and Iniskin bays area, 25 to 30 miles north of the proposed Amakdedori port site (Pentec et al. 2011). Amakdedori lies on the western shore of Kamishak Bay, with meteorology and oceanography characteristics more similar to Cook Inlet than the more sheltered locations where the baseline data were collected. Consequently, the baseline data relate to a distinctly different marine environment and could not be used to describe the Amakdedori port site.

Available site-specific data regarding oceanographic conditions at and near the Amakdedori port site are described in PLP 2018-RFI 039. Publicly available information includes regional wave data from three National Oceanographic and Atmospheric Administration (NOAA) buoys, two of which are in Lower Cook Inlet (NDBC 46108 and NDBC 46105), and the third (NDBC 46105) in the Gulf of Alaska, southeast of Kennedy Entrance. An acoustic wave profiler (AWAC) was deployed near entrance to Iliamna Bay between 2010 and 2012. Two acoustic Doppler current profilers have been deployed near Amakdedori port site in a metocean program, which is scheduled for completion in March 2019. Locations of these instruments are shown in Figure 3.16-6

Figure 3.16-6: Locations of Available Wave Data

Source: PLP 2018-RFI 039, Figure 1

Regional Wave Climate

With regard to the suitability of Amakdedori as a port site, the most important meteorological aspects are exposure to wind and the resultant waves (especially from northeast and east), as well as the presence of sea ice. Wave data from the three NOAA buoys were analyzed to

AMERICAN OVERSIGHT

determine "return periods" of various magnitudes of the "significant wave height." These data were used to evaluate wave conditions at Amakdedori, and also at Lightering Locations A and B (Alternative 1) and Iniskin Bay (Alternatives 2 and 3) (See Chapter 2, Alternatives).

The return period of an event is based on the probability of occurrence of that event in any given year. For example, if an event has an annual probability of occurrence of 0.10, or 10 percent, it is referred to as having a 10-year return period; the 25-year return period refers to an event having an annual probability of occurrence of 0.04, or 4 percent, and so on. The "significant wave height" is defined as the mean height of the highest one-third of the waves.

Table 3.16-7 lists return periods from 2 to 25 years of significant wave heights from all three NOAA buoys and the Iliamna Bay AWAC. Figure 3.16-7 and Figure 3.16-8 are wave "roses" for buoys NDBC 46105 and NDBC 46108 that show the directions from which waves were observed as percentages of total observations for ranges of significant wave heights measured by each buoy. NDBC 46105 is fully exposed to waves from east and southeast, but also receives significant wave activity from the west due to locally generated storms.

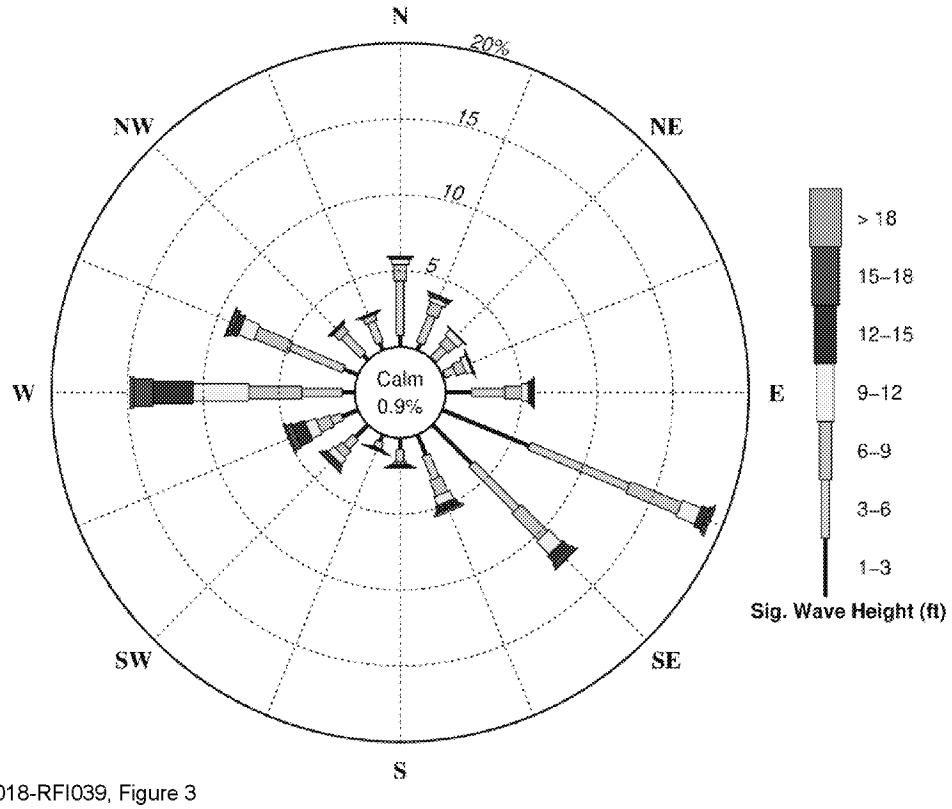


Table 3.16-7: Offshore Data Available from NBDC and External Sources

Source	Dates of Data Available	Return Period H_s (ft)				T_p(s) for large events

AMERICAN OVERSIGHT

Local Wave Climate

As waves travel into the immediate vicinity of Amakdedori port, they are transformed both in height and direction by processes of "shoaling" and "refraction" due to the decreasing water depth and varying seabed topography. Evaluation of port options included running of numerical wave models (SWAN [simulating waves nearshore] and Delft3D) which are widely used by port designers for this purpose. Figure 3.16-9 and Figure 3.16-10 show SWAN model outputs for waves from east-northeast and east-southeast, respectively. The results of modeling indicates that long-period swell from the Gulf of Alaska is able to penetrate Kamishak Bay and reach the Amakdedori port site. Results also showed that waves from northeast have slightly smaller significant wave height than waves from southeast.

Numerical results from the model runs (Table 3.16-8) enabled determination of wave conditions (significant heights, periods, and direction) for a range of wind speeds from northeast (058^0), east (090^0), and east-southeast (116^0). Also shown is the percent reduction in significant wave height due to shoaling and refraction as waves travel from offshore to nearshore.

Source: PLP 2018-RFI 039, Table 5

During scoping meetings in April 2018, the following remarks were recorded from Mr. Chester Passic, Commander in the US Coast Guard (Peninsula Reporting 2018):

> *I'm a commander in the United States Coast Guard. I'm the captain of a Coast Guard vessel Hickory stationed here in Homer. I do all of the aids to navigation in the Cook Inlet, the buoys and the lights…. We do not keep buoys in Cook Inlet for six months a year because of the weather and ice, and we can't keep buoys in Cook Inlet at that time. Kamishak Bay where the deepwater port is proposed is one of the worst places in the*

AMERICAN OVERSIGHT

world to operate in terms of combination of tide, current, winds, weather. And I don't know if -- I think the Corps needs to investigate the deepwater port there. My concern would be that we can't keep aids to navigation for the vessels going in and out of there.

Marine Water Dynamics – Tides, Currents, and Storm Surge

At Nordyke Island (about 6 miles south-southeast of Amakdedori), the mean tide range is 13.0 feet, while the maximum diurnal range is 15.3 feet). Prevailing currents are those associated with the tide, and are generally aligned with bottom contours of the seabed.

Storm surge occurs when strong winds cause a change in local mean sea level. An elevation of sea level is called a "positive" surge, while a depression of sea level is a "negative" surge. Strong winds from the northeast or east could produce a positive storm surge in Kamishak Bay. However, the relatively steep slope of the seabed near the proposed port site would minimize the effects of a storm surge at the port site if it occurred.

Sea Ice

Two compilations of sea ice information for Cook Inlet are available: The Marine Ice Atlas for Cook Inlet (Mulherin et al. 2001) and Pebble Project Ice Database 1997 to 2016 (Dickens 2018). Mulherin et al. (2001) included maps depicting various measures of ice conditions for each biweekly interval between December 1 and March 31 for the period January 1986 to April 1999 (14 winters), which were based on ice charts constructed by the National Weather Service using aerial and satellite photography as well as visual reports. The Dickens (2018) study was undertaken to create an updated database that is representative of current climatic conditions and to provide more locally relevant sea ice information for three locations near the proposed project: 1) Amakdedori port site, 2) lightering location A in middle of Kamishak Bay, and 3) the alternative Diamond Point port site, accessed through Iliamna Bay (See Chapter 2, Alternatives).

The database developed by Dickens (2018) is based on the US National Ice Center archive of 359 Cook Inlet ice charts that span the 19-year period from 1997 to 2016. Data are summarized in tables for each of the study sites, showing dates of first and last observed ice of any severity, the number of weeks of "significant" ice, and maximum concentration of any ice thicker than 10 centimeters (cm), excluding new ice, which is easily broken up by wind, waves and vessel operations. The following paragraphs provide the conclusions drawn from the independent review of Dickens (2018) report.

The database shows that ice conditions at the Amakdedori and Diamond Point port sites are very different. Over the 19 ice seasons during the period 1997 to 2016, the Amakdedori port site rarely experienced compact ice for any extended period and averaged only 3 weeks per year of "significant" ice, while Diamond Point saw nearly twice as long with an average of 5 to 6 weeks per year. In general, the Diamond Point port site had thicker ice in higher concentrations for longer periods than Amakdedori port site.

Ice cover at lightering location "A" was sporadic, during each season and from year to year. In five of the 19 winters studied, there was no ice at this location. The maximum duration of "significant" ice at lightering location "A" was five weeks in two seasons. In the other 17 seasons, "significant" ice was present for 2 weeks or less.

A preliminary comparison suggests that ice severity at Amakdedori port site and lightering location "A" might have decreased in last two decades, as compared to the 1984 to 1999 period studied by Mulherin et al. (2001). For example, the two-week period from March 1 to March 15,

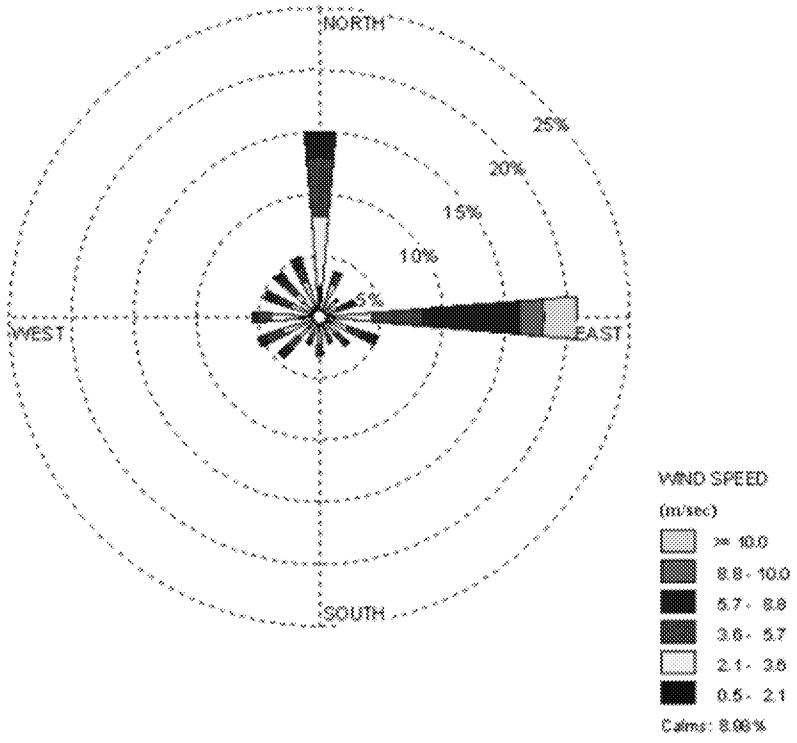
AMERICAN OVERSIGHT
EPA-0135-0002569

studied by Mulherin (2001), showed probabilities of ice concentrations[1] (using concentration criterion of ≥ 5/10) of 75 to 100 percent at Amakdedori port site and 50 to 75 percent at lightering location "A." For the period 1997 to 2016 and using the same ≥5/10 concentration criterion, the Dickens (2018) database showed probabilities of 58 percent and 26 percent at Amakdedori and Diamond Point, respectively. However, Dickens (2018) reported that there is no clear trend for any of the sites over the 19 ice seasons covered in the more recent database.

Iliamna Lake

Available Information

Iliamna Lake is the largest lake in Alaska. Approximately 75 miles long by 22 miles wide, its surface area is about 1,000 square miles. Its greatest depth is more than 980 feet, but its mean depth is only about 144 feet. HDR 2011a provides baseline information regarding water quality, sediment, and biological components for Iliamna Lake (see Section 3.18, Water and Sediment Quality).



Meteorology and Wave Climate

Regarding the ferry terminal locations (and alternative locations described in Chapter 2, Alternatives) on Iliamna Lake and the ferry route(s), the most important meteorological aspects are exposure to wind and the resultant waves (especially from northeast and east), and the presence of lake ice. Meteorological data for Iliamna Lake are available from Iliamna Airport, for which the record extends from the 1940s; however, no statistical summary other than the Iliamna wind rose (for 2000 through 2008) was located (Figure 3.16-11).

[1] Ice concentration is the amount of ice covering an area, written as either a fraction or percentage of ice coverage. In general 3/10 (30%) is navigable by ship; 9/10 (90%) is considered solid ice (http://seaiceatlas.snap.uaf.edu/glossary).

AMERICAN OVERSIGHT

Figure 3.16-741: Iliamna Airport Wind Rose, 2000 through 2008

m/sec = meters per second. 1 m/sec = 2.2 miles per hour

Source: Hoefler 2010a, Figure 2-2

Figure 3.16-12 indicates that winds at Iliamna are essentially bimodal, either from the east or north, with direction likely governed by local terrain. For the 4 years of meteorological studies included in Hoefler (2010a), for the period of measure 2005 to 2008, maximum hourly mean wind speeds ranged from 20 to 22 miles per hour (mph) (summer), to 43 to 47 mph (winter) for 2005 to 2007, but were somewhat less at 16 to 25 mph in the least windiest year of 2008.

A cursory (i.e., non-statistical) review of data from both Iliamna and Igiugig (at the western end of Iliamna Lake), available at National Climatic Data Center (https://www.ncdc.noaa.gov/data), showed that maximum wind speed of 40 mph is common.

Using wave forecasting equations from the US Army Corps of Engineers (USACE) Coastal Engineering Manual (USACE 2002), for a fetch length of 35 miles from the proposed ferry crossing to the northeastern end of Iliamna Lake, a significant wave height of 10 feet meters and dominant wave period of 6.5 seconds were calculated. Anecdotal information, collected at scoping meetings, suggests that 40 miles per hour might be a gross underestimate of maximum wind speeds experienced on Iliamna Lake, as noted below (Midnight Sun Court Reporters 2018):

> *I spent many years in Igiugig in the fall, and it probably blows 100 miles an hour at Lake Iliamna three to five times a year. 100 miles an hour. They want to cross it all the time.*

Lake Ice Hazards

The ice-covered season at Iliamna Lake is highly variable. Complete freeze-over occurs between late October and mid-March, and can last for 2 to 5 months before break-up. The average length of the ice-covered season is expected to be about 115 days, based on 15 years

AMERICAN OVERSIGHT

of data collected in several southwestern Alaska lakes (Verrier and Kirchner 2016). Limited data are available on ice thickness in Iliamna Lake; anecdotal reports indicate that it can be about 4 feet thick in late spring (Billmeier 2016), but can range from several inches to several feet at the same time over a short distance (ADF&G 2008). The variation in lake ice thickness may be at least partially attributable to stacking of ice floes. Lake ice hazards, such as pressure ridges driven by wind, are known to occur in Iliamna Lake (Billmeier 2015; Andrew 2017).

Ice coverage areas of Iliamna Lake were compiled and georeferenced, using Moderate Resolution Imaging Spectroradiometer (MODIS) imagery for the period December 1 through June 1 for each winter from 1999/2000 through 2017/2018 (ABR 2018a). Daily images of the lake were reviewed to identify areas of ice cover or open water to develop a time series of ice cover for each winter. The plotted time series showed timing and speed of ice cover formation as well as the range of uncertainty due to cloud cover. Ice duration (days with ice) was calculated for each of 340 square grid cells and used to determine median durations for the entire time series.

The analysis spanned 19 winters, with 15 that had prolonged periods of complete or nearly complete ice cover. Four winters had minimal or no periods of complete ice cover. During one winter (2015/2016) only trace ice cover was observed during entire winter. Often, there were weeks of uncertainty regarding ice conditions because of cloud cover.

Figure 3.16-12 (ABR 2018a) is a map of median ice duration that shows pattern of shortest duration (<105 days) in the eastern portion of the lake, as far west as Iliamna. Median ice duration is intermediate across the lake to Kokhanok (96 to 110 days), except along the shore in the bays and islands east of Kokhanok. Farther west, the median ice duration increases gradually, ranging from 106 to 140 days.

AMERICAN OVERSIGHT

3.16.1.4 Natural Gas Pipeline Corridor

Available surface water data in the natural gas pipeline corridor are the same as those described for the transportation corridor, with the exception of the Cook Inlet crossing and the eastern Cook Inlet pipeline landfall at Anchor Point. The marine portion of the pipeline corridor is addressed above under Amakdedori Port, Marine Water – Western Cook Inlet Landfall.

Drainage Basins

The drainage basin descriptions for most of the natural gas pipeline corridor are the same as those provided for the transportation corridor.

3.16.2 Action Alternative 2 – North Road and Ferry

A detailed description of Alternative 2 is described in Chapter 2, Alternatives.

Drainage Basins

The principle (named) streams along the transportation corridor between Diamond Point port site and the mine site include Williams Creek, Chinkelyes Creek, Iliamna River, Long Lake Creek, Pile River, Knutson Creek, Canyon Creek, Chekok Creek, Roadhouse Creek, and the Newhalen River. Williams Creek flows into Iliamna Bay in Cook Inlet, and all the other watercourses flow directly or indirectly into Iliamna Lake. East of the Newhalen River crossing, the mine access road and pipeline corridor cross into the UTC watershed, and follow the route described under Alternative 1 to the mine site.

The onshore pipeline segment that would cross between Ursus Cove and Cottonwood Bay would follow a glacial valley bounded by steep terrain. There are no principle (named) streams along this segment of the route.

The Diamond Point port site would be on the eastern side of the Aleutian Mountain Range, a coastal mountainous terrain with a maritime climate. Along these coastal mountains, rapid snowmelt and rainstorm runoff is facilitated by the steep terrain, and thin surficial sediments on mountain slopes. Closer to the mine site, peak flow attenuation and baseflow augmentation are facilitated by gentler terrain, increased thickness of surficial sediments, and increased number of surface waterbodies (Knight Piésold et al. 2011a).

Streamflow

Along the Alternative 2 ferry access route between Diamond Point port and Pile Bay ferry terminal, the USGS operates one crest gaging station on Chinkelyes Creek Tributary (Figure 3.16-17 and Table 3.16-9). Along the Alternative 2 pipeline route between Pile Bay and the mine site, the USGS operates one continuous streamflow gaging station on Roadhouse Creek, and one on the Newhalen River (Figure 3.16-13 and Table 3.16-12). Newhalen River streamflow is described under Alternative 1.

AMERICAN OVERSIGHT

Annual hydrographs of mean monthly flows at Roadhouse Creek and Iliamna River gaging stations are presented in Figure 3.16-14. The hydrographs show that Roadhouse Creek experiences lowest flows during winter months, and the highest monthly flows of the year during the autumn rainstorm season. Iliamna River has a somewhat similar pattern of annual flows, except that the highest monthly flows of the year occur during the spring snowmelt due to the large snowpack that accumulates in the mountainous basin. The summer low-flow period is also less pronounced in Iliamna River than in Roadhouse Creek due to ongoing flow contributions from high-elevation snowmelt and glacier melt through the summer (Knight Piésold et al. 2011a).

Figure 3.16-~~10~~14: Mean Annual Hydrograph Comparison – Iliamna River and Roadhouse Creek USGS Gaging Stations

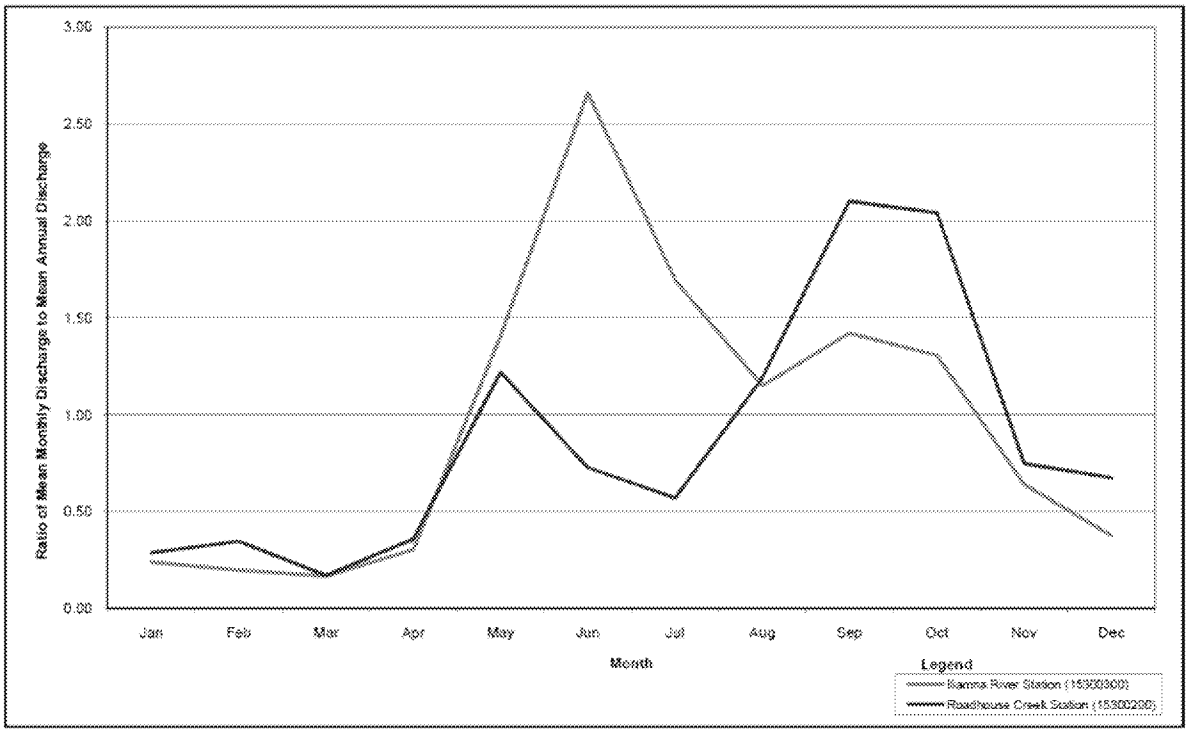

FIGURE 7.3-2
Normalized Mean Annual Hydrographs from USGS Gaging Stations in the Transportation Corridor Study Area

Source: Knight Piésold et al. 2011a (Figure 7.3-2)

In addition to the USGS gaging stations, instantaneous discharge measurements were recorded on select streams along the Alternative 2 transportation and natural gas pipeline corridors. Summer instantaneous discharge measurements were collected in 2004 (Table 3.16-10). Winter instantaneous discharge measurements were recorded in 2005 (Table 3.16-11). Summer instantaneous discharge measurements were recorded in 2005 (Table 3.16-12).

Flood Magnitude and Frequency

Peak streamflows on streams along the Alternative 2 transportation and natural gas pipeline corridors were estimated using USGS regional regression equations (Knight Piésold et al. 2011a). Estimated peak streamflow values for Alternative 2 stream crossings are presented in Table 3.16-13.

AMERICAN OVERSIGHT

3.16.3 Action Alternative 3 – North Road Only

Stream crossing are the same as those described under Alternative 2.

3.16.4 Surface Water and Groundwater Use

This section addresses both surface and groundwater use in the project area and considers all alternatives and variants described above.

3.16.4.1 Domestic Water Use

Three community water systems in the Iliamna Lake area extract surface water for domestic use: Nondalton, Kokhanok, and Igiugig (Figure 3.16-15). The Nondalton system uses infiltration galleries from Sixmile Lake (at the south end of Lake Clark) which drains into the Newhalen River; Kokhanok draws water directly from Iliamna Lake; and Igiugig has one active intake within the Kvichak River, which drains out of the southwest side of Iliamna Lake (ADEC 2018). In addition to community water systems which supply surface water, local residents may collect surface water for personal use. To date, no additional Traditional Ecological Knowledge regarding collection of surface water for personal use within the project area has been received.

Other communities in the area rely on groundwater wells for their domestic water supply (Figure 3.16-16). The village of Newhalen has both community and private groundwater wells, while Iliamna and the community of Pedro Bay (on Alternative 2 and 3 transportation corridors)) rely on private groundwater wells. Residents of Anchor Point near the compressor station at the eastern terminus of the natural gas pipeline corridor on the Kenai Peninsula use private groundwater wells for their domestic water supply. There are 11 private groundwater wells within 0.5 mile of the pipeline infrastructure (ADNR-WELTS) (Figure 3.16-17).

Section 3.18, Water and Sediment Quality describes current water quality of community water systems relevant to the project area. No water quality data is available for private groundwater wells. No public data is available on drinking water sources for Pile Bay and Williamsport, near the Alternative 2 and 3 transportation corridors (ADEC 2018; ADNR-WELTS).

To meet the requirements of the Safe Drinking Water Act, elements of the EPA 1986 Wellhead Protection (WHP) and 1997 Source Water Assessment and Protection (SWAP) programs have been combined under the ADEC Drinking Water Protection Areas (DWPA) program. The DWPA program's intent is to delineate the boundaries of public (community) drinking water sources, identify potential risks from contamination, and determine vulnerability of water sources. The data may be used by local governments and state agencies when reviewing permits for activities that may affect public drinking water sources. There are currently no regulatory restrictions associated with DWPAs (ADEC 2018).

DWPAs surround the shores of Lake Clark, Iliamna Lake, and the community groundwater wells in the communities described above. Various zones within the DWPAs reflect groundwater travel time, buffers around surface drinking water sources, and watershed boundaries.

3.16.4.2 Mine Site Water Use

Surface water within the mine site may be used by local residents for hunting, fishing and other subsistence activities, but has not been documented. To date, no additional Traditional Ecological Knowledge regarding collection of surface water for personal use within the project area information has been received.

Groundwater wells across the mine site area are used to collect data on aquifer properties, site water balance, and water quality (Schlumberger 2011, 2015). In the mine site, groundwater use

AMERICAN OVERSIGHT

is currently limited to sampling and hydrogeologic testing. PLP has received multiple Temporary Water Use Authorizations (TWUAs) for exploration activities between 2004 and 2013. The TWUAs allow a limited volume to be withdrawn per day, up to a specified annual limit, from specified sources, mostly groundwater wells.

The applicant has applied for surface water rights for some of the main drainages within the mine site area, including the SFK river, the NFK river (designated in baseline studies as tributary NK 1.190), and UTC (ADNR 2018).

The project would include installation of at potable groundwater wells on the northern side of the mine site (in the Big Wiggly Lakes area) to serve mine site personnel water needs. Results of groundwater quality tests at this site indicate that minimal water treatment (multimedia filtration, chlorination, and pH adjustment) would be required to develop the wells for a potable water source (PLP 2018).

3.16.4.3 Port Water Use

There is no known or documented surface or groundwater use at either Amakdedori or Diamond Point port sites (ADEC 2018). For Alternative 1, a potable groundwater well would be installed at the Amakdedori port site to serve personnel. The well would be located in an upland area far enough from shore to avoid the potential for saltwater intrusion (PLP 2018-RFI 022a).

3.16.4.4 Hydropower

A hydropower project (Tazimina Hydro) was installed nine miles upstream from the confluence of the Newhalen and Tazimina rivers, near the transportation corridor (Alternatives 2 and 3). As of 2012, the run-of-the-river-type hydropower plant supplied over 95 percent of the power for the communities of Iliamna, Newhalen, and Nondalton (INNEC 2012). The hydropower system uses the natural waterfalls at the site to provide the mechanical energy to spin power-generating turbines, and there is no dam required. Streamflow is therefore not significantly affected, and no water is removed from the drainage for power production.

AMERICAN OVERSIGHT

4.16 SURFACE WATER HYDROLOGY

This section addresses the following potential impacts on surface water hydrology (movement and distribution of surface water) (e.g., streams, lakes, marine waters):

- Effects of pre-mine ground disturbance and construction
- Effects of fill placement, water management ponds, and associated facilities
- Effects of controlled water treatment plants discharge on streamflow
- Effects of mine operations on streamflow
- Effects of closure and post-closure on streamflow
- Effects on lake water hydrology
- Effects on marine water hydrology
- Effects on water use sources

The impacts analysis for surface water hydrology was based on evaluation of baseline conditions in Section 3.16, Affected Environment, and considers operational and closure water management plans, water balance models, and modeling results for all phases of the project (Knight Piésold 2018a, 2018d, 2018i, and 2018j). Relevant mitigation measures (Chapter 5, Mitigation) are also considered. Related discussion of impacts to water and sediment quality are addressed in Section 4.18, Water and Sediment Quality. Impacts to groundwater and surface water/groundwater interaction are addressed in Section 4.17, Hydrogeology. Impacts to fish and fish habitat are described in Section 4.24, Fish Values. Mitigation measures are described in Chapter 5, Mitigation.

In addition, this section comprehensively addresses impacts to water use—both surface and groundwater.

4.16.1 No Action Alternative

Under the No Action Alternative, the project would not be constructed, and there would not be any new effects on surface water hydrology.

4.16.2 Alternative 1 – Applicant's Proposed Alternative

This section describes impacts of the project on surface water hydrology for each project component for all phases of the project.

4.16.2.1 Mine Site

This section describes the water balance models, water management plans, and the potential impacts to surface water hydrology by watersheds in the mine site area by project phase.

The water management strategies that support the development of water management plans and the design of water management facilities for operations and closure (Knight Piésold 2018a and 2018d) were based on results of predictive mine site water balance models calibrated to mine area precipitation and streamflow data. The water balance models[1] include meteorological input (e.g., precipitation, temperature), water use requirements, water management pond (WMP) storage volumes, water treatment volume and rates, and surface water flow rates. A description of baseline water balance input parameters and model calibration is presented in Section 3.16, Affected Environment.

[1] In general, a water balance model is a numerical equation used to describe flow and storage of water.

AMERICAN OVERSIGHT

Water balance models are generally described under operations and closure phases, below. Additional details of the water balance model, input, and approach are discussed in Appendix K4.18, Water and Sediment Quality.

Construction

Water Management

The primary goal of water management during construction is to manage runoff and minimize surface water contact with disturbed surfaces. Critical water management elements during construction would include (Knight Piésold 2018a):

- Water diversion channels, berms, and collection ditches constructed using erosion-control features (e.g., geotextile, riprap), and with design criteria to meet a 100-year, 24-hour rainfall event.
- Stormwater and sediment control best management practices (BMPs), including temporary settling basins and silt fencing.[2]
- Hydraulic energy dissipation structures, such as spill basins or similar control features where necessary to reduce erosion at the outlets of diversion channels and collection ditches.
- A dewatering system to lower the groundwater surface in the pit area in preparation for operations, including a pit WMP to temporarily contain the water.
- Installation of temporary modular water treatment plants to treat runoff (if needed) and recovered pit area groundwater before discharge to the environment (see Section 4.18, Water and Sediment Quality).

All site embankments, except for the Bulk and Pyritic Tailings Storage Facility (TSF) embankments, would be fully constructed prior to the operations phase. Those required to support pre-production mining would be in place prior to pre-production mining (PLP 2018-RFI 019a).

Streamflow Effects

Surface water quantity and distribution in the North Fork Koktuli River (NFK) and South Fork Koktuli River (SFK) watersheds would be affected during construction through diversion of surface water and initial drawdown of groundwater in preparation for mining activities. Activities during the construction phase, including development of retention structures and initial groundwater pumping, would have direct impact on water flow in tributaries of both of these watersheds.

Operations

Water Balance

A water balance model for the operations phase, based on a 20-year mine life, was developed for the project (Knight Piésold 2018a). Details of the water balance model, input, and approach are discussed in Appendix K4.18, Water and Sediment Quality. The water balance model is composed of three modules (components): watershed module, groundwater module, and mine plan module. The operations water balance model was developed to estimate the amount of water that would be managed at the mine site during operations under a full range of historic

[2] These aspects of construction water management would be further developed in a Stormwater Pollution Prevention Plan (SWPPP) required for mine permitting.

AMERICAN OVERSIGHT

climate conditions. Incorporation of climate variability into the water balance model is described in Appendix K4.18.

The Operations Water Management Plan (Knight Piésold 2018a) provides a table of the mine site water balance results under dry, average, and wet precipitation conditions (realizations) during operations, and the corresponding water balance flow schematic diagram (Knight Piésold 2018a, Table A.1 and Figure A.1). The numbers on the figure correspond with flow path number designations on Table A.1. Used together, the information describes the flow in and out of mine site features during operations for each of the dry, average, and wet realizations. The three realizations all have similar average precipitation values, but differ in how the precipitation occurs from year to year. The selected precipitation values for the realizations are:

- Under relatively dry conditions, the assumed average annual precipitation is 56 inches, with an annual precipitation in the final year of operations of 33 inches.
- Under average conditions, the assumed average annual precipitation is 57 inches, with an annual precipitation for the final year of operations of 58 inches.
- Under relatively wet conditions, the assumed average annual precipitation 57 inches, with an annual precipitation for the final year of operations of 93 inches.

Water Management

The primary goal of water management during operations is to minimize generation of contact water that requires subsequent treatment. The main objectives are to manage fresh water (non-contact water), stormwater (runoff from facilities, non-contact water), mine drainage (contact groundwater or surface water), and process water (contact wastewater generated from operations). Water not diverted before becoming contact water would be collected and used as process water, or treated and discharged to the environment. No additional water sources outside the mine site would be needed for operations.

The main mine site water management structures during operations include those listed below and depicted on Figure 4.16-1.

- Freshwater diversion channels
- Open pit water management pond (open pit WMP)
- Main water management pond (main WMP)
- Bulk tailings storage facility (bulk TSF)
- Bulk TSF main seepage collection pond (SCP)
- Pyritic tailings storage facility (pyritic TSF)
- Seepage collection and recycle ponds
- Treated water discharge structures
- Sediment ponds

AMERICAN OVERSIGHT

Figure 4.16-1 Mine Site Features at End of Mine

AMERICAN OVERSIGHT

Design criteria[3] for each mine site water management structure during operations are listed in Table 4.16-1. Water management structures would be designed to account for storm storage allowance based on the following considerations:

- Probable Maximum Precipitation (PMP) – precipitation that results from the most severe meteorological conditions predicted.
- Probably Maximum Flood (PMF) – flow resulting from the most severe combination of PMP and basin hydrological conditions.

Current practice is to determine the PMF as the flood resulting from the PMP plus the coincident melt of a 100-year snowpack.

Table 4.16-1: Design Criteria for Water Management Structures – Operations

Water Management Sructure	Design Criteria
Fresh Water Diversion Channels	Convey undisturbed surface water runoff around the mine site activities to the downstream environment.
OP WMP	Maximum operating pond volume of 40 Mft^3 (920 ac-ft) to manage dewatering from the open pit. Water in excess of this capacity would be pumped to the main WMP for management. Storm storage freeboard allowance for the required IDF[2] and a spillway to safely pass larger events with additional freeboard.[1]
Main WMP	Minimum operating pond volume of 300 Mft^3 (6,900 ac-ft) to ensure that there is sufficient water available for the process during dry climate conditions. Maximum operating pond volume of 2,450 Mft^3 (56,250 ac-ft) to manage surplus water from the project mine site during wet climate conditions. Storm storage freeboard allowance for the required IDF with additional freeboard.[1]
Bulk TSF	Maximum operating pond volume varies by embankment stage and mine development, but is constrained by the need to maintain a minimum 2,000 feet beach length. Storm storage freeboard allowance for the required IDF without release from the facility with additional freeboard.[1]
Bulk TSF Main SCP	Maximum operating pond volume of 130 Mft^3 (3,000 ac-ft) to manage seepage and runoff from the main embankment of the bulk TSF. Storm storage freeboard allowance for the IDF and a spillway to safely pass larger events with additional freeboard.[1]
Pyritic TSF	Minimum operation pond volume varies by embankment state and mine development, but is constrained by the requirement to maintain a water cover to promote geochemical stability of the pyritic tailings and PAG waste rock. Storm storage freeboard allowance for the required IDF and a spillway to safely pass larger events with additional freeboard.[1]
Seepage Collection and Recycle Ponds	Ponds are to be operated with the minimum pond volume required by the pump systems. Storm storage freeboard allowance for the required IDF and a spillway to safely pass larger events with additional freeboard.[1]
Sediment Ponds	Treat sediment for all inflows resulting from the 1 in 10-year, 24-hour rainfall event, with no flow passing over the spillway. Spillway to safely pass the peak outflows resulting from the 1 in 200-year, 24-hour rainfall event, with the starting pond level at the spillway invert. Additional freeboard provided.[1]

Notes:

Mft^3 = millions of cubic feet

[3] Design criteria are essentially goals that are used to guide the design of the structures. Design criteria are developed based on actual and modeled conditions.

AMERICAN OVERSIGHT

IDF = inflow design flood

ac-ft= acre feet

[1] Each water management pond would include an additional freeboard allowance for wind-generated wave height and potential seismic deformation.

[2] The required IDF for each water management pond would be determined through the Alaska Dam Safety Program (ADSP).

Source: Knight Piésold 2018a, Table 3.1

The mine would be designed for zero-discharge of untreated contact water during construction, operations, and closure. Water management strategies have been developed to achieve this design and maintain sufficient fresh water for ore processing and other mine site uses.

A surplus of process water would be anticipated during operations under average and above-average precipitation scenarios (Knight Piésold 2018a). Water available for discharge to the environment after treatment would be less than the pre-mine flows because of water lost in tailings voids, evaporation, and other minor uses. The average annual process water surplus during maximum operations is estimated to be 29 cubic feet per second (cfs), which would be treated and discharged throughout the year in a manner to optimize downstream fish and aquatic habitat (Knight Piésold 2018i).

Adaptive water management strategies during operations would include the ability to provide additional water storage capacity in the bulk TSF, provide surplus storage capacity in the WMPs, and provide for expansion of the water treatment plant (WTP) rate by building excess capacity (Knight Piésold 2018a).

Additional water storage capacity would be made available under above-average precipitation conditions by directing excess water to the open pit; then pumping, treating, and discharging water to restore the pit water to the design level (Knight Piésold 2018a).

Streamflow

Most of the mine site features would be in the NFK watershed. The open pit, open pit WMP, and WTP#1 and WTP#1 discharge-south would be in the SFK watershed, and only the WTP#1 discharge-north and a segment of the mine access road would be in the Upper Talarik Creek (UTC) watershed. Surface water quantity and distribution in the NFK and SFK watersheds would be affected during operations.

The maximum mine footprint, based on an average groundwater pit inflow of about US 2,700 gallons per minute (gpm), was superimposed on the calibrated water balance model to estimate mine-affected streamflows in the NFK, SFK, and UTC watersheds (Knight Piésold 2018f).

Estimated mean annual streamflow and groundwater flow at gaging station locations in the NFK, SFK, and UTC watersheds, for both the pre-mine and end-of-mine (representative of operations) conditions are presented in Table 4.16-2 for comparison. The far right column of Table 4.16-4 lists the corresponding estimated mean annual reduction in surface water flow (as a percent) (Knight Piésold 2018i). Gaging stations and discharge sites are shown on Figure 3.16-2 in Section 3.16, Affected Environment.

Source: Knight Piésold 2018i, Table 3

AMERICAN OVERSIGHT
EPA-0135-0002597

The estimated mean annual streamflow change indicates that streamflows in the respective watersheds would closely resemble pre-mining.

NFK: The greatest estimated mean annual streamflow reductions would be expected to occur in the NFK watershed, where most of the mine features are sited. The mean annual treated water added to the NFK watershed would be approximately 21.6 cfs, and the estimated mean annual streamflow reduction would be approximately 7 percent at both NK100C and NK100A.

SFK: The mean annual treated water added would be 6.6 cfs, lowering the reduction in streamflow at SK100F to within 4 percent of pre-mining conditions. At SK100A, streamflow would be within 2 percent of pre-mining conditions.

UTC: The mean annual treated water added would be 0.8 cfs, lowering the reduction in streamflow at UT100D to within 1 percent of pre-mining conditions. Further downstream, there would be no expected reduction in streamflow at UT100B.

Closure and Post-Closure

Water Balance

A water balance model (and water quality model, see Section 4.18 and Appendix K4.18) for the closure and post-closure periods of the mine site was developed by Knight Piésold (2018d) to access water entering and leaving the mine site, and to aid in developing water management processes. The closure and post-closure water balance model was developed similar to the operations model to estimate the water flow volumes for the various facilities during the closure periods under varying historical climate conditions, and is based on a four-phase closure plan as outlined below:

- Phase 1 – Reclamation of quarries and bulk TSF, placement of pyritic tailings and potentially acid-generating (PAG) waste rock in the open pit to be completed by closure Year 15. Figure 4.16-2 shows the arrangement of features at closure phase at Year 9, and Figure 4.16-3 shows features that would be present at the end of Closure Phase 1.
- Phase 2 – reclamation of bulk TSF and quarries, reclamation of pyritic TSF and main WMP, no water treatment to be completed in closure Year 16 through approximately Year 20. Figure 4.16-4 shows general arrangement of features that would be present during closure at the end of Phase 2.
- Phase 3 – pyritic TSF and main WMP reclaimed, ongoing treatment of surplus water in the open pit to be completed in closure Years 20 through 50. Figure 4.16-5 shows general arrangement of features that would be present at Closure Phase 3.
- Phase 4 – Post-closure long-term conditions. Figure 4.16-6 shows general arrangement of features that would be present at Post-Closure Phase 4.

Primary activities and actions planned for each phase of closure are described in more detail in Knight Piésold 2018d.

The Closure Water Management Plan provides mine site water balance under dry, average, and wet precipitation conditions (realizations) and the corresponding water balance flow schematic diagram (Knight Piésold 2018d, Tables A.1 through A.5 and Figures A.1 through A.4). The numbers on the figure correspond with flow path number designations on the tables. Used together, the information describes the flow in and out of mine site features during closure phases for each of the dry, average, and wet realizations.

Water Management Plan

During closure, the total flows released downstream of the mine site are a combination of fresh water from the diversion channels, surface runoff from reclaimed facilities, and treated water from the WTPs. The WTP flows are expected to vary based on the amount of water captured at the mine site, depending on the seasonal climate variability. Flows from the fresh water diversions and reclaimed facilities are expected to vary according to natural flow patterns, which are also linked to seasonal climate variability.

Streamflow

Estimated mean annual streamflows during post-closure are shown in Table 4.16-3 by gaging station location (Figure 3.16-2).

2. Groundwater leaving the subcatchment.
3. Includes diversions as shown on Figure 4.16-6.
4. Flow change calculated as post-closure without treated water streamflow minus pre-mine streamflow.

Source: Knight Piésold 2018i, Table 3

AMERICAN OVERSIGHT

The modeled effects on streamflow during post-closure are summarized as follows:

- NFK: During post-closure Phase 4, estimated mean annual streamflow at NK100A would be 4 percent lower than pre-mining conditions
- SFK: During post-closure Phase 4, estimated mean annual streamflow would be lower than pre-mining conditions by approximately 9 percent at SK100F and 1 percent at SK100A lower than pre-mining conditions.
- UTC: During post-closure Phase 4, estimated mean annual streamflow at UT100D and UT100B would be the same as pre-mining conditions.

Discharge from WTPs is an important element of overall modeled streamflow during operations and post-closure. The 1st, 10th, 50th, 90th, and 99th percentile values of total water released from the WTPs are summarized on an annual average basis for closure Phases 1 through 4 in Table 4.16-4. The total amount of water treatment required would be greatest during the early phases of closure, when the mine site footprint is larger than later phases of closure; and would be lowest during Phase 4, once all of the mine facilities are reclaimed and the only water being treated is the surplus pumped from the open pit to maintain water levels.

Total flow releases from the WTPs can vary from a high of 58 cfs during Phase 1 (99th percentile results) to a low of 3 cfs during the final Phase 4 (1st percentile results). There would be no releases from the WTPs planned during Phase 2, which would be after the PAG waste rock and pyritic tailings transfer to the open pit is complete, but before the open pit reaches the not-to-exceed (NTE) water elevation. Phase 2 occurs for an approximately 5-year period, during which the total captured surface runoff, direct pond precipitation, and groundwater inflow rate is approximately 40 cfs, under average climate conditions.

AMERICAN OVERSIGHT

4.16.2.2 Transportation Corridor

The evaluation of impacts on surface water and substrate incorporates an understanding of their probability of occurrence, and of planned mitigation in the form of engineering design and maintenance that can meaningfully reduce impacts.

Road Stream Crossings

Potential impacts of the mine access road on surface water hydrology during mine construction and operations include increased stormwater runoff from road and pad surfaces, and increased erosion and sedimentation if crossings are improperly designed and road ditches and stream crossings are not maintained during flood events. Stream crossings associated with the mine access road would be designed to minimize potential impacts on surface water hydrology, water quality, and fish passage. Road and pad maintenance BMPs, including application of dust suppressants during dry periods, routine grading, and routine maintenance of drainage ditches and stream crossings, would be implemented and maintained during the mine operation period.

Potential for erosion and sedimentation from disturbed areas would be greatly reduced as revegetation is established after construction activities end. The road surface would potentially yield additional runoff compared to native terrain. Because the roads would generally run perpendicular to the drainages to be crossed, the limited disturbance of the road would minimally increase the quantity of runoff to any single receiving tributary; therefore, the intensity of the direct and indirect impacts would result in maintained surface water flow, and changes in water quantity would be within the limits of historic seasonal variation.

Bridge Crossings

A total of nine bridges would be constructed for the proposed project under Alternative 1: a bridge across Upper Talarik Creek on the mine access road, a bridge across the Newhalen River on the Iliamna spur road, and seven bridges along the south access road. Bridge engineering and design would vary with stream size and hydrologic properties. Instream channel work, including installation of bridge footings and embankments, would occur year-round during the first 2 years of construction.

During construction of bridges, the potential exists for increased runoff, erosion, and sedimentation as a result of vegetation removal and excavation of soil, rock, and sediment. Erosion and sediment control BMPs, including routine maintenance of drainage ditches and stream crossings, would be implemented and maintained during the mine operation period.

Culverts

A total of 88 culverts would be installed at drainages along the transportation corridor. Culverts would be used to allow proper discharge at stream crossings, to reduce erosion, and for some crossings, would be used for fish passage (Section 4.24, Fish Values). Culvert design would vary by stream size and whether or not fish passage is required. Culvert sizes and types would be determined to address anticipated flow, and designs would be refined during final engineering and design, and in accordance with permit requirements.

During construction of culverts, the potential exists for increased runoff, erosion, and sedimentation as a result of vegetation removal and excavation of soil, rock, and sediment. Erosion and sediment control BMPs, including routine maintenance of drainage ditches and stream crossings, would be implemented and maintained during the mine operation period.

AMERICAN OVERSIGHT

Surface Water Extraction

Water to be used during construction and operation would be extracted from 21 designated sites along the transportation corridor (Figure 4.16-7). Water extraction sites may be used at any time of the year; although during the winter months, low-flow conditions may limit water availability.

Alaska Department of Fish & Game (ADF&G) Fish Habitat Permit requirements regulate the minimum streamflow required in anadromous streams, as well as the locations of extraction and the amount permitted for withdrawal. Before the extraction of water from anadromous streams along the road and pipeline corridors, sufficient streamflow would need to be demonstrated to permit summer/winter extraction. Permit compliance would avoid the potential for impacts from water withdrawal at streams.

AMERICAN OVERSIGHT

Figure 4.16-7: Water Extraction Sites along Transportation Corridor

AMERICAN OVERSIGHT

The maximum projected surface water use along the transportation corridor during construction would be a total of 50 million gallons: 19 million gallons along the mine access road, seven million gallons along the Iliamna spur road, and 24 million gallons along the south access road. A total of 16 million gallons would be extracted from two sites on Iliamna Lake, and 5 million gallons would be extracted from the large drainage of the Newhalen River. The remaining 39 million gallons would be extracted from smaller ponds and streams. Estimated average extraction rates would range from 500 to 1,000 gallons per minute, depending on the streamflow/volume of the waterbody (PLP 2018-RFI 022). All surface water extraction would require compliance with approved state permits, stipulations, and reporting requirements.

Potential impacts to surface water resources along the transportation corridor from lake and stream water withdrawal would include reduced water levels and streamflow. Water withdrawal for all uses would be controlled by applicable permits, which would establish limits on the amount of water withdrawn from each source, and provide requirements for fish protection. Water withdrawal would be permitted, and would therefore meet the requirements of ADF&G and Alaska Department of Natural Resources for a water withdrawal permit. It is reasonable to assume that the rate and volume of water withdrawals would be monitored at each source to ensure permit requirements are met. Therefore, the intensity of the impacts to surface water resources is generally expected to result in changes in water quantity likely within the limits of historic and seasonal variation.

Erosion and Scour at Stream Crossings

The transportation corridor would include numerous road and/or pipeline crossing of waterbodies with culverts and bridges. If not properly designed, constructed, and maintained, culverts and bridge abutments may cause constricted natural streamflow, causing increased water velocity at the downstream end of the structure. This could lead to localized bank erosion and scour, or erosion around the infrastructure. Erosion and scour could modify stream morphology by deepening and widening the stream channel downstream, modifying aquatic habitat, and causing sedimentation downstream. If the infrastructure would not allow for adequate flow, water could pool up on the upstream side, leading to erosion of the roadbed. In extreme cases, improper bridge or culvert design or improper construction materials could lead to collapse of the infrastructure. Culverts and bridges would be designed to allow for safe fish passage. See Section 3.24, Fish Values, for information on fish and aquatic resource impacts, and required permits that would be obtained prior to construction.

The potential for erosion and scour at stream crossings is dependent on streamflow and streambed substrate, and would be mitigated through engineering design and maintenance. Culvert and bridge design would be further evaluated during final engineering and design.

[Placeholder: Results of the summer 2018 fish survey field studies were recently received and include information regarding substrate (e.g., silt, gravel) and turbidity in fish-bearing streams along the corridor (PLP 2018-RFI 036). This section will be revised for the DEIS to include descriptions as needed.]

4.16.2.3 Amakdedori Port

Runoff, Erosion, and Sedimentation

The port terminal building would be constructed on an engineered fill patio, designed to be at an elevation high enough to avoid tidal surge from major storms. The port terminal would be built at an elevation of 35 feet above mean sea level (amsl), which is estimated to be 15 feet above the

AMERICAN OVERSIGHT

Amakdedori Creek floodplain. Stormwater drainage infrastructure such as ditches and culverts would be maintained during operations so that they convey flow as designed.

During construction, the potential impacts of the Amakdedori port facility on surface water runoff and erosion would be minimized by implementing BMPs for erosion control and construction at the port (Section 4.14, Soils; Section 4.18, Water and Sediment Quality; and Chapter 5, Mitigation). Surface water flow systems would be maintained and final design parameters would account for changes in water quantity and velocity. Therefore, any direct and indirect impacts on water quantity and velocity would result in maintained surface water flow systems and changes in water quantity that are likely to be within the limits of historic seasonal variation.

Marine Water in the Port Vicinity

Impacts to water quality and substrate from causeway and jetty construction are described in Section 4.18, Water and Sediment Quality. The capability of a causeway to alter oceanographic processes is well-known and understood (e.g., Colonell et al. 1992). However, the capability of a causeway to alter the density structure of the water column is more subtle. Causeway-induced influences on the water column can be important. In some cases, water column density may become stratified, which would appear as vertical or horizontal gradients in temperature and/or salinity (such as when fresher water overlies denser saltier water). In Kamishak Bay, only small sources of fresh water enter salt water; therefore, it is very unlikely that the project causeway would cause notable variations in water density. In addition, it is very unlikely that the causeway would affect overall circulation in Kamishak Bay, given its relatively short length.

The causeway would support servicing of the lightering vessels that would transport ore concentrate to the Handysize ships moored offshore. Although ship wakes and propeller wash can contribute substantially to shoreline erosion in relatively quiescent waters, neither is expected to be an issue in Kamishak Bay. Wave forecasts for wind conditions typical of Kamishak Bay (Section 3.16, Affected Environment) suggest that the bay already has a dynamic wave climate to which the shoreline has achieved a stable equilibrium; the bay is not likely susceptible to incrementally increased wave activity as a result of the lightering vessels' wakes. Whether the seabed at or near the causeway would be susceptible (i.e., erodible) to propeller wash would depend on the composition of the seabed materials (e.g., sand, silt, rock), and on the management of lightering vessel operations. Establishment of suitable BMPs for vessel operations should be sufficient to minimize adverse impacts; namely, BMPs should include specifications for managing ferry speed (minimizing wakes) and engine power settings (minimizing bottom erosive stress) during approach and departure from the causeway berths.

During winter, sea ice could become an operational issue. The causeway may provide shelter from ice on its leeward side, but this is likely to be variable throughout the winter because of shifts in prevailing winds.

Removal of the causeway at the end of the project would cause substantial increases in suspended sediment in Kamishak Bay that would persist for days to weeks after decommissioning is completed (see Section 4.18, Water and Sediment Quality).

4.16.2.4 Iliamna Lake

Ferry Terminals

Ferry terminals would be built on the northern and southern shores of Iliamna Lake. Project description noted that planned construction of causeways consisted of rock and aggregate. Some shoreline and lakebed disturbance would be expected to occur on both sides of the lake, resulting in temporary increases in suspended sediment concentrations during construction and

AMERICAN OVERSIGHT

decommissioning. Such disturbances would be limited to the immediate vicinities of the ferry terminals. Transport of suspended sediment concentrations by wind-driven currents along shore is not expected to be of long duration or to cover a large geographic area.

Vessel Operations

Vessel wakes and propeller wash could contribute to shoreline erosion in relatively quiescent waters, but neither wake nor propeller wash is expected to affect the shoreline of Iliamna Lake under proper vessel operation BMPs. Wave forecasts for wind conditions typical of Iliamna Lake (Section 3.16, Affected Environment) suggest that the lake already has a dynamic wave climate to which the shoreline has achieved a stable equilibrium; the lake is not likely susceptible to incrementally increased wave activity that could be caused by the ferry's wake. Whether the lake bottom at or near the ferry terminals would be susceptible (i.e., erodible) to propeller wash would depend on the lake bottom materials (e.g., silt, sand, gravel, rock), and on the management of ferry operations. BMPs should include specifications for management of ferry speed (minimizing wakes) and engine power settings (minimizing bottom erosive stress) during approach and departure from the terminals.

4.16.2.5 Natural Gas Pipeline Corridor

Surface Water Extraction

Potential impacts to surface water resources along pipeline corridor from lake and stream water withdrawal would be the same as those described under the transportation corridor. Water withdrawal for all uses would be controlled by applicable permits, which would establish limits on the amount of water withdrawn from each source, and provide requirements for fish protection. It is reasonable to assume that the rate and volume of water withdrawals would be monitored at each source to ensure permit requirements are met. Therefore, the intensity of the impacts to surface water resources is expected to result in changes in water quantity, likely within the limits of historic and seasonal variation.

Erosion and Scour at Stream Crossings

Impacts would be similar to those described for the transportation corridor.

4.16.2.6 East Kokhanok Ferry Terminal Variant

Impacts to surface water hydrology under this variant would be similar to those for the terminal location under Alternative 1.

4.16.3 Action Alternative 2 – North Road and Ferry

4.16.3.1 Mine Site

Impacts to surface water hydrology under Alternative 2 are expected to be the same as those described under Alternative 1.

4.16.3.2 Transportation Corridor

Road: Mine Site to Eagle Bay and Pile Bay to Diamond Point Roads

Surface water hydrology impacts associated with the road segments from the mine site to Eagle Bay and Pile Bay to Diamond Point port would be similar to impacts described for Alternative 3

AMERICAN OVERSIGHT

(see below), which includes a full road access from the mine site to Diamond Point. The road segments for Alternative 2 would result in fewer stream crossings than Alternative 3.

Ferry: Eagle Bay to Pile Bay Ferry

Ferry operations from Eagle Bay to Pile Bay would have similar impacts to surface water hydrology as ferry operations as Alternative 1.

4.16.3.3 Summer-Only Ferry Variant

Summer-only ferry variant would preclude the need for ice-breaking operations. Ferry operations for the summer-only ferry variant would have similar impacts to surface water hydrology as ferry operations in Alternative 1.

4.16.3.4 Diamond Point Port

Terminal and Lightering Locations

[Placeholder: The proposed layout for the Diamond Point port facility is currently under development by PLP. This section will be revised as necessary once information is received (PLP 2018-RFI 099)].

Dredge Disposal Area

Dredge material would be placed in an onshore bermed facility west and upland of the dock site. The water placed in the bermed containment would seep into underlying soils, and would mix with any shallow groundwater present. Therefore, runoff from the disposal site would remain contained in the bermed area, and would not affect surface water hydrology.

4.16.3.5 Natural Gas Pipeline Corridor

Impacts to surface water hydrology would be the same as described under Alternative 1 for the portion of the pipeline beginning on the Kenai Peninsula and crossing Cook Inlet to Kamishak Bay. Impacts would be the same as described under Alternative 3 for the portion from Diamond Point to the mine site.

Ursus Cove to Diamond Point

The pipeline corridor through Ursus Cove to Diamond Point would result in approximately three additional stream crossings, and the associated impacts to surface water hydrology would be similar to the natural gas pipeline corridor for Alternative 1.

4.16.3.6 Pile-Supported Dock Variant

Construction of a pile-supported dock at Diamond Point would not impact onshore surface water or marine hydrology.

4.16.4 Action Alternative 3 – North Road Only

Under Alternative 3, impacts to the pipeline corridor would be the same as those described under Alternative 2. The following section describes impacts for the mine, transportation corridor, and port that would be different under Alternative 3.

AMERICAN OVERSIGHT

4.16.4.1 Mine Site

Under Alternative 3, impacts to the project mine site would be the same as under Alternative 1.

4.16.4.2 Transportation Corridor

The road in Alternative 3 would increase the project footprint. The road route would result in a small increase in the number of stream crossings relative to other alternatives (see Chapter 2, Alternatives). Impacts associated with stream crossings would be the same as those described under Alternative 1.

4.16.4.3 Diamond Point Port

Concentrate Storage and Bulk Handling

Concentrate would be dewatered and stored at the port sites, and the dewatered concentrate would be stored in a large storage building until the lightering system would be used to load the concentrate onto bulk carriers for transport. The lightering system would use bulk handling or the concentrate to load the bulk carriers, with controls to reduce dust emissions (e.g., covered conveyors) (PLP 2018-RFI 066). Because the material would be stored inside, impacts to surface water hydrology are not expected.

4.16.4.4 Concentrate Pipeline Variant

Impacts to surface water hydrology under this variant would be the same as for Alternative 2. The concentrate pipeline variant would include a water-return pipeline to move water back to the mine site. This variant would result in no additional project footprint at Diamond Point, and preclude the need for the discharge of treated water into Cook Inlet. The concentrate pipeline variant would eliminate the need for a WTP at the port; and instead, would require a return water pump station of appropriate capacity (PLP 2018-RFI 066). This option would result in negligible change in footprint at the port site as compared to Alternative 1, and there would be no additional impact to surface water hydrology as a result of the pump station footprint.

A concentrate pipeline from the mine site to the port location would require two electric pump stations—one at the mine site, and one booster station at an intermediate location between the mine site and the port—resulting in an increased footprint of approximately 0.7 acre (PLP 2018-RFI 066). This alternative would reduce the amount of WTP water released at discharge locations at the mine site by approximately 1 to 2 percent (PLP 2018-RFI 066). Reduced discharge water from WTPs could result in a greater reduction in streamflows than those described under Alternative 1.

4.16.5 Summary of Key Issues/Impacts Summary

AMERICAN OVERSIGHT

Table 4.16-5 provides a summary of impacts on surface water hydrology, marine water, and lake water (Iliamna Lake).

Table 4.16-5: Key Issues Summary – Surface Water Hydrology

Impact Causing Project Component or Activity	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Mine Site – Streamflow During Operations, Maximum Footprint	**NFK Watershed (Bulk and Pyritic TSFs, Main WMP, Process Facility):** 100% of NKF tributary NK1.190 flow diverted or stored due to Bulk TSF. NFK River – Mean annual streamflow reduction from pre-mining conditions of 7% at both NK100C and NK100A (with treated water discharge). **SFK Watershed (Mine Pit and Groundwater Dewatering Wells, Overburden Stockpile)**: SFK River – Mean annual streamflow reduction from pre-mining conditions of 4% at SK100F and 2% at SK100A (with treated water discharge). **UTC Watershed (Mine Access Road):** Upper UTC – Mean annual streamflow reduction from pre-mining conditions of 1% at UT100D (with treated water discharge).	**NFK Watershed:** Same and Alternative 1. **SFK Watershed:** Same and Alternative 1. **UTC Watershed:** Same and Alternative 1.	**NFK Watershed:** Same and Alternative 1. **SFK Watershed:** Same and Alternative 1. **UTC Watershed:** Same and Alternative 1.
Mine Site – Streamflow Post-Closure (Phase 4)	**NFK Watershed:** 100% of NKF tributary NK1.190 flow diverted or stored due to Bulk TSF. NFK River – Mean annual streamflow reduction from pre-mining conditions of 4% at NK100A (with treated water discharge). **SFK Watershed:** SFK River – Mean annual streamflow reduction from pre-mining conditions of 9% at SK100F and 1% at SK100A (with treated water discharge). **UTC Watershed:** UTC – No mean annual	**NFK Watershed:** Same and Alternative 1. **SFK Watershed:** Same and Alternative 1. **UTC Watershed:** Same and Alternative 1.	**NFK Watershed:** Same and Alternative 1. **SFK Watershed:** Same and Alternative 1. **UTC Watershed:** Same and Alternative 1.

Natural Gas Pipeline			
Construction and Installation of Pipeline	**Surface Water**: Likely the same as for the Transportation Corridor Alternative 1.	**Surface Water**: Impacts similar to transportation corridor Alternative 2. Additional acreage and an additional 3 stream crossings to segment crossing Ursus Cove.	**Surface Water**: Likely the same as for the transportation corridor Alternative 3.

4.16.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to surface water hydrology impacts. Section 4.1 details the past, present, and RFFAs considered for evaluation. The limited number of past and present actions considered is not expected to result in lingering effects that would be anticipated to have a timing nexus with the project, and are therefore not considered further as potential contributors to cumulative impacts.

RFFAs that could contribute cumulatively to surface water hydrology impacts, and are therefore considered in this analysis, are limited to those activities that would occur in the Mine Site area, or in other waterbodies intersected by the transportation corridor. The following specific RFFAs were carried forward in this analysis based on their potential to contribute cumulatively to surface water hydrology in the study area:

- Pebble Project buildout – develop 55 percent of the resource over 78-year period
- Pebble South*
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun
- Diamond Point Rock Quarry

*Indicates exploration activities only.

The most important potential future actions included in this analysis are those that are likely to contribute to surface water hydrology and are regionally common to the project. Because development at remote locations can be financially prohibitive, RFFAs in proximity to the project that could potentially minimize costs through co-use of project infrastructure are also considered important in this analysis.

AMERICAN OVERSIGHT

The Pebble Project buildout and commercialization of the Shotgun prospect are the only mineral deposit RFFAs considered for exploration and development. All other mineral deposit RFFAs are considered for exploration only. The Pebble Project buildout is the most notable RFFA, and would result in additional development not included under Alternative 1:

- Increased pit footprint
- Increased TSF and waste rock storage capacity
- Additional processing infrastructure
- Construction of a new port site with diesel fuel and concentrate pipeline(s) extending to the mine site.

The estimated area of disturbance would be greater than Alternatives 1 and 2 combined, based on infrastructure build-out at the mine site. The build-out would correspond to an increase in magnitude and local extent of disturbance impacts, with a duration increase of up to 98 years with processing of low-grade PAG waste. Potential for surface water hydrology impacts would increase, and could be comparable to or greater than Alternatives 1 and 2 combined. Additional design features to capture and treat impacted water and subsequent discharge of treated water to the SFK, NFK, and UTC watersheds would be necessary to manage mine site impacts.

Development of the Shotgun prospect, while potentially contributing cumulatively to regional surface water hydrology impacts in the Nushagak watershed, would not physically overlap with the Pebble Project area, and the cumulative impact in the common areas of the lower Nushagak watershed would be expected to be minimal if the design features applied to the Pebble Project achieve the anticipated water discharge controls.

Some limited RFFAs associated with mineral exploration activities (e.g., Pebble South, Big Chunk North, Big Chunk South, Fog Lake, and Groundhog) could have some limited surface water hydrology impacts in common watersheds to the Pebble Project (e.g., drill pads, camps); however, they would be seasonally sporadic, temporary, and localized based on remoteness. Although exploration activities are considered to have minimal cumulative impacts to soil resources, there could be potential for greater surface water hydrology impacts from future development through transportation infrastructure co-use with the Pebble Project.

The footprint of the Diamond Point rock quarry coincides with the Diamond Point port footprint under Alternatives 2 and 3. Cumulative impacts would be limited to a potential increase in localized surface water hydrology impacts from commonly shared project footprints with the quarry site under Alternatives 2 and 3.

Overall, the magnitude of cumulative impacts to surface water hydrology from RFFAs in general would be expected to be minimal, with the exception of RFFA activities in the immediate mine site (e.g., Pebble Project buildout). The cumulative effects in the mine site footprint, expanded to include buildout development, would increase; but it is expected that controls would be in place to manage those impacts to prevent adverse effects on the outside environment.

AMERICAN OVERSIGHT

K3.13 GEOLOGY -

This appendix contains supplemental information on the affected environment for the following topic(s) related to:

- Baseline paleontological resources

K3.13.1 Mine Site

Cretaceous age Kahiltna flysch sedimentary units are largely derived from eroded volcanic rocks, and are not likely to contain fossils. Other volcanic and intrusive igneous rocks in the mine site area are not suitable lithologies for fossil formation and preservation. Quaternary age glacial sediments at the mine site are unlikely to host fossils, and without measurable permafrost, significant findings of frozen Pleistocene age megafauna are not likely (Blodgett and Zhang 2018; Arctos 2018).

K3.13.2 Transportation Corridor

As with the mine site, the intrusive igneous and volcanic bedrock that spans most of the mine access transportation corridor is not an amenable lithology for fossil formation and preservation. Pleistocene age glacial sediments along the transportation corridor are unlikely to host fossils and, without the preserving effects of measurable permafrost, significant findings of Pleistocene age megafauna are not likely (Blodgett and Zhang 2018; Arctos 2018).

There are known paleontological resource sites at the southern terminus of the transportation corridor, where the road meets the port. Quaternary age beach deposits present in the area are locally fossiliferous, originating from erosion of nearby Jurassic age marine sedimentary rock (see Amakdedori Port section below); therefore, fossils are likely present in that area (Detterman and Reed 1973). About 20 acres of the transportation corridor footprint is on Quaternary age beach deposits that could contain significant fossil resources. Additionally, the transportation corridor comes within 800 feet of the Talkeetna and Naknek formations, which have produced significant vertebrate paleontological resources (Wilson et al. 2012).

K3.13.3 Amakdedori Port

Jurassic age marine sedimentary rocks around the port site are host to numerous diverse marine invertebrate fossils. Fossil ammonites, brachiopods, cephalopods, and pelecypods are abundant in the Naknek and Talkeetna Formation members exposed in the bluff directly northeast of the port facility (Blodgett and Zhang 2018; Detterman and Reed 1973, 1980; Wilson et al. 2012). Cephalopod fossils eroded from nearby Jurassic age sedimentary rock have been found in the same beach deposits located within the port facility footprint (Arctos 2018). While these are common fossils, they are considered significant as sources of new data concerning Jurassic period evolutionary trends, species survival beyond Triassic period extinctions, and the global and regional development of Jurassic age marine biological communities (Sandy and Blodgett 2000). The Naknek Formation at other sites in the region contains vertebrate fossils from the Jurassic marine reptile *Megalneusaurus*, which represents the only find of this species in Alaska, and one of only two occurrences of this genus in North America (Blodgett et al. 1995; Weems and Blodgett 1996). Terrestrial vertebrate trackways have also been discovered in the Naknek Formation at other locales in the region (Blodgett et al. 1995). These findings demonstrate a potential for paleontological resources in the Amakdedori port footprint.

AMERICAN OVERSIGHT

K3.13.4 Natural Gas Pipeline Corridor

The paleontological environment of the natural gas pipeline corridor is the same as that discussed above for the transportation corridor. Quaternary age sediments along both sides of Cook Inlet are unlikely to contain fossils, and without the preserving effect of measurable permafrost, significant findings of Pleistocene age megafauna are not likely (Blodgett and Zhang 2018; Arctos 2018). In the offshore section of corridor, the shallow floor of the Cook Inlet is filled with abundant sand, pebbles, cobbles, and boulders flushed into the inlet from young glacial deposits across the region; no fossil resources would be expected.

K3.15 GEOHAZARDS

This appendix contains additional technical information on the following topics related to the affected environment for geohazards described in Section 3.15, Geohazards:

- Liquefaction processes and depth
- Baseline geotechnical data coverage at the mine site

K3.15.1 Liquefaction

Liquefaction occurs when a saturated or partially saturated soil substantially loses strength and stiffness in response to an applied stress, such as earthquake shaking, which causes it to behave like a liquid. When a soil is saturated by water, which often exists below the groundwater table, the water fills gaps between soil grains (i.e., pore spaces). In response to the soil compressing, this water increases in pressure and is forced to flow out of the soil to zones of low pressure, usually up to the ground surface. However, if the loading is rapidly applied and large enough, or is repeated many times (e.g., earthquake shaking), the water cannot flow out in time before the next cycle of load is applied, and the water pressure could build up and exceed the forces (contact stresses) between the grains of soil that keep them in contact with one another. These contacts between grains are the means by which weight from structures and overlying soil layers are transferred from the ground to deeper soil or rock. This loss of soil structure causes the soil to lose its strength, and triggers liquefaction.

The depth to which liquefaction can occur has implications for the behavior of saturated tailings in an earthquake (see Section 4.15, Geohazards). Knowledge on the maximum depth of liquefaction has evolved in recent years because of large global earthquakes and resultant liquefaction (Bray 2013; Stewart and Knox 1995; Tchakalova 2018; WSDOT 2013). The Washington State Department of Transportation Geotechnical Design Manual M 46-03.09 limits the depth for considering liquefaction to 80 feet, but suggests that analyses be performed to determine liquefaction probability if loose materials are below 80 feet. Stewart and Knox (1995) conclude it is possible for excessive porewater pressures to exist considerably below 100 feet, that are sufficient to overcome the stiffness created by overburden pressures and exceed the thickness for liquefaction, and that great earthquakes can generate stresses of sufficient intensity and duration to produce liquefaction conditions in unconsolidated sediments below 1,000 feet. Tchakalova (2018) adds that the maximum depth at which liquefaction can occur is probably the same as the maximum depth at which sands and silts can remain unconsolidated and maintain a sufficient porosity and hydraulic conductivity, and that whatever those depths, earthquakes of M8.0 or greater can produce stresses in the hypocenter and epicenter zones sufficient to overcome overburden pressures below 1,000 feet.

K3.15.2 Baseline Geotechnical Data Coverage

The following table summarizes the number of geotechnical drillholes, test pits, and seismic line collected in and near the footprint of different facilities at the mine site. A summary of overburden deposits and bedrock encountered in each area is provided in Section 3.13, Geology.

AMERICAN OVERSIGHT

Table K3.15-1: Baseline Geotechnical Data Coverage at Mine Site

Area	Facilities	Number of Drill Holes	Number of Test Pits	Number of Seismic Lines
NFK-West	Bulk TSF main embankment, impoundment, and quarries	39	37	9
NFK-East	Pyritic TSF and associated SCPs	14	38	9
NFK-North	Main WMP, bulk TSF main embankment SCP, emergency dump pond	29	13	0
Pit Area	Open pit and rim	31	30	6

K4.13 GEOLOGY

This appendix contains supplemental information on the following topic(s) related to:

- Historical field and desktop studies
- Impacts to paleontological resources

K4.13.1 Historical Geology-Related Field and Desktop Studies

The geology-related findings presented in Sections 3.13, Geology, and Section 4.13, Geology, were based on the review of field and office studies completed within the Pebble project area, including the following:

- Relevant existing literature and studies completed by the Applicant and others, including published geological reports and maps prepared by the US Geological Survey, Alaska Division of Geological & Geophysical Surveys and others (Knight Piésold. 2011a and 2011d; Detterman and Reed 1973 and 1980; Hamilton and Klieforth 2010; Nokleberg et al. 1994; Plafker et al. 1994; Wilson et al. 2012).
- Evaluation and interpretation of aerial photographs taken from aircraft, which can provide a good understanding of the surficial geological conditions (Knight Piésold. 2011a and 2011d).
- Field reconnaissance studies, including helicopter and on-the-ground geologic mapping to verify the aerial photograph-related findings (Knight Piésold. 2011a and 2011d).
- Offshore drill holes and bathymetry (depth of water) surveys to support the ferry transportation corridors and natural gas pipeline alternative-related studies (Knight Piésold. 2011a, 2011d and 2018).
- Within the mine study area:
    - More than 700 drill holes were completed within the mine study area using helicopter-portable drilling equipment (Figure 3.15-3). About 500 of the drill holes were completed to understand the mineralogy, and the remaining drill holes supported civil engineering-related studies. Rock and soil samples were collected for detailed evaluation during and after the field work (Knight Piésold 2011a, 2011d and 2018).
    - Excavation of more than 300 test pits within the mine study area that ranged in depth between about 1.5 to 3 meters and were completed by a helicopter-portable excavation apparatus (Knight Piésold. 2011a, 2011d).
    - Ground-based (versus from aircraft) geophysical surveys were completed with helicopter- and boat-portable instruments within the mine study and project area to understand the physical characteristics of the mineralized bedrock and near-shore sediments. These studies were non-invasive (did not include drilling or excavations) and relied on electronic sensors to map the geology. The geophysical studies included seismic reflection, infrared imagery, and induced polarization (Knight Piésold. 2011a, 2011d, 2018_[report pending]).

AMERICAN OVERSIGHT

K4.13.2 Paleontological Resources

Ground- and bedrock-disturbing actions have the potential to directly impact fossil-bearing deposits through physical disturbance, fragmentation, or destruction of fossil material. The following describes potential impacts to paleontological resources by project component.

K4.13.3 Mine Site

Due to the type of geological formations present, the possibility for paleontological resources in the mine site is unlikely.

K4.13.4 Transportation Corridor

Because of the prevalence of igneous rock type on the transportation corridor, paleontological findings along the transportation corridor outside the port area are unlikely (see Amakdedori Port below). However, depending on depth of the paleontological resources beneath the surface Quaternary age beach deposits, 20 acres in the vicinity of the port facility have the potential to impact paleontological resources.

In the vicinity of the Amakdedori port, the transportation corridor has a footprint that covers about 20 acres of the fossil-bearing Quaternary age (2.6 million years) beach deposits. The corridor near the port also comes within about 800 feet of the Talkeetna and Naknek formations (Wilson et al. 2012), which have produced vertebrate paleontological resources, as previously described. Further, there would be potential for indirect impact to paleontological resources present in the nearby Naknek and Talkeetna Formation exposures from increased access to the area resulting from the development of the transportation corridor.

K4.13.5 Amakdedori Port

Indirect impacts may be caused by increased erosion or other landscape changes, or from increased accessibility to paleontological resources, resulting in an increased likelihood of vandalism or unauthorized collection. Increased access to the area from project development could result in unauthorized collection, removal, excavation, or casting of fossils, including dinosaur tracks, which could result in the damage or destruction of paleontological resources.

Potential paleontological resources that could be removed would likely be common, widespread invertebrate fossils found in sedimentary rocks. There is a chance that rare or unique fossils could be removed or destroyed, such as dinosaur fossils or tracks in Jurassic age rock, or Pleistocene age vertebrate/mammal fossils/remains in surficial glacial deposits.

The Amakdedori port construction footprint covers roughly 250 acres, all within Quaternary age beach deposits that have locally produced fossils considered to be significant paleontological resources (Sandy and Blodgett 2000; Wilson et al. 2012). Additionally, the Talkeetna and Naknek Formations are exposed in outcrops in the immediate vicinity of the port facility. These formations are highly fossiliferous, with the Naknek Formation in the vicinity producing a vertebrate specimen of an extremely rare Jurassic age marine reptile, *Magelneusaurus*, which represents the only find of this species in Alaska, and one of only two occurrences of this genus in North America (Blodgett et al. 1995; Weems and Blodgett 1996). Because the subsurface geology of the port site has not been mapped in detail, it is possible that bedrock underlying the port site footprint is the Naknek and/or Talkeetna Formations, with the potential for paleontological resources to be present beneath the port footprint.

Port facility construction, operations, and maintenance have the potential to directly impact paleontological resources (if present) over the entire 250-acre port site footprint. The potential also exists for indirect impacts to paleontological resources present in the nearby Naknek and

AMERICAN OVERSIGHT

Talkeetna Formation exposures, due to increased access to the area from port site development.

K4.13.6 Natural Gas Pipeline Corridor

Although there is a possibility of the occurrence of paleontological resources in the pipeline corridor outside the port area, potential impacts to paleontological resources along most of the pipeline corridor are unlikely. The pipeline corridor in the vicinity of the Amakdedori port has a footprint that covers roughly 12 to 15 acres of the fossil-bearing Quaternary age beach deposits. The natural gas pipeline corridor would be within 820 feet of the Talkeetna and Naknek formations (Wilson et al. 2012). Accordingly, 12 to 15 acres of the pipeline corridor have the potential to impact paleontological resources. If ground-disturbing activities from pipeline construction, operations, or maintenance activities extend outside these 12 to 15 acres, there is additional potential for impacts.

K4.15 GEOHAZARDS

This appendix contains additional technical information related to potential geohazards at the mine and port sites, including the following topics:

- Mine site
  - Embankments and impoundments
    - Construction materials
    - Design and construction
    - Seepage analysis
    - Static stability analysis
    - Seismic hazard and deformation analysis
  - Open pit
    - Pit wall stability analysis
- Port sites
  - Seismic hazard analysis.

K4.15.1 Mine Site

The following discussion addresses mine site facilities that would have the potential to be affected by geohazards, which could include internal erosion and slope failure of embankments and impoundments, and rock wall instability within the open pit.

K4.15.1.1 Overview of Mine Embankments and Impoundments

The mine embankments and impoundments would be designed and constructed to store tailings and contact water during mine operation that could pose a risk to the environment if released due to geohazards. The proposed mine site–related embankments and impoundments, shown in Figure 2-3 and summarized in Table K4.15-1, include the bulk tailings storage facility (TSF), the pyritic TSF, water management ponds (WMPs), and seepage collection ponds (SCPs). Table K4.15-1 presents the buildout dimensions of the embankments and impoundments that would contain tailings, waste rock, and/or contact water at the mine site. These facilities are discussed hereafter.

K4.15.1.2 Embankment Construction Materials

The embankments for the tailings and water management facilities would be constructed of drilled and blasted bedrock removed from quarries A through C and the overburden in the open pit (Figures 2-3 and K4.15-1). The three rock quarries would be developed in the western portion of the mine site in bedrock consisting of granodiorite associated with the Kaskanak batholith. The overburden in the open pit would consist of various types of sedimentary and igneous rock. See Section 3.13, Geology, for further discussion of mine site geology.

AMERICAN OVERSIGHT

EPA-0135-0002648

Figure K4.15-1: Quarries A through C – Typical

AMERICAN OVERSIGHT

The characterization of rock types in the three rock quarries and the open pit area was based on both surface geological mapping and geotechnical drill holes (PLP 2018-RFI 015). Additional information regarding rock quality will be made available after the geotechnical field data collected in the latter part of 2018 have been processed.

Table K4.15-2 presents the estimated rock volumes of the three rock quarries plus the open pit overburden, based on the maximum footprints as presented in Figure 2-3. The table considers the differences between in-place versus post removal and post placement volumes and unit densities of the rockfill materials, as described in the table footnotes below.

Table K4.15-2: Summary of Available Embankment Rockfill Material

Material Source	Banked Volume		Reduction Factor[2]	Bulking Factor	Loose Volume		Compaction Factor	Compacted Materials		
	(Mft^3)	(Mcy)			(Mft^3)	(Mcy)		(Mft^3)	(Mcy)	(Mton)
Quarry A	1,440	53	0.9	1.6	2,074	77	1.3	1,685	62	101
Quarry B	2,693	100	0.9	1.6	3,878	144	1.3	3,151	117	189

Source: PLP 2018-RFI 015b

Notes:

Mcy: million cubic yards

Mft^3: million cubic feet

Mton: million tons

lb/ft^3: pounds per cubic foot

1 Material Definitions:

Banked Volume – Volume before excavation.

Banked Density – Density of in-situ material before excavation.

Loose Volume – Volume after excavation.

Loose Density – Density of material after excavation.

Compacted Volume – Volume after compaction.

Compacted Density – Density of materials after compaction.

Bulking Factor – Loose volume/banked volume.

Compaction Factor – Compacted volume / banked volume.

Usable Material Reduction Factor (reduction to account for out-of-specification/unusable materials) = 0.9 (quarries), 0.5 (open pit overburden; reduced because of variability of rock quality).

2 Loose and banked densities based on estimated compacted density and bulking/compaction factors.

3 Neatline material volumes were rounded to the nearest million. Quarry volumes based on project description layout.

4 Material densities assumed as follows:

AMERICAN OVERSIGHT

Material Densities (lb/ft^3)			
Material	Banked	Loose	Compacted
Rockfill	156	98	120
Overburden	105	87	110

The material banked densities and bulking factors were estimated based on Look (2007) and are considered reasonable. Compaction factors were based on Durham University (1997). The values for compacted density were applied to the material estimates.

Table K4.15-3 presents the estimated amount of rockfill material that would be needed to construct all proposed embankments at the mine site. The data indicate that quarries A–C plus the open pit overburden would generate about 13 percent more rockfill material than needed to construct the embankments.[1]

Table K4.15-3: Embankment Rockfill Material Needs

Rockfill	Total	
	(Mft^3)	(Mton^3)
Pyritic TSF (All Pyritic Tailings/PAG Waste Rock Storage Facilities)	2,830	170
Bulk TSF Main Embankment	2,063	124
Bulk TSF South Embankment	296	18
Main Water Management Pond	796	48
Main Embankment Seepage Collection Pond	50	3
Mine Site Road Coarse Replacement	22	3
Road Sanding	50	1
TOTAL	**6,107**	**367**

Source: PLP 2018-RFI 015b

Notes:

Mton^3: million cubic tons

PAG: potentially acid-generating

lb/ft^3: pounds per cubic foot

1 Volumes of neatline material were rounded to the nearest million.

2 Rockfill compacted density assumed to be 120 lb/ft^3.

3 Mine site road sanding assumes 150,000 tons per year.

4 Mine site road coarse replacement assumes 6 inches of material replaced every 3 years.

Table K4.15-1 shows several smaller impoundments (e.g., sediment ponds) that are not presented in Tables K4.15-2 and K4.15-3. These are generally smaller in height, and were of less concern during scoping with regard to geotechnical stability and contents that could be released in the event of failure (sediment vs. contact water or tailings in the larger facilities). As

[1] If an average usable bulking factor is used, which is 0.81, the calculated compacted material in Table K4.15-2 would be 515 Mtons versus 417 Mtons as shown, which would be 40 percent more material than needed.

AMERICAN OVERSIGHT

with the larger embankments, detailed design and analysis of the smaller impoundments would be completed as part of project permitting as required under the Alaska Dam Safety Program (ADSP).

K4.15.1.3 Design and Construction of Embankments and Impoundments

The various mine site–related embankments and impoundments would be constructed of rockfill. Inherent in the construction of rockfill embankments and impoundments is the potential for groundwater to seep through the structures. The seepage would have the potential to reduce the stability of the structures by causing internal erosion. Therefore, the embankments and impoundments would be designed and constructed to minimize internal erosion during operation. The facilities would also be designed for stability during static (nonseismic) and seismic (earthquake) conditions.

The following discussion explains the general design and construction features relevant to geohazards, including elements to prevent internal erosion and instability, relevant closure-related aspects, and management and monitoring.

Bulk TSF

General. The proposed bulk TSF would consist of a main embankment (downgradient in terms of groundwater flow) and a south (upgradient) embankment (Figure 2-8). The bulk TSF would be within watersheds that flow north into the North Fork Koktuli River (NFK) and the South Fork Koktuli River, and would be mostly surrounded by bedrock knobs and slopes, which would generally promote stable foundation conditions at embankment abutments.

Under Alternative 1, the upper 280 feet of the 545-foot-high bulk TSF main embankment would be centerline constructed. That is, during raising of the rockfill dam, rockfill would be placed concurrently on top of both the centerline and the downstream slope of the previous raise. This would result in a near-vertical upstream face at the dam crest for the upper portion of the embankment, and some rockfill fill could be placed on the upstream tailings beach (Figure 2-8).

In contrast, the south embankment would be downstream constructed. That is, during raising of the rockfill embankment, rockfill would be placed on top of the downstream slope of the previous raise during the raise process, which would result in a nearly symmetrical embankment (Figure 2-8).

Under Alternatives 2 and 3, the bulk TSF main embankment would be downstream constructed with downstream buttresses to increase the embankment's stability.

The two embankments would be constructed of rockfill sourced primarily from quarry A. The rockfill would be placed and compacted in planned sequences and raise heights (PLP 2018d).

The size of the bulk TSF would assume a split in tailings from the process plant (average of 88 percent bulk tailings and 12 percent pyritic tailings), based on batch flotation tests on drillhole samples from the pit area. If this split were to deviate substantially from that planned, the embankment raise schedules for the bulk and pyritic TSFs would be adjusted to accommodate the changed tailings volumes (PLP 2018-RFI 010).

The bulk tailings volume and the related sizes of the bulk TSF embankments also assume that the tailings would be thickened to 55-percent-solids slurry by weight. If this could not be achieved and greater water volumes were generated, additional pumping capacity would be provided to transfer the tailings slurry from the process plant to the TSFs, and to pump additional supernatant water from the TSFs and their seepage ponds (PLP 2018-RFI 010).

AMERICAN OVERSIGHT

Embankment lifts and freeboard requirements would be reviewed as part of each dam lift and safety review (required by the ADSP), and would be adjusted as necessary to reflect actual tailings throughput, settled densities, mine water management conditions, and different site conditions encountered.

The south embankment would be constructed higher than the main embankment to ensure that the phreatic surface of water entrained in the tailings would slope to the north and that seepage would be contained within the NFK west catchment facilities.

Seepage-Related Elements. The bulk TSF main embankment (both the centerline- and downstream-constructed options) would use a flow-through design to prevent internal erosion by minimizing water buildup in the TSF and seepage pressure on the embankment, and to provide controlled flow away from the other embankments (PLP 2018-RFI 006a). In contrast, the upstream south embankment would use a liner on the downstream slope face and would not include a flow-through design (Figure 2-8).

The main embankment's core would consist of two to three filter and transition zone materials (a designed gradation of sand- to gravel-sized particles), based on the industry-accepted no-internal-erosion filter criteria developed by Sherard and Dunnigan (1985) (Fell et al. 2015; USACE 2004; USDA 2017).

The core materials would be developed and sourced from locations at the mine site to meet design gradation specifications. Materials with a fines content between 30 and 60 percent passing the #200 sieve are expected to be suitable for use as core zone material. Materials meeting these gradation requirements were identified in the open pit area during geotechnical investigation programs completed between 2004 and 2011 (PLP 2018-RFI 006a).

The quantity of on-site, low-permeability core materials would be confirmed during additional geotechnical investigations as the design progresses. If sufficient quantities of low-permeability materials are determined not to be available on site, alternatives such as a low-permeability face liner or asphalt core would be used.

The bulk TSF main embankment would be constructed in a manner to ensure the design performance of the core (AECOM 2018k). Material zones would be placed sequentially and not concurrently, and it is expected that the height differential would be limited to the thickness of one material lift.

The embankments would include basin and embankment underdrains to help maintain a reduced phreatic surface (or groundwater table) in the facility. Water would be managed to allow the continual development and maintenance of a tailings beach behind the bulk TSF main embankment. This would serve to protect the dam from seepage pressure that could reduce stability (Knight Piésold 2018a; PLP 2018-RFI 006, RFI-008f).

A grout curtain would be installed near the downstream toe of the south embankment to prevent upgradient groundwater from flowing into and beneath the impoundment (Figure 2-8) (PLP 2018-RFI 008f). The grout curtain would be keyed into the bedrock underlying the main embankment before the placement of the embankment materials. The grout curtain zone would be injected through pipe sleeves embedded along a concrete plinth at the bedrock interface beneath the embankment.

The design freeboard would contain the entire volume of the inflow design flood (IDF) above the tailings beach. The freeboard would also account for wave run-up and wind set-up protection and postseismic settlement (Knight Piésold 2018a; PLP 2018-RFI 019a, 028).

A tailings beach would be developed in the east corner of the bulk TSF to promote pond development and subsurface drainage away from the topographic saddles. Water levels and

AMERICAN OVERSIGHT

freeboard in the bulk TSF pond would be maintained through proactive raise construction to account for the IDF within the elevation of the tailings beach (AECOM 2018k). Excess water would be controlled by pumping to the main TSF SCP or the main WMP (Knight Piésold 2018a).

Concern was expressed during the environmental impact statement (EIS)–phase failure modes effects analysis (FMEA) regarding the possibility of uneven deposition of tailings around the perimeter of the bulk TSF (because of spigot spacing and segregation of thickened tailings), leading to smaller beaches and added seepage pressure on the embankments. Deposition of tailings on ice in the winter (practiced at Red Dog Mine) was discussed as a possible method to mitigate this effect (AECOM 2018k).

Stability-Related Elements. The TSF embankment foundations would be prepared by removing overburden to expose competent bedrock before placement of the rockfill. Should colluvium and/or talus surficial deposits be encountered beneath the structure footprints, which could result in downslope movement (described in Section 3.15, Geohazards), they would be removed to avoid posing a stability issue 6for the embankments and/or liners.

As noted above, the bulk TSF main embankment under Alternatives 1 and 3 would use centerline construction to reduce the footprint. The upstream portion of successive dam raises would partially rest on tailings, and additional buttresses would be provided downstream to enhance overall stability. Alternative 2 would use a downstream construction design, which is typically considered more stable than centerline construction. The results of the preliminary stability analyses for both the centerline and downstream alternatives are described in Appendix K4.15.

The bulk TSF embankments would be regulated as Class I (high) hazard potential dams under ADSP guidelines (Alaska Department of Natural Resources [ADNR] 2017a), with an operating basis earthquake (OBE) and maximum design earthquake (MDE) established in accordance with criteria described in Appendix K4.15.

The main embankment's internal filter zone would be thick enough to fulfill standard filter zone design criteria to prevent internal erosion and also remain intact after the MDE. The thickness of the filter zone must be wider than the maximum horizontal deformation that the embankment would undergo as a result of the MDE.

For example, assume the filter zone thickness is determined to be *X*, and the maximum horizontal deformation is calculated to be *Y.* In this case, the filter zone must be at least *X*+*Y* thick so that it would remain continuous and functional with a thickness of at least *X* throughout the full height of the embankment after it has been sheared by the *Y* movement. The *X* and *Y* details would be conceptually developed after geotechnical programs are completed, the results analyzed, and dimensions finalized as design progresses.

Closure. The bulk TSF would be closed in place after Year 20 and would undergo dry closure and become a permanent landform (PLP 2018-RFI 024). Free water would be pumped out and the tailings would be allowed to consolidate until they become suitable for equipment traffic.

The permeable design of the main embankment would allow the tailings to continue to drain, thereby lowering the phreatic (groundwater) level and improving embankment stability. The tailings surface would be regraded to facilitate surface drainage away from the TSF. The closure cover would consist of a capillary break layer composed of rockfill to promote horizontal drainage and minimize infiltration; an overlying low-permeability layer consisting of glacial till; topsoil and growth media placed over the final tailings surface; and revegetation (PLP 2018d; PLP 2018-RFI 091).

AMERICAN OVERSIGHT

Management and Monitoring. Monitoring would be included in all phases of the TSF (PLP 2017, 2018d). In accordance with ADNR (2017) guidelines, monitoring would include the following elements:

- Construction quality assurance (CQA) and construction quality control (CQC) plans to assure that the TSF embankments are built in accordance with the approved design, drawings and specifications, as well as design modifications that might arise during construction as a result of differing site conditions.
- An emergency action plan (EAP) that includes a dam break analysis with inundation maps and describes actions to be taken in the event of dam failure, along with information and in-place preparations needed to take those actions immediately and without unnecessary delays.
- An operations and maintenance (O&M) manual describing procedures to be implemented under normal and extreme water levels; an operator training program; monitoring to confirm that embankments are performing in accordance with the design; periodic safety inspections; extraordinary inspections after extreme events (e.g., major earthquakes, large floods, freeboard exceedance, vandalism); and mitigation to conduct repairs or structural modifications if the dam is not performing as designed.
- Monitoring after closure would include inspections for mass stability, seepage flows, and inspections after extreme events.

Pyritic TSF

General. The pyritic TSF would consist of a continuous embankment around the north (downgradient), east, and south (upgradient) sides (Figures 2-3 and 2-9). This facility would be designed to isolate the most contaminated tailings and waste rock in a fully lined, subaqueous storage cell during operations to minimize acid generation (PLP 2018d).The majority of the pyritic TSF would be located in a single tributary valley that drains north toward the NFK, referred to as the "NFK east site." The southern portion of the pyritic TSF south embankment would be situated in a drainage divide between the NFK east watershed and a tributary that drains south toward the South Fork Koktuli River.

As with the bulk TSF, the embankments would be regulated as Class I (high) hazard potential dams under ADNR (2017) guidelines. An OBE and MDE would be established similar to those described above for the bulk TSF.

Seepage-Related Elements. The pyritic TSF would be a lined facility using a high-density polyethylene (HDPE) geosynthetic membrane to retain water. Therefore, the facility would likely not include core/filter/transition zones as described for the bulk TSF main embankment (PLP 2018-RFI 055). SCPs with pumpback and groundwater monitoring wells would be situated downgradient of the north, east, and south embankments, as required by the ADSP (ADNR 2017).

A bedding layer would be placed under the liner. The surface of the liner would be protected with processed materials (sand and gravel) after installation to prevent damage from equipment punctures or damage during placement of PAG waste rock material. Waste rock would be end-dumped in 20-ft lifts. Concern was expressed in the EIS-phase FMEA that this could result in liner damage even with a protective layer. Placing waste rock in smaller lifts was discussed as a possible method to minimize the risk of liner damage (AECOM 2018k).

Liner installation would be completed in accordance with standard industry practices for similar facilities such as heap leach pads, and would be closely monitored during installation to confirm

AMERICAN OVERSIGHT

proper welding of the seams. The likelihood of liner leakage leading to internal erosion and potential failure of the embankment was the subject of failure modes in the EIS-phase FMEA (AECOM 2018l) as discussed in Section 4.27, Spills.

Referring to Figure 2-9, PAG waste rock would be placed around the facility perimeter to limit commingling of the tailings and waste rock. Pyritic tailings would be discharged into the interior of the facility, with deposition occurring concurrently with waste rock placement (PLP 2018-RFI 055).

Liner failure from chemical causes is considered unlikely because the pyritic tailings and PAG waste rock would be inundated throughout the mine life with a 5-ft water cover, which would limit the potential for the materials to be oxidized, turn acidic, and potentially react with the liner material. HDPE geomembranes are well understood to be extremely durable products with design service lives of up to several hundred years. The service life of an HDPE membrane is typically defined as its half-life, which is the point at which a 50 percent reduction in a specific design property is expected to occur (PLP 2018-RFI 055).

Water levels would be maintained for the life of the facility. Water quality would be monitored during the operation to confirm that acidic conditions are not developing (PLP 2018-RFI 055). As with the bulk TSF, water levels and freeboard in the facility would be maintained to account for the IDF, wave run-up, and wind set-up. Excess water would be controlled by pumping to the main WMP (Knight Piésold 2018a; PLP 2018-RFIs 019a, 028, 028a, 028b).

Stability-Related Elements. The embankment foundations would be prepared by removing overburden to competent bedrock, including solifluction surficial deposits if encountered beneath the embankment footprint. This type of deposit is present on the west side of the watershed and could be subject to downslope movement (described in Section 3.15, Geohazards).

Closure. At closure, the pyritic tailings and PAG waste would be placed into the open pit, the liner removed, and the facility reclaimed (PLP 2018-RFI 024). The pyritic tailings would be removed from the pyritic TSF as a slurry using floating dredge pumps during closure. The tailings slurry would be pumped to the open pit for long-term storage. The PAG waste rock material would be removed using conventional hauling methods (excavators and haul trucks), and trucked into the open pit via the pit haul ramps. It is expected that the start of waste rock removal would lag behind tailings removal by approximately 1 year to allow the tailings and supernatant pond level to be lowered to dewater the waste rock. The tailings would be deposited subaqueously into the open pit and the PAG waste rock would be inundated to limit exposure to a maximum of approximately 1 year. A minimum water cover would be maintained above the PAG waste rock and pyritic tailings throughout long-term closure.

After closure, the embankments would be breached, flattened, and contoured/graded to conform to the surrounding landscape and promote natural runoff and drainage. Thus, potential impacts associated with static and seismic stability of this facility would last no longer than the 20-year mine life.

Management and Monitoring. Monitoring would be included in all phases of the TSF (PLP 2017, 2018d). In accordance with ADNR (2017) guidelines, monitoring would include the same elements as described for the bulk TSF.

Water Management Ponds

General. Two WMPs would be at the mine site (Figure 2-3 and Table K4.15-1): the main WMP north of the pyritic TSF, and the open pit WMP. Each of these facilities would require an embankment or berm with design considerations and potential geohazards effects similar to

AMERICAN OVERSIGHT

those described for the bulk TSF. The embankments are proposed to be downstream constructed.

Seepage-Related Elements. WMP berms or embankments would be constructed using rock and earthen fill (PLP 2017, 2018d) and the same general approach as described for the bulk TSF. The embankments would be fully lined.

Concern was expressed in the EIS-phase FMEA that the number of seepage pumpback wells currently proposed around the perimeter of the main WMP may be insufficient to identify and capture liner seepage along this 9,000-ft long embankment. As indicated by PLP, the number of wells would be determined during final design based on additional field investigations and may exceed those proposed to date. Deep continuous drains around the perimeter were also discussed as possible mitigation for intercepting potential seepage flow from the main WMP (AECOM 2018k).

Stability-Related Elements. The foundation materials would be prepared and the embankments designed and constructed to be stable under static and seismic conditions. The embankment foundation of the main WMP would be prepared by removing overburden to competent bedrock (proposed as a design change by PLP based on the results of the October 2018 EIS-phase FMEA) (AECOM 2018k, 2018l). The design concept for the open pit WMP embankment requires addressing any potential weak foundation conditions encountered in the overburden materials (e.g., glacial lake deposits found in this area) by excavating that material. Any potential mitigation requirements (including removal of the overburden if required) would be addressed based on the geotechnical and hydrogeological information collected for the area during site investigations.

Closure. The WMPs would be removed and reclaimed in post-closure when no longer required for water management and treatment (PLP 2018-RFI 024). Embankments and berms would be breached, flattened, and contoured/graded to conform to the surrounding landscape and promote natural runoff and drainage.

Therefore, potential impacts of seepage and internal erosion on the static and seismic stability of these facilities would be long-term, lasting until some point in post-closure after reclamation activities are complete and monitoring no longer required; however, the potential impacts would not be permanent.

Management and Monitoring. Monitoring would be included in all phases of the WMPs (PLP 2017, 2018d). In accordance with ADNR (2017) guidelines, monitoring would include the same elements as described for the bulk TSF.

Seepage Collection Ponds

General. SCPs would be located downstream of the TSF embankments and WMPs (Figure 2-3 and Table K4.15-1) and would include the SCPs associated with the bulk TSF main and south embankments, and the pyritic TSF north, east, and south embankments.

These facilities would require an embankment or berm with design considerations and potential seismic and geohazards effects similar to those described for the bulk TSF south embankment. The embankments are proposed to be downstream constructed.

Seepage-Related Elements. These embankments would use similar design features as the bulk TSF south embankment, including low-permeability core zones with filter and transition zones; grout curtains to control seepage and enhance embankment stability; and downstream groundwater pumpback and monitoring wells to pump groundwater back into the TSF and monitor the quality of the downstream groundwater (PLP 2018-RFI 006).

AMERICAN OVERSIGHT

Stability-Related Elements. The foundation materials would be prepared and the embankments designed and constructed to be stable under static and seismic conditions (see Section K4.15.1.1.5).

Closure. The seepage ponds associated with the pyritic TSF would be removed and reclaimed in post-closure, similar to the description of the WMPs (PLP 2018-RFI 024). Therefore, potential impacts of seepage and internal erosion on the static and seismic stability of these facilities would be long-term, lasting until some point in post-closure after reclamation activities are complete and monitoring no longer required; however, the potential impacts would not be permanent.

The SCPs associated with the bulk TSF would remain in post-closure indefinitely, or until no longer required for water management and treatment. It is expected that seepage flow through the bulk TSF embankment would slow with increasing consolidation and reduced infiltration in closure. A preliminary estimate of maximum consolidation of the bulk tailings is on the order of 50 years (AECOM 2018k). However, there are no current plans to remove the bulk TSF SCPs. Thus, potential impacts associated with seepage and stability of these facilities would range from long-term to permanent.

Management and Monitoring. Monitoring would be included in all phases of the WMPs (PLP 2017). In accordance with ADNR (2017) guidelines, monitoring would include the same elements as described for the bulk TSF.

K4.15.1.4 Seepage Analysis

Seepage analyses were completed to support of the design of the bulk TSF, which as noted above (K4.15.1.3.1) would include a flow-through design with core filter/transition zones to control seepage and internal erosion. The results of the analyses are presented below.

The pyritic TSF and main WMP would be fully lined facilities and the requirements for filter/transition zones for these lined structures would be evaluated during the design process.

Bulk TSF

The potential rate of seepage through the bulk TSF main embankment was estimated using a two-dimensional seepage model that incorporated the key project design assumptions and referenced available seepage rates at existing mine facilities with similar flow-through designs. The seepage analysis estimated a range of seepage rates, from 3 to 14 cubic feet per second (cfs), during operations when the tailings pond would be at a normal operating size. The seepage rate could increase up to 20 cfs if the tailings pond were to extend within 500 feet of the main embankment (PLP 2018-RFI 006).

This range of predicted seepage rates represents the bounds of a sensitivity analysis that accounted for a variety of tailings characteristics, such as permeability and the anticipated width and length of the coarse-grained tailings unit located immediately upstream of the main embankment.

Detailed seepage analyses would be completed for each embankment during the detailed design stage, which would comply with the stringent requirements of the ADSP permitting process as dictated by ADNR (2017a) (PLP 2018-RFI 006).

K4.15.1.5 Stability Analysis

As described above (K4.15.1.1.3), all proposed embankments and impoundments in the mine site area would store water or potentially liquid-behaving contents that could pose a risk to the

AMERICAN OVERSIGHT

environment if released during a geologic event. The mine site facilities were designed to be stable during both static (nonseismic) and seismic conditions, which are addressed in the following subsections.

Static Stability Analysis

Input Parameters. The analyses of static slope stability considered conceptual-level embankment configurations and homogeneous material parameters. Table K4.15-4 below presents the geotechnical values assumed for these analyses.

Stability analyses were completed for embankment configurations under static loading conditions using the assumptions presented in Table K4.15-4 and using the limit equilibrium computer program SLOPE/W to model potential slip surfaces and resulting factor of safety (FoS) values. Cross sections were generated showing critical circles and calculated FoS for the following embankments:

- Bulk TSF main embankment
- Bulk TSF south embankment
- Pyritic TSF north embankment
- Main WMP
- Bulk TSF main SCP
- Open pit WMP.

The latter two embankments (not presented in Table K4.15-4) used the same input parameters as the other embankments.

Table 4.15-4: Geotechnical Material Parameters Used in Stability Analyses

Embankment	Material	Unit Weight[1] (pcf)	Strength Function[2]	Tau/Sigma Ratio[3]	Cohesion (psf)	Phi[4] (°)
Bulk TSF Main Embankment	Bedrock	160	–	–	0	40

Notes:

pcf: pounds per cubic foot

psf: pounds per square foot

1. The basis for selection of the densities for bulk tailings, pyritic tailings, rockfill, and bedrock was the results of geotechnical laboratory testing performed in conjunction with previous field studies.

2. Shear strength for rockfill was defined based on Leps (1970), using a function that defines the variation of shear strength with normal stress, rather than using a single friction angle or cohesion value.

a. Rockfill shear strength typically reduces at higher stresses because of the crushing of particle contact points within the material and a reduction in material dilatancy. Rockfill shear strength is also related to the density and durability of the material and the particle size distribution.

b. A lower bound strength function (representative of low-density, poorly graded, weak particle rockfill) was considered. The lower bound strength function was based on published information on the shear strength properties of rockfill materials.

3. The basis for selection of the tau/sigma ratio of 0.25 for tailings was the peak undrained strength ratio (Su/p') for hard rock fine-grained tailings materials, which is typically in the range of 0.2 to 0.3. A value of 0.25 was assumed for the preliminary stability analyses.

4. The basis for selection of the phi angles for bedrock was the results of past geotechnical drillhole investigations, which indicate the bedrock underlying the bulk TSF area comprises Cretaceous sedimentary and volcanic rocks including mudstone, siltstone conglomerate, sandstone, and basalt; and Cretaceous intrusive rocks comprised of monzonite, diorite, and gabbro.

a. Bedrock was defined as a homogeneous geological unit for the stability analyses.

b. A friction angle of 40 degrees was used in the stability analyses based on findings of past geotechnical drillhole investigations.

Bulk TSF Main Embankment. The bulk TSF main embankment is proposed to operate as a drained facility to promote long-term drainage and stability of the bulk tailings mass. The main embankment would be approximately 530 feet high with an overall downstream slope of approximately 2.6:1 horizontal:vertical (H:V). Under Alternatives 1 and 3, centerline construction methods with buttressing would be used to limit the footprint, which would result in a serrated near-vertical upstream face at the dam crest for the upper 280 feet of the embankment (Figure 2-8). The preliminary stability analysis for this design calculated a FoS value on the order of 1.9 to 2.0 under static loading conditions. Figure K4.15-2 shows a schematic section of the main embankment at its ultimate height with the predicted potential slip surface.

The stability of the centerline design was reviewed by a panel of geotechnical experts from the US Army Corps of Engineers (USACE) EIS team (AECOM), the State of Alaska, and PLP (including its geotechnical contractor, Knight Piésold) during an EIS-phase FMEA in October 2018. The upstream portion of successive dam raises in the upper half of the embankment would partially rest on tailings, but the results of the stability analysis do not rely on the strength of these materials; rather, they rely on the strength of the rockfill materials directly beneath and downstream of successive raises, materials in the core/filter zone, and rockfill buttressing the downstream side of the core zone.

AMERICAN OVERSIGHT

In other words, regardless of the strength of the tailings, the overall embankment did not fail in a downstream direction in the stability analysis. The potential for instability on the upstream side of the raises would be buttressed by the tailings mass, such that an unstable condition could occur only in an upstream direction (toward the tailings deposit) along an isolated slip surface restricted to the last raise/lift, which would not overwhelm freeboard (designed to be contained within the elevation of the tailings beach). Thus, the FMEA panel concluded that the likelihood of global instability of the buttressed centerline embankment design would be very low (probability of less than 1 in 10,000) (AECOM 2018k, 2018l).

Under Alternative 2, the main embankment would be downstream constructed, and would also include downstream buttresses to increase the stability. The preliminary stability analysis for the downstream-constructed main embankment calculated a FoS value on the order of 1.9 to 2.0 under static loading conditions, similar to the buttressed centerline design, thus offering minimal additional stability over the proposed design. Figure 2-45 shows a schematic section of the main embankment at its ultimate height with the predicted potential slip surface.

Bulk TSF South Embankment. The bulk TSF south embankment would be downstream constructed with a fully lined downstream dam face. The conceptual south embankment would be approximately 305 ft high with an overall downstream slope of approximately 2.6H:1V (PLP 2018-RFI 008b). Figure K4.15-3 shows a schematic section of the current concept for the south embankment at its ultimate height with the predicted potential slip surface. The preliminary stability analyses for the south embankment calculated a FoS value on the order of 1.9 to 2.0 under static loading conditions.

Pyritic TSF North Embankment. The pyritic TSF is proposed to be a fully lined facility. The north, south, and east embankments would be approximately 425, 315, and 305 ft high, respectively, with overall downstream slopes of approximately 2.6H:1V and upstream slopes of 3H:1V (Figure 2-9). The stability of the upstream slopes would be enhanced by placement of PAG waste rock. Figure K4.15-4 shows a schematic section of the north embankment of the pyritic TSF at its ultimate height with the predicted potential slip surface. The preliminary stability analyses calculated a FoS value on the order of 1.9 to 2.0 under static loading conditions. Based on this conceptual design, the EIS-phase FMEA panel concluded that the likelihood of global instability of the north and south embankments of the pyritic TSF would be very low (probability of less than 1 in 10,000) (AECOM 2018l).

AMERICAN OVERSIGHT

Figure K4.15-2: Bulk TSF Main Embankment Static Stability Analysis – Buttressed Centerline Construction

AMERICAN OVERSIGHT

Main WMP. The main WMP would be the primary water management structure at the mine site and a fully lined facility. The embankment would be approximately 200 ft high with an overall downstream slope of approximately 2H:1V. A schematic section of a previous concept for the main WMP embankment that was founded on overburden calculated a FoS value on the order of 1.7 to 1.8 under static loading conditions. The calculation assumed that any potential weak foundation conditions encountered in the overburden materials would be mitigated during design and construction after the collection of additional geotechnical drillhole investigation data.

During the EIS-phase FMEA, geotechnical experts expressed concern regarding the possibility that weak foundation conditions (such as buried glacial clay layer) could be undetected by geotechnical investigations, and concluded that the probability of global instability could range from very low to low (less than 1 in 10,000 to 1 in 1,000). As a result, PLP proposed a design change to remove overburden to competent bedrock. The results of the static stability analysis of the revised design would be revisited after additional geotechnical investigation during final design. With foundation in bedrock, the static stability of the main WMP is expected to be similar to that of other downstream rockfill embankments founded in bedrock at the mine site (i.e., very low likelihood or probability of less than 1 in 10,000).

Bulk TSF SCP. The bulk TSF main SCP is proposed to be constructed using downstream methods. The embankment would be approximately 120 feet high with an overall downstream slope of approximately 2.6H:1V and an upstream slope of 2H:1V (PLP 2018-RFI 008b). The preliminary stability analyses for this embankment used the same input parameters as for the bulk TSF, and calculated a downstream FoS value on the order of 1.9 to 2.0 under static loading conditions. Figure K4.15-5 shows a schematic representation of the stability analysis results for the bulk TSF SCP with the predicted potential slip surface.

Open Pit WMP. The open pit WMP would be founded on overburden, constructed using the downstream method, fully lined, and would have an overall downstream slope of approximately 2H:1V and an upstream slope of 3H:1V (PLP 2018-RFI 008b). At approximately 40 feet high, the embankment of this structure would be much smaller than that of the main WMP. Figure K4.15-6 shows a schematic representation of the stability analysis results for this embankment with the predicted potential slip surface.

The open pit WMP was not evaluated in the EIS-phase FMEA (Section 4.27 provides the rationale for the selection of structures for analysis in the FMEA). Potentially weak layers such as glacial lake deposits are known to be present under most of the open pit WMP area (Figure 3.13-2) and could underlie the embankment foundations. However, the concern that potentially undetected layers could affect global stability would be lower than at the main WMP, because the embankment height would be lower and the known glacial lake deposits would be targeted and analyzed as design progresses. Assuming that any potential weak foundation conditions encountered in the overburden materials would be mitigated during design and construction after the collection of additional geotechnical drillhole investigation data, the preliminary stability analyses calculated a FoS value on the order of 1.9 to 2.0 under static loading conditions.

1. Results based on homogeneous overburden foundation with potential weak layers mitigated in design and construction. The stability analysis would be updated based on revised bedrock foundation as design progresses (AECOM 2018k, 2018l).

Allowances were included in the conceptual embankment cross sections for internal filter and transition zones, which were represented as a homogeneous rockfill material in the model domains. These zones would be defined further and included in future stability modeling. Potential future modifications to the embankments are not expected to affect the embankment footprint.

The static stability analyses would be updated for each embankment structure as the design progresses and additional field data are collected to support the understanding of geotechnical and hydrogeological conditions and the ADSP permitting process under ADNR.

Analyses of Seismic Hazards and Deformation

The mine site is situated in a seismically active area because of the convergence of the Pacific and North American tectonic plates (Figures K4.15-7 and K4.15-8). The most important seismically active geologic structure near the mine site is the Bruin Bay Fault, which lies about 70–80 miles to the east-southeast. Figure K4.15-7 shows a relatively high concentration of lower magnitude earthquake events more than 25 miles in depth near Iliamna and Iniskin bays.

Seismic hazard analyses were completed in support of the proposed Pebble project. ADSP requires seismic analyses of dams to include both OBE and MDE scenarios. Table K4.15-6 shows the OBE and MDE return periods as related to ADSP classification of dam hazards.

AMERICAN OVERSIGHT

Figure K4.15-7: Seismicity and Earthquake Depth

AMERICAN OVERSIGHT

Figure K4.15-8: Cross-section through Alaska Subduction Zone

AMERICAN OVERSIGHT

The OBE represents the ground motions or fault movements from an earthquake considered to have a reasonable probability of occurring during the functional life of a project. All critical elements of a structure need to be designed to remain functional during the OBE, and any resulting damage should be easily repairable in a limited time. The OBE can be defined based on probabilistic evaluations, in which the level of risk (the probability that the magnitude of ground motion would be exceeded during a particular length of time) is determined relative to the hazard potential classification and dam location (ADNR 2017).

The MDE represents the ground motions or fault movements from the most severe earthquake considered at the site, relative to the acceptable consequences of damage in terms of life and property. All critical elements of a dam and appurtenant structures for which the collapse or failure could result in or precipitate an uncontrolled release from the reservoir must be designed to resist the MDE. The MDE may be defined based on either probabilistic or deterministic evaluations, or both (ADNR 2017).

Table K4.15-6: Earthquake Return Periods for Alaska Dam Hazard Classifications

Dam Hazard Classification	Return Period, Years	
	Operating Basis Earthquake	Maximum Design Earthquake
I	150 to >250	2,500 to MCE
II	70 to 200	1,000 to 2,500
III	50 to 150	500 to 1,000

Notes:

1. MCE = Maximum Credible Earthquake.

2. The MCE is defined as 'the largest earthquake magnitude that could occur along a recognized fault or within a particular seismo-tectonic province or source area under the current tectonic framework.

3. TSFs and the main WMP have a Class I dam hazard classification. Other mine site embankments may have a lower dam hazard classification.

Source: ADNR 2017

As shown in Table K4.15-6, the OBE should be selected from a range of return periods from 150 years to more than 250 years for a dam with a Class I hazard classification. A conservative OBE corresponding to a return period of 475 years was adopted for the Pebble TSF designs. The MDE should be selected from a range of return periods from 2,500 years up to the maximum credible earthquake (MCE) for a dam with a Class I hazard classification range. The MCE was selected as the MDE for the Pebble TSFs. As discussed below, both probabilistic and deterministic evaluations were completed for the proposed Pebble project to evaluate potential ground shaking associated with these earthquakes.

Probabilistic Seismic Hazard Analysis. Table K4.15-7 shows the results of a probabilistic seismic hazard analysis completed for the mine site. The estimated maximum acceleration for the 1-in-475-year earthquake (OBE) is 0.14g.

Table K4.15-7: Probabilistic Seismic Hazard Analysis for Mine Site

Return Period (Years)	Probability of Exceedance [1]	Maximum Acceleration [2] (g)
50	63	0.06
100	39	0.07
200	22	0.10
475	10	0.14

AMERICAN OVERSIGHT

1,000	5	0.19
2,500	2	0.25
5,000	1	0.31
10,000	0.5	0.38

Source: KP 2013; PLP 2018-RFI 008a

Notes:

1. Probability of exceedance calculated for a design life of 50 years; Q = 1 - exp (-L/T), where Q = probability of exceedance, L = design life in years, T = return period in years.

2. Maximum accelerations are for values on firm rock.

3. Information based on the USGS Seismic Hazard Program database.

Based on experience with similar studies at other mines in Alaska, the probabilistic seismic hazard analysis in Knight Piésold (2013) appears reasonable for its stated intentions (AECOM 2018f). The analysis relies on US Geological Survey (USGS) ground motion maps for Alaska (Wesson et al. 2007). As noted in the report and confirmed by AECOM (2018f), USGS plans to update these maps, but has not done so yet. The seismic hazard analysis would be updated as design progresses to support the design and reporting requirements outlined in the ADSP. A seismic report is one of the engineering science reports to be included in the preliminary design package submitted to ADNR. The analysis would incorporate current best practices for analysis and updated USGS ground motion data as available (PLP 2018-RFI 008c).

Deterministic Seismic Hazard Analysis. Table K4.15-8 shows the results of a deterministic analysis for the mine site based on the regional seismic sources.

The maximum acceleration values shown in Tables K4.15-7 and K4.15-8 were completed in 2013. Seismic activity since 2013 included the following large earthquakes, which were within the magnitude and maximum acceleration values shown in Table K4.15-8:

- Magnitude 7.9 earthquake experienced within the Gulf of Alaska (about 600 miles southeast of the mine site) on January 23, 2018
- Magnitude 7.1 earthquake experienced about 7 miles east of Iliamna Bay (about 75 miles east/southeast of the mine site) on January 24, 2016.

Knight Piésold (2013) cites New Generation Attenuation (NGA) equations (Earthquake Spectra 2008) used in the deterministic analysis for shallow crustal earthquakes. Revised NGA West 2 equations were published in 2014 after the Knight Piésold report date (e.g., Boore et al. 2014; Borzorgnia et al. 2014). The portion of the deterministic analysis that relies on these relationships would typically be updated using the NGA West 2 equations in the next phase of engineering. As indicated above, PLP plans to update the seismic hazard analyses as design progresses, incorporating current best practices into the analysis (AECOM 2018f; PLP 2018-RFI 008c).

Table K4.15-8: Deterministic Seismic Hazard Analysis for Mine Site

Notes:

1. PGAs are for values on firm rock.

2. The PGA values for the interface subduction (megathrust) event have been calculated using a representative magnitude 8.5 event.

3. The adopted faulting mechanism for each shallow crustal fault was based on a review of available information defining the fault type. The predominant faulting mechanism assumed for all of the shallow crustal faults is strike-slip, with the exception of the Bruin
4. Bay and Lake Clark faults for which reverse faulting was used. Reverse faulting was also conservatively assumed for the maximum background earthquake.

4. Fault locations are from KP (2011, 2015).

Source: KP 2013, PLP 2018-RFI 008a

Pseudo-Static Deformation Analysis. Embankment stability during hypothetical earthquake loading conditions was assessed previously for an earlier, larger (650-ft high) design of the bulk TSF main embankment by performing a pseudo-static analysis. Estimates of horizontal and vertical displacement for mine site embankments would be analyzed further for current embankment designs during future seismic analysis as part of detailed design work undertaken in fulfillment of the ADSP review process. That work is anticipated to be performed after the EIS process is completed.

AMERICAN OVERSIGHT

In the previous pseudo-static analysis, preliminary deformation values were estimated to support the conceptual level of study. A horizontal force (seismic coefficient) was applied to the embankment to simulate earthquake loading, and to determine the critical (yield) acceleration required to reduce the FoS to 1.0. Embankment deformation could occur if the yield acceleration would be lower than the predicted maximum ground acceleration along a potential slip surface. Preliminary deformations were previously evaluated for the bulk TSF main embankment for the following seismic sources:

- OBE
- Magnitude 9.2 interface subduction earthquake
- Magnitude 8.0 deep intraslab subduction earthquake
- Magnitude 7.5 shallow crustal earthquake on the Lake Clark fault
- Magnitude 6.5 maximum background earthquake

Previous deformation analyses indicated that some deformation of the embankments may occur during extreme earthquake shaking. Potential displacements under earthquake loading from the OBE and different MCE scenarios were estimated using the methods of Newmark (1965), Makdisi-Seed (1977), and Bray (2007). The yield acceleration values for the bulk TSF main embankment for the upstream and downstream configurations were higher than the ground accelerations associated with the OBE event, indicating that minimal deformations were anticipated as a result of an OBE event. The yield acceleration values were lower than the ground accelerations associated with the various MCE events, indicating that some deformation may occur as a result of an MCE event. Displacements were estimated to be on the order of 4–5 feet along the potential slip surface under MCE loading conditions.

Potential settlement of the embankment crest was also previously estimated for different MCE scenarios using the empirical relationship provided by Swaisgood (2003). This relationship was developed from an extensive review of case histories of embankment dam behaviors resulting from earthquake loading. Settlement of the embankment crest was estimated to be on the order of 4 feet under MCE loading conditions (Knight Piésold 2018c; PLP 2018-RFI 008).

The displacements were apparently not large enough to truncate the filter or transition zones, and would not affect the functionality of the embankment. The estimated crest deformation/settlement values were added to the minimum freeboard requirements for the bulk TSF embankments, so that the minimum required freeboard would be maintained after the MDE event.

Seismic stability analyses and crest deformation would be updated for each embankment structure as design progresses and additional field data are collected to support the understanding of geotechnical and hydrogeological conditions and the ADSP permitting process under ADNR. Future design phases would include cross sections for pseudo-static stability analyses that would show critical circles and calculated FoS, plus target FoS for embankments at the following facilities as required by the ADSP:

- Bulk TSF (main embankment)
- Pyritic TSF
- Bulk TSF main SCP
- Main WMP
- Open pit WMP

Additional detailed modeling, including FLAC analyses, would be completed during detailed design of the facilities to better define embankment displacements.

AMERICAN OVERSIGHT

Post-liquefaction Analyses. Previous results from a post-liquefaction analysis completed for the bulk TSF main embankment indicate that the FoS exceeded the required value of 1.2 under post-liquefaction conditions, using the post-liquefaction residual strength of the tailings. This finding indicated that the embankment was not dependent on the strength of the tailings for stability. Post-liquefaction analysis for the current design concepts would be completed as the project advances through the ADSP permitting phase (Knight Piésold 2018c; PLP 2018-RFI 008).

K4.15.1.6 Analysis of Open Pit Wall Stability

Referring to Figures 2-3 and K4.15-9, the open pit would be constructed in the easternmost portion of the mine site. The pit would be 6,800 by 5,600 ft in width and 1,970 ft deep (PLP 2018d). As described in Section 3.13, the geology of the open pit area is complex and consists of a variety of rock types. The surface is blanketed with mostly glacial deposits that are underlain by bedrock consisting of a mixture of Mesozoic-age andesitic sedimentary flysch with Cretaceous quartz monzodiorite, granodiorite, and diorite sills.

AMERICAN OVERSIGHT

Figure K4.15-9: Open Pit Topographic Cross-section

AMERICAN OVERSIGHT

Pit wall stability analyses were calculated by SRK (2018c) and PLP (2018-RFI 023a) through three sections of the pit as shown in Figure K4.15-10 and summarized in Table K4.15-9.

The modeling evaluated two different water table scenarios: (1) during mining with the groundwater levels immediately below the pit bottom, and (2) during early closure after discontinuation of groundwater drawdown with water levels recovered to about half full. A peak ground acceleration (PGA) of 0.14g was used for the dynamic modeling case.

The white (grey) lines that roughly parallel the pit wall face in Figures K4.15-12 and K4.15-13 are modeled disturbance factor (D) zones that represent zones of bedrock damage caused by relaxation and rebound of the rock mass from pit excavation and blast damage close to the excavation surface (Hoek 2012). Two inactive faults that intersect Section A (Figure K4.15-11) appear to affect wall stability along with heavily jointed rock represented by the white cross hatching in Figures K4.15-12 and K4.15-13.

Most of the modeling was completed simulating 20 years of mining (immediately before closure), which would represent the worst-case scenario. As the pit is deepened, there do not appear to be any large intersections of weaker rock exposed, other than localized areas near the faults. Future designs would investigate improved optimization angles of the interim walls.

Table K4.15-9 presents the initial results of the open pit wall modeling. The minimum acceptable FoS for the open pit walls during operations was set at 1.3 for static conditions and 1.05 for dynamic conditions (Read and Stacey 2009). These values were selected as the upper bound, as there is only a single entry into the pit and any instability involving the ramp would likely result in a loss of production. Acceptance criteria for the pit just after closure would be set at 1.1 because of the lack of access required into the pit during this time, but this would be reviewed during detailed design. The initial results indicate a FoS below 1.1 for the worst-case scenario in Section A under both static and dynamic conditions. The results for Sections B and C indicated FoSs of 1.1 or greater.

Table K4.15-9: Pit Wall Stability Modeling Results

Section	EoM FoS	EoM FoS Early Closure	EoM FoS Pit Lake	EoM FoS	EoM FoS Early Closure	EoM FoS Pit Lake
	Static			Dynamic		
A	1.3	0.8	1.4	1.2	0.7	1.4
B	1.6	1.4	1.9	1.4	1.2	1.7
C	1.4	1.2	2.2	1.2	1.1	2.0

Notes:

EoM = end of mine

FoS = factor of safety

1. Dynamic stability due to earthquake loading.

Figure K4.15-12: Pit Wall Stability Section A – Scenario with Active Drains in Early Closure

AMERICAN OVERSIGHT

Figure K4.15-13: Pit Wall Stability Section A – Scenario with Half-Full Pit Lake

AMERICAN OVERSIGHT

At closure, the pit walls would be stabilized and monitored to meet ADNR (2006) requirements such that they would not be expected to collapse (PLP 2018-RFI 024). However, the results for Section A in early closure suggest that depressurization caused by dewatering and lowering the water table would need to continue until the pit lake rise could buttress/stabilize the area of potential instability, which is below the faults. Two additional scenarios were therefore examined for Section A:

- Continued groundwater depressurization focused on the toe of the slope
- Pit lake at a level above the instability (the two faults in the face).

The results of the additional analyses, shown in Figures K4.15-12 and K4.15-13, indicate FoSs for the two scenarios of 1.1 and 1.4, respectively. These results suggest that with continued depressurization in the localized area of Section A during early closure activities (e.g., backfilling), the wall stability would meet acceptability criteria.

K4.15.2 Port Site

The port sites are located at Amakdedori and Diamond Point for Alternative 1 and Alternatives 2 and 3, respectively (Figure 2-64). As noted in Figure 4.15-10, the port sites are situated in a seismically active area. Therefore, seismic hazard analyses were conducted for the port sites in conjunction with the analysis for the mine site using the same methods, including analyses of probabilistic and deterministic seismic hazards.

K4.15.2.1 Probabilistic Seismic Hazard Analysis

The same OBE corresponding to a return period of 475 years that was adopted for the Pebble TSF designs was used for the port sites. Table K4.15-10 shows the results of the probabilistic seismic hazard analyses completed for the Diamond Point port site.

Table K4.15-10: Probabilistic Seismic Hazard Analysis for Diamond Point Port Site

Return Period (Years)	Probability of Exceedance [1] (%)	Maximum Acceleration [2] (g)
50	63	0.12
100	39	0.17
200	22	0.22
475	10	0.29
1,000	5	0.38
2,500	2	0.51
5,000	1	0.62
10,000	0.5	0.74

Source: Knight Piésold 2013

Notes:

1. Probability of exceedance calculated for a design life of 50 years; Q = 1 - exp (-L/T). Where Q = probability of exceedance, L = design life in years, T = return period in years.

2. Maximum accelerations are for values on firm rock.

3. Information based on the USGS Seismic Hazard Program database.

AMERICAN OVERSIGHT

The resulting estimated maximum acceleration for the 1-in-475-year earthquake is 0.29g, or nearly double that predicted for the mine site. This reflects the closer proximity of the port to the potential instraslab subduction earthquakes shown in Figures K4.15-7 and K4.15-8.

Based on fault conditions and seismicity in the region (Figures 3.15-2 and K4.15-7), ground shaking effects at the Amakdedori port site are expected to be similar to or less than the effects predicted for the Diamond Point port site.

K4.15.2.2 Deterministic Seismic Hazard Analysis

Table K4.15-11 shows the results of a deterministic analysis for the Diamond Point port site based on the regional seismic sources. As noted for Table K4.15-8, the maximum acceleration values shown in Tables K4.15-10 and K4.15-11 were completed in 2013. Seismic activity since 2013 included two large earthquakes (listed in Section K4.15.1.1.5.2), which were within the magnitude and maximum acceleration values shown in Tables K4.15-8 and K4.15-11.

Table K4.15-11: Deterministic Seismic Hazard Analysis for the Diamond Point Port Site

Earthquake Source Type	Earthquake Source Name	Source/ Fault Mechanism	Maximum Magnitude	Epicentral Distance	Focal Depth	Peak Ground Acceleration[1]	
			(Mw)	(miles)	(miles)	Median (g)	84th Percentile (g)
Interface Subduction[2]	Alaskan-Aleutian Megathrust	Thrust	9.2 (8.5)	70	25	0.13	0.23
Intraslab Subduction	Intraslab Event[3]	In-slab	7.5	35	45	0.20	0.37
			8.0	35	45	0.29	0.55
	Deep Intraslab Event[3]	In-slab	7.5	0	70	0.24	0.45
			8.0	0	70	0.40	0.74
Shallow Crustal Fault[4]	Lake Clark Fault	Reverse (Thrust)	7.5	50	3	0.06	0.10
	Bruin Bay Fault	Reverse (Thrust)	8.0	5	3	0.38	0.64
	Border Ranges Fault	Strike-slip	8.0	65	3	0.06	0.10
	Kodiak Island / Narrow Cape Faults	Strike-slip	7.5	150	3	0.01	0.02

Source: Knight Piésold 2013

Notes:

Mw: Moment magnitude

1. PGAs are for values on firm rock.

2. The PGA values for the interface subduction (megathrust) event have been calculated using a representative magnitude 8.5 event.

3. See Figures K4.15-7 and K4.15-8 for the locations of intraslab subduction earthquakes relative to the Pebble port sites (roughly 40–80 miles beneath and away from the port sites).

4. The adopted faulting mechanism for each shallow crustal fault was based on a review of available information defining the fault type. The predominant faulting mechanism assumed for all shallow crustal faults is strike-slip, with the exception of the Bruin Bay and Lake Clark faults, for which reverse faulting was used.

AMERICAN OVERSIGHT

The previous analyses of seismic stability based on the PGA values presented in Tables K4.15-10 and K4.15-11 would be the design basis for the ports, with updates as design progresses at the selected port site. The values are similar to those presented in Table K4.15-8 for the mine site, but differences are attributable to the respective proximities to the earthquake sources.

As noted for the probabilistic analysis for the port sites, based on the fault conditions and seismicity in the region (Figure 3.15-2), ground shaking effects are expected to be similar or less at the Amakdedori port site than at Diamond Point.

K4.15.2.3 Analysis of Rockfill Causeway and Sheet Pile Dock

A rockfill causeway and sheet pile dock design is proposed for both the port at Amakdedori under Alternative 1 and the port at Diamond Point under Alternatives 2 and 3. As described in Chapter 2, the Amakdedori port would consist of a causeway constructed of earthfill embankment and a barge berth and wharf constructed of a sheet pile wall wharf structure filled with granular material (Figures 2-27 and 2-28). The Diamond Point port would use the same design concept as the Amakdedori port, but would have a different, larger layout (Figure 2-50).

The stability of port structures is typically determined through stability analyses conducted under both static and seismic conditions. Inputs are based on water depths, tidal fluctuations, winter ice formations, subsurface geotechnical conditions, construction materials, and proposed design features. Material site characterization and stability analyses would be conducted for the respective ports' major structures (such as the terminal patio and sheet pile wharf) during final design (PLP 2018-RFI 005).

Available subsurface foundation information for the Amakdedori port site is limited and includes two vibracores to a depth of 3 ft below mudline, a multibeam bathymetric survey, and extrapolation of onshore geophysical data (Section 3.15, PLP 2018-RFI 039; Zonge 2017). While geotechnical conditions at the port site could be variable, bedrock is likely sufficiently deep that marine structures would not need to be socketed and that sheet piles could be designed for installation to a design embedment depth (PLP 2018-RFI 005).

Subsurface foundation conditions at the Diamond Point site are also generally unknown. Water depth is shallower at this location than at Amakdedori, which would require dredging a 20-foot-deep navigation channel (PLP 2018d). More detailed subsurface foundation information is available for Williamsport, about 3 miles north of Diamond Point. Based on geotechnical borings and a geophysical survey completed by USACE in 1995, the depth to bedrock in the vicinity of the existing dock ranged between approximately 65 and 130 ft. The bedrock was mainly overlain by fine-grained sediments. In contrast, the marine channels through Iliamna Bay and Iniskin Bay (east of Iliamna Bay) were noted as having a mantle of unconsolidated, fine-grained sediment, with particle size typically decreasing with water depth and distance from the shoreline. Coarse-grained sediments with cobbles and boulders were observed along the shorelines of both Iliamna Bay and Iniskin Bay (Knight Piésold et al. 2011d).

Design details available for the Amakdedori site are provided in PLP (2018-RFI 005). Construction of the Amakdedori terminal would require installing approximately 2,200 lineal feet of protected rock slope along an access causeway and 2,000 lineal feet (in plan) of steel sheet piles that may be 110 ft long (the length may be as short as 50 feet), with tie-backs into the fill behind the sheets to provide sufficient lateral capacity. The lineal sheet pile and tie-back design proposed for the wharf is not considered as vulnerable to an "unzipping" type of failure in a large earthquake as the open-cell structure at the Port of Anchorage (CH2MHill 2013). The sheet piles would be installed in 15–20 feet of water. The causeway would be constructed by infilling on top of the seabed with competent fill and rock protection for the slopes. The sheet piles

AMERICAN OVERSIGHT

would be installed using a vibratory hammer. If it discovered that bedrock or similarly hard soil is within 20–30 feet of the design seabed elevation, driving the sheets for the last 1–2 feet may be required to anchor the sheets in the ground. If bedrock or similarly hard soil is found to be very shallow, pile socketing and a revised concept may be required. If investigations find that the seabed is susceptible to liquefaction under seismic conditions, soil improvement work such as stone column installation may be required (PLP 2018-RFI 005).

The types of impacts that could occur at the ports include structural instability and potential failure of the sheet pile wharf as a result of seismic loading or foundation conditions; erosion at the base of the sheet piles; icing that increases gravity load on the sheets; and corrosion requiring regular monitoring of cathodic protection systems. These impacts would be addressed as design progresses. Experience at other sheet pile docks in Cook Inlet (Port of Anchorage, Port MacKenzie) suggest that these issues could also be of concern at the Amakdedori and Diamond Point port sites, as discussed below.

Subsurface conditions (e.g., buried sensitive clay layers like at the Port of Anchorage) that have the potential to lead to translational failure of a structure in a major earthquake (Simpson Gumpertz & Heger 2013) likely do not exist at the Amakdedori port site where, based on the information available, subsurface deposits consist primarily of silty sand and gravel (Section 3.15). It is also unlikely but possible that these conditions exist at the Diamond Point site.

A stability analysis of the sheet pile wharf at the Amakdedori and Diamond port sites that takes seismic loads into account would be considered to be the state of the practice for this type of structure in this seismic setting. The PGA for a major earthquake at this location could range from an estimated 0.3g to 0.5g for a 500-year to 2,500-year event, respectively (Figure 3.15-2) (Wesson et al. 2007). These PGA values are supported by the probabilistic and deterministic seismic hazard analyses described above that were completed at the Diamond Point site (Knight Piésold 2013). The results indicated a PGA of 0.51g for a 2,475-year event. This is consistent with Figure 3.15-2 in Section 3.15 (Wesson et al. 2007), which suggests that the PGA at the Amakdedori port site would be slightly less, i.e. 0.50g. Additional seismic analyses would be completed before detailed design to support engineering and construction (PLP 2018-RFI 005).

Liquefaction of the seabed during a major earthquake could also cause wharf damage, although the expected sand and gravel conditions at the Amakdedori site may be too coarse and inhomogeneous for liquefaction to occur (Section 3.15, Geohazards) (e.g., Youd and Perkins 1978). However, as noted above, the particle size of the relevant sediment at the Diamond Point site is less certain. Should the seabed conditions be found to be susceptible to liquefaction, soil improvement work such as installation of stone columns or other densification methods would be considered (PLP 2018-RFI 005).

Boulders have been documented on the seafloor near both port sites and may be present in subsurface deposits (Section 3.15, Geohazards). The boulders could prevent the installation of sheet piles and/or possibly damage the piles. Both the Port of Anchorage and Port MacKenzie experienced sheet pile damage caused by subsurface obstructions such as old earthquake fill, riprap, or unexpected hard layers that were not detected by geotechnical investigations (e.g., CH2MHill 2013; Port of Alaska 2018; Alaska Public Media 2016).

If sheet pile defects were to occur during construction, they could allow retained fill to escape, potentially covering the seafloor near the wharf, and may damage the wharf's surface and equipment and interrupt shipping operations.

Another hazard experienced at the Port MacKenzie dock is erosion from seawater and tidal currents undermining the base of the sheet pile at the mudline and causing a loss of fill (e.g.,

AMERICAN OVERSIGHT

Anchorage Daily News 2017). This hazard is unlikely to occur at the Amakdedori port site, given the design depth of sheet pile anchoring and design contingencies described above, but may be a concern at the Diamond Point site.

If struck by a tsunami, the sheet pile bulkhead design would expose the cross sectional area to the hydrodynamic impact of the wave. A critical loading condition for the bulkhead could be the very low water level during the "retreat phase" of the tsunami, during which the stabilizing effect of water on the outside of the sheetpile is absent or diminished.

Based on the uncertainties and impacts experienced at other sheet pile structures as described above, it is possible that the sheet pile wharf could experience a release of fill material, ranging from partial loss through a damaged or eroded sheet pile to a major loss in an earthquake. The fill material for the Amakdedori port site would be sourced from a local geologic materials site (blasted granitic material) or imported by ship (PLP 2018-RFI 005), and could range from rockfill to material similar to that present on the seafloor (sand and gravel). At the Diamond Point site, the sheet pile wharf is proposed to be backfilled with the material dredged from the adjacent 20-foot-deep navigation channel.

In the event of the loss of fill from the sheet pile, the released material could cause a temporary turbidity plume in the water column. Wharf damage and loss of fill could also disrupt barging and concentrate lightering activities, potentially causing a buildup of concentrate containers at the port and ferry terminals. Chapter 5, Mitigation, provides measures to reduce the likelihood of these impacts, such as geotechnical investigations and stability analyses.

In summary, the proposed rockfill causeway and sheet pile dock design would have the potential to result in adverse impacts on the environment during construction, operation, and closure. Additional field investigations would be performed to support detailed design to confirm that the design is feasible, and if so, to ensure construction, operation, and closure procedures that would be protective of the environment. Alternative design solutions, such as the pile-supported dock variant considered under Alternatives 1 and 2, could also be considered and implemented.

AMERICAN OVERSIGHT

3.13 GEOLOGY

3.13.1 Introduction

This section describes the baseline geology of the project area. Information provided here is based on field and office studies conducted by the applicant and others in the project area between 1985 and the present as described in Appendix K3.13. Paleontological resources are also addressed in Appendix K3.13. Other sections that directly correspond to the geology discussion Section 3.14, Soils and Section 3.15, Geohazards.

3.13.2 Regional Setting

The project area lies approximately 250 miles northwest of the Alaska-Aleutian megathrust, where the Pacific tectonic plate subducts (i.e., sinks), beneath the North American plate. Section 3.15, Geohazards, describes the tectonic setting, seismicity, faults, and volcanic activity. Tectonic activity at the plate boundary is the cause of the region's seismicity and volcanic activity, and has promoted the growth of the Alaskan landmass through the accretion of crustal blocks called terranes. Tectonic plate boundaries shifted throughout the Mesozoic era (245 to 65 million years ago). These shifts produced igneous intrusives (magma) of Late Cretaceous (about 90 million years old) responsible for the mineralization of the Pebble deposit (PLP 2011a).

Over the last 2.6 million years (Quaternary), glaciers have repeatedly advanced over the landscape causing erosion of glacial valleys, rounding landforms of hills and mountains and depositing reworked materials throughout the region. The unconsolidated sediments occur in the valleys between bedrock hills and mountains. No active glaciers exist in the project area.

3.13.3 Geologic Overview of the Project Area

The geology of the mine site is generally comprised of bedrock hills with thin or no unconsolidated sediment with overburden in the wide valleys. Overburden in this area is comprised of glacial, glaciofluvial, and alluvial sediments. Iliamna Lake lies within a basin generally filled with glacial sediments of Pleistocene (2.6 million to 11,700 years old) that are exposed southwest, west, and north of the lake, with occasional bedrock outcrops. The area between Iliamna Lake and Cook Inlet generally consists of exposed or near-surface bedrock, with limited sediments overlying the bedrock at the lower elevations (Figure 3.13-1).

The geologic structure of the project area is broadly defined by the northeast- to southwest-trending Bruin Bay Fault (Figure 3.13-1) (see Section 3.15, Geohazards).

Extensive surficial glacial deposits similar to those near Iliamna Lake overlie the southwestern portion of the Kenai Peninsula (Detterman and Reed 1973). There is no known permafrost in the project area. See Section 3.14, Soils, for a discussion of permafrost.

AMERICAN OVERSIGHT

Figure 3.13-1: Pebble Project Area Geology

AMERICAN OVERSIGHT

3.13.4 Alternative 1 – Applicant's Proposed Alternative

This section describes the geology relevant to Alternative 1.

3.13.4.1 Mine Site

Unconsolidated sediments (overburden) cover a large portion of the mine site. These sediments consist of glacial till, outwash, alluvium, fan and deltaic deposits, and glaciolacustrine (glacial lake) deposits (Figure 3.13-2). Sediment sizes vary from silt, sands, and gravels to boulders. Overburden ranges in thickness from a few feet to about 165 feet (Detterman and Reed 1973; Knight Piésold et al. 2011a).

When glaciers were present, lakes formed where glacial ice blocked the major drainage basins (Hamilton and Klieforth 2010), resulting in deposition of lacustrine deposits. Glacial lake deposits are mapped in the eastern half of the open pit area, extending south of Frying Pan Lake, and in the area of the proposed water treatment plant (WTP) #1 discharge-south (Figure 3.13-2). The lake deposits are composed of stratified to weakly stratified (layered) silts, sands, and fine gravels, and display poorly drained surface morphology (Hamilton and Klieforth 2010). Glacial meltwater channels and a moraine ridges are also present (Figure 3.13-2).

Colluvium and felsenmeer occur along the flanks of Kaskanak Mountain, including within the footprint of the bulk tailings storage facility (TSF) and on slopes surrounding the mine site. Solifluction lobes composed mostly of silt are present on isolated lower slopes within the mine site, including the footprint of the pyritic TSF (Knight Piésold et al. 2011a). Thin, organic soils less than 1 foot thick cover the mine site, and are often intermixed with sands and gravels (Hamilton and Klieforth 2010) (see Section 3.14, Soils).

Bedrock occurs at the higher elevations (above about 1,400 feet amsl) in the mine site area (Figure 3.13-2). The bedrock geologic map (Figure 3.13-3) shows details of the mine site's complex bedrock geology, which are also addressed below.

AMERICAN OVERSIGHT

Figure 3.13-2: Mine Site Surficial Geology

AMERICAN OVERSIGHT

Mine Site Bedrock Geology and Mineralization of the Pebble Deposit

The mine site bedrock geology is complex (Figure 3.13-3). Much of the bedrock within and around the open pit is, a type of Mesozoic sedimentary rock derived from eroded andesitic volcanic rock (Kahiltna flysch). Tertiary (Paleogene and Neogene, about 65 to 2.6 million years old) volcanic and sedimentary rocks outcrop at higher elevations on the south end of the bulk TSF and in the southeast corner of the mine site area. A variety of Cretaceous (about 145 to 65 million years old) intrusive rocks outcrop within the mine site, including the granodiorite of the Kaskanak batholith, which outcrops in the western portion of the mine site (Knight Piésold et al. 2011a) (Figure 3.13-3).

Other diverse magmas intruded in the flysch in a north-northeast trending belt throughout the Cretaceous, and were then folded by tectonic forces (Nokleberg et al. 1994). The mineralization that formed the Pebble deposit was likely caused by these diverse magma intrusions that comprise the rock in the open pit area (Knight Piésold et al. 2011a).

Offshoots of the magma injected into joints and fractures in the surrounding sedimentary bedrock, heating the rock and causing hot fluids to circulate in a large magmatic-hydrothermal system. The hot fluids carried dissolved metals from the magma, including copper, gold, and molybdenum. As the fluids cooled, the metals and associated sulfide minerals (such as iron sulfide [pyrite]) precipitated within the surrounding rock, concentrated within metal-rich quartz veins. These rocks make up the Pebble deposit, a copper-gold-molybdenum porphyry system.

Table 3.13-1 presents the estimated deposit resource for copper, molybdenum, and gold, and compares the total deposit to the amount that would be mined over the 20-year lifespan of the project (PLP 2018d). The proposed project would mine approximately 10 percent of the total estimated Pebble deposit resource.

Table 3.13-1: Estimated Pebble Deposit Resource (Measured, Indicated, and Inferred)

	Total Deposit		20-Year Open Pit	
	Weight	Grade	Weight	Grade
Copper	81.5 Blb	0.34%	7.4 Blb	0.29%

AMERICAN OVERSIGHT

Figure 3.13-3: Mine Site Bedrock Geology

AMERICAN OVERSIGHT

Construction Materials

Material to construct the embankments would be sourced from quarries A, B, and C with granodiorite rock at these locations. Granodiorite is a competent (e.g., strong and resistant) rock that is suitable for use as rockfill. Construction would also use overburden removed from the from the open pit area that is determined suitable as rockfill (Figure 3.13-3).

3.13.4.2 Transportation Corridor

Roads

Bedrock and surficial geology varies somewhat across the transportation corridor (Chapter 2, Alternatives, Figure 2-12 through Figure 2-14), but is generally comprised of the same rock types and overburden as present at the mine site. Few bedrock exposures exist north of Iliamna Lake and glacial sediments cover most of the terrain (Detterman and Reed 1973, 1980).

Along the mine access road, the buried bedrock is mostly the same Tertiary volcanic rock present within the mine site. South of Iliamna Lake, the south access road traverses Tertiary volcanic rocks similar to north of the lake, and Jurassic intrusive bedrock outcrops at higher elevations (Detterman and Reed 1980; Wilson et al. 2015).

Near the port site, the transportation corridor would cross outcrops of Jurassic metamorphic rock and marine sedimentary rock that is locally abundant in marine invertebrate fossils (Detterman and Reed 1980; Wilson et al. 2009). The entire Iliamna spur road would be underlain by Quaternary glacial deposits, with no apparent exposed bedrock (Detterman and Reed 1973, 1980).

Ferry Terminals

The north ferry terminal would be underlain by Pleistocene glacial deposits consisting mostly of sand. The south ferry terminal would be underlain by Tertiary volcanic rock near the shoreline and by Pleistocene terrace deposits farther upslope (Detterman and Reed 1973, 1980).

Construction Material Sources

Material sites along the transportation corridor would supply earthen materials (e.g., rock, gravel) for construction and maintenance of the transportation corridor. Material sites underlain by bedrock (labeled in red on Figure 3.13-4) would likely require blasting. The remaining material sites would likely be developed in surficial glacial deposits and could be excavated without blasting (Detterman and Reed 1973; Hamilton and Klieforth 2010).

AMERICAN OVERSIGHT

Figure 3.13-4: Bedrock Blasting Intervals

AMERICAN OVERSIGHT

3.13.4.3 Amakdedori Port

The footprint of the Amakdedori port would be on marine terrace and beach deposits consisting of sand, pebbles, and cobbles (Detterman and Reed 1973). Alluvial fan-delta deposits from Amakdedori Creek extend about 1,000 feet offshore into Kamishak Bay (PLP 2018-RFI 039). Seafloor sediment at and around the Amakdedori port site comprises primarily subtidal gravel and beach complex, with sub-bottom sediments consisting primarily of fine silty sand, occasional coarse gravel and shell fragments, and a fines content ranging from 14 to 19 percent (GeoEngineers 2018a).

Bedrock is not exposed within the port footprint, but is exposed in the bluffs to the northeast and consists of Jurassic igneous and metamorphic rock, and fossiliferous marine sedimentary rocks (Detterman and Reed 1973, 1980; Wilson et al. 2015).

Rock to be used in construction of the port would be supplied from Material Site MS-A08 (PLP 2018-RFI 035) (Chapter 2, Alternatives, Figure 2-14). MS-A08 is in an area of thin or absent surficial deposits underlain by bedrock (Detterman and Reed 1973).

3.13.4.4 Natural Gas Pipeline Corridor

The surficial and bedrock geology of the natural gas pipeline corridor is the same as that addressed above for the transportation corridor, except for the Cook Inlet crossing and the segment of the corridor on the Kenai Peninsula.

Cook Inlet is a relatively shallow sedimentary basin filled with actively migrating, sand- to boulder-sized material. Cook Inlet seafloor deposits are described in further detail in Section 3.18, Water and Sediment Quality.

Surficial deposits along the Kenai Peninsula segment include Quaternary glacial outwash sediments and minor alluvial deposits (Wilson et al. 2015). Bedrock on the Kenai Peninsula segment is almost entirely buried by deep glacial deposits, but limited outcrops to the east reveal late Tertiary estuarine and non-marine sedimentary bedrock (Wilson et al. 2015).

Construction material sources for the natural gas pipeline corridor would be the same as that identified for the transportation corridor between the mine site and Amakdedori port. No material sites would be required on the Kenai Peninsula portion of the pipeline route (PLP 2018-RFI 035).

3.13.4.5 Action Alternative 1 – Kokhanok East Ferry Terminal Variant

The Kokhanok east ferry terminal is underlain by Quaternary beach deposits near the Iliamna Lake shoreline, and by Tertiary volcanic bedrock farther upslope (Detterman and Reed 1973, 1980).

3.13.4.6 Action Alternative 1 – Pile-Supported Dock Variant

Marine sediments at the Amakdedori port site that are relevant to the dock variant are the same as those addressed above for the port.

3.13.5 Action Alternative 2 – North Road and Ferry

3.13.5.1 Mine Site

The geology and material sites at the mine site would be the same as Alternative 1.

AMERICAN OVERSIGHT

3.13.5.2 Transportation Corridor

Roads

Geology of the transportation corridor between the mine site and the Eagle Bay ferry terminal is similar to the geology described for the Iliamna spur road in Alternative 1. Bedrock is overlain by glacial moraine, beach deposits, solifluction, stream channels, and terrace deposits (Detterman and Reed 1973).

From the Pile Bay ferry terminal to Williamsport, the transportation corridor would largely follow the existing road underlain by Jurassic (200 to 145 million years old) igneous rock, Quaternary alluvium, talus, and rubble deposits (Detterman and Reed 1980; Wilson et al. 2015).

From Williamsport to the Diamond Point port, the road would cross a slope underlain by Jurassic to Triassic (251 to 200 million years old) igneous volcanic rock and intrusive granodiorite and quartz monzonite, and slightly metamorphosed basaltic flows and sedimentary rocks (Detterman and Reed 1980; Wilson et al. 2015).

Ferry Terminals

The Eagle Bay ferry terminal would be underlain by glacial deposits (Detterman and Reed 1973, 1980). The Pile Bay ferry terminal area is likely Jurassic igneous rocks and possibly isolated glacial beach deposits (Detterman and Reed 1973, 1980).

Construction Material Sources

Material sources for construction of the transportation corridor from the mine site to Iliamna Lake would be supplied by the material sites within mostly glacial deposits (Detterman and Reed 1973). Construction of the transportation corridor between Williamsport and Diamond Point might also use bedrock that would be removed (excavated or drilled/blasted) to support construction of the roadbed (Detterman and Reed 1980; Wilson et al. 2015).

3.13.5.3 Diamond Point Port

The geology of the Diamond Point port is mapped as Jurassic igneous intrusive rocks (Detterman and Reed 1980; Wilson et al. 2015). Construction of a port facility at Diamond Point would likely require drilling and blasting.

3.13.5.4 Natural Gas Pipeline Corridor

The pipeline would cross beneath Cook Inlet and make landfall on the shore of Ursus Cove. The corridor would then follow a possible geological bedding and/or linear structural feature that is largely overlain by glacial deposits. Cretaceous to Jurassic igneous and volcanic rocks are mapped within the feature (Detterman and Reed 1973, 1980).

Between the Cottonwood Bay and Pile Bay road intersection, the geology of the pipeline corridor is the same as the geology of the transportation corridor. From the Pile Bay road intersection to near Pedro Bay, the corridor is underlain by mostly Cretaceous to Jurassic igneous rocks (Detterman and Reed 1973, 1980).

From Pedro Bay to the western portion of Knutson Bay, the geology consists mostly of surficial glacial deposits and bedrock similar to that found near Pedro Bay. From Knutson Bay to the mine site, the geology consists of surficial glacial deposits, similar to the geology of the Alternative 2 transportation corridor to the Eagle Bay ferry terminal (Detterman and Reed 1973, 1980).

AMERICAN OVERSIGHT

3.13.5.5 Action Alternative 2 – Pile-Supported Dock Variant

Marine sediments at the Amakdedori port site that are relevant to the dock variant are addressed above.

3.13.6 Action Alternative 3 – North Road Only

3.13.6.1 Mine Site

The geology and construction materials would be the same for as for Alternative 2.

3.13.6.2 Transportation Corridor

The geology of the road from the mine site to near the western portion of Knutson Bay consists of surficial glacial deposits, similar to the geology of the Alternative 2 transportation corridor to the Eagle Bay ferry terminal. From Knutson Bay to Pedro Bay, the geology consists mostly of surficial glacial deposits and then bedrock, including Cretaceous and Jurassic igneous rocks.

From Pedro Bay to the intersection with the road to Pile Bay the geology consists of Cretaceous and Jurassic intrusive igneous rocks. From the Pile Bay road intersection to the Diamond Point port site, the transportation corridor would largely follow the existing road, as under Alternative 2 (Detterman and Reed 1973, 1980).

3.13.6.3 Diamond Point Port

The geology and construction material sources for the Diamond Point port site would be the same as for Alternative 2.

3.13.6.4 Natural Gas Pipeline Corridor

The geology and construction material sources would be the same as for Alternative 2.

3.13.6.5 Alternative 3 – Concentrate Pipeline Variant

The concentrate pipeline corridor would follow the same alignment as the transportation and natural gas pipeline corridors for Alternative 2. The geologic environment would therefore be the same.

3.15 GEOHAZARDS

This section provided information currently available regarding geological hazards (geohazards) in the project area. Geohazards include geophysical processes (e.g., earthquakes, volcanoes), surficial or geomorphological processes (e.g., landslides) and other hazards (e.g., ice effects, erosion, tsunamis). Regional scale descriptions of the geohazards are presented in this section, followed by local descriptions enhanced with information gathered from geotechnical engineering studies where available. The project area is within a region of active tectonic (geophysical) processes and the potential for multiple types of geohazards across the project area depends on location, topography, natural materials present, and proximity to hazard sources.

3.15.1 Earthquakes

3.15.1.1 Active Faults

The Pebble Project is in a tectonically active region of southern Alaska near the subduction zone between the Pacific and North American plates. Both shallow crustal earthquakes and deeper earthquakes associated with the subduction zone megathrust affect this region.

In general, faults that have demonstrated geologic displacement and earthquakes during the Holocene epoch (the last 11,000 years) are considered to be active, and have the potential for future movement. Earthquake hazards generally increase with the magnitude (M) of the event, proximity to the site, and fault length. The likelihood of fault movement is typically described in terms of recurrence interval or return period (i.e., how often the fault is expected to generate a large earthquake based on field evidence and past seismic record). This is described below under "Ground Shaking," and in Section 4.15, Geohazards (Environmental Consequences), as applied to project facilities. Active and potentially active faults in the project area are shown on Figure 3.15-1, and include the following:

- The closest active surface fault to the project area is the northeast-trending Lake Clark-Castle Mountain Fault, about 15 miles northeast of the mine mite at the western end of Lake Clark (Haeussler and Saltus 2004). Studies of surficial geology and geomorphology in the mine area did not find evidence of Holocene fault activity between Lake Clark and the mine site (Hamilton and Klieforth 2010; Koehler 2010; Haeussler and Waythomas 2011; Knight Piésold 2015a). This fault exhibits evidence of Holocene activity in the Susitna Valley area, where it is considered capable of a maximum earthquake of M7.1 (Wesson et al. 2007), but shows no evidence of activity younger than Late Pleistocene along the Lake Clark segment southwest of Tyonek (Koehler and Reger 2011). This conclusion is further supported by a review of LiDAR data collected in 2004 in the vicinity of the mine site. No lineaments were observed that suggest possible fault-related movement in surficial deposits southwest of the previously mapped termination point of the Lake Clark fault (AECOM 2018m).
- The Alaska-Aleutian Megathrust, associated with the subduction zone of the Pacific Plate beneath the North American Plate, is responsible for some of the largest earthquakes globally, including the 1964 M9.2 Great Alaskan (Good Friday) Earthquake and 1938 M8.3 Alaska Peninsula earthquake. The megathrust lies at the seafloor more than 200 miles southeast of the project area, and dips to the northwest beneath the project area. Its 30-mile-thick zone of seismicity ranges from 20 to 50 miles deep beneath the eastern end of the natural gas pipeline corridor, to about

AMERICAN OVERSIGHT

90 to 120 miles deep near the mine site (Plafker et al. 1994; Knight Piésold 2015). The Kodiak and Prince William Sound areas of the megathrust are considered capable of a maximum M9.2 earthquake every 650 years. Intraslab faults associated with the deeper part of the subduction zone are considered capable of earthquakes in the range of M7+ (Wesson et al. 2007).

- The Denali-Farewell Fault, about 120 miles northwest of the project area, was the source of the 2002 M7.9 Denali earthquake that originated along the central part of the fault in Interior Alaska. The westernmost extension of this fault system, called the Togiak-Tikchik Fault, about 140 miles west of the mine site, exhibits evidence of mid-Quaternary activity. Although evidence of Holocene activity along the western part of the fault is limited compared to that of Interior Alaska, it is considered capable of generating large earthquakes in the range of M7.5 to M8.0 (BGC 2011; Knight Piésold 2015).
- The Telaquana-Capps Glacier and Mulchatna faults are about 40 miles north and northwest of the mine site, respectively (Haeussler and Saltus 2004; Gillis et al. 2009). Evidence of Holocene activity along these faults has not been established. If active, they are considered capable of maximum earthquakes in the range of M6.0 to M7.0 (Knight Piésold 2015).
- The Bruin Bay Fault extends along the western shore of Cook Inlet near the Amakdedori port site. Although there is no evidence for Holocene offset at the surface, this fault is associated with several small to moderate earthquakes up to M7.3 in 1943 (Stevens and Craw 2003).
- Several fault-cored folds in Upper Cook Inlet show evidence of Quaternary-age activity and possible bending of the seafloor. The closest of these lies about 130 miles east of the mine site and 10 miles north of the eastern end of the pipeline corridor. These structures are considered capable of generating earthquakes up to M6.8 (Haeussler et al. 2000). Recent activity has not been documented on similar folds and faults in Lower Cook Inlet near the Amakdedori port and natural gas pipeline corridor submarine crossing (Haeussler and Saltus 2011; Koehler et al. 2012).
- The Kodiak Shelf fault zone, comprised of a series of northeast-trending faults, lies in the upper plate of the subduction zone. These faults, about 120 miles southeast of the closest project components, show geomorphic evidence of Holocene activity, and are considered capable of earthquakes up to M7.5 (Wesson et al. 2007; Carver et al. 2008).
- The Border Ranges Fault, extending northeasterly through Kodiak Island and Kenai Peninsula, has been inactive since the early Tertiary (65 million years ago), but contains a 3- to 6-mile-wide shear zone that is considered by some to be capable of a future earthquake in the range of M7.0 (Suleimani et al 2005; Knight Piésold 2015).

AMERICAN OVERSIGHT

Figure 3.15-1: Earthquakes and Active Faults

AMERICAN OVERSIGHT

3.15.1.2 Ground Shaking

Earthquake-induced ground shaking is typically expressed in terms of peak ground acceleration (pga), measured as a fraction of gravity (g), with a probability of exceeding a certain level over a specific period of time in the future. For example, a pga of 0.1g in bedrock is considered the approximate threshold at which damage occurs in buildings that are not specially constructed to withstand earthquakes. An earthquake with a 10 percent probability of exceedance in 50 years (about a 500-year return period) is the most common event used in building codes for seismic design (e.g., Gould 2003). Larger, more infrequent seismic events, such as those with a 2,500-year return period (a 2 percent probability of exceedance in 50 years) are typically used for design of critical structures such as dams (ADNR 2017).

Ground shaking prediction in Alaska has been studied both regionally by the US Geological Survey (USGS) (Wesson et al. 2007) and for the Pebble Project area by Knight Piésold (2011c, 2015a, 2018c). Based on published USGS data for the 2,500-year event, Figure 3.15-2 depicts a general trend from high ground shaking near the subduction zone offshore of Kodiak to less ground shaking further inland. Predicted ground shaking for the 2,500-year event ranges from a pga of about 0.3g near the mine site to 0.6g at the eastern end of the natural gas pipeline corridor. In comparison, predicted ground shaking for a smaller 500-year earthquake ranges from about 0.2g near the mine site to 0.4g at the eastern end of the natural gas pipeline corridor (Wesson et al. 2007). Site-specific seismic hazard analyses conducted for project facilities are discussed in Section 4.15.

3.15.1.3 Liquefaction

Liquefaction is an earthquake-caused phenomenon that reduces the strength and stiffness of a soil by ground shaking. Where the groundwater table is near surface, or the ground is otherwise saturated, the pore space between soil particles containing water can increase (i.e., increase pore pressure), changing the physical character of the landform and weakening the natural material; in essence, the ground temporarily behaves like a liquid. Liquefaction generally affects unconsolidated, fine-grained (sand and silt) deposits in lowland areas. The susceptibility of an area to liquefaction is a consideration in design and construction in earthquake-prone areas because the loss of strength of the foundational material can cause structural damage. The potential for liquefaction from ground shaking at the mine site is less for features built where bedrock is near the surface, than in lowland areas underlain by unconsolidated material. A more detailed explanation of liquefaction is provided in Appendix K3.15. Areas believed to be susceptible to liquefaction in the project area are described below.

Areas susceptible to liquefaction are typically found along rivers, streams, lake shorelines, and in areas with relatively shallow groundwater. Lateral spread of liquefied soil up to a few feet can occur on gentle slopes or in areas near a free face, such as an incised river channel. Section 3.18, Water and Sediment Quality, provides a description of sediment types in areas of the project that could be subject to liquefaction. These include portions of the mine site with shallow groundwater and fine-grained soils, such as the glacial lake deposits in the eastern part of the mine site (Section 3.13, Geology), and in project facilities that contain fine-grained saturated tailings (bulk and pyritic TSFs). Wide stream crossings along the road and pipeline corridors and marine sediment at port sites that contain predominantly sand and silt, such as along the northern portion of the mine access road, protected bays in Iliamna Lake, and Cottonwood and Iliamna bays in Cook Inlet, may be subject to liquefaction. Other sediment with high gravel content, such as at the north ferry terminal, high-energy stream crossings along the south access road and north road route (Alternatives 2 and 3), and nearshore Kamishak Bay are less likely to liquefy (PLP 2018-RFI 036; PLP 2018-RFI 039).

AMERICAN OVERSIGHT

Figure 3.15-2: Seismic Hazard Map

AMERICAN OVERSIGHT

3.15.2 Geotechnical Conditions

Subsurface geotechnical conditions form the basis of foundation design and stability analysis of major structures such as dams, buildings, tanks, facilities, bridges, docks, and fills. Geotechnical conditions are summarized below where important to the analysis of potential geohazard effects on the project, including discussion of features (e.g., roads and port sites) described in alternatives (see Chapter 2, Alternatives), and related environmental impacts.

3.15.2.1 Mine Site

Geotechnical data from site-wide geologic reconnaissance and mapping, drill holes, test pits, and geophysical (seismic) surveys were collected at the mine site between 2004 and 2018 (Knight Piésold 2011c; PLP 2013a; PLP 2018-RFI 014). The mine site was divided into several study areas by Knight Piésold (2011a) based on geomorphology and watershed divisions for the purposes of baseline characterization. These areas are shown on Figure 3.15-3, along with geotechnical data locations and the mine site footprint, and are described below. The number of drill holes, test pits, and seismic survey lines beneath locations of major facilities in each area are provided in Appendix K3.15. As discussed in Section 3.14, Soils, permafrost has not been encountered at the mine site.

- **North Fork Koktuli (NFK) West.** Most of the data collected in this north-draining watershed, which contains the bulk TSF main embankment and impoundment footprint, are in the northern part of the watershed, with fewer data points beneath the southern part of the impoundment. Overburden materials range in thickness from 2 to 51 feet, and overlie sedimentary, volcanic, or intrusive bedrock. Overburden deposits consist of frost-shattered angular boulders; glacial drift, and colluvium containing mostly sand and gravel with varying amounts of silt; and peat in the valley bottom. Bedrock quality, measured using a Rock Mass Rating (RMR) system on a scale of 0 to 100, with higher numbers representing stronger rock quality (Bieniawski 1989), ranges from 35 to 66 (poor to good). Weathered bedrock extends up to 80 feet deep, and is deeper in the southern part of this area than the northern part.
- **NFK East.** Field investigations in this north-draining watershed that contains the pyritic TSF and associated ponds indicate that depth to bedrock ranges from 0 to 8 feet on hilltops, and from 6 to 111 feet in the valley and beneath side slopes. In the NFK East, bedrock is generally more fractured and has deeper weathering than beneath the bulk TSF area in NFK West. Overburden consists of sand and gravel with variable amounts of silt.
- **NFK North.** This area contains seepage and sediment ponds downstream of the bulk TSF main embankment and the main water management pond (WMP). Overburden consisting mainly of alluvial and morainal gravel and sand deposits ranges in thickness from 2 feet to more than 9 feet, and overlies basalt bedrock with RMRs in the range of 52 to 65 (fair to good).
- **Pit Area**. Geotechnical data in the area of the open pit and rim indicate the presence of overburden ranging in thickness from 25 to 272 feet, and consisting of varying mixtures of gravel, sand, silt, and clay of glacial origin, with occasional peat. Bedrock types consist primarily of volcanic and sedimentary rock, with average RMRs ranging from 45 to 55 (fair) (Knight Piésold 2011c).
- **Bulk TSF South**. The northern portion of this south-flowing watershed contains the footprints of the bulk TSF southern embankment and associated seepage and sediment ponds. Previous investigations indicate overburden thicknesses ranging from about 1 to 95 feet, with thicker deposits in the valley bottom, consisting of

AMERICAN OVERSIGHT

primarily sand and gravel with variable amounts of fines. Bedrock is of similar type and quality to the southern part of NFK-West.

- **South of Pit Area.** The northern end of this south-flowing tributary, which drains towards Frying Pan Lake, contains the open pit WMP, pit overburden stockpile, and sediment ponds related to these facilities. Overburden ranges in thickness from about 70 to 150 feet, and consists of mostly silty sand and gravel glacial deposits with peat in the valley bottom.

3.15.2.2 Other Project Components

Surficial deposits, near-surface soils, and stream substrates along the transportation corridor are described in Sections 3.13, Geology; 3.14, Soils; and 3.18, Water and Sediment Quality, respectively. Geotechnical conditions along the northern part of the mine access road would be similar to those described above for the mine site. Surficial deposits along the southern part of the mine access road, Iliamna spur road, and the western part of the North Route (Alternatives 2 and 3) consist primarily of glacial and alluvial deposits. Surficial deposits along the eastern part of the North Route and the south access road are sparse, and bedrock outcrops near ground surface (Detterman and Reed 1973). Surficial deposits between Pedro Bay and Williamsport (Alternatives 2 and 3) consist mainly of alluvium and alluvial fan deposits along lower slopes of steep-sided valleys.

Surficial units mapped beneath the terminal footprint at the Amakdedori port site consist of Holocene marine terrace and modern beach deposits containing mostly pebbles, cobbles, and sand (Detterman and Reed 1973). Zonge (2017) geophysical data suggest that overburden is on the order of 50 to 100 feet thick in the terminal area. Topographic and stratigraphic relationships in Amakdedori Valley indicate that alluvium, alluvial fan, and beach deposits fill a bedrock-sided valley about 2 miles across between Chenik Mountain to the south, and peak "1996" to the north. These deposits may extend to several tens of feet below sea level in the port and wharf areas, where valley fill and nearshore delta fan material have been deposited towards the east and southeast, following trends of deepening bathymetric contours between Augustine Island and Douglas Reef (NOAA 2015; PLP 2018-RFI 039). Based on geophysical survey data and marine vibracores consisting of silty sand and gravel to 3 feet below mudline (PLP 2018-RFI 039; Zonge 2017), sand and gravel likely exist in Kamishak Bay to the depth of sheetpile or pile-supported dock installation. Boulders derived from sloughing of rocky cliffs and ice-raft movement may also be present in subsurface deposits at the port site.

Surficial deposits mapped beneath the footprint of the Diamond Point terminal site consist of thin alluvial fan deposits on top of shallow bedrock (Detterman and Reed 1973). Offshore deposits in the Diamond Point area, and along the road corridor between Diamond Point and Williamsport, consist primarily of silt and fine sand, with extensive mudflats in the upper reaches of Cottonwood and Iliamna bays. Boulders lie on the mudflats, and extensive reefs, shoals, and offshore rocks occur at the entrance to the bays (Pentec et al. 2011a). A combination of marine siltation and tectonic uplift is raising the seafloor near Williamsport at a rate of about 0.3 inch per year (ADNR 2014a).

AMERICAN OVERSIGHT

Figure 3.15-3: Geotechnical Data Coverage and Depth to Bedrock

AMERICAN OVERSIGHT

Site-specific geotechnical information is not available for the eastern landfall pipeline section that is planned to be installed by horizontal directional drilling (HDD) beneath Cook Inlet bluff. The coastal bluff is about 230 feet high at this location; has a relatively steep slope angle of about 1.4H:1V; and is composed primarily of Pleistocene glacial deposits (Reger and Petrik 1993; Karlstrom 1964). A stratigraphic section of the bluff, 2 miles south of the pipeline landfall, contains sand and gravel with occasional boulders, overlying a 50-foot-thick glaciolacustrine clay-silt unit (Reger and Petrik 1993). Perched groundwater is known to seep out of the bluff above similar fine-grained units along eastern Cook Inlet. Tertiary sedimentary rocks of the Beluga Formation are exposed in the lower sea cliff several miles further to the south, and may underlie glacial deposits at the pipeline landfall in the depth of the HDD. These rocks consist of weakly indurated, interbedded sandstone, siltstone, and shale with thin layers of coal (Reger and Petrik 1993). The potential for slope stability impacts on the project from these deposits is proved in Section 4.15.

3.15.3 Unstable Slopes

Unstable slopes typically occur under combined conditions of steep terrain, heavy precipitation, and certain types of surficial deposits, weathered bedrock, or weak stratified layers. The terrain and geomorphology of the mine site consists primarily of gently rolling hills with rounded exposed bedrock hilltops, and valleys of glacial deposits with low-angle slopes and mostly low potential for slope instability. Surficial deposits that have the potential to produce unstable slopes occur sporadically around the mine site and include the following (Hamilton and Klieforth 2010):

- Colluvium, consisting of rock rubble and debris with fines deposited at the base of slopes, may be subject to frost creep and gradual mass wasting slope processes related to freeze-thaw activity (solifluction). These deposits have been mapped throughout much of the bulk TSF footprint: on slopes adjacent to the bulk TSF south embankment, beneath the southern sediment pond, on the western side of the pyritic TSF, beneath several overburden and growth media stockpiles, and in the northeastern corner of the pit.
- Solifluction deposits, consisting of moderately sloped sheets of stony and organic silt, are subject to gradual downslope movement related to freeze-thaw action. These have been mapped on the eastern side of the pyritic TSF footprint.
- Active talus rubble deposits have been mapped on the northern slope of Kaskanak Mountain on the southeastern slope of the bulk TSF impoundment.

Small areas of colluvium and solifluction deposits have also been mapped along the mine access road and Iliamna spur road. These occur about 2 miles east of the mine site, about 6 miles east of the mine site on the northern side of Koktuli Mountain, and near the junction between the two roads (Detterman and Reed 1973; Hamilton and Klieforth 2010). Steep alluvial fan and talus deposits occur in incised valleys crossed by the eastern portion of the North Route, and along the lake front south of Knutson Mountain. Landslide and solifluction deposits have been mapped near the North Route corridor at the head of Lonesome Bay, and on the flanks of Roadhouse and Knutson mountains. Steep alluvial fan deposits have also been mapped at the southern end of the South Access Road, about 1 mile north of the port site (Detterman and Reed 1973).

Factors that contribute to unstable coastal bluffs near the pipeline landfall on the eastern side of Cook Inlet are described above in the Other Project Components section. The bluffs in this area have a history of erosion problems caused by wave action, tidal currents, groundwater seepage, and overland flow. The bluffs have experienced gullying, periodic landsliding, and debris flows

AMERICAN OVERSIGHT

following major storms (Reger and Petrik 1993; USACE 2008). Bluff retreat estimates range from 0.3 to 0.5 foot per year (ft/yr) in lower Cook Inlet near Kachemak Bay, to as much as 3 ft/yr near the town of Kenai (Adams et al. 2007; USACE 2007a).

Large earthquakes can also trigger landslides. The 1964 Great Alaskan Earthquake caused numerous landslides, rockslides, debris flows, soil slumps, and avalanches on the slopes of Kodiak Island and shoreline of Cook Inlet. The earthquake also caused translational landslides, tension cracks, and earth fissures on the top of bluffs; and rotational slides in Tertiary sedimentary rocks such as those that outcrop along the eastern coast of Cook Inlet (Plafker and Kachadoorian 1966; Waller 1966).

3.15.4 Volcanoes

Alaska contains more than 50 volcanoes considered to be historically active, having erupted in the last few hundred years (Alaska Volcano Observatory [AVO] 2018). Several are within about 100 miles of proposed project infrastructure (Figure 3.15-4), including Augustine, 20 miles east of the Amakdedori port site; Iliamna and Redoubt volcanoes, north of the project area; and a cluster of volcanoes on the northern Alaska Peninsula.

Augustine Volcano was last active in 2015. Past eruptions of Augustine caused ashfall accumulations of up to about ¼ inch on the Alaska and Kenai peninsulas, floating rafts of pumice that interfered with boat traffic in Cook Inlet, and ash clouds that disrupted air travel as far away as the Lower 48 (Waythomas and Waitt 1998). Volcanic debris avalanches that flow into Cook Inlet are known to occur with an average recurrence interval of about 150 to 200 years (Beget and Kienle 1992).

Redoubt and Iliamna volcanoes were last active in 2015 and 2016, respectively. Redoubt has had three major eruptions in the last 100 years, the most recent of which created significant ash plumes that disrupted air traffic on and off for months, and trace amounts of ashfall in Southcentral Alaska communities. Iliamna Volcano is mainly known for active steam vents and avalanches related to seismic activity (AVO 2018).

The Katmai group of seven volcanoes on the northern Alaska Peninsula includes three that have experienced historical eruptions (Katmai, Novarupta, and Trident), and four that are primarily known for steaming fumaroles (Snowy, Griggs, Martin, and Mageik) (AVO 2018). The largest historical eruption in this group occurred at Katmai and Novarupta in 1912, resulting in deposition of approximately 1 foot of ash in Kodiak, 100 miles away (Fenner 1920). Trident's last eruption began in 1953, producing ballistic blocks about 2 miles away from the vent, and intermittent ash clouds over a period of 21 years (AVO 2018).

AMERICAN OVERSIGHT

Figure 3.15-4: Active Volcanoes

AMERICAN OVERSIGHT

3.15.5 Tsunamis, Seiches, and Coastal Hazards

Tsunamis and seiches are different phenomena. Tsunamis are a series of water waves that are caused by displacement of large bodies of water due to seismic disturbances and underwater landslides. Seiches are large waves triggered by earthquakes that occur in enclosed bodies of water such as lakes and harbors, which can damage shoreline structures, boats, and moored vessels (e.g., Kabiri-Samani 2013).

Lower Cook Inlet has the potential for tsunamis and related coastal geohazards from seismic events. Impacts from tsunamis are dependent on bathymetry, coastline configuration, and tidal interactions. The 1964 Great Alaskan Earthquake generated numerous tsunami waves, including several that destroyed the harbor at Kodiak (Plafker and Kachadoorian 1966). Tsunami wave height predictions for 100- to 500-year return period events (combined with high tide) in lower Cook Inlet are estimated to be 12 to 23 feet above mean sea level (AMSL) in the Amakdedori area of Kamishak Bay, and 13 to 15 feet AMSL in the Happy Valley area of eastern Cook Inlet (Crawford 1987). More recent tsunami modeling predicts a runup elevation of 28.5 feet above mean high water (MHW) for a 2,500-year return period event at high tide at the Amakdedori port site (ASCE 2017). Based on an approximate MHW elevation of 6.3 feet AMSL at the port site (Pentec et al. 2011a, 2015a; NOAA 2018a), the latter event translates to a runup elevation of 34.8 feet MSL.

Volcanic eruptions can also produce tsunamis from catastrophic dome collapses and rapidly moving pyroclastic flows entering the sea (Waythomas et al. 2009; AVO 2018). The 1883 eruption of Augustine Volcano produced a wave that affected areas up to 55 feet above high tide on Augustine Island, and 23 feet above high tide on Kenai Peninsula (Begét et al. 2008). A similar phenomenon was documented in Bristol Bay from a prehistoric Aniakchak caldera flow that generated a 25-foot wave and deposited debris 60 feet above sea level in Nushagak Bay (Allen 1994; Armes 1996; Waythomas and Neal 1998).

Occurrence of seiches has not been monitored in the region, and the occurrence of seiches in Iliamna Lake during past large earthquakes is unknown (PLP 2018-RFI 013). During the 1964 Great Alaskan and 2002 Denali earthquakes, seiches several feet high occurred in the intracoastal waterways of Southeast Alaska, and in a number of lakes and reservoirs in the Lower 48 (McGarr et al. 1968; Barberopoulou et al. 2004; City and Borough of Juneau [CBJ] 2018). Damage to houseboats on Lake Union in Seattle from seiches was documented during both of these events. Modeling of an earthquake-induced landslide into Bradley Lake in Southcentral Alaska predicted that a 10-foot seiche would occur (Stone & Webster 1987); Bradley Lake is in a similar seismic zone, but is much smaller than Iliamna Lake. Coastal planning in Southeast Alaska anticipates that seiches up to 20 feet high could occur from large distant earthquakes originating in Southcentral Alaska (Community and Systems Analysis [CASA] 1982). For context, storm-driven waves on Iliamna Lake have been documented as high as 6 feet in the community of Iliamna, where they have caused shoreline erosion and damage to the dock and boats (USACE 2009a).

The 1964 Great Alaskan Earthquake generated additional coastal hazards in Cook Inlet—such as tectonic uplift and subsidence, ground fissuring, and submarine landslides—that destroyed the Homer Harbor breakwater. Vertical uplift was on the order of 1 to 2 feet along the western shore of lower Cook Inlet, and subsidence in the range of 0.5 to 4 feet along the eastern shore of lower Cook Inlet (Foster and Karlstrom 1967). Ground cracking, liquefaction, and local subsidence up to several feet occurred in saturated beach and alluvial deposits around Kodiak Island, along Cook Inlet shorelines, and around large lakes in the area (Plafker and Kachadoorian 1966). Along the western shore of Cook Inlet, stream mouths were drowned and narrow beaches experienced vigorous erosion at bluff faces (Stanley 1968).

AMERICAN OVERSIGHT

Other coastal and marine hazards in lower Cook Inlet include large sand waves, current scour features, shallow natural gas accumulations, and boulders on the seafloor (BSEE 2018). The boulders originate from coastal bluff slumping or glacial erratics, and can be ice-rafted along shore during winter, causing potential navigation hazards. Boulders and rocky shallows have been mapped along the coast within 1 to 2 miles north and south of the mouth of Amakdedori Creek (PLP 2018-RFI 039), and extend offshore in an east-trending ridge from 1 to 5 miles due east of the creek. Rocky areas and boulders are common on mudflats in the upper reaches of Cottonwood and Iliamna bays (Pentec et al. 2011a). Reconnaissance geophysical surveys indicate the presence of rocks and boulders on the seabed and buried in shallow sediment in the vicinity of Diamond Point, reaching a maximum density near the mouth of Iliamna Bay (PLP 2018-RFI 063). Boulders are also common along the eastern Cook Inlet shoreline near the pipeline landfall (NOAA 2015).

4.13 GEOLOGY

This section describes project-related impacts on the geological resources discussed in Section 3.13 for all project alternatives. The impacts include removal and relocation of rock, soil, and sediment. Appendix K4.13 presents an analysis of potential impacts on paleontological resources. The impacts of the project on other aspects of the geological environment are described in the following sections: Section 4.14, Soils; Section 4.15, Geohazards; Section 4.17, Hydrogeology; Section 4.18, Water and Sediment Quality; and Section 4.22, Wetland/Special Aquatic Sites, which also describes the affected footprint of project features and facilities of the components for all phases of the project.

The impact analysis considered the following factors: magnitude, duration, geographic extent, and potential. All three action alternatives would result in a similar magnitude and duration of and potential for impacts related to geology. The primary difference between the alternatives would be the areas and volumes of associated geological resources that would be affected.

Geotechnical investigations and studies have been completed to support engineering design (see Appendix K4.13.1). Additional investigations and studies are ongoing and will continue as needed to support detailed design and ensure project compliance with all relevant regulations that are protective of the environment.

4.13.1 No Action Alternative

Under the No Action Alternative, the project would not be constructed; therefore, no impact on geological resources would occur.

4.13.2 Alternative 1 – Applicant's Proposed Alternative

The analysis of impacts from Alternative 1 on geological resources is presented below.

4.13.2.1 Mine Site

Removal/Relocation of Geologic Materials

Constructing and operating the mine site would affect approximately 8,129 acres and associated geological resources through removal and relocation of rock, sediment, and soil (Figure 2-3 and Figure 2-4) (PLP 2018). Closure of some facilities and regrading of facility footprints during site reclamation would minimize some of this impact (Figures 4.16-2 through 4.16-6).

Open Pit

Removing and relocating overburden and rock at the open pit would result in direct impacts on these geologic resources that would be permanent, unavoidable consequences of the action alternatives.

Excavating the open pit during construction and operation would result in removal and relocation of 1.3 billion tons (2.6 trillion pounds) of mineralized rock. The open pit would be approximately 8 percent of the total mine site surface area (Figure 2-3).

The majority of rock removed from the open pit would remain at the mine site in perpetuity in the form of tailings. Bulk tailings would remain in the bulk tailings storage facility (TSF) in perpetuity. Pyritic tailings would be stored in the pyritic TSF during operations and relocated to the open pit at closure.

AMERICAN OVERSIGHT

A relatively small fraction of the excavated rock from the open pit would make up the economic minerals that would be processed (concentrated) then exported off site. This economic mineral portion would include 7.4 billion pounds of copper, 398 million pounds of molybdenum, and 12.1 million ounces of gold (PLP 2018).

Approximately 200 million tons of overburden would be removed from the open pit. Suitable rocky overburden materials would be used for embankment fill, regrading purposes, and other rockfill for the project. Appendix K4.15, Geohazards, addresses the volumes and geotechnical characteristics of the rockfill generated from the open pit and the quarries. Some overburden material would be used for regrading purposes, topsoil would be used as a growth medium during reclamation, and the remainder would be placed in the overburden stockpile.

At the end of mining, the pit would be partially backfilled with pyritic tailings and potentially acid-generating (PAG) waste rock. The partial backfilling would reduce the volume of the open pit, but a permanent void in the landscape would remain. Impacts would be limited to the footprint of the excavated pit and the locations where the materials would be relocated within the mine site.

Tailings Storage Facilities

A bulk TSF and pyritic TSF would store tailings and waste rock generated from the mined and processed open pit rock (Figure 2-3). Approximately 88 percent (1,140 million tons) would be bulk tailings and approximately 12 percent (155 million tons) would be pyritic tailings (PLP 2018).

The bulk TSF would have the largest footprint of the mine site facilities, about 30 percent of the mine site area. The pyritic TSF would compose about 5 percent of the mine site area.

Direct impacts on geological resources would result from the removal and relocation of rock and sediment required for construction of the two TSFs. The impacts would be limited to the footprints of the facilities. The pyritic tailings would be would be backfilled into the open pit, and the footprint of the pyritic TSF would be regraded to near preexisting topography at mine closure, such that its impact would be long term. The bulk TSF would be closed, recontoured, and vegetated at closure, and would remain as a new landform. The impact of the bulk TSF on the landscape would be permanent.

Quarries

Surficial sediments and bedrock would be removed from three quarries in the western portion of the mine site to provide rockfill for the construction of embankments, roads, and other mining-related facilities (Figure 2-3). The quarries would be developed in granodiorite bedrock, and blasting would be required to remove the rock. The combined areas of the three rock quarries would be an estimated 16 percent of the total mine site area (Figure 2-3). The estimated volumes of material that would be excavated from the quarries and respective dimensions are as follows (PLP 2018; PLP 2018-RFI 015):

- 1.6 billion cubic feet (ft^3) from Quarry A (approximately 5,000 feet by 2,900 feet)
- 3.2 billion ft^3 from Quarry B (approximately 5,800 feet by 7,000 feet)
- 1.4 billion ft^3 from Quarry C (approximately 5,200 feet by 3,300 feet).

The area of Quarry A would be covered during construction of the bulk TSF; Quarries B and C would be backfilled and reclaimed during mine closure (Figure 4.16-4). Excavation of the quarries would result in direct, long-term to permanent impacts on geological resources.

AMERICAN OVERSIGHT

Other Mine Site Facilities

Geological resources would be removed from and/or relocated to various other facility footprints within the mine site, including the water management facilities, the milling and processing facilities, the power plant, water treatment plants, camp facilities, storage facilities including laydown areas, and access roads (Figure 2-3).

Removal and relocation of geologic materials at these sites would result in direct long-term impacts on geological resources, limited to the footprints of the respective facilities. Closure and regrading of some of these facilities at mine closure would minimize impacts on geologic materials (Figure 4.16-6).

Power generation facilities, some camp and storage facilities, access roads, and the mine water treatment plant would remain to support post-closure water treatment and site monitoring that would likely continue 50-plus years into the future. Therefore, the impacts of these facilities on geological resources would be permanent.

4.13.2.2 Transportation Corridor

Removal/Relocation of Geologic Materials

Access Roads

The construction of access and spur roads (Figure 2-12) would require removing and relocating surficial glacial deposits and bedrock (PLP 2018-RFI 032a). The 29-mile-long mine access road from the mine site to the north ferry terminal on Iliamna Lake would be constructed within mostly surficial glacial deposits, with the potential for bedrock along approximately 2 miles. The spur road to Iliamna would be approximately 7 miles long and underlain by mostly surficial glacial deposits. Therefore, the road right-of-way (ROW) width and associated disturbed geological resources would be similar to those for the mine access road. The port access road from the south ferry terminal to the Amakdedori port would be approximately 37 miles long and underlain mostly by bedrock.

The width of the ROW would vary based on the terrain and underlying geology. The estimated range of disturbed geological resources to construct the road prism may be roughly 60 to 80 feet (PLP 2018; Figure 2-15). This would include the 30-foot-wide road, embankment slopes, drainage ditches, natural gas pipeline, and cut slopes within surficial glacial deposits and bedrock. Portions of the roadbed underlain by bedrock would likely require blasting (Figure 3.13-4).

Under Alternative 1, roads would include a total of 97 stream crossings. These crossing structures would consist of nine bridges and 88 culverts, 35 of which would be designated as fish passage culverts. All structures would require rock and riprap consisting of blasted bedrock from the geologic material sites (MSs) discussed below (Figures 2-16 through 2-18; PLP 2018).

Impacts on geological resources would be direct, and limited to the access road ROW, stream crossings footprints, and the MSs discussed in the next subsection. The access road would be required for site maintenance and monitoring through post-closure. Therefore, impacts on geological resources would be permanent.

Material Sites

The access roads would require rockfill and aggregate for embankments and road surfacing during mine construction, operation, and closure. The rockfill and aggregate would be provided by 18 MSs adjacent to the transportation corridor (Figures 2-12 through 2-14).

AMERICAN OVERSIGHT

Footprints of the MSs would vary from 8 to 22 acres, for a total of approximately 241 acres (Table 2-3). The total volume is estimated to be 7.9 million cubic yards (yd^3).

Two of the seven MSs located along the mine access road would be situated within bedrock and therefore would likely require blasting (Table 2-3; Figure 3.13-4). The remaining five MSs would be located within surficial glacial deposits generally consisting of silt- to gravel-sized materials that would not require blasting.

No blasting is anticipated for the three MSs on the spur road to Iliamna that would be situated within surficial glacial deposits (PLP 2018-RFI 035).

All eight MSs located along the port access road would be situated within bedrock and would likely require blasting.

The impacts of removing rock and gravel from the MSs would be direct and long-term in terms of geological resources, but would be limited to the material site footprints. The MSs would eventually be stabilized and progressively reclaimed, but generally would not be backfilled during mine closure and post-closure. Therefore, impacts would be permanent.

Ferry Terminals

Constructing the north and south ferry terminals on Iliamna Lake would require excavation of surficial glacial deposits and possibly bedrock on the combined 27 acres of the terminal footprints (Figures 2-20 through 2-25).

Ferry terminal construction would result in direct impacts on geological resources within the footprints of the facilities, because of the need to remove and relocate geologic materials.

The ferry terminals would be closed and the sites reclaimed during closure. Impacts related to geology would be long term.

4.13.2.3 Amakdedori Port

Removal/Relocation of Geologic Materials

The Amakdedori port would be approximately 14 acres and would require construction of a port terminal, a truck route and causeway, and a barge berth (Figures 2-27 and 2-28).

Surficial glacial deposits and possible alluvium (mostly of sand and gravel) would be affected during construction of the port terminal.

The truck route and causeway would be constructed of an earthfill embankment. The barge berth would be constructed using an enclosed steel sheet pile wall wharf structure filled with earthfill. The combined area of the causeway and barge berth would be an estimated 13 acres (Figure 2-28; PLP 2018-RFI 071). The source of the earthfill would likely be the nearest geologic materials site, MS-A08 (Figure 2-14), and possibly the footprint of the port terminal.

The rockfill access causeway would be constructed within nearshore sediment deposits on the floor of the bay (see Section 4.16, Surface Water Hydrology, for impacts on marine water; see Section 4.18, Water and Sediment Quality, for impacts on marine water quality). Dredging would not be required.

Removing and relocating geologic materials during construction of Amakdedori port would result in direct impacts on geological resources. The impacts would be limited to the construction footprint and the geologic materials site. The port would be closed and undergo reclamation after completion of the off-site transport of concentrate. The impacts would therefore be long term.

AMERICAN OVERSIGHT

4.13.2.4 Natural Gas Pipeline Corridor

Removal/Relocation of Geologic Materials

Construction of the shoreline component of the pipeline west of the compressor station at Anchor Point would use horizontal directional drilling (HDD) (see Section 4.15, Geohazards, for a more detailed discussion). The eastern nearshore portion of the pipeline would be installed beneath the seafloor to a depth determined to avoid navigational hazards. Then the pipeline would be laid on the seafloor (PLP 2018-RFI 011). The segment of pipeline placed on the Cook Inlet seafloor would not affect geological resources.

From the western landfall near Amakdedori port, pipeline construction in uplands would require removing and relocating both surficial glacial deposits and bedrock (depending on the location along the corridor) to bury the pipeline. Upland pipeline construction would be integrated with access road construction within the ROW where practicable.

Installing the pipeline would likely require drilling and blasting for those segments mapped as underlain by bedrock (Figure 3.13-4).

Impacts of pipeline construction would occur in the areas of the construction ROW and pipeline installation and in established areas used for material laydown, staging of equipment, etc.

Where the pipeline installation is coincident with access road construction, the pipeline-related impact on geological resources would be considered part of the impact of the access road ROW (Figure 2-15).

Where the pipeline installation is not coincident with access road construction, the ROW and the related corridor of affected geological resources resulting from the pipeline installation would be approximately 100 feet (Figure 2-53). However, the disturbed area would be reclaimed after installation of the pipeline. Therefore, the impact on geological resources beyond the installation trench would be short term.

For the crossing of Iliamna Lake, the pipeline would be buried nearshore in sediments to prevent inadvertent damage, but would then be placed on the floor of the lake (PLP 2018). The pipeline segment placed on the lake floor would not affect geological resources.

The natural gas pipeline would be required to support mine site maintenance and monitoring through post-closure. Therefore, the impact on geological resources would be permanent because of the displacement of materials required to accommodate the pipeline.

4.13.2.5 Alternative 1 – Summer-Only Ferry Operations Variant

Mine Site Concentrate Storage

During the winter, concentrate would be stored in a shipping container storage area northeast of the pyritic TSF (Figure 2-37). The storage container laydown area would be constructed of rock and gravel fill, and would therefore have a direct impact on geological resources. The impact would be limited to the footprint of the storage area. The facility would be removed during mine closure and the impacts on geological resources would be long term.

Amakdedori Port

The summer-only ferry operations variant would require Amakdedori port to include an expanded storage yard. Impacts on geological resources would be limited to the construction footprint. The port would be closed and undergo reclamation after completion of the off-site transport of concentrate for the project. Impacts would therefore be long term.

AMERICAN OVERSIGHT

4.13.2.6 Alternative 1 – Kokhanok East Ferry Terminal Variant

The Kokhanok east ferry terminal would be constructed east of Kokhanok (Figures 2-39 and 2-40). Construction of the ferry terminal under this variant would encounter similar geology as construction of the Kokhanok ferry terminal.

The Kokhanok east ferry terminal would require approximately 64 percent more rockfill material than the south ferry terminal (PLP 2018). Also, because the natural gas pipeline alignment would not coincide with the road corridor in the northern portion of the alignment, installing the pipeline would result in additional disturbance of geological resources within the ROW (Figure 2-53).

Three of the material sites for the Kokhanok East ferry terminal variant would change from MS-A01 through MS-A0 (totaling approximately 39 acres) to MS-K01 through MS-K03 (totaling approximately 163 acres. This would result in an approximately 70 percent increase in the area of MSs needed to construct the Kokhanok east ferry terminal variant.

The Kokhanok east ferry terminal site would therefore result in direct and indirect construction-related impacts on geological resources, from removal and relocation of geological materials within the construction footprints of the ferry terminal site, the natural gas pipeline alignment, and the access road to the ferry terminal.

The closure-related impacts of the Kokhanok East ferry terminal variant would be similar to those for the south ferry terminal site. Both ferry terminal sites would be closed and reclaimed in closure, so that the impacts would be long term.

4.13.2.7 Alternative 1 – Pipe-Supported Dock Variant

The pile-supported dock variant (Figure 2-56) would include approximately 518 piles that would disturb approximately 6,500 square feet of area (less than 2 acres) (PLP 2018-RFI 071). This would compare with an estimated 27 acres for the port without the pile-support design (Figure 2-50). Therefore, the pile-supported dock variant would affect approximately 94 percent less geological resources than the earthfill causeway and sheet pile wall wharf structure.

As described above for the earthfill causeway and sheet pile wall wharf, the pile-supported dock variant would be closed and undergo reclamation after completion of the off-site transport of concentrate, as described under Alternative 1. Therefore, impacts would be long term.

Closure of the pile-supported port facility would be similar to closure of the port without pile support. However, instead of removing the earthfill from the footprint of the causeway and from behind the sheet pile wall berth and wharf structure, closure would involve removing the steel piling and disposing of it off site (PLP 2018). Therefore, closure-related impacts would also be approximately 98 percent less than the closure-related impacts of the earthfill causeway and sheet pile wall wharf design.

4.13.3 Action Alternative 2 – North Road and Ferry

The analysis of impacts from Alternative 2 on geological resources is presented below.

4.13.3.1 Mine Site

Removal/Relocation of Geologic Materials

Impacts of Alternative 2 on geological resources at the mine site would be similar to impacts of Alternative 1. The difference is that the bulk TSF main embankment would be developed by downstream construction with downstream buttresses under Alternative 2, compared to

AMERICAN OVERSIGHT

centerline construction with downstream buttresses under Alternative 1 (Figures 2-43 through 2-45). This would result in a footprint increase of approximately 119 acres and the embankment fill would increase from 78 million yd^3 to 124 million yd^3 (PLP 2018-RFI 075a).

Therefore, there would be an increase of approximately 5 percent in direct impacts on geological resources under Alternative 2 when compared to Alternative 1 for the bulk TSF main embankment, and an increase of approximately 1 percent for the overall mine site (PLP 2018). The impacts would be permanent because the bulk TSF would be closed and reclaimed in place.

4.13.3.2 Transportation Corridor

Removal/Relocation of Geologic Materials

Access Road

Alternative 2 would involve constructing and operating an access road that would total approximately 54 miles (Figure 2-46; PLP 2018). An estimated 5 miles of the Alternative 2 access road would use an existing road and the remainder would require new road construction or widening of the existing road.

The mine access road to the ferry terminal at Eagle Bay would be approximately 36 miles long and underlain by geology similar to that of the mine access road under Alternative 1, including possible blasting for approximately 2 miles of the corridor (Figure 2-47; Figure 3.13-4). A spur road to Iliamna would not be required under Alternative 2.

The access road from the Pile Bay ferry terminal to Williamsport would generally follow the existing road (Figure 2-48; PLP 2018). However, the road would need to be expanded and possibly bypassed in places to make the road suitable for use by haul trucks. This would have the potential to result in fewer impacts on geological resources than constructing a new road. However, MSs would still be needed for both construction and maintenance of the road surface (see "Material Sites" below).

Portions of the corridor are underlain by surficial glacial deposits where there may be less need for blasting. However, if the existing road were to be bypassed or widened to accommodate the requirements for a haul road, it is possible, and in places likely, that bedrock would be encountered outside the ROW of the existing road. For example, several MSs are likely located within bedrock.

A new, approximately 3-mile-long access road from Williamsport to Diamond Point would be constructed. Constructing this road would require removing and relocating mostly bedrock. Blasting would likely be required because of the type of bedrock (competent igneous intrusive rock) (Figure 3.13-4; Section 3.13).

Impacts on geological resources from constructing the access road would be direct and limited to the access road ROW. The total road distance for Alternative 2 would be approximately 19 percent less than under Alternative 1. If the 5 miles of existing road are considered, the net impact on geological resources under Alternative 2 would be approximately 26 percent less than the impact under Alternative 1.

As described for Alternative 1, the Alternative 2 road would be required for site maintenance and monitoring through post-closure. Therefore, the impact on geological resources would be permanent.

AMERICAN OVERSIGHT

Material Sites

Road construction and operational maintenance under Alternative 2 would require MSs to provide required aggregate for road surfacing during mine construction, operation, and closure (Figures 2-46 through 2-48 and Table 2-7).

For Alternative 2, 17 MSs (including the existing Diamond Point quarry) would be required versus 15 sites under Alternative 1. The footprints of the Alternative 2 MSs would vary from approximately 8 acres to 54 acres, for a total of approximately 431 acres (PLP 2018). This would be approximately 179 percent more area than needed under Alternative 1.

Blasting would likely be required to remove bedrock from five of the 17 Alternative 2 MSs (Figure 3.13-4). No blasting is anticipated for the 10 MSs associated with the mine access road to the Eagle Bay ferry terminal. Five of the seven MSs between Pile Bay and the port would likely require blasting. This would result in approximately 66 percent less blasting than under Alternative 1.

As under Alternative 1, impacts of removing rock and gravel from MSs under Alternative 2 would be direct and limited to the footprints of the MSs. The MSs would be eventually stabilized and progressively reclaimed but generally would not be backfilled during mine closure and post-closure. Therefore, impacts would be permanent.

Ferry Terminals

The transportation corridor under Alternative 2 would require ferry terminals at Eagle Bay and Pile Bay, which would be approximately the same size as the ferry terminals described for Alternative 1 (Figures 2-47 through 2-49). The geology at the ferry terminals under Alternative 2 would be similar to the geology at the ferry terminals under Alternative 1.

The impacts of the Alternative 2 ferry terminals on geological resources would be similar to the impacts of Alternative 1 during construction and operation, which would include direct impacts on geological resources from removal and relocation. The ferry terminals would be closed and would undergo decommissioning and reclamation after the completion of off-site transport of concentrate, so the impacts would be long term.

4.13.3.3 Diamond Point Port

Removal/Relocation of Geologic Materials

The Diamond Point port facility would use the same design concept as the Amakdedori port under Alternative 1. The total footprint of the Diamond Point port would be larger than that of the Amakdedori port. The Diamond Point port would encompass an estimated 102 acres (PLP 2018-RFI 071). The estimated dredged area would be an additional estimated 60 to 70 acres. The entire port area would total roughly 162 to 172 acres of affected geological resources, compared to the roughly 27 acres at the Amakdedori port under Alternative 1.

Dredging would create approximately 650,000 yd^3 of geologic materials to deepen the channel adjacent to and near the port wharf structure. Most dredged material (615,000 yd^3) would be used as earthfill behind the sheet pile wall. Any remaining material would be placed in a material stockpile area west of the port terminal (Figure 2-5; PLP 2018).

Removing and relocating geologic resources would result in direct impacts that would be more than five times the geographic extent of the Amakdedori port site under Alternative 1. As described for the Alternative 1 Amakdedori port site, the earthen access causeway would affect the nearshore sediment deposits of Iliamna Bay (see Section 4.16, Surface Water Hydrology,

AMERICAN OVERSIGHT

for impacts on marine water; see Section 4.18, Water and Sediment Quality, for impacts on marine water quality).

The Diamond Point port would be closed and would undergo reclamation after the completion of off-site transport of concentrate, as described for Alternative 1. Therefore, impacts would be long term.

4.13.3.4 Natural Gas Pipeline Corridor

Removal/Relocation of Geologic Materials

Construction of the natural gas pipeline under Alternative 2 would require removing and relocating both surficial glacial surficial and bedrock for all upland portions of the pipeline (Figure 2-52), as described for Alternative 1 (Section 4.13). The corridor route, length, and respective geological resources would differ from those of Alternative 1. See Chapter 2 for the Alternative 2 pipeline corridor route.

Pipeline construction materials and methods for Alternative 2 would be similar to those for Alternative 1. However, the pipeline segment between the Pile Bay road intersection and the mine site would require an installation corridor independent of the transportation system. The pipeline installation equipment would require a corridor or ROW estimated at 100 feet wide; the actual width would vary depending on the terrain and underlying geology (Figure 2-53).

For the pipeline segment from the pipeline segment between the Pile Bay road intersection and about Pedro Bay, the corridor is mapped as underlain by bedrock and relatively steep topography for portions of the alignment. From Pedro Bay to the western portion of Knutson Bay, the geology would consist mostly of surficial glacial deposits and then bedrock similar to that found near Pedro Bay. From Knutson Bay to the mine site, the geology would generally consist of surficial glacial deposits, similar to the geology of the Alternative 2 transportation corridor to the Eagle Bay ferry terminal.

The total length of the upland section of the pipeline from Ursus Cove to the mine site would be approximately 88 miles. Blasting would be required during installation of an estimated 20 to 25 miles of the pipeline, an estimated 20 to 40 percent less blasting than for Alternative 1.

Impacts on geological resources from installation of the natural gas pipeline would be direct and limited to within the ROW for pipeline installation.

As described for Alternative 1, the natural gas pipeline would be required for site maintenance and monitoring through post-closure. Therefore, the impact on geological resources would be permanent.

4.13.3.5 Alternative 2 – Summer-Only Ferry Operations Variant

Impacts would be the same as those described above for Alternative 1.

4.13.3.6 Alternative 2 – Pile-Supported Dock Variant

A pile-supported dock variant (Figure 2-41) with a total of 253 steel piles would replace the earthfill causeway, sheet pile wall, and earthfill wharf structure of Alternative 1. This would result in approximately 3,200 ft^2 of disturbance of geological resources (PLP 2018-RFI 071). Impacts on geological resources would be direct and limited to the footprint of the piling.

As described above for the non-pile-supported dock, the pile-supported dock variant would be closed and would undergo reclamation after the completion of off-site transport of concentrate, as described for Alternative 1. Therefore, impacts would be long term.

AMERICAN OVERSIGHT

Closure of the pile-supported dock port would be similar to closure of the port without pile support. However, instead of removing the earthfill from the footprint of the causeway and from behind the sheet pile wall berth and wharf structure, the closure would include removing the steel piling and disposing of it off site (PLP 2018). Therefore, the closure-related impacts would also be substantially less than the closure-related impacts of the earthfill causeway and sheet pile wall wharf design.

4.13.4 Action Alternative 3 – North Road Only

The analysis of impacts from Alternative 3 on geological resources is presented below.

4.13.4.1 Mine Site

Impacts of Alternative 3 on geological resources at the mine site would be the same as those described for Alternative 1.

4.13.4.2 Transportation Corridor

Removal/Relocation of Geologic Materials

Access Road

Impacts on geological resources resulting from the construction and operation of the Alternative 3 access road (Figure 2-59) would be generally the same as the impacts of the natural gas pipeline corridor described for Alternative 2. The differences in potential related impacts are summarized below.

From the mine site to near Knutson Bay, the geology would consist of surficial glacial deposits, similar to the geology of the Alternative 2 transportation corridor to the Eagle Bay ferry terminal. From the western portion of Knutson Bay to Pedro Bay, the geology would consist mostly of bedrock and surficial glacial deposits. From Pedro Bay to the Pile Bay road intersection, the corridor is mapped as underlain by bedrock and relatively steep topography for portions of the alignment.

The access road from the Pile Bay road intersection to Williamsport would generally follow the existing road (Figure 2-48; PLP 2018), which is underlain by a combination of bedrock and surficial glacial deposits. The last approximately 3 miles of new road from Williamsport to the Diamond Point port would be underlain by bedrock.

Impacts on geological resources from constructing the access road would be direct and limited to the access road ROW. Alternative 3 would require removing and relocating approximately 25 percent more geologic materials for the access road than under Alternative 1, and 54 percent more than under Alternative 2. As with Alternatives 1 and 2, the road would be required for site maintenance and monitoring through post-closure. Therefore, the impact on geological resources would be permanent.

Material Sites

As with Alternatives 1 and 2, access road construction and operational maintenance under Alternative 3 would require MSs, to provide required aggregate for road surfacing during mine construction, operation, and closure (Figure 2-58, Figure 2-59, and Table 2-9).

Twenty-seven MSs (including the existing Diamond Point quarry) would be required for Alternative 3, versus 15 sites under Alternative 1 and 12 sites under Alternative 2. The footprints of the Alternative 3 MSs would vary from 8 acres to 54 acres, for a total of an estimated 808

AMERICAN OVERSIGHT

acres (PLP 2018; PLP 2018-RFI 035). This would be 208 percent more than needed under Alternative 1 and 72 percent more than needed under Alternative 2.

Blasting would likely be required to remove bedrock from seven of the Alternative 3 MSs (Figure 3.13-4). All other MSs would be within surficial glacial deposits. Thus, approximately 72 percent less blasting would be required under Alternative 3 than under Alternative 1 and 227 percent more than under Alternative 2.

As under both Alternatives 1 and 2, the impacts of rock and gravel removal from MSs under Alternative 3 would be direct, limited to within the footprints of the MSs, and eventually stabilized and progressively reclaimed but not backfilled during mine closure and post-closure. Therefore, the impacts would be permanent.

Ferry Terminals

No ferry terminals would be needed under Alternative 3. Therefore, no impacts on geological resources would occur.

4.13.4.3 Diamond Point Port

Impacts on geological resources at the Diamond Point port site would be the same as those described above for Alternative 2.

4.13.4.4 Natural Gas Pipeline Corridor

Removal/Relocation of Geologic Materials

As described for Alternatives 1 and 2, construction of the natural gas pipeline under Alternative 3 would require removing and relocating geological resources to bury the pipeline in an excavated trench for all upland portions of the pipeline.

The Alternative 3 pipeline route would be the same as the route under Alternative 2. However, the Alternative 3 corridor may average approximately 10 to 20 percent narrower because the access road would be available for staging materials during pipeline installation, instead of needing an estimated 100-foot-wide ROW for pipeline installation when not adjacent to an access road (Figures 2-15 and 2-53).

As described for both Alternatives 1 and 2, the natural gas pipeline under Alternative 3 would be required for site maintenance and monitoring through post-closure. Therefore, the impact on geological resources would be permanent.

4.13.4.5 Alternative 3 – Concentrate Pipeline Variant

The Alternative 3 concentrate pipeline variant would involve installing and operating a concentrate pipeline from the mine site to the Diamond Point port. The pipeline would be installed in the same trench as the natural gas pipeline, and within a ROW estimated to be 100 feet wide (Figure 2-53). Therefore, impacts would be the same as those for the Alternative 2 natural gas pipeline corridor.

From Williamsport to Diamond Point, the concentrate pipeline would be installed within the transportation corridor, which would still be required for construction and maintenance of the Diamond Point port (Figure 2-63). The port would be modified to accommodate a concentrate pipeline filter plant and bulk storage building. The impact on geological resources, however, would be similar to that of the port terminal without concentrate-related facilities.

AMERICAN OVERSIGHT

The concentrate pipeline variant would also require a pump house at the mine site with a footprint of about 0.7 acre, resulting in associated impacts on geological resources (Figure 2-60).

The concentrate pipeline would be decommissioned in place at mine closure; however, to avoid further ground disturbance, the pipeline would not be removed. Therefore, the impact on geological resources would be permanent.

4.13.5 Key Issues/Impacts Summary Table

Table 4.13-1 provides a summary of the key issues and impacts from the project on geological resources.

Table 4.13-1: Summary of Key Issues for Geology

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Mine Site Construction and Operation	Construction and operation of the mine site would result in removal and/or replacement of geological resources in conjunction with all facilities. Impacts would occur from blasting of most bedrock in construction areas. All impacts would be direct and limited to footprints of facilities. No change in impacts for variants.	Impacts similar to those of Alternative 1, except the bulk TSF main embankment would be downstream constructed with downstream buttresses, which would result in ~5% increase in the total mine site footprint and resulting direct impacts on geological resources. No change in impacts for variants.	Impacts similar to those of Alternative 1. Concentrate Pipeline Variant: Increased project footprint by less than 1 acre and associated impacts.
Mine Site Closure	All embankments other than those at the bulk TSF would be removed and the areas reclaimed at closure, resulting in direct, long-term impacts. Pyritic TSF: Material would be placed in open pit, resulting in long-term direct impacts. Open Pit: Would be partially backfilled, resulting in permanent direct impacts. Bulk TSF: Would be closed and reclaimed in place, resulting in permanent direct impacts. No change in impacts for variants.	Impacts same as those of Alternative 1, except larger bulk TSF footprint. No change in impacts for variants.	Impacts same as those of Alternative 1. No change in impacts for variants.

AMERICAN OVERSIGHT

Table 4.13-1: Summary of Key Issues for Geology

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Transportation Corridor			
Transportation Corridor Construction and Operation	**Access Road:** Total 75 miles. Mine Access Road: 27 miles to north ferry terminal, mostly surficial glacial deposits. Bedrock ~2 miles, likely blasting impacts. Iliamna Spur Road: 7 miles, mostly surficial glacial deposits. Port Access Road: 32 miles, mostly bedrock, likely blasting. **Geologic MSs:** 18 MSs, 241 acres. Mine Access Road MSs: 7 total and 2 blasting. Iliamna Spur Road MSs: 3 total and no blasting. Port Access Road MSs: 8 total and all blasting. **Ferry Terminals**: 27 acres of direct impacts. **Kokhanok East Ferry Terminal Variant:** Direct impact ~70% more geological resources to construct than the Alternative 1 terminal, and indirect impact of wider gas pipeline ROW where not adjacent to road.	**Access Road:** Total 54 miles (~5 miles using existing road) Mine Access Road: 36 miles to Eagle Bay mostly surficial glacial deposits. Bedrock ~2 miles, likely blasting. Iliamna Spur Road: N/A Port Access Road: 32 miles mostly shallow bedrock blasting. **Geologic MSs:** 17 MSs, 431 acres Mine Access Road MSs: 10 total & 0 blasting Iliamna Spur Road MSs: N/A. Port Access Road MSs: 7 total & 5 blasting. **Ferry Terminals:** 27 acres direct impacts. **Variants** N/A	**Access Road:** Total 82 miles. Mine Access to Port Road: Mostly surficial glacial deposits from mine site to Knutson Bay, then a combination of glacial deposits and bedrock to port. Blasting likely for northwest Knutson Bay, Pedro Bay to Pile Bay road intersection, and Williamsport to port. **Geologic MSs:** 27 MSs, 808 acres. Mine Access Road to Port MSs: 27 total and 7 blasting. Iliamna Spur Road MSs: N/A. Port Access Road MSs: N/A. **Ferry Terminals:** N/A. **Concentrate Pipeline Variant:** Same impacts as those of Alternative 1 for the gas pipeline.
Transportation Corridor Closure	**Geologic MSs:** Progressively reclaimed but not backfilled, so there would be permanent impacts. **Ferry Terminals**: Decommissioning and reclamation at mine closure, so long-term impacts. **Kokhanok East Ferry Terminal Variant:** Same as for Alternative 1.	**Geologic MSs:** Same as for Alternative 1. **Ferry Terminals**: Same as for Alternative 1. **Variants** N/A.	**Geologic MSs:** Same as for Alternative 1. **Ferry Terminals**: Same as for Alternative 1. **Concentrate Pipeline Variant:** Same impacts as those of Alternative 2 gas pipeline.

Table 4.13-1: Summary of Key Issues for Geology

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Ports			
Port Construction and Operation	Amakdedori Port: Earthfill embankment causeway and steel sheet pile wall wharf with earthfill design. Port Terminal +Causeway/ Barge Wharf: 27 acres. No dredging. **Pile-Supported Dock Variant:** Reduce causeway/barge wharf to ~0.1 acre **Summer-Only Ferry Variant:** Expanded port terminal by 28 acres.	Diamond Point Port: Earthfill embankment causeway and steel sheet pile wall wharf with earthfill design. Port Terminal Causeway/ Barge Wharf: 101 acres Dredging: ~60 to 70 acres (most dredged material used as earthfill). **Pile-Supported Dock Variant**: Reduce causeway/barge wharf to ~2 acres	Same as for Alternative 2. **Concentrate Pipeline Variant:** Modify port terminal, but footprint nearly same as for Alternative 2.
Port Closure	Amakdedori Port: Structures and earthfill removed after mine closure, so impacts would be long-term. **Pile-Supported Dock Variant**: Same as above, but impact less because of smaller piling footprint and no causeway and wharf earthfill. Long-term impacts. **Summer-Only Ferry Variant:** Same as for Alternative 1, but larger area and long-term impacts.	Diamond Point Port: Same as for Alternative 1 but about 4 to 5 times larger area. **Pile-Supported Dock Variant**: Larger area of impact on seafloor. Long-term impacts.	Impacts same as those of Alternative 2. **Concentrate Pipeline Variant**: Minimal impact difference. Long-term impacts.
Natural Gas Pipeline Corridor			
Gas Pipeline Construction and Operation	Total Upland Length: 66 miles Kenai Peninsula: HDD at Anchor Point to safe depth in Cook Inlet, then on seafloor. Amakdedori Port to Mine Site: Generally installed within access road alignment, so same geological resources affected. 66 miles upland (plus lake crossing, pipeline on lake floor). Impacts same as for Alternative 1 access road.	Total Upland Length: 88 miles Kenai Peninsula: Same as for Alternative 1. Ursus Cove to Mine Site: Independent alignment from Ursus Cove to Diamond Point port. Installed within access road to Pile Bay road intersection. Then independent ROW to mine site. Impacts for ROW independent of access road about 10 to 20% more because of design width. Would directly affect	Same as for Alternative 2 except installed within access road ROW. **Variants** N/A

4.13.6 Cumulative Effects

Past, present, and reasonably foreseeable future activities (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to removal and relocation of geological resources.

Section 4.1 details the past, present, and RFFAs that may affect geological resources by an increase in removal and relocation of rock, sediment, and soil. Cumulative effects associated with other aspects of the geological environment are described elsewhere in this document: erosion of soil in Section 4.14, geologic hazards in Section 4.15, hydrogeology or groundwater impacts in Section 4.17, water and sediment quality in Section 4.18, and wetlands in Section 4.22.

The following RFFAs identified in Section 4.1 were carried forward in this analysis based on their potential to affect geologic resources in the analysis area:

- Pebble Project buildout—develop 55 percent of the resource over a 78-year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*
- Donlin Gold

**Indicates exploration activities only.*

- Diamond Point Rock Quarry
- Alaska Stand Alone Pipeline Project
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure, and Energy Projects.

AMERICAN OVERSIGHT

All RFFAs would involve earthworks resulting in removal and relocation of geological resources. The following RFFAs are located within or immediately adjacent to the project area and would therefore have the potential to add to the direct impacts identified for the proposed project:

- Pebble Project buildout—develop 55 percent of the resource over a 78-year period
- Diamond Point Rock Quarry
- Lake and Peninsula Transportation, Infrastructure, and Energy Projects.

The Pebble Project buildout would require additional earthworks, such as underground mining, additional TSFs, and additional water management facilities. However, because the project would likely use much of the existing infrastructure under the proposed project, the net affected area may be less than developing mines at new greenfield sites. The magnitude of impact would thus likely be smaller.

The Diamond Point Rock Quarry is in the same location proposed for the Diamond Point port under Alternatives 2 and 3, described above. If either Alternative 2 or 3 were to be selected, a relatively minor net increase in impact on geological resources would likely occur. If Alternative 1 were to be selected, the total geographic extent of impacts would increase.

The Lake and Peninsula Transportation, Infrastructure, and Energy Projects include possible upgrades to the Williamsport–Pile Bay Road, which is roughly the same alignment that would be used under Alternatives 2 and 3. If either of these alternatives were to be selected, the net magnitude and geographic extent may be relatively low because the new MSs would already be developed for maintaining the road surface. If the road were to be widened as part of the Lake and Peninsula Transportation project, additional impacts would likely occur.

The Nondalton–Iliamna River Road Corridor and Bridge and the Kaskanak Road/Cook Inlet to Bristol Bay (Igiugig) road would result in additional impacts on geological resources under the possible Lake and Peninsula Transportation Projects.

The remaining RFFAs would have indirect cumulative effects on geological resources.

AMERICAN OVERSIGHT

4.15 GEOHAZARDS

This section describes potential impacts of geohazards on project components that could affect the environment. The EIS analysis area for geohazards ranges from the immediate vicinity of the project footprint (e.g., slope instability) to regional areas with geohazards that could affect project facilities from long distances (e.g., earthquakes, volcanoes).

The evaluation of geohazards impacts on the project and the environment incorporates an understanding of their probability of occurrence, and of planned mitigation in the form of planning, design, construction, operations, maintenance, and surveillance that can meaningfully reduce impacts through to closure and post-closure. Based on PLP plan documents and engineering reports, planned mitigation methods (e.g., design and monitoring to withstand or detect geohazards) are considered part of the project description, and the impacts analysis includes this understanding. In some cases, planned mitigation may not be specified, but is considered typical or standard engineering practice. In cases where planned mitigation is unknown or unclear and the situation is not commonly addressed, the impact analysis takes the lack of planned mitigation into account, and provides recommendations for mitigation that could reduce impacts.

This section describes the following potential impacts related to geohazards:

- The stability of major mine structures during operations and closure
- The effects of earthquakes on project facilities
- The effects of unstable slopes on project facilities
- The effects of geotechnical conditions and coastal hazards on port structures and pipeline landfalls
- The effects of tsunamis and seiches on port and ferry terminals
- The effects of volcanoes on project facilities.

Potential impacts to the environment resulting from geohazards-caused upset conditions, such as an embankment failure, are addressed in Section 4.27, Spill Risk. As described in Section 3.14, Soils, permafrost has not been encountered in any mine site or other project area field investigations; therefore, potential effects from permafrost hazards are not addressed in this section.

4.15.1 No Action Alternative

Under the No Action Alternative, no new construction of facilities would occur in the project area. Therefore, effects on project components from geohazards, seismic events, and other geotechnical conditions would not occur as a result of this alternative, and no impacts on the environment would result from such effects. Natural geohazards such as those described in Section 3.15, Geohazards, would continue to affect existing communities and infrastructure in the region.

4.15.2 Action Alternative 1 – Applicant's Proposed Alternative

4.15.2.1 Mine Site

This section describes potential effects of seismic events and other geohazards on major structures at the mine site; the ability of the structures to withstand these hazards; and the likelihood that such hazards could produce related environmental impacts. Figure 2-3 and Figure 2-4 in Chapter 2, Alternatives, display the mine site layout; and Table K4.15-1 in

AMERICAN OVERSIGHT

Appendix K4.15 provides the buildout dimensions of embankments and impoundments that would contain tailings, waste rock, and/or contact water at the mine site. This section also addresses potential geohazards effects on the open pit.

Embankment Construction Material

The embankments for the tailings and water management facilities would be constructed of drilled and blasted bedrock removed from quarries A through C[1], and the overburden in the open pit (Chapter 2, Alternatives, Figure 2-3). Analyses were completed to determine the quantities of on-site embankment construction materials and the project-related needs. Appendix K4.15 (Table K4.15-2 and Table K4.15-3) provide embankment material quantities that would be generated by Quarries A through C and the open pit overburden, and the embankment material needs for the relevant mine site-related facilities, respectively.

The results of the analyses indicate that the combination of the three quarries and the open pit overburden would generate sufficient materials (between 13 and 40 percent more rockfill material than needed) to construct the embankments. The likelihood that additional material needs would be identified as the project progresses (with related project footprint increases) is low.

Embankment and Impoundment Design and Construction

The embankments and impoundments could be impacted by geohazards, including instability associated with seepage, internal erosion[2], and seismic (earthquake) events. The embankments would therefore be designed and constructed to be stable under both static (non-seismic) and seismic conditions, which is also required by relevant draft dam safety guidance documents (ADNR 2017a). The following summarizes the geohazard considerations for the proposed design and construction of the major embankments and impoundments, including the bulk tailings storage facility (TSF), pyritic TSF, water management ponds (WMPs), and seepage collection ponds (SCPs). More detailed information is provided in Appendix K4.15.

Bulk TSF. The bulk TSF would be designed to impound the bulk tailings, and includes a main (north) and south embankment with the following design and construction elements to prevent geohazards-related impacts:

- Siting in a single tributary watershed surrounded by bedrock knobs to focus potential impacts in one watershed and incorporate natural containment elements.
- Main (north) embankment centerline constructed[3] to reduce the footprint, with a buttressed downstream slope to enhance stability, which would result in 2.6 horizontal: 1 vertical (H:V) downstream embankment slope and a serrated near-vertical upstream face at the dam crest for the upper 280 feet of the embankment (Chapter 2, Alternatives, Figure 2-8).
- Permeable flow-through design with core/filter/transition zones materials to minimize water buildup in the TSF, prevent internal erosion, and remain functional after a seismic event.

[1] Quarry A is shown as situated within the footprint of the bulk TSF; this quarry would be developed before the construction of the bulk TSF.
[2] Internal erosion, also referred to as piping, is the formation of voids in a soil caused by the removal of material by seepage, and occurs when the hydraulic forces exerted by water seeping through the pores and cracks of the material in the embankment are sufficient to detach particles and transport them out of the embankment structure.
[3] Centerline construction method uses the placement of rockfill on top of both the centerline and the downstream slope of the previous raise during the raise process, which results in a near-vertical upstream face at the dam crest for the portion of embankment.

AMERICAN OVERSIGHT
EPA-0135-0002732

- South embankment constructed using downstream methods[4], to include a downstream liner combined with a grout curtain to prevent upgradient groundwater flow into and beneath the impoundment.
- Bottom of south embankment core/filter/transition zones would tie into the top of the grout curtain zone, which would be keyed into bedrock to prevent leakage beneath the embankment.
- Underdrains beneath the entire TSF to further manage seepage flow.
- Water management to protect the dam from seepage pressure-related instability.
- Freeboard to contain the entire inflow design flood (IDF) above the tailings beach.
- Excess pond water to be pumped to the main TSF SCP or main WMP.
- Higher south embankment elevation to direct overflow to water catchment facilities.
- Wide tailings beach to reduce seepage pressure on embankments, and promote subsurface drainage to the north with pond development against bedrock high to the southeast.
- Reduced tailings volume by using thickening methods or additional pumping capacity.
- Foundations to be placed on competent bedrock for increased stability.
- Each dam lift to undergo a thorough safety review, and adjusted as necessary.
- Dry closure methods to improve the stability for permanent in-place closure, with a closure cover design that would minimize infiltration.
- Monitoring performed during construction, operations, closure, and post-closure.

Pyritic TSF. The pyritic TSF would be designed to impound the pyritic tailings and potentially acid-generating (PAG) waste rock, and would include a continuous embankment around the northern, southern, and eastern sides with the following design and construction elements to prevent geohazards-related impacts:

- Fully lined, subaqueous storage cell during operations to minimize acid generation.
- Majority of the pyritic TSF in a single tributary valley.
- Liner protected with processed materials (sand and gravel) after installation to prevent damage from punctures or damage during waste rock placement.
- Liner installation completed in accordance with standard industry practices, and closely monitored.
- Water levels maintained for the life of the facility.
- Water levels and freeboard maintained to account for the IDF, wave run-up, and wind set-up.
- Excess pond water controlled by pumping to the main WMP.
- Embankments prepared by removing overburden to competent bedrock.
- Tailings and waste rock moved into the open pit at closure.
- After closure, the liner removed and embankments graded/recontoured to conform to surrounding landscape and promote natural runoff and drainage.
- Monitoring included in all phases.

[4] Downstream construction method uses the placement of rockfill on top of the downstream slope of the previous raise during the raise process.

AMERICAN OVERSIGHT

WMPs and SCPs. Two primary WMPs would be at the mine site (the main WMP north of the pyritic TSF, and the open pit WMP) to impound contact and open pit water, respectively. The SCPs would be downstream of the TSF embankments, and include those associated with the bulk TSF main and south embankments, and the pyritic TSF north, east, and south embankments. The facilities would include the following design and construction elements to prevent geohazards-related impacts:

- Fully lined to minimize seepage and risk of internal erosion.
- Rockfill embankments to promote stability.
- Main WMP embankment prepared by removing overburden to competent bedrock.
- Open pit WMP embankment design concept requiring potential weak foundation conditions encountered in the overburden materials (e.g., glacial lake deposits) to be excavated.
- Pond water volumes managed through reuse in the process plant, and treatment and discharge.
- Monitoring/seepage pumpback wells downgradient to detect and capture potential liner leakage.
- At closure, the WMPs to be removed and embankments graded/recontoured to conform to the surrounding landscape and promote natural runoff and drainage.
- Monitoring included during all phases.

Static Stability Analyses

Analyses were completed to evaluate the stability of the proposed embankments under static and non-seismic conditions. The following summarizes the static stability analysis. A more detailed discussion is presented in Appendix K4.15. The following major embankments and impoundments were analyzed:

- Bulk TSF main and south embankments
- Pyritic TSF north embankment
- Main WMP
- Bulk TSF main SCP
- Open pit WMP

The static stability analyses were completed using the computer program SLOPE/W. Input parameters were based on the results of field and office studies, and included the embankment configurations and assumed rockfill material, foundation materials, and stored materials.

The results predicted the analyzed embankments would have a static factor of safety (FoS) between 1.7 and 2.0 (a static FoS of 1.1 or greater is considered stable). Additional static stability analyses would be completed in support of the final design.

As noted above, the Alternative 1 bulk TSF main embankment design would result in a serrated near-vertical upstream face at the dam crest for the upper 280 feet of the embankment that would partially rest on tailings. There is some concern that this configuration has the potential to liquefy during seismic events. As discussed in Appendix K4.15, the stability of the centerline design was reviewed by a panel of geotechnical experts during the EIS-Phase Failure Modes and Effects Analysis (FMEA) (AECOM 2018l). The stability analysis results do not rely on the strength of these materials; but rather, on the strength of rockfill materials directly beneath and downstream of successive raises in the core zone and buttresses (Figure 2-8 and Figure K4.15-2). In other words, regardless of the low strength assigned to the tailings, the overall embankment did not fail in a downstream direction in the stability analysis. Therefore, the FMEA

AMERICAN OVERSIGHT

panel concluded that the likelihood of global instability of the buttressed centerline embankment design would be very low.

Seismic Stability Analysis

Active Surface Faults. The mine site is situated in a seismically active area due to the convergence of the Pacific and North American tectonic plates. The most significant seismically active geologic structure near the mine site is the Bruin Bay fault, which is situated about 70 to 80 miles to the east-southeast.

No mine facilities would be constructed on top of known active surface faults. As presented in Section 3.15, Geohazards, the closest potentially active fault to the mine site, the Lake Clark fault, is about 15 miles to the northeast. Recent mapping at the mine site and vicinity has not shown evidence of offset of surficial deposits along faults or lineaments in the area (Hamilton and Klieforth 2010; Haeussler and Waythomas 2011; Koehler 2010). This conclusion is further supported by Light Detection and Ranging (LiDAR) data that were collected in 2004 in the mine site area. The LiDAR-derived image was reviewed for possible indications of fault-related movement in surficial deposits. No lineaments were observed that suggest possible Quaternary fault-related movement southwest of the mapped termination (AECOM 2018m).

More detailed discussion regarding seismic sources and hazards in the greater project area is presented in Section 3.15, Geohazards, Appendix K3.15, and Appendix K4.15.

Seismic Hazard Analyses. The TSF embankments at the mine site would be regulated as Class I (high) hazard potential dams under the Alaska Dam Safety Program (ADSP) draft dam safety guidelines (ADNR 2017a; PLP 2017). Based on these draft guidelines, two levels of design earthquake must be established for Class I dams:

- *Operating Basis Earthquake* (OBE) that has a reasonable probability of occurring during the project life (return period of 150 to more than 250 years), for which structures must be designed to remain functional, with minor damage that could be easily repairable in a limited time. In other words, minor damage within allowable design criteria may be sustained at the TSF embankments following an OBE earthquake.
- *Maximum Design Earthquake* (MDE) that represents the most severe ground shaking expected at the site (return period from 2,500 years up to that of the Maximum Credible Earthquake [MCE]), for which structures must be designed to resist collapse and uncontrolled release.

The OBE can be defined based on probabilistic evaluations, with the level of risk (probability that the magnitude of ground motion will be exceeded during a particular length of time) being determined relative to the hazard potential classification and location of the dam (ADNR 2017a). The MDE may be defined based on either probabilistic or deterministic evaluations, or both (ADNR 2017a). A conservative OBE corresponding to a return period of 475 years was adopted for the Pebble TSF designs. Based on this return period, the estimated maximum acceleration (which is a measure of the intensity of an earthquake as it is applied to a structure, such as the embankments) has been determined to be 0.14 g (or 14 percent of gravity acceleration). The MCE was selected as the MDE for the Pebble TSFs (KP 2013). Appendix K4.15 provides further discussion of the seismic sources and probabilistic and deterministic evaluations completed for the Pebble Project to evaluate potential ground shaking associated with these earthquakes.

Seismic Deformation Analysis. A pseudo-static deformation analysis was completed to predict the response of the largest embankment (the bulk TSF) to a seismic event, based on the OBE, as well as MCEs from four potential seismic sources (faults) with magnitudes ranging from 6.5 to 9.2 (Appendix K4.15). Predicted displacements in the embankment were estimated to be

AMERICAN OVERSIGHT

negligible for the OBE, and on the order of 4 to 5 feet of horizontal displacement and crest settlement under MCE loading conditions. The displacements were not large enough to truncate the filter or transition zones, and would not affect the functionality of embankment. The results were used to design the minimum freeboard requirements for the bulk TSF embankments.

The deformation and settlement analyses would be updated as part of the ongoing design of the TSFs and other embankments. Additional detailed modeling, including analyses using Fast Lagrangian Analysis of Continua (FLAC) numerical modeling software, would be completed during detailed design of the facilities to better define embankment displacements.

Summary of Stability Effects. Direct effects on mine embankments from earthquakes, floods, static loading, slope failure, and foundation conditions could range considerably. Effects would be unnoticeable to negligible where designs are adequate for expected geohazards, such as moderate earthquakes, large precipitation events, or known unstable foundation conditions that are removed in construction. Effects could include damage that is repairable in the short term (e.g., months) in the event of an OBE; or in the event of an MDE, effects could range up to damage that is not be easily repairable, but is not expected to lead to structural collapse or uncontrolled release of contaminated materials. Assuming that facilities are planned, designed constructed, operated, maintained, and surveilled as proposed and in accordance with Alaska Department of Natural Resources (ADNR 2017a) guidelines, potential damage to facilities and indirect effects on the environment are expected to remain within the footprint of the mine site.

The duration of effects would vary depending on the facility and likelihood of geohazard occurrence. In the case of earthquake damage that is easily repairable, impacts would be infrequent, but not longer than the life of the mine for facilities that would be removed at closure (e.g., embankments at the pyritic TSF). Impacts could occur in perpetuity for structures that would remain in place (e.g., bulk TSF embankments). Based on the conceptual designs, and assuming current standard of engineering practice is followed, the likelihood of global instability of the major embankments was considered very low (less than 1 in 10,000 probability) by geotechnical experts in the Environmental Impact Statement (EIS)-Phase FMEA (AECOM 2018l). Indirect effects on other downstream resources in the unlikely event of an embankment spill or release are discussed in Section 4.27, Spill Risk.

Open Pit Slopes

Numerical modeling was completed to predict the stability for three sections of the open pit walls with known weak rock conditions (Figure K4.15-10). As described in Appendix K4.15, the analyses evaluated both static and seismic conditions, and included modeling of disturbance factor zones that represent the predicted bedrock damage caused by rock mass relaxation[5] and crustal rebound[6] due to the excavation of the open pit, as well as blast damage close to the excavation surface (Hoek 2012). The modeling targeted a minimum acceptable FoS for the open pit walls of 1.3 for static conditions, and 1.05 for dynamic (earthquake) conditions. These values recognize that there would only be a single entry into the pit, and any instability involving the ramp could impact the operations. After closure, the static FoS would be reduced to an FoS of 1.1 due to the lack of access required into the pit, but this would be further reviewed during detailed design.

The modeling results showed an FoS of 1.1 or greater for two of the three pit sections, indicating they would be stable under both static and earthquake loadings, and an FoS below 1.1 (indicating potentially unstable conditions) for the section through the northwestern side of the pit under both static and dynamic loadings in early closure after dewatering ceases.

[5] Unloading of rock stresses due to the removal of bedrock (i.e., underground mines and/or open pits)
[6] The rise of a land mass due to removing an overlying weight or mass, such as excavating bedrock during open pit mining, which could be significant enough to be measurable, and therefore included in the computer modeling.

AMERICAN OVERSIGHT

Two additional closure scenarios were examined for the northwest section: 1) early closure with continued groundwater depressurization focused on the toe of the slope; and 2) with pit lake levels recovered to about half full (above the area of instability). The results indicate an FoS of 1.1 and 1.4, respectively, for the two scenarios (Figures K4.15-12 and K4.15-13), and suggest that with continued depressurization in the localized area of the northwestern section during early closure activities (backfilling, etc.), the pit wall would be stable.

Other Geohazard Considerations

Quality Assurance/Quality Control (QA/QC). A Construction QA/QC Plan would be developed to assure all quarries, embankments, impoundments, and liners are constructed and operated in accordance with the approved designs and specifications. The plan would specify actions for approving embankment materials, construction methodology, field testing, surveying, monitoring, and documentation. ADNR (2017a) guidelines provide details on plan requirements, personnel responsible for QA/QC, key inspection items, and required post-construction document submittals.

Mining-Induced Seismicity. Induced seismicity refers to earthquakes and tremors that are thought to be caused by human activity through altering the stresses and strains in the Earth's crust. Mining-related activities such as rock mass relaxation, crustal rebound, and blasting associated with the excavation of an open pit, have the potential to generate induced seismicity.

The US Geological Survey (USGS) compiled a list of mining-related induced seismicity in the US over the 27-year period between 1973 and 2000, during which there were a total of 47 seismic events attributable to mining-related induced seismicity. The recorded tremors were generally small, ranging in magnitude between 2.0 and 4.8 (USGS 2018). One of the events occurred at the Usibelli Coal Mine in Alaska, with a magnitude 3.3 attributed to blasting, and possibly concurrent rock mass relaxation. The Usibelli Coal Mine is an open pit operation situated in a seismically active area similar to the proposed Pebble mine site[7] (WSM 2018). There does not appear to be an observed direct correlation between the weight of TSFs and/or stockpiles and induced seismicity at mining sites.

The open pit slope analysis above assumed seismic conditions that are likely more significant than the highest-magnitude mining-related induced seismic event recorded by the USGS (2018). In addition, the seismic stability analysis performed in support of the mine site design (Appendix K4.15) took into consideration unknown shallow crustal earthquakes (KP 2013), which is how a large mining-related induced seismic event would likely behave.

Seismic Impacts on Hydrogeology. The potential exists for impacts on hydrogeology resulting from a seismic event. For example, at the mine site, there are near-surface groundwater occurrences such as seasonal seeps and deeper groundwater that could be impacted (see Section 4.17, Groundwater Hydrology). Potential groundwater impacts could include changes in groundwater levels, volumes, and chemistry, including the locations of seeps. However, these types of changes commonly occur in the absence of seismic events due to other factors such as weather conditions (i.e., precipitation, temperatures) and changes in water chemistry (i.e., precipitation of naturally occurring constituents and/or bacteria in the water).

Groundwater conditions would be monitored throughout all stages of the mine project for both flow and chemistry purposes (Sections 4.17, Groundwater Hydrology, and 4.18, Water and Sediment Quality). If a major earthquake were to occur during project operations, an "extraordinary inspection" for any impacts would be required in accordance with the ADSP draft dam safety guidelines (ADNR 2017a), and in compliance with specific requirements of an

[7] Both are situated in strike-slip regimes with similar associated seismic mechanisms, but the magnitude of stress is higher at the Usibelli Coal Mine due to the tectonic forces that created Denali.

AMERICAN OVERSIGHT
EPA-0135-0002737

operations and maintenance (O&M) manual. The inspection would also identify adherence to design criteria for all major structures to ensure they continue to perform as designed. Changes to the groundwater monitoring program, facility design, and/or operation would be implemented as necessary to ensure protection of the environment.

Summer-Only Ferry Variant

Under the summer-only ferry operations variant, copper concentrate would be stored in shipping containers at the mine site during the winter at a storage area northeast of the pyritic TSF (Figure 2-37). Based on the surficial geology map (Figure 3.13-2); the proposed copper concentrate storage area is primarily underlain by surficial glacial outwash deposits, which generally consists of a mixture of sand- to gravel-sized material. The glacial outwash appears to thin to the northeast, with possible bedrock exposed near the northeastern boundary of the storage area.

During a large earthquake, the potential would exist for the stacked shipping containers to be impacted by differential settlement of the underlying glacial outwash due to being thicker to the southwest than the northeast, potentially resulting in toppling of the containers. The likelihood would depend on the magnitude and duration of the seismic event, height of container stacking, the in-place density of the foundation materials, and other factors. The impact would likely be mitigated through further investigation and foundation preparation such as compaction of near-surface materials.

4.15.2.2 Transportation Corridor

Earthquakes and Seiches

The transportation corridor would not cross any known active surface faults (Figure 3.15-1). A trace of the Bruin Bay fault zone crosses the south access road within several miles of the Amakdedori port site; however, there is no evidence of Holocene offset at the surface for this segment of the fault (Plafker et al. 1994; Koehler 2013). Therefore, effects on transportation corridor facilities related to surface fault displacement are not expected to occur.

Ground shaking in the event of a major earthquake could have direct effects on transportation facilities, such as cracking, spreading, and settlement of terminal platforms, or damage to the ferry during construction. However, because the ferry terminals would not include fuel tank storage facilities, indirect effects on environmental resources from such damage are expected to be minimal.

Earthquake- or landslide-induced seiches can damage shoreline structures, boats, and moored vessels in enclosed waterbodies, particularly if the natural period of a moored ship matches that of a seiche (Kabiri-Samani 2013). The historical occurrence of seiches in Iliamna Lake is unknown (see Section 3.15, Geohazards)(PLP 2018-RFI 013). Seiches several feet high that have been documented in Southeast Alaska and the Lower 48 during past major Alaska earthquakes (McGarr et al. 1968; Barberopoulou et al. 2004; CBJ 2018) are likely within the size of maximum storm-driven waves on Iliamna Lake (USACE 2009). Larger predicted seiche heights of 10 to 20 feet have been suggested for Bradley Lake on Kenai Peninsula and Lynn Canal at Skagway, respectively (CASA 1982; Stone & Webster 1987), although seiches are more likely to occur in narrow bodies of water such as these than in Iliamna Lake.

A preliminary estimate of seiche potential in Iliamna Lake was conducted based on a 60- by 15-mile area representing the wide part of the lake where the Alternative 1 ferry would operate (AECOM 2018d). The results indicate the natural oscillation period of an earthquake-induced seiche would fall well outside the period range where earthquake ground motions carry the most energy, suggesting that such an event is unlikely.

AMERICAN OVERSIGHT

Unstable Slopes

As discussed in Section 3.15, Geohazards, the north ferry terminal location is underlain by surficial deposits consisting of beach and lake terrace sand and gravel, and the south ferry terminal location by both volcanic bedrock and similar surficial deposits, neither of which is prone to unstable slope conditions (Figures 2-20 and 2-21).

Several small areas of unstable slope deposits occur along the mine access road, near the junction between the mine access and Iliamna spur roads, and near the southern end of the south access road (Section 3.15, Geohazards) (Detterman and Reed 1973; Hamilton and Klieforth 2010). Oversteepened, potentially unstable slopes could also be created during the development of the geologic material sites. Typical engineering and construction practices such as engineered cuts, benching, and drainage controls (Figure 2-15) would be used at these locations to minimize the potential for landslide impacts on the roads, material sites, and disruption of truck haulage. Therefore, the likelihood of such effects occurring is expected to be minimal, and impacts on the project and related effects on environmental resources are also expected to be minimal, temporary (easily repairable in the short term), and of limited extent (in the immediate vicinity of the road footprint).

Based on the topography along the road corridor, the potential for avalanches occurring during the operation of the mine is considered minimal for the transportation system.

Summer-Only Ferry Variant

There would be no difference in geohazards-related impacts under the summer-only ferry variant. Lake ice hazards (for year-round ferry operations under Alternative 1) are discussed under Section 4.16, Surface Water Hydrology.

Kokhanok East Ferry Terminal

Referring to Section 3.15, Geohazards, the Kokhanok east ferry terminal is underlain by beach deposits near the shoreline, and volcanic bedrock further upslope. The potential seismically related and unstable slope impacts are expected to be similar to the south ferry terminal location west of Kokhanok.

4.15.2.3 Amakdedori Port

The Amakdedori port site is underlain by raised beach terrace deposits consisting of sand and gravel (Section 3.15, Geohazards), which are not prone to unstable slope conditions.

Stability of Sheet Pile Dock

An assessment of the stability of the proposed sheet pile dock is presented in Appendix K4.15 and summarized below. As described in Section 3.15, Geohazards, the foundation materials for the offshore components are limited to shallow borings about 3 feet deep, a near-surface geophysical survey, and extrapolation from a deeper onshore geophysical survey, which suggest that subsurface deposits consist primarily of sand and gravel. Additional geotechnical investigation would be conducted as the project design progresses.

In the absence of the additional foundation information and related engineering analyses, the proposed rockfill causeway and sheet-pile dock would have the potential to result in adverse impacts to the environment during construction and operations. The potential impacts could include:

- Structural instability and potential failure of the sheet-pile wharf as a result of seismic loading, foundation conditions, erosion at the base of the sheet pile, icing increasing

AMERICAN OVERSIGHT

gravity load on the sheets, and corrosion requiring regular monitoring of cathodic protection systems;

- Damage to the structures due to liquefaction of the seabed during a seismic event; and
- Damage to the sheet pile wall during installation due the presence of boulders within the nearshore sediment, which could result in the release of the earthfill during operation.

The additional field investigation-related information would support more detailed design analyses to confirm whether the design is feasible; and if so, to ensure construction, operation, and closure would be protective of the environment.

The port would be closed and undergo reclamation after the offsite transport of concentrate has been completed at Year 20. All structures and related earthfill would be removed, and the site reclaimed (PLP 2018-RFI 024). The potential geohazards-related impacts would therefore be long-term, and generally limited to the close vicinity of the dock footprint. With additional geotechnical investigation and stability analyses, the likelihood of potential impacts occurring would be low.

Stability of Pile-Supported Dock Variant

The pile-supported dock would be constructed on trestle and dock piles (Figure 2-41), and the footprint area would be about 0.5 percent of that required for the rockfill causeway and sheet-pile dock.

As with the sheet-pile dock, detailed engineering analysis has not been completed in support of initial design. The stability of a pile-supported dock is typically a function of structural design details and pile-soil interaction. The current state-of-practice is to use bending in the pile to resist lateral loads (wind, seismic, vessel impacts, mooring loads, etc.) that may control pile embedment depths. Static stability analysis is typically conducted to determine the ability of the dock to accommodate and control maximum displacements from these loads, as well as global stability issues such as liquefaction. The survivability of a pile-supported structure in a large earthquake is generally considered better than bulkhead type structures, which do not perform well in major earthquakes, and are difficult to repair. For example, sections of the existing Port of Anchorage pile-supported dock survived the 1964 earthquake.

The piles would likely experience similar metal corrosion as the sheet-pile dock; similar issues with construction in the event of boulders in the subsurface; and ice-related impacts that could be worse due to exposure of the piles to the elements (PLP 2018-RFI 071). As with the sheet-pile, additional geotechnical investigation and stability analysis would be performed during final design, and the results would provide a better understanding of dock behavior in response to geohazards, and whether boulders are present that would hinder pile installation.

Based on the conceptual level of design and experience with similar structures, the likelihood of stability issues is generally considered lower with the pile-supported dock, and survivability in a major earthquake generally greater, than the sheet-pile dock. Unlike the sheet-pile dock, the pile-supported dock would not have the potential to release fill into the marine environment as a result of geohazards-related event. In the event of potential geohazards-related impacts to the pile-supported dock, the duration of effects would range from temporary (e.g., ice loads that are repairable) to long-term, and would likely be limited to the footprint of the structure.

Tsunamis

Published tsunami modeling for lower Cook Inlet (Crawford 1987; ASCE 2017) predicts runup elevations in the Amakdedori area (in combination with high tide) of 15 to 23 feet above mean sea level (amsl) for medium to large earthquakes (100- to 500-year events), and up to 34.8 feet amsl for a very large earthquake with a 2,500-year return period (Section 3.15, Geohazards).

AMERICAN OVERSIGHT

The proposed elevation of the terminal patio is 35 feet above mean lower low water (MLLW) (PLP 2017), or about 28 feet amsl (based on an approximate MLLW at the port site of -7.3 feet mean sea level [Hart Crowser 2011, 2015; NOAA 2018a]).

Therefore, for tsunamis with a probability of occurrence in the range of 1 in 100 to 500 years, the predicted runup elevation is below that of the port facilities, and impacts on facilities at the terminal (e.g., fuel tanks, storage of concentrate containers) and related effects on the environment are expected to be minimal. Assuming the causeway and wharf elevations are the same as the terminal elevation, impacts on equipment and activities on top of these structures would also be minimal. For a very low-probability tsunami with a 2,500-year return period, the predicted runup elevation could exceed the design elevation of the terminal, causeway, and wharf by about 7 feet. Effects could include risks to worker safety, equipment, and structures, such as the fuel storage tanks, concentrate containers, trucks, and cranes. The effects of potential spill releases from project facilities are discussed in Section 4.21, Spill Risk.

Damage during a tsunami could result from initial wave crushing or buoyancy failures, which can cause tipping or sliding (Brooker 2011). The sheet-pile bulkhead design would expose the cross-sectional area to the hydrodynamic impact of the wave. A critical loading condition for the bulkhead could be the very low water level during the "retreat phase" of the tsunami, during which the stabilizing effect of water on the outside of the sheet-pile is absent or diminished. Wave impacts and flooding of the upper part of the causeway are expected to cause little damage and erosion because the same type of riprap would be used to protect both the upper and lower parts (PLP 2017), and because the riprap would be designed to resist tide buoyancy and storm impacts. Some boat damage could result from barge/wharf or barge/ship collisions if loading and lightering activities at the wharf or offshore mooring locations were to coincide with the arrival of a tsunami wave; however, tsunami warning infrastructure, which typically sends warnings within several minutes (NOAA 2018b), may provide enough time to move vessels to avoid these impacts.

The probability of tsunamis occurring at the port ranges from unlikely (for 100- to 500-year events) to very unlikely (for 2,500-year events). If a tsunami were to occur, the intensity of impacts could range from minimal disruption of activities or boat damage to terminal flooding and damage to infrastructure, with possible related effects on environmental resources in the event of a diesel or concentrate spill (see Section 4.27, Spill Risk). Infrastructure damage would be localized in the near vicinity of the port and mooring sites. The duration of impacts could range from hours to months (in the event repairs are required). Typical mitigation might include a vulnerability analysis of equipment and facilities, incorporation of flooding into tank design (e.g., tie-downs), emergency action planning with tsunami escape routes, or consideration of design changes to facility armoring and elevation (Chapter 5, Mitigation).

Volcanoes

A number of active volcanoes have erupted in the last few decades within about 100 miles of the project area (Figure 3.15-3). Of particular potential concern is Augustine volcano, which is located approximately 20 miles east-northeast of the Amakdedori port site. Impacts from any of the active volcanoes could include ash clouds transported by wind, and fallout that disrupts construction and operations of project components, depending on prevailing wind direction and plume height. Volcanic ash particles are particularly abrasive, corrosive, and pervasive.

The likelihood of effects occurring at the more distant project components is low (e.g., once or twice over the life of the mine), but impacts from an Augustine plume on Amakdedori port facilities and moored ships are considered more likely. If ash fallout were to occur, it could affect most types of activities within the port footprint. Direct effects could include damage to equipment, engines, and compressor stations; and disruption of staffing, shipping, and fuel

AMERICAN OVERSIGHT

supplies. Effects would be temporary, potentially lasting several days per incident. Ashfall effects on the project are unlikely to result in indirect effects on other environmental resources. Typical mitigation might include a vulnerability analysis of facilities and equipment and hazard planning (Chapter 5, Mitigation).

As noted in Section 3.15, Geohazards, volcanic debris avalanches that flow into Cook Inlet are known to occur once every 150 to 200 years on average (Beget and Kienle 1992). Therefore, the likelihood of this scenario occurring during the project's life is low, as is the potential for these flows to reach the pipeline or port facilities. The primary lightering location is about 10 miles southwest of Augustine Island, but a secondary lightering location is 2 miles west of the island (PLP 2018d).

4.15.2.4 Natural Gas Pipeline Corridor

Earthquakes and Surface Faults

As described above for the transportation corridor, the natural gas pipeline corridor would not cross any known active surface faults (Figure 3.15-1). Therefore, effects on the pipeline from surface fault displacements are not expected to occur.

A major earthquake could cause liquefaction in unfrozen lowlands, stream crossings, and marine areas with fine sandy soils. This condition has the potential to cause buried pipelines to become buoyant; which, if not properly accounted for in design, could lead to pipe flotation and possible damage. The loss of soil shear strength during liquefaction could also lead to permanent ground movements through lateral spreading, flow failure, and settlement. Control measures for liquefaction and buoyancy (e.g., estimation of lateral spreading, use of select compacted backfill, increased cover depth, swamp weights, and post-earthquake inspection) are considered typical state-of-practice for high-liquefaction areas so that design deflection and stress on the pipe are not exceeded. The proposed use of thicker walled pipe in marine areas would also help minimize the effects of liquefaction in Cook Inlet and Iliamna Lake. Therefore, pipe rupture and potential related environmental effects in the event of liquefaction would be unlikely. If pipe damage were to occur, it would likely be localized and easily repairable within a temporary timeframe (e.g., days to months).

Unstable Slopes

A relatively unstable bluff roughly 200 feet high exists between the Anchor Point compressor station on Kenai Peninsula and Cook Inlet. To avoid the bluff, the pipeline would be horizontal directionally drilled (HDD) from the compressor station to the pipeline's emergence point on the Cook Inlet seafloor to the west.

The HDD would begin at an elevation of about 207 feet on the eastern side of Sterling Highway, and drop down to an elevation of -12 feet MLLW or deeper[8] in accordance with Pipeline and Hazardous Materials Safety Administration requirements (PLP 2018-RFI 011). The exact water depth at which the pipeline would emerge at the seafloor has not been determined, but is proposed to be deep enough to avoid navigational hazards (PLP 2018d).

During the life of the project, the bluff at Cook Inlet would likely continue to erode and retreat landward as a result of natural causes. With the use of HDD methods, the pipeline would pass well below and landward of the steep bluff at Cook Inlet, and avoid the unstable slope hazards (PLP 2018-RFI 011). Therefore, potential impacts on the project and related effects on the environment from this geohazard would be minimal.

[8] An 1,800-foot-long HDD pipeline would exit in approximately 12 feet of water MLLW, while a 2,000-foot-long HDD would exit in approximately 18 to 24 feet of water at MLLW. Current technology can accommodate a 2,000-foot-long HDD for in the 12-inch-diameter range as proposed (PLP 2018-RFI 011).

AMERICAN OVERSIGHT

Coastal Hazards

The depth of pipeline cover west of the HDD installation location, and below the 12-foot water depth on the western side of Cook Inlet and in Iliamna Lake, would be sufficient to ensure the top of the pipe is below the mudline. The minimum depth of cover above the 12-foot water depth would be 3 feet, which would minimize potential effects from coastal hazards such as shoreline drift, ice-rafting of surface boulders, or shifting sand waves. Section 4.16, Surface Water Hydrology, provides additional discussion of potential effects on the submerged pipeline.

4.15.3 Action Alternative 2 – North Road and Ferry

4.15.3.1 Mine Site – Downstream Embankment

The bulk TSF main embankment under Alternative 2 would be constructed using downstream raises (Chapter 2, Alternative, Figure 2-43 through Figure 2-45), as compared to the buttressed centerline design under Alternative 1 (PLP 2018d; PLP 2018-RFI 075). Under Alternative 2, the overall downstream slope would be 2.6H:1V, which would be the same as the buttressed centerline-constructed embankment under Alternative 2 (Figure 2-15). The upstream slope of the main embankment under this alternative would be 2H:1V, versus the upstream slope under Alternative 1 that would be a serrated near-vertical upstream face at the dam crest for the upper 280 feet, and partially rest on tailings (Figure 2-8).

As described in Appendix K4.15, the preliminary stability analysis for the downstream constructed main embankment calculated an FoS value on the order of 1.9 to 2.0 under static loading conditions, similar to that of the buttressed centerline design (Table 4.15-5), thereby offering minimal additional stability over the Alternative 1 design. A schematic section of the main embankment at its ultimate height with the predicted potential slip surface is shown on Figure 2-45.

The bulk TSF main embankment under Alternative 2 would be raised approximately 25 feet higher than the Alternative 1 design (embankment height approximately 570 feet) to provide equivalent bulk TSF storage capacity. The embankment fill would increase from 78 million cubic yards (yd^3) to 124 million yd^3, and the impoundment footprint area would increase by 119 acres (PLP 2018-RFI 075a). This would result in increased impacts on other resources such as material sites, substrate, and wetlands (Section 4.13, Geology; Section 4.18, water and Sediment Quality, and Section 4.22, Wetlands/Special Aquatic Sites), but would not change the global stability of the embankment.

4.15.3.2 Transportation Corridor

Mine Site to Eagle Bay, and Pile Bay to Diamond Point Roads

Earthquakes. Referring to Figures 2-47 and 3.15-1, the access road under Alternative 2 would not cross any known active faults. Potential impacts related to ground shaking for the roads would be similar to those described above under Alternative 1. Even though the access road from Williamsport to Diamond Point would be adjacent to the shoreline of Iliamna Bay, as described below for the Diamond Point port site, potential tsunami-related impacts in Iliamna Bay would be less intense than at the Amakdedori port site because Iliamna Bay is more protected and shallower than Amakdedori.

Unstable Slopes. Several areas of unstable solifluction, colluvium, and landslide deposits have been mapped in the area northwest of Eagle Bay on the flanks of Roadhouse Mountain and along the mine access road west of Newhalen River (Section 3.15, Geohazards) (Detterman and Reed 1973; Hamilton and Klieforth 2010). Steep alluvial fan and talus deposits occur in

AMERICAN OVERSIGHT

incised valleys crossed by the eastern portion of the route east of Pile Bay (Detterman and Reed 1973). Rockfall hazards could also occur in this area of exposed bedrock where rock cuts are likely. Steep unstable slopes and rockfall hazards are also likely along the Diamond Point-Williamsburg waterfront section of the road.

Typical engineering and construction practices such as engineered cuts, benching, and drainage controls, as well as road maintenance, would be used to manage unstable slopes, to minimize the potential for landslide impacts on the roads during construction and disruption of truck haulage. Several locations along the existing road between Pile Bay and Williamsport would be rerouted under this alternative to avoid steep slopes, including approximately the eastern third of this area, and a shorter road segment close to Pile Bay. Unstable slopes could also lead to an increase in the likelihood of spills (Section 4.27, Spill Risk provides an analysis of spill impacts from a truck spill scenario). Although the likelihood of such effects occurring is expected to be greater than under Alternative 1, with appropriate controls during construction and operations, impacts on the project and related effects on environmental resources are expected to be minimal, temporary (easily repairable in the short term), and of limited extent (within the immediate vicinity of the road footprint).

The potential exists for avalanches to occur for portions of the road alignment between Williamsport and Pile Bay. However, the avalanches would be preventable using relevant BMPs such as hazard mapping, forecasting, and blasting if necessary. If they were to occur, they would temporarily impact a local portion of the road until the snow could be removed.

Eagle Bay to Pile Bay Ferry

Potential impacts on the ferry terminals related to ground shaking would be similar to those described above under Alternative 1. Although the eastern end of the lake is narrower and deeper compared to the Alternative 1 ferry route—factors which can increase earthquake-generated seiche potential—the potential for occurrence is still considered unlikely (AECOM 2018j). This analysis assumes that the risk of major landslide-generated seiches at the eastern end of the lake is low, and that there is little evidence of past major landslides in the lake bottom, assumptions that would be further investigated through collection of more detailed bathymetric survey data as design progresses.

Summer-Only Ferry Variant

Under the summer-only variant, road traffic would be concentrated during the 6-month transportation season, which would include rainy months. Because heavy rain is often a trigger for slope failure, the potential for these impacts on road traffic and spill potential could be slightly greater under this variant, but would be balanced by fewer avalanche impacts due to lack of winter season traffic. Lake ice hazards are discussed under Section 4.16, Surface Water Hydrology.

4.15.3.3 Diamond Point Port

Referring to Figures 2-50 and 2-51, the Diamond Point port facility would use the same design concept as the Amakdedori port under Alternative 1[9], although with a footprint about four times bigger than at Amakdedori (PLP 2018-RFI 071).

As discussed in Appendix K4.15, ground shaking potential in the Diamond Point area is slightly greater than at Amakdedori. The Bruin Bay Fault extends along the western shore of Cook Inlet near the Diamond Point port site. Although there is no evidence for Holocene offset at the

[9] A causeway constructed of earthfill embankment, and barge berth and wharf constructed of a sheet-pile wall wharf structure filled with earthfill.

AMERICAN OVERSIGHT

surface, this fault is associated with several small to moderate earthquakes up to M7.3 in 1943 (Stevens and Craw 2003).

Stability of Dock Structure

Sheet Pile Dock. The proposed sheet pile dock would have the same types of potential impacts to the environment during construction and operation as discussed for the Amakdedori site (Section 4.15.2.3 and Appendix K4.15). As with the Amakdedori dock, additional geotechnical investigation would support more detailed design analyses to confirm the design is feasible; and if so, to ensure construction, operations, and closure would be protective of the environment.

The potential for tsunami impacts at the Diamond Point port site would be similar or less than those to the Amakdedori port site under Alternative 1. Although tsunami predictions at the mouth of Iliamna Bay are similar to those of Kamishak Bay (Crawford 1987), impacts would likely be less at Diamond Point due to Iliamna Bay being more protected and shallower than at Amakdedori.

The magnitude of potential impacts for Alternative 2 could be more than Alternative 1 due to the larger footprint and fill volume required for the Alternative 2 dock, and possible higher likelihood of boulders in the subsurface with related risk of short embedment or sheet-pile damage. As described in Section 4.18, Water and Sediment Quality, substrate conditions are generally finer-grained in Iliamna Bay than in Kamishak Bay. Because dock fill would partly consist of dredged material, in the event that potential geohazards-related impacts cause a release of fill to the marine environment, the extent of redeposition could be greater than under Alternative 1, and could range widely depending on season, tides, and wave conditions (e.g., from the close vicinity of the dock structure to the mouth of Iliamna Bay). As with Alternative 1, the port would undergo reclamation after the end of mine operations, and therefore, the potential for geohazards-related impacts could range from temporary (in the event of repairable damage) to long-term.

Pile-Supported Dock Variant. The pile-supported dock variant for the Diamond Point port would have potential geohazards-related impacts similar to the pile-supported dock variant at the Amakdedori port under Alternative 1. The offshore foundation conditions would likely be different than the Amakdedori site, which would affect the overall performance of the pile-supported system. The field conditions would be further investigated in support of final design.

Volcanoes

The Diamond Point port is approximately the same distance from volcanoes in the area, including Augustine, as the Amakdedori port under Alternative 1. The types of potential impacts would be similar to Alternative 1, with the magnitude, duration, and extent of impacts dependent on the severity of an ash cloud and the wind direction at the time of an eruption. In winter, however, the likelihood of potential impacts from Augustine on the Alternative 2 port site could be greater than Alternative 1 due to dominant northwesterly winds in this area (KP 2018g).

4.15.3.4 Natural Gas Pipeline Corridor

Referring to Figure 2-52, natural gas pipeline construction under Alternative 2 would follow a different corridor route west of Cook Inlet, and would therefore encounter different geology and related potential geohazards than Alternative 1 (Section 3.13, Geology, and Section 3.15, Geohazards).

Earthquakes and Surface Faults

In western Cook Inlet, the Alternative 2 pipeline would be routed to Ursus Cove to avoid known boulders and reefs at the mouth of Iliamna Bay (PLP 2018-RFI 063). At about 3 miles before

AMERICAN OVERSIGHT

making landfall, the pipeline would cross a mapped fault trace of the potentially active Bruin Bay fault (Figure 3.13-1 and Figure 3.15-1). Additional field investigation prior to final design (e.g., an offshore geophysical survey or onshore fault study at Ursus Head where the fault is mapped as having an upland component), would identify whether the fault is active and whether potential displacement mitigation in design would be necessary. The probability that a significant seismic event would occur on this fault during operations that would cause pipeline displacement and rupture is considered unlikely.

Unstable Slopes

Steep unstable slopes are a known hazard to pipeline integrity, and have been known to cause operation interruptions and ruptures in other mountainous areas of the world (e.g., the Andes, Eastern Europe, and Sakhalin Island) (Lee et al. 2016). Unstable slopes mapped between Ursus Cove and Pile Bay, and for the Alternative 2 route west of Eagle Bay, are discussed above under the Alternative 2 transportation corridor. The pipeline segment between Pile Bay and Eagle Bay crosses areas of exposed steep bedrock with the potential for rock instability, and alluvial fan and talus deposits, which could be unstable on steeper slopes. The corridor would avoid mapped landslide deposits on the flanks of Knutson and Roadhouse mountains.

Typical engineering and construction practices such as engineered cuts, rock stabilization, benching, and drainage controls would likely be used at these locations to minimize the potential for rockslide and landslide impacts to the pipeline. Additional mitigation, such as long-term slope monitoring, may be necessary in select areas. With these controls, the likelihood of slope failures occurring during the construction and operation that would affect pipeline integrity is expected to be minimal. Related effects on environmental resources are also expected to be minimal, temporary (repairable in the short term), and of limited extent (in the immediate vicinity of the pipeline right-of-way [ROW]).

Coastal Hazards

The depth of the pipeline as it approaches Ursus Cove from Cook Inlet, as well as the underwater crossing of the bay to Diamond Point, would be sufficient to ensure that the top of the pipe is below the mudline. The minimum depth of cover above the 12-foot water depth would be 3 feet, which is expected to minimize potential effects from coastal hazards such as shoreline drift or ice-rafting of surface boulders.

4.15.4 Action Alternative 3 – North Road Only

Under Alternative 3, geohazards impacts to the mine site (including concentrate pumphouse) and pipeline corridor would be the same as those described under Alternative 2. The following section describes impacts for the transportation corridor and port that would be different under Alternative 3.

4.15.4.1 Transportation Corridor

All Road Routes, Mine Site to Port

Geohazards-related impacts resulting from construction and operation of the Alternative 3 access road from Diamond Point to the mine site would be generally the same as the combination of road and natural gas pipeline corridors described under Alternative 2. However, the likelihood of slope stability issues occurring along the all-road route would be higher between Eagle and Pile Bays than under Alternative 2, due to the wider road ROW (compared to the Alternative 2 pipeline-only in this area) and greater need for engineering controls (such as wider cut and fills) to mitigate potential slope impacts. There would also be a slightly higher likelihood of spills due to the longer road route through steep terrain (Section 4.27, Spill Risk

AMERICAN OVERSIGHT

provides an analysis of spill impacts from a truck spill scenario), and greater potential for avalanches to occur that would be preventable using relevant BMPs described above for Alternative 2.

With appropriate engineering controls and BMPs, the overall likelihood of slope failures occurring along the all-road route is expected to be low. Related effects on environmental resources are also expected to be minimal, temporary (repairable in the short term), and of limited extent (in the immediate vicinity of the access road ROW footprint).

Concentrate Pipeline Variant

Because the concentrate pipeline would be installed in the same trench as the natural gas pipeline, impacts from geohazards such as unstable slope would be similar to the Alternative 2 natural gas pipeline corridor and Alternative 3 all-road route. There would also be a slightly higher likelihood of minor spills due to the additional potential contaminant source along steep terrain, which would be partially mitigated through leak detection systems (Section 4.27, Spill Risk, provides analysis of spill impacts from a concentrate spill scenario).

4.15.4.2 Diamond Point Port

Geohazards-related impacts would the same as Alternative 2, except for the concentrate storage and bulk handling described below.

Stability of Concentrate Storage and Bulk Handling Variant

Due to the mapped presence of alluvial fan deposits within the proposed footprint of the concentrate storage facility and steep slopes above the facility, the potential for unstable slopes would exist during the construction and operation (Detterman and Reed 1973). The final design would include a geotechnical investigation to confirm foundation and slope conditions to ensure the facility construction and operation would avoid or mitigate unstable slopes.

As noted under Alternative 2, the likelihood of a tsunami impacting the Diamond Point port site would be similar or less intense than the Amakdedori port under Alternative 1. However, if a tsunami were to occur, it would have a higher potential to result in a contaminant release to the marine environment under this variant. Section 4.27, Spill Risk, provides analysis of spill impacts from a concentrate spill scenario. Effects would be unlikely to occur, and the duration of impacts could range from hours to months (in the event repairs are required). Typical mitigation might include a vulnerability analysis of equipment and facilities, incorporation of flooding into design (e.g., tie-downs), emergency action planning with tsunami escape routes, or consideration of design changes to facility armoring and elevation (Chapter 5, Mitigation).

4.15.5 Alternatives Summary

Table 4.15-1 provides a summary of the key impact-related issues for geohazards.

AMERICAN OVERSIGHT

Table 4.15-1: Summary of Key Issues for Geohazards

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
TSF and WMP Embankment Stability	Low probability of embankment instability with static stability analysis (FoS 1.7-2.0), foundation preparation, seepage design, and flood controls incorporated into design. Temporary repairable damage in OBE, and 4 to 5-foot displacement/ settlement in MCE, would not result in effects on the environment outside of the footprint. Duration long-term with removal of pyritic TSF and WMPs at closure and dry closure of bulk TSF.	Design provides marginal additional stability over Alternative 1 design (FoS 1.9-2.0 for both).	Same as Alternative 1.
Open Pit Slope Stability	Low to medium likelihood of localized unstable slopes in lower pit in early closure, to be mitigated through targeted groundwater depressurization while lake rises.	Impacts same as Alternative 1.	Impacts same as Alternative 1.
Container Storage and Pumphouse	*Summer Only Ferry Variant:* Low likelihood of earthquake toppling effects at container storage area with foundation preparation.	Same as Alternative 1.	*Concentrate Pipeline Variant*: Impacts at pumphouse similar to Alternative 1.
Transportation Corridor			
Road Construction and Operations	Low likelihood of unstable slope impacts on roads. *Summer-Only Ferry Variant and Kokhanok East Variant:* Similar impacts to Alternative 1.	Low to medium likelihood of unstable slope impacts along road corridor; effects temporary and localized with engineering controls and maintenance. *Summer-Only Ferry Variant:* Impacts to Alternative 2.	Slightly higher likelihood of unstable slope effects than Alternative 2 due to longer route in steep terrain; effects similar to Alternative 2 with engineering controls and maintenance. *Concentrate Pipeline Variant*: Low likelihood of minor spills due to unstable slopes.
Ferry Terminals and Operations	Earthquakes: Low likelihood of temporary ground-shaking effects such as cracking, spreading, and settlement of terminals. Low likelihood of seiches and unstable slope effects. *Summer-Only Ferry Variant and Kokhanok East Variant:* Similar impacts to Alternative 1.	Impacts similar to Alternative 1.	Impacts similar to Alternative 1.

AMERICAN OVERSIGHT

Table 4.15-1: Summary of Key Issues for Geohazards

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Ports			
Dock Construction and Operations	*Proposed Sheet-Pile Dock:* Low to medium likelihood of stability effects on dock, and potential for fill escaping sheet-pile into marine environment. Tsunamis: low likelihood of temporary (repairable) effects such as dock or fuel tank damage. Volcanic ash from Augustine: low likelihood of port operations interruption. *Pile-Supported Dock Variant*: Lower likelihood of stability effects than sheet pile dock.	*Proposed Sheet-Pile Dock:* Slightly higher likelihood and extent of stability effects than Alternative 1, due to 4x larger structure and finer fill material. Tsunamis: lower likelihood than Alternative 1 due to protected shallower bay. Volcanic ash from Augustine: slightly higher likelihood of effects during winter due to prevailing winds. *Pile-Supported Dock Variant*: Lower likelihood of stability effects than Alternative 2 proposed sheet-pile dock.	*Proposed Sheet-Pile Dock:* Impacts same as Alternative 2. *Concentrate Pipeline Variant*: Low likelihood of unstable slope effects on storage facility. Tsunamis: Same likelihood as Alternative 2, but with slightly higher risk of contaminant release.
Natural Gas Pipeline Corridor			
Construction and Operations – Cook Inlet	Low likelihood of pipe damage form liquefaction. No active fault crossing effects.	Liquefaction impacts similar to Alternative 1. Low likelihood of active fault crossing (Bruin Bay fault) and displacement effects.	Liquefaction impacts similar to Alternative 1. Surface faults: same as Alternative 2.
Construction & Operations – Upland Areas	Low likelihood of unstable slope effects on pipeline.	Low-medium likelihood of unstable slope effects (such as operations interruption or rupture) between Diamond Point and Roadhouse Mountain; expected to be mitigated through typical engineering controls and monitoring.	Same as Alternative 2.

4.15.6 Cumulative Effects

Past, present, and reasonably foreseeable future activities (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to geologic hazards-related impacts. Section 4.1, Impact Assessment Framework, and Appendix K detail the RFFAs that may affect various environmental resources. All of the RFFAs would involve earthworks resulting in possible geologic hazards-related impacts. The following RFFAs are in or immediately adjacent to the project area, and would therefore have the potential to add to the geohazards impacts identified for the proposed project:

AMERICAN OVERSIGHT
EPA-0135-0002749

- Pebble Project buildout – development of 55 percent of the resource over a 78-year period
- Pebble South/PEB
- Diamond Point rock quarry
- Lake and Peninsula transportation, infrastructure and energy projects.

Both the Pebble Project buildout and Pebble South/PEB prospect would require additional earthworks and mine-related facilities. The magnitude of potential geohazards-related impacts would be similar to the proposed project, with added stability risk and potential cumulative effects on the Upper Talarik Creek drainage due to the large waste rock pile that would be required in the buildout scenario. However, because the projects would likely use some of the infrastructure already developed under the proposed project, the net impacted geographic area would likely be less than developing mines at new greenfield sites in terms of geohazards. This could include the transportation corridor, port, and natural gas pipeline corridor.

The Diamond Point rock quarry is the same location proposed for the Diamond Point port site under Alternatives 2 and 3, described above. If either Alternative 2 or Alternative 3 were to be selected, there would likely be a relatively minor net increase in geohazards-related impacts, such as dock stability effects on the marine environment. If Alternative 1 were to be selected, the total impacted geographic extent would be increased, but would likely not be significantly different in terms of geohazards.

The Lake and Peninsula Borough's transportation, infrastructure, and energy projects include possible upgrades to the Williamsport-Pile Bay Road, which is the same alignment that would be used under Alternatives 2 and 3. If either of these alternatives is selected, the net magnitude and geographic extent of unstable slope effects may be relatively low, because the Pebble road would already be rerouted or upgraded for maintaining slopes. If the road were to be further widened as part of the Lake and Peninsula Borough's transportation project, there would likely be additional impacts.

K3.14 SOILS

This appendix contains additional technical information on the following topics related to baseline soil conditions provided in Section 3.14:

- Technical classification of soils in the project footprint
- Permafrost occurrence in the project footprint
- Baseline soil chemistry

K3.14.1 Project Footprint Soil Classification

Some soils information provided in the Exploratory Soil Survey of Alaska (ESS) does not translate directly to current 2006 classification system standards, *Keys to Soil Taxonomy, 10th edition* (USDA 2006) but comparative equivalent soil type estimates can be made. Two additional soil orders that occur in the project area (i.e., Andisols and Gelisols) have been added to the ESS since 1979. Where applicable, soil descriptions from the ESS have been translated to current 2006 classification system equivalents (3PPl et al. 2011). Corresponding equivalents are based on available ESS descriptions and extrapolations from other nearby studies for the village of Nondalton and Chisik Island (Table K3.14-1).

Table K3.14-1: Corresponding ESS and 2006 Classifications for Applicable Soils

ESS Map Units	1979 Classification	2006 Classification
HY4, SO11, IA7	Pergelic cryofibrists	Typic fibristels
SO11	Humic cryothods	Typic humicryods
IA7, IA9	Typic crandepts	Typic haplocryands Typic vitricryands

Notes:
ESS = Exploratory Soil Survey of Alaska
Source: 3PPL, Table 5-2.

All the soil types in the project footprint are not likely addressed in the ESS because the ESS is limited to a general soils map and does not provide site-specific interpretations. Although not a direct comparison to NRCS soil descriptions, available project soil classification information acquired from shallow sampling activities (18 inches depth) have been incorporated (where available) into a surficial geologic map (Figure 3.13-2). A more detailed surficial geologic map of the mine site is provided in Section 3.13, Geology.

K3.14.1.1 Mine Site Soil Types

Soil types (i.e., principal component) and acreages associated with the mine site based on information provided in the ESS are listed below.

- IA9 Typic Cryandepts – 5,798 acres (approximately 71 percent): Very gravelly, hilly to steep association. Soils are well-drained, strongly acidic, and formed in volcanic material with a thin surface cover of decomposed plant matter mixed with volcanic ash. Common vegetation includes alder, grasses, or low shrubs.

AMERICAN OVERSIGHT

- IA7 Typic Cryandepts – 2,331 acres (approximately 29 percent): Very gravelly, nearly level to rolling Peregelic Cryofibrists, nearly level association. Soils are also associated with rolling plains bordering Iliamna Lake and rolling ground moraines, terminal moraines, outwash plains, and paleo-beach ridges, small lakes, and muskegs. Typic Cryandepts are well-drained, acidic, and formed in shallow volcanic material over gravelly glacial material dominated by low-tundra vegetative species. Shallow permafrost can reportedly be associated with a Pergelic Cryofibrists component (where present) consisting of sedge peat muskegs and coarse acid moss.

K3.14.1.2 Transportation Corridor Soil Types

The ESS recognizes four soil map units in the transportation corridor study area that are described below with corresponding acreages.

- IA7 Typic Cryandepts – 344 acres (approximately 39 percent)
- IA9 Typic Cryandepts – 203 acres (approximately 23 percent)
- IA17 Dystric Lithic Cryandepts – 328 acres (approximately 37 percent): Hilly to steep association. Soils are associated with low hill and ridges bordering mountainous areas. Well-drained loamy soils are formed in volcanic ash over shallow (20 inches) metamorphic bedrock or gravelly till, and overlain with a thin layer of organic material.
- HY4 Pergelic Cryofibrists – 13.5 acres (approximately 1 percent): Nearly level association. Soils are associated with nearly level, broad, wet lowlands near lakes and coastal margins. Organic-rich sedge and moss (e.g., muskeg) soils underlain by silt and sand mixtures are poorly drained and can reportedly be associated with the presence of shallow permafrost. Vegetation includes water-tolerant sedges, low shrubs, and black spruce.

K3.14.1.3 Pipeline Corridor Soil Types

Soil types along the shared route for the transportation corridor are the same as those described above. Two detailed soil map units are associated with the approximate 6 acres of pipeline infrastructure ground disturbance on the east side of Cook Inlet:

- 640 – Qutal silt loam, 0 to 4 percent slopes, 5.5 acres: Medial over loamy, amorphic over mixed, superactive Aquandic Haplocryods. Soils are associated with moraines on till plains and depressions on till plains dominated by a spruce-birch forest spruce-willow community. Soils consist of very gravelly sand overlain with silt loam and a thin interval of decomposed plant material. Soils are somewhat poorly drained with no flooding or ponding, with a slight hazard of erosion for water, but severe by wind.
- 568 – Island silt loam, 0 to 4 percent slopes, 0.25 acres: Medial over loamy, amorphic over mixed, superactive Pachic Fulvicryands. Soils are associated with till plains dominated by shallow kettles. Soils consist of gravelly sandy loam overlain with silt loam and a thin interval of decomposed plant material. Soils are well-drained with no flooding or ponding with a slight hazard of erosion by water, but severe hazard of erosion by wind.

AMERICAN OVERSIGHT

K3.14.1.4 Soil Types Unique to Alternatives

ESS soil types (i.e., principal component) that coincide with footprints associated with Alternatives are described below.

- RM1 Rough Mountainous Land: Steep rocky slopes.
- SO1 Typic Cryorthods: Nearly level association. Soils are associated with low rolling glacial moraines, broad terraces and lake and muskeg filled depressions. Well- to very poorly drained soils formed in silty loess (20 to 40 inches) over gravelly glacial till to fibrous organic soils in depressions between moraines.
- SO11 Humic Cryorthods: Hilly to steep association. Soils are associated with foot slopes and moraines. Well drained soils formed in silty volcanic ash (10 to 24 inches) over very gravelly glacial till, and overlain by partially decomposed organic matter.

K3.14.2 Permafrost Occurrence

Recent permafrost distribution estimates that coincide with project components on the western side of Cook Inlet are considered to be isolated occurrences (Jorgenson et al. 2008). Isolated permafrost varies from 0 to 10 percent of the landscape subsurface. No permafrost occurrence is anticipated to coincide with project infrastructure on the eastern side of Cook Inlet. Thermokarst landform features which are the result of permafrost freeze and thaw processes can be indicative of permafrost or residual expressions of where permafrost no longer exists. Existing thermokarst landscape features and future areas susceptible to thermokarst processes in the project footprint are generally not present (Olefeldt et al. 2016). Frozen ground conditions have been observed in near-surface soils in a few test pits and soil borings, but conditions were indiscernible from active layer processes that annually freeze and thaw at depths of up to 10 feet. Ground temperature measurements at depth within the mine site study area reported a mean temperature of 39.1 degrees Fahrenheit (°F). Groundwater temperature measurements from the deposit area were also above freezing throughout the year. Although such conditions do not preclude the occasional occurrences of permafrost, current conditions do not support increased permafrost development, and any remaining permafrost is considered to be a relic. Where present, relict permafrost is likely limited to shaded areas and north-facing slopes; poorly drained shallow surface soils overlain with insulative organics; and deep, coarse-grained soils (3PPI et al. 2011). Based on information provided in the ESS, principal components associated with Pergelic Cryofibrists (HY4) and Typic Cryandepts (IA7) soil types in the project footprint may coincide with relict permafrost occurrence in areas of very poorly drained organic soils (e.g., fibrous sedge and muskeg) of nearly level association that include depressions and valley bottoms.

K3.14.3 Baseline Soil Chemistry

Baseline shallow surface soil samples (less than 0.5 feet deep) were collected to determine the variability in naturally occurring constituents at the mine site. A total of 237 surface soil samples was collected from 117 locations in the mine site study area. Theses samples were analyzed for trace elements, cyanide, and sodium at 237 surface soil locations; anions and cations at 235 surface sample locations; petroleum hydrocarbons as diesel-range and residual range organics (diesel range organics [DRO] and residual range organics [RRO], respectively) at 23 surface soil locations; and total organic carbon (TOC) at 53 surface sample locations. The sample locations were considered representative of undisturbed baseline conditions. A list of naturally occurring compounds (NOCs) (i.e., analytes) evaluated as part of the surface soil studies is presented in Table K3.14-2 and Table K3.14-3.

Source excerpt: SLR et al. 2011a, Table 10.1-5.

AMERICAN OVERSIGHT

Anions and cations evaluated in surface soil samples included chloride, cyanide, fluoride, sulfate, ammonia (as nitrogen), and sodium. The highest mean concentration among evaluated ions was ammonia, followed by sodium. The lowest mean concentration among evaluated ions was cyanide. Depth-based variations in ion concentrations were apparent based on comparison to co-located shallow subsurface soil sample results. Mean concentrations of cyanide and ammonia were greater in surface samples, while mean sulfate concentrations were greater in shallow subsurface samples (SLR Alaska et al. 2011a).

RRO hydrocarbons were detected at all 23 surface sample locations, and DRO was detected at 13 surface sample locations. Mean concentrations of 209 milligrams per kilogram (mg/kg) and 2,028 mg/kg were reported for DRO and RRO, respectively (Table 3.14-3). The elevated presence and wide range of reported hydrocarbon concentrations are attributed to naturally occurring biogenic sources, based on absence of prior disturbances, analytical fingerprint methods, and presence of total organic carbon (TOC) (SLR Alaska et al. 2011b).

Similar to hydrocarbons, reported TOC concentrations varied significantly. TOC concentrations varied from 0.36 percent to 65.1 percent among surface soil locations. The wide range is attributed to variable quantities of organic material retained in sampled matrices during collection.

3.14 SOILS

This section describes the soil types in the project area evaluates project disturbance/removal; susceptibility to erosion; and soil chemical quality. In addition, soil conditions such as permafrost and soil impairment from contaminated sites are briefly addressed in this section. Descriptions of unconsolidated overburden at the mine site and other project components are provided in Section 3.13, Geology, and Section 3.15, Geohazards.

3.14.1 De Minimis / Insignificant Soil Conditions

Some soil conditions that may be important in other areas of Alaska have minimal presence in the project area, as described below.

3.14.1.1 Permafrost

Permafrost is soil that is permanently frozen. This condition can cause problems during development, because changes to the overlying vegetation can cause a thermal disturbance to this condition, resulting in melting and erosion.

To date, investigations in the project area (including all project components) have not reported widespread permafrost. Small patches of permafrost may occur in the project area; however, occurrence is presumed to be relict permafrost from prior glacial periods (Knight Piésold 2011). Recorded variations in ground temperature at depth in the mine site study area do not support the presence of permafrost, based on measured mean annual ground temperatures above freezing (39.1 degrees Fahrenheit [°F]). Recorded groundwater temperatures from the deposit area were also above freezing throughout the year. Although such conditions do not preclude the occurrence of small localized areas of permafrost, current conditions do not support permafrost development or wide-spread occurrence. Additional technical discussion regarding potential permafrost occurrence in the study area is provided in Appendix K3.14.

3.14.1.2 Soil Impairments

A review was conducted of the Alaska Department of Environmental Conservation (ADEC) Contaminated Sites Program database. The database lists known contaminated sites and leaking underground storage tanks throughout Alaska. The database provides information regarding the type of contaminant released to the environment, the type(s) of media (air, water, soil, and rock) affected by the contaminant, the potential responsible party for the documented release, and the location where the release occurred (ADEC 2018a). No contaminated site records coincided with or were in proximity to the project footprint.

3.14.2 Alternative 1 – Applicant's Proposed Alternative

3.14.2.1 Mine Site

Soil Types

Available literature directly associated with the mine site and transportation corridor components is limited to the Exploratory Soil Survey of Alaska (ESS), which was completed by the US Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS; formerly known as the Soil Conservation Service) (Rieger et al. 1979). Literature provided by the NRCS generally covers a variety of baseline soil data intended to assist in land resource planning and

AMERICAN OVERSIGHT

management, including classifications based on soil taxonomy, drainage, slopes, vegetative growth potential, and suitability for various land uses and development.

The ESS is not sufficient for site-specific interpretations, but is useful as a general soils map. Although some soils information provided in the ESS does not translate directly to current classification system standards, comparative equivalent soil type estimates can be made. Technical information regarding soil types within the project footprint is provided in Appendix K3.14.

Soils at the mine site are generally well drained, acidic, gravelly, and formed from volcanic source rocks. Most of the mine site area (approximately 71 percent) is associated with hilly to steep terrain that supports vegetation such as alder, grasses, or low shrubs in a thin surface cover of decomposed plant material. The remaining area (29 percent) is relatively level with surface features consisting of rolling topography, small lakes, and sedge peat muskegs. More detailed descriptions of soil types and distribution present at the mine site are provided in Appendix K3.14.

Erosion

Erosion resulting from surface and subsurface soil disturbances would be attributed to both wind and hydraulic processes. Numerous conditions can influence a soil's susceptibility to wind and hydraulic erosion. Such conditions include weather (e.g., wind, precipitation), season (e.g., ground freeze), soil type (e.g., texture and cohesion), slope angle and length, vegetative cover, and severity of disturbance. In most circumstances, soil disturbances and subsequent exposure would accelerate erosion by wind and water. Finer-grained soil types such as silt and sand are generally more susceptible to erosion than gravels and coarser material. Flowing water over ground surfaces results in hydraulic erosion that also removes and transports soils. Possible consequences of erosion include sediment loading in surface water runoff, and alteration of soil profile characteristics and ecological communities. Downslope movement of surface materials from other slope instability processes (e.g., landslides, solifluction) are addressed in Section 3.15, Geohazards.

Soil Chemistry

A baseline soil chemistry description is provided for the mine site to compare anticipated effects resulting from the deposition of fugitive dust from sources of concern. Fugitive dust sources of concern at the mine site include mining operations; material (e.g., rock) storage, processing, and handling (including concentrate); tailings storage; and repurposing materials derived from the mine site (e.g., aggregates).

The baseline soil chemistry evaluation is exclusive to the mine site. Further evaluation of limited upland soil chemistry baseline data for the transportation corridor and natural gas pipeline corridor was not conducted because neither of these components is considered to have mechanisms or chemical sources that could result in adverse impacts to soil. Dust that would be created by traffic along the road bed would not be expected to introduce adverse chemical impairments to soil in the vicinity because the transportation corridor and natural gas pipeline corridor and associated material sites would be well outside the Pebble deposit. Transportation of ore concentrate along the road corridor would not be anticipated to result in adverse fugitive dust conditions based on shipment in sealed containers with locking lids. All concentrate transfers would be conducted at offshore facilities. Furthermore, the limited upland soil chemistry data for the transportation corridor and natural gas pipeline corridor are chemically consistent with those described for the Mine Site study area (SLR et al. 2011a).

AMERICAN OVERSIGHT

In order to establish baseline soil chemistry conditions at the mine site, more than 200 shallow surface soil samples (i.e., less than 0.5 feet below surface) were collected from a total of 117 locations (SLR et al. 2011a). The samples were analyzed to determine the variability in naturally occurring constituents (NOCs), which included trace elements, hydrocarbons, total carbon, cyanide, sodium, and ions. Sample results and more detailed discussion are provided in Appendix K3.14.

All trace elements (mostly metals) evaluated were detected in some of the surface samples. Although reported concentrations of most NOCs were generally low and consistent with undeveloped areas of Bristol Bay drainages, analytical results of some sample locations reported elevated NOCs at levels considered elevated in literature. Variations across up to 16 different landform types and seven different habitat types reportedly influence the ranges of elemental concentrations throughout the study area (SLR et al. 2011b).

Iron and aluminum are the most abundant elements reported throughout the mine site study area surface soils, followed by calcium and magnesium. Concentrations of other trace elements are substantially lower. Trace elements with the lowest average concentrations include mercury and silver. The relative distribution of trace elements in the mine site study area surface soils is generally consistent with those reported across the United States, based on published US Geological Survey evaluations. Comparison of co-located shallow subsurface soil sample results (18 inches in depth) reported similar relative and mean concentrations of trace elements; however, less variability among sample locations was observed (where present). Notable deviations include those associated with bismuth and mercury. The mean concentration of bismuth and mercury in surface soil is 13 and two times greater, respectively, than shallow subsurface soil (SLR et al. 2011a).

Because arsenic, copper, and lead are considered key trace elements associated with the deposit, additional depth-based and temporal (i.e., yearly) statistical tests were performed to identify differences. The statistical tests identified no significant[1] differences in depth-based or temporal variables (SLR et al. 2011a).

3.14.2.2 Transportation Corridor and Amakdedori Port

Soil Types

Because land-based portions of the natural gas pipeline corridor on the western side of Cook Inlet would be buried in the road bed of the transportation corridor, soil types for both the transportation and natural gas pipeline corridors are collectively described in this section, in addition to those present at the Amakdedori port site.

Based on soil type descriptions provided in the ESS, approximately 60 percent of the soil types (547 acres) associated with the transportation corridor footprint are the same as those described for the mine site. Most of the remaining acreage (328 acres) consists of varying sand, silt and clay mixtures (i.e., loam) over shallow bedrock or gravel till materials. The soils are generally well-drained and occur in steep to hilly terrain. A limited occurrence (13.5 acres) of poorly drained organic rich muskeg soils also coincides with the transportation corridor. Soil type distribution and additional details are provided in Appendix K3.14.

The Amakdedori port site is generally level; and includes upland (shore-based) soil types that transition seaward to intertidal dunes and a gravel-lined shoreline. ESS soil types associated with the Amakdedori port site and immediate area are limited to loamy upland soils with hilly to steep associations.

[1] The term “significant” appears to be used correctly as it applies to statistical testing, p-value.

AMERICAN OVERSIGHT

Erosion

The ESS does not provide wind and water erosion descriptors (i.e., suitability ratings) for all soil types, and where present, are limited to unique physical conditions or soil types. None were listed for map units corresponding to the transportation corridor; however, generalized inferences regarding susceptibility to erosion can be made assuming surface cover would be removed or disturbed. Finer grained loamy soils over shallow bedrock in hilly or steep terrain are considered to be conditions that would be most susceptible to erosional processes in the transportation corridor (including Amakdedori port site). This is attributed to the erosional susceptibility of finer-grained materials that overlie bedrock conditions that are generally resistant to erosional processes and potentially facilitate overland flow. Comparatively increased surface water flow velocities associated with hilly to steep terrain would likely increase the susceptibility of soils to erosion. Soils associated with nearly level terrain are likely the least susceptible to hydraulic erosion in the transportation corridor. However, information provided in the ESS is broadly based, and is not intended to be used for site-specific applications.

3.14.2.3 Natural Gas Pipeline Corridor

Soil Types

Because the natural gas pipeline on the eastern side of Cook Inlet would predominantly incorporate existing infrastructure, potential soil disturbances directly associated with the project would be limited to the horizontal directional drilling (HDD) work area and compressor station area. The most detailed resource for soil data in this area is the USDA NRCS Soil Survey of Western Kenai Peninsula Area, Alaska. Available NRCS data for the area include a land capability classification. This classification provides a general suitability index for agriculture or farming (USDA 2005). Soils in the footprint are considered to have severe limitations for these purposes.

Two detailed soil map units coincide with approximately 6 acres of proposed pipeline footprint ground disturbance on the eastern side of Cook Inlet. The soils consist of silt and sand mixtures (i.e., silt loam). Additional details for soils associated with the pipeline infrastructure on the eastern side of Cook Inlet are provided in Appendix K3.14.

Erosion

Soils in the pipeline infrastructure footprint on the eastern side of Cook Inlet predominantly consist of silt and sand mixtures (i.e., silt loam) along slope angles ranging from 0 to 4 percent. The soil is somewhat poorly to well-drained, with no flooding or ponding. The soils have a severe susceptibility to wind erosion, assuming disturbance and removal of surface cover, and a "slight" water erosion hazard.

3.14.2.4 Action Alternative 1 – Summer-Only Ferry Operations Variant

The summer-only ferry operations would necessitate additional project footprint to store and manage concentrate (see Chapter 2, Alternatives, for more detail). The soils descriptions provided in this section address the proposed locations where surface soils may be affected by increased project footprint.

3.14.2.5 Action Alternative 1 – Kokhanok East Ferry Terminal Variant

This area is east of the proposed south ferry terminal site. Soil conditions at the south ferry terminal include soils common to the transportation corridor, but are exclusive to (13.5 acres) varying sand, silt, and clay mixtures (i.e., loam) over shallow bedrock or gravel till materials.

AMERICAN OVERSIGHT

3.14.3 Action Alternative 2 – North Road and Ferry

3.14.3.1 Mine Site

Soils in the mine site area are described above under Alternative 1.

3.14.3.2 Transportation Corridor and Diamond Point Port

This section addresses the road and pipeline corridor from the mine site to Diamond Point port site.

Soil Types

Approximately one-half of the transportation corridor footprint and Eagle Bay ferry terminal under Alternative 2 consists of the same soil types as those described for the mine site. Approximately one-third of the transportation corridor footprint and Pile Bay ferry terminal footprint consists of well drained soils on foot slopes associated with hilly to steep terrain. The shallow soils are formed in silty volcanic ash (10 to 24 inches thick) overlying very gravelly glacial till. Based on generalized ESS descriptions, the remaining area in the transportation corridor consists of rough mountainous land along steep rocky slopes overlying shallow bedrock and boulder-sized rock fragments. Less than one percent of the total footprint consists of silty loess (20 to 40 inches) over gravelly glacial till to fibrous organic soils in depressions. These soils are associated with level or nearly level terrain and range from well- to very poorly drained soils. Additional soil type details are provided in Appendix K3.14.

Erosion

Soils associated with nearly level terrain are likely the least susceptible to hydraulic erosion in the transportation corridor. Soils considered most susceptible to erosion include those with finer grained textures (e.g., volcanic ash) that are associated with hilly to steep terrain. This is attributed to the erosional susceptibility of finer-grained materials and comparatively increased surface water flow velocities associated with hilly to steep terrain.

Coarse grained soil textures or shallow bedrock in rough mountainous terrain should not preclude the potential for erosion susceptibility or location-specific conditions where erosion may be comparatively greater. Enhanced design or stabilization measures may be required on a case-by-case basis to mitigate steep side slopes, cross slope toe-cuts, or slope failure. Erosion associated with potential high energy environments in mountainous terrain includes, but is not limited to, increased surface water runoff flow velocities, up or down slope failure (e.g., slumping, washout), or impacts to infrastructure from natural process (e.g., landslides). Because the ESS is broadly based and is not intended to be used for site-specific information, general terrain conditions (e.g., topography) are considered in Section 4.14, Soils.

3.14.3.3 Natural Gas Pipeline Corridor

This section addresses the overland portion of the natural gas pipeline corridor (Diamond Point to Ursus Cove). The pipeline would be constructed below grade along a valley floor and eventually resurface at the Diamond Point port site after a short marine crossing of Cottonwood Bay. The 5.5 miles of uplands pipeline along this segment coincides with shallow bedrock and coarse soil textures (e.g., boulder and cobble) in rough mountainous terrain; however, it is likely that appreciable gravel/sand-bearing colluvium is present along the valley floor. The pipeline from the port would follow a shared road corridor towards the Pile Bay ferry terminal.

AMERICAN OVERSIGHT

3.14.3.4 Action Alternative 2 – Summer-Only Ferry Operations Variant

Baseline soil characteristics are the same as described under this variant in Alternative 1.

3.14.4 Action Alternative 3 – North Road Only

The occurrence and distribution of soil types and terrain under Alternative 3 is generally the same as Alternative 2. The primary difference between Alternative 2 and Alternative 3 is a shared overland transportation and pipeline infrastructure under Alternative 3 and absence of ferry terminal infrastructure. Soil resource impacts specific to each action alternative are provided in Section 4.14.

3.14.4.1 Alternative 3 – Concentrate Pipeline Variant

The concentrate pipeline under this variant would follow the same corridor as the north road and natural gas pipeline corridor. The soil characteristics are the same as described for the north road corridor.

AMERICAN OVERSIGHT

4.14 SOILS

This section describes potential impacts on soils resulting from each project component. Mitigation and control measures would incorporate structural and non-structural best management practices (BMPs) to address erosion and stormwater runoff. The evaluation also assumes that activities would be performed in accordance with prepared water management and sediment control plans, and necessary Alaska Department of Environmental Conservation (ADEC) permits and stormwater pollution prevention plans (SWPPPs). This includes typical or standard practice activities and BMPs when none are specified in project documents.

4.14.1 No Action Alternative

Under the No Action Alternative, the project would not be constructed, and there would be no new impacts to soils.

4.14.2 Action Alternative 1 – Applicant's Proposed Alternative

Impacts to soil resources from Alternative 1 would include those related to soil disturbance and erosion. Soil quality is also evaluated for the mine site due to potential fugitive dust impacts from sources of concern. Factors used to evaluate soil impacts include soil type and area of disturbance; erosion based on BMPs and foreseeable control measures using common industry practices; planned reclamation and objectives; and anticipated effects on soil quality based on planned project activities.

Evaluation of soil impacts assumes that sediment control measures, BMPs, and adaptive control strategies would be established in a water management and sediment control plan prepared prior to construction and operations; and that proposed earthwork would sufficiently meet necessary conditions required under the Alaska Pollutant Discharge Elimination System program (APDES) for approval of an ADEC Clean Water Act Section 402 Stormwater Construction and Operation Permit and a Stormwater Discharge Pollution Prevention Plan prior to construction. Discharge of pollutants from construction would be addressed under an APDES Construction General Permit (CGP) for disturbances of at least 1 acre of land. The CGP requires establishing authorized stormwater and non-stormwater discharges, including those that are not authorized. A permittee is required to contain runoff from exposed soils to minimize erosion and sediment transport. The CGP also requires established conditions that meet water quality standards through operator control measures. The CGP would be required prior to project start and would include filing of a signed Notice of Intent and SWPPP to ADEC. The SWPPP would be prepared by an ADEC-qualified person and would establish sources of pollutants and how control measures would be implemented to meet permit standards. The SWPPP also requires establishing inspection-related criteria, how corrective actions are addressed, and permit eligibility related to endangered species. Additional information and reference to applicable requirements are provided in the ADEC APDES CGP-Final, Permit No. AKR100000 (ADEC 2016); Alaska Storm Water Guide (ADEC 2011); and Alaska Department of Transportation and Public Facilities (ADOT&PF) Best Management Practices for Erosion and Sediment Control (ADOT&PF 2016).

Other agencies that may require additional considerations related to upland soils include the Alaska Department of Natural Resources (ADNR) for an Approved Pipeline Right-of-Way (ROW) Permit; the ADOT&PF for a Utility Permit on ROW; Kenai Peninsula Borough; and US Army Corps of Engineers (USACE) Section 404/10 Permit.

AMERICAN OVERSIGHT

4.14.2.1 Mine Site

This section describes potential effects on soils at the mine site from construction through reclamation and post-closure management.

Soil Disturbance

The total acreage of soil disturbance that would potentially occur at the mine site is approximately 8,129 acres. Most of the disturbances would occur in soils associated with soil map unit IA9 (5,798 acres), with the remaining disturbance associated with soil map unit IA7. The total acreage of soil disturbances includes major earthworks over the 4-year construction period, and mine site operations up to closure. The total acreage estimate does not include reclamation of various mine site infrastructure that would be partially restored or reduced soil disturbances during the closure period.

Mine site facilities not required for post-closure activities would be reclaimed in accordance with an ADNR-approved reclamation plan per Alaska Reclamation Act requirements and mining reclamation regulations per Alaska Statute 27.19 and 11 Alaska Administrative Code 97. The reclamation performance standard is the adequate reclamation of disturbed areas from mining operations and to leave the site in a stable condition or reestablishment of renewable resources on the site within a reasonable period of time by natural processes.

Facilities that would be reclaimed include the pyritic tailings storage facility (TSF), bulk TSF, overburden stockpiles, milling and processing facilities, and non-essential roads. Progressive reclamation of the seepage recovery systems, main water management pond, and water treatment plants would be performed in post-closure. With the exception of overburden stockpiles, all reclamation would occur after operations have ceased. Mine site infrastructure that would not undergo reclamation includes the open pit (approximately 608 acres); mine water treatment plants (approximately 28 acres); power generation facilities (approximately 22 acres); inert monofill (approximately 9 acres) in the disturbed footprint; quarry sites (approximately 873 acres); and limited camp, storage facilities, and access roads. These components would result in permanent disturbances to existing soil conditions.

Although soil conditions underlying the TSF footprints would result in permanent soil disturbances, each would be reclaimed to conform to designated post-mining land use, as administered by the ADNR. The liner below the pyritic TSF would be removed, and bermed structures would be recontoured. This would be followed by application of salvaged growth media and surface restoration. The bulk TSF would remain in place after controlled dewatering and dry closure, resulting in a permanent landform. The bulk TSF surface would be graded and contoured as needed for drainage control. Growth media would be added for seeding and revegetation, including the embankments.

Summary of Soil Disturbance Impacts

Indirect soil disturbance impacts are most likely to be associated with erosion and stormwater sediment transport processes, and are evaluated under erosion.

Soil Quality

Potential soil quality effects could result from wet and dry deposition of fugitive dust derived from mine site sources including mining operations in the pit (e.g., drilling and blasting); material transport, storage, processing, and handling (including ore, waste rock, concentrate, and aggregate); and wind erosion of exposed bulk tailings. The cumulative deposition (i.e., loading) of dust throughout construction and operation were evaluated for the potential to impart an

AMERICAN OVERSIGHT

adverse change to surface soil chemistry. Dust deposition effects on water quality are discussed in Section 4.18, Water and Sediment Quality.

Fugitive Dust Constituents of Concern

Total potential criteria pollutant and hazardous air pollutants (HAPs) emissions were calculated for the mine site and other project components assuming that each emission unit was operated continuously unless otherwise noted (PLP 2018-RFI 007). Annual fugitive particulate matter (PM) emissions were calculated based on conservative scenarios that assumed worst-case conditions for each activity or source component such as peak ore crushing capacity, maximum ore hauling distance from final pit, and maximum waste rock hauling.

Of the 189 HAPs listed in the 1990 Clean Air Act Amendment and 40 Code of Federal Regulations (CFR) Part 63, applicable metals from fugitive sources were further evaluated for incremental increase over the 20-year operations period (Table 4.14-1). Hydrocarbons, anions, and cations are not considered compounds of concern from fugitive dust emissions.

Dust Deposition on Soils

Potential increase in metal concentration in the top 1-inch of soil at the mine site was estimated utilizing AERMOD modeling data for airborne metals concentrations and dust deposition (PLP 2018-RFI 009). The EPA defines ambient air as the portion of the atmosphere, external to buildings, to which the general public has access (40 CFR 50.1 (e)). Airborne metal concentration was modeled along the mine site ambient air boundary to determine the maximum cumulative concentration of metals bordering the ambient environment. Extrapolating from the upper bound airborne concentration, dust deposition was modeled by calculating deposition values for metals (PLP 2018-RFI 009). The incremental increase in metals concentration in mine site soil over the 20-year mine life was calculated using the following formula (EPA 2005):

$$Cs = 100 t_D * \left(\frac{D}{Z_S * B_D}\right)$$

Where: C_s is the average soil concentration over the exposure duration (milligrams [mg] constituents of potential concern [COPC] per kilograms [kg] soil); D is the yearly dry deposition rate (in grams COPC per square meter per year [g COPC/m^2-yr]); t_D is the time period over which deposition occurs (in years); Z_S is the soil mixing zone depth (in centimeters [cm]), B_D is the soil bulk density (grams per cubic meter [g/cm^3]), and 100 is a unit conversion factor. The expected constituent soil concentration after the 20-year mile life due to operational dust deposition was calculated by adding the incremental increase to baseline soil concentrations provided in Appendix K3.14. Calculated results are summarized in Table 4.14-1.

Table 4.14-1: Calculated Mine Site Post-Dust Deposition Metal Concentrations in Soil

Analyte	Baseline Mean[1] (mg/kg)	Post-Dust Deposition			Comparative Action Levels	
		Incremental Increase over 20 Years (mg/kg)[2,3]	Baseline + 20 Years of Dust Deposition	Percent Increase after 20 Years	Human Health[4] (mg/kg)	Migration to Groundwater[4] (mg/kg)

Notes:

[1] Three Parameters Plus 2011a

[2] Based on PLP 2018-RFI 009 total HAPs concentration in dust and EPA 2005.

[3] Assumptions include life of mine (20 years) deposition period, soil mixing zone of 2 centimeters, and bulk soil density of 1.5 grams per cubic centimeter based on USGS estimate for silty soils (NRCS 2018 and EPA 2005).

[4] ADEC 18 AAC 75, Oil and Other Hazardous Substances Pollution Control, September 29, 2018, Table B1. Method Two – Soil Cleanup levels, Human Health, Over 40 Inch Zone, and Migration to Groundwater (ADEC 2018b).

[5] USEPA Residential Regional Screening Level, May 2018.

mg/kg = milligrams per kilogram

The calculated percent increase in HAP metals from 20 years of dust deposition at the mine site is not considered to have an adverse impact on surface soils relative to baseline conditions and ADEC action levels used for purposes of comparative evaluation. The greatest percent increase in baseline metals concentration (3.04 percent) is associated with antimony, although the concentrations with dust are still below ADEC levels. All calculated percent increase of other HAP metals were all below one percent. With the exception of arsenic, all evaluated metals were well below ADEC levels. The presence of naturally occurring arsenic above the ADEC level is readily apparent with a reported mean of 10.2 mg/kg. For these reasons, the incremental arsenic increase of 0.57 percent from fugitive dust in surface soils is considered negligible relative to baseline conditions and documented presence of elevated concentrations in soils throughout the state. The natural occurrence of elevated chromium and arsenic concentrations in soil is acknowledged in ADEC Technical Memorandum, Arsenic in Soil, dated March 2009, and Notes 11 and 12 of Table B1 (ADEC 2018b).

Similar to arsenic, elevated baseline concentrations of total chromium are present at the mine site, but well below the ADEC action level for trivalent chromium. Because there are no anthropogenic sources of hexavalent chromium (Cr^{6+}), nor are mineral assemblages considered favorable for Cr^{6+} genesis (e.g., chromite), no further evaluation was conducted.

Dust Control

AMERICAN OVERSIGHT

The project design incorporates a number of measures to minimize fugitive dust. Coarse ore would be stockpiled in a covered steel-frame building to minimize dust emissions. Baghouse type dust collectors would be present at each conveyor-fed ore transfer point between the coarse ore stockpile and semi-autogenous grinding (SAG) ("ball") mills. Water would be added during operations at the SAG mill to suppress dust. Specialized bulk cargo containers equipped with removable locking lids would contain thickened concentrates for transport to Amakdedori port.

The pyritic tailings and potentially acid generating (PAG) waste would be stored subaqueously during operations, removing the potential for wind erosion and dust dispersion from sources with elevated metals concentrations. The bulk TSF would have tailings beaches, which would be susceptible to wind erosion and fugitive dust emissions throughout operations. The bulk TSF would eventually be reclaimed through contouring of surfaces and application of growth media for revegetation and surface stabilization, eliminating the beaches as a dust source following closure activities.

Erosion

The greatest potential for hydraulic erosion under planned conditions at the mine site would likely occur during the year-round construction phase, coinciding with the longest period of soil disturbances. Removal of vegetative matting would expose fine-grained silty loam, volcanic ash mixtures in shallow surface soils (less than 30 inches deep) that are susceptible to water and wind erosion. Deeper soils consisting of coarser-grained glacial till and colluvium mixtures would be comparatively less susceptible to erosion. Much of the finer-grained (i.e., shallow) soil mixtures exposed during construction would be removed due to undesirable engineering properties (e.g., loading and compaction) required for infrastructure construction, and placed in salvaged growth media stockpiles.

Insignificant wind and hydraulic erosion is anticipated when soils are frozen during winter. Frozen soil conditions generally occur between 4 and 5 months per year (HCG 2011). The greatest potential for hydraulic erosion would be during rainfall events that typically occur during the fall. Soil susceptibility to wind erosion is influenced by moisture and particle size. Wind-induced erosion would be comparatively less than hydraulically driven processes in the construction phase, due to seasonal meteorological conditions and cohesive forces associated with soil moisture. A soil matrix composed of larger grains is less capable of retaining moisture, but less susceptible to wind transport. Although finer-grained soils are generally less tolerant to wind erosion, they are more capable of retaining cohesive moisture. Moisture is anticipated to minimize wind erosion of finer-grained surface soils for most of the year; however, the potential for erosion would be greatest during drier periods lasting 1 to 2 months during the summer.

All runoff water that comes in contact with mine site facilities, or is derived from the open pit, would be captured including any entrained sediment in runoff from erosion. A Water Management Plan has been developed and includes water treatment options and strategic discharges of treated water (PLP 2018-RFI 019). A sediment control plan would address construction runoff and associated sediment control measures, BMPs, and adaptive control strategies

Water management structures (e.g., berms, channels, collection ditches) would be designed to accommodate a 100-year, 24-hour rainfall event. Sediment control ponds would be designed to treat a 10-year, 24-hour rain event, and safely accommodate a 200-year, 24-hour rainfall event. Mine site water management infrastructure would include fresh water diversion channels, an open pit water management pond (WMP), the main WMP, the bulk and pyritic TSFs, the bulk TSF main embankment seepage collection pond (SCP), seepage collection and recycle ponds,

AMERICAN OVERSIGHT

sediment ponds, and two water treatment plants. Water management design criteria and structure configurations are further discussed in Chapter 4.16, Surface Water Hydrology, and in the Operations Water Management Plan (Knight Piésold 2018a).

During construction, runoff upgradient of the TSFs would be intercepted by a cofferdam and released at a discharge point downgradient of all construction activities in the same watershed. Runoff from the TSF embankments during construction would also be captured. Similarly, runoff from larger excavations associated with the construction of long-term infrastructure (e.g., process plant, camps, power plant, storage areas) would be routed to settling ponds prior to discharge. During operations, comparatively less soil erosion from water would occur because of diminished need for soil removal. Non-contact runoff would be captured in engineered diversion channels and discharged downgradient. In addition, completed construction of most long-term infrastructure would coincide with established water management and sediment control plan measures. Stormwater runoff from mine facilities that only requires sediment removal would be captured in sediment ponds, treated and discharged under general APDES stormwater permits. Mine site drainage surface water that comes in contact with infrastructure would be diverted to water treatment plants for processing prior to discharge. Although water and sediment control during the operations phase would emphasize contact water minimization and management, runoff and sediment control measures would continue to be managed through BMPs and adaptive control strategies per the SWPPP(s). Reduction in water management during operations would be limited to concurrent reclamation of overburden stockpiles.

Planned management of slurried tailings delivered to the bulk TSF could result in the transport of dried, fine grained tailings materials through wind erosion during operations. Bulk tailings would be pumped and discharged through spigots along the interior of the perimeter cell, with the slurry preferentially discharged to maintain an exposed tailings beach between the TSF embankment and supernatant pond. Although this approach minimizes potential risks associated with seepage effects on embankment stability, the fine tailings (e.g., beaches) would be susceptible to wind erosion when dried. Additional information regarding fugitive dust derived from the bulk TSF is presented in the Soil Quality discussion for the mine site.

The mine site would be reclaimed per an ADNR-approved reclamation plan that establishes requirements for designated post-mining land use. The reclamation plan would supplement or describe measures to control and mitigate erosion at the mine site through the post-closure period. Erosion during closure would be less than during construction, primarily because of comparatively less surface disturbances. Erosion would be greater during closure than operations because of reclamation earthwork required during closure. Reclamation would likely destabilize large soil surface areas from decommissioning activities. Earthwork associated with the preparation and application of growth media would likely result in erosion until surface stabilization is achieved. At a minimum, similar measures established for construction in the sediment control plan would address runoff through sediment controls and BMPs. Additional measures may include future developments in available technologies or practices, and refined adaptive control strategies acquired throughout operations. Removal and reclamation of long-term water management infrastructure would progressively coincide with surface stabilization objectives established in the ADNR approved reclamation plan.

The potential for erosion during reclamation from destabilized surfaces would likely continue for several years beyond closure. Prescribed design standards for reclaimed infrastructure and monitoring requirements would be established in the reclamation plan. Continued monitoring would be required to implement any erosional control maintenance or adaptive control measures. Prescribed monitoring would likely occur annually until surface conditions are stabilized and meet land use objectives. Although reclaimed infrastructure would be designed to

AMERICAN OVERSIGHT

withstand anomalous storm events (e.g., 100-year, 24-hour rain event), monitoring would be necessary immediately after any occurrence.

4.14.2.2 Amakdedori Port

This section describes potential effects on shore-based, upland soils at the Amakdedori port site during construction through closure. Offshore sediment impacts resulting from intertidal and open-water construction, operations, and closure of marine facilities are discussed in Section 4.18, Water and Sediment Quality.

Soil Disturbance

No current development exists at the Amakdedori port site. Shore-based soil disturbances would mostly be attributed to construction of the terminal. The total acreage of soil disturbances at Amakdedori port site would be approximately 15 acres. The magnitude of soil disturbances at the port would include the complete removal of soil cover at the terminal during construction and placement of engineered fill at the terminal. Because no construction would be required during operations, subsequent disturbances to soil would likely be limited. With the exception of necessary infrastructure to support shallow-draft tug and barge access to the dock, onshore port facilities would be removed during closure. No additional soil disturbances are anticipated during closure, and restoration of post-disturbance soil conditions would occur through reclamation activities (e.g., scarification, growth media, contouring, seeding).

Soil Quality

Materials sites for engineered fill are well outside the Pebble Deposit, and field review has not identified PAG rock at any of the road material sites. If PAG material were to be identified at a site evaluation prior to use, the material site would be moved (PLP 2018-RFI 035). Furthermore, coarse-grained, engineered fill textures would be less susceptible to erosion or fugitive dust generation, which would be suppressed through watering (PLP 2018-RFI 007). Therefore engineered fill or locally sourced materials at the port site are not expected to introduce chemical impairments to soils.

The most probable source/activity of soil quality impairment would be concentrate handling. Sealed bulk containers would be emptied offshore in the hold of bulk carriers (i.e., ship), at a depth of no less than 20 feet below the hatch (PLP 2018-RFI 007). The calculated total fugitive particulate matter generated on a yearly basis during offshore transfers is 0.002 tons per year (4 pounds). For these reasons, the magnitude and potential of soil quality impact from project activities at the port is considered negligible and unlikely to impact soil quality in upland conditions. The geographic extent of soil quality impacts (if any) would be confined to the immediate port footprint, of which the duration would be predominantly limited to the construction and operations phases.

Erosion

Water- and wind-induced erosion would occur at the port site throughout construction, and to a limited extent during operation and closure. The potential for soil erosion would be greatest during the initial construction phase.

Earthwork during construction would incorporate erosion control measures specified in an approved SWPPP. Typical measures may include silt fences, hay bales, temporary sedimentation basins; and repurposed brush for berms and watering for dust suppression. BMPs may include crowning or in-sloping of running surfaces; and temporary drainage channels, berms, and catchment basins.

AMERICAN OVERSIGHT

Hydraulic erosion during operations would be comparatively less than during construction due to little additional soil removal and effects of established SWPPP design features (e.g., culverts, swales). Erosion during closure would be less than during construction, but likely greater than during operations. Exposed ground surfaces at sites of removed infrastructure not required for post-closure would be susceptible to wind and water erosion for an interim period until reclamation and restoration activities are completed. The potential for erosion would be mitigated using measures similar to those described for construction.

4.14.2.3 Transportation Corridor

This section describes potential effects on soils along the transportation corridor. Impacts associated with the natural gas pipeline are also included in this section, because the pipeline would be buried in the road prism.

Soil Disturbance

Soil disturbance acreages associated with the proposed transportation corridor include the following:

- South Access Road – 408 acres
- Mine Access Road – 343 acres
- Kokhanok Airport Spur Road – 15 acres
- Iliamna Spur Road – 119 acres
- North Ferry Terminal – 4 acres
- South Ferry Terminal – 21.5 acres
- Material Sites – 241 acres total

Material Sites

Disturbances would include the complete removal and segregation of surface soils and overburden materials considered unsuitable for construction purposes. These materials would be salvaged for future reclamation as a growth medium. Portions of sites no longer used for material extraction would be progressively reclaimed. This would mainly occur after the construction phase, once the bulk demand for materials has been met with infrastructure completion (e.g., roads). Material sites and access roads would continue to be used throughout operations for maintenance of project infrastructure, as needed. Less soil disturbance would occur during operations than during construction, but soil disturbance during operations would be caused by excavation or blasting on an as-needed basis. A need for materials would also persist throughout the post-closure period for continued road maintenance and other limited post-closure needs. Incremental reclamation of disturbance at materials sites would be required. Typical reclamation at gravel material sites would likely include grading and contouring of sidewall slopes; scarification or ripping to promote surface water infiltration and vegetation growth; application of salvaged growth media; and seeding with proposed mixtures as needed. No sidewall reclamation would be conducted at shot-rock material sites with 20-foot bench heights on exposed rock walls.

Soil Quality

Dust from truck traffic and wind erosion of road bed aggregate is considered to have a low potential for changing chemical concentrations in soils along the access roads. Material sites along the roads are well outside the Pebble deposit, and surface soil conditions associated with the transportation corridor are chemically consistent with those described for the mine site study

AMERICAN OVERSIGHT

area (SLR et al. 2011a). Field review has not identified PAG rock at any of the road material sites. If PAG material were to be identified at a site evaluation prior to use, the material site would be moved (RFI 035). Therefore, the material sources are not expected to introduce chemical impairments to soil. Transportation of concentrates from the mine site would be in sealed containers with locking lids, and therefore are not expected to be a source of fugitive dust along the roads.

Erosion

Similar to all other project components, stormwater and erosion mitigation and control measures would incorporate structural and non-structural BMPs (PLP 2018). Wind-induced erosion would be comparatively less than hydraulically driven processes throughout all phases of the project along the transportation corridor due to seasonal meteorological conditions, physical attributes associated with soil types, infrastructure configuration and construction methods, and planned mitigation. Soils capable of retaining moisture in the project area are generally considered to have a low susceptibility to wind erosion, due inherent moisture content from periodic precipitation or snowmelt throughout the year. For this reason, the potential for wind erosion would be greatest during drier periods lasting one to two months during the summer. If necessary, wind erosion can be mitigated through dust-control watering as needed during the summer.

The potential for hydraulic erosion exists throughout the entire project lifecycle along the transportation corridor; this is evident based on erosion assessments conducted on the existing Williamsport-Pile Bay Road, approximately 30 miles northeast of the south access road. Precipitation events resulting in the greatest erosional losses from surface runoff and flooding generally occur from late September through November. Gently sloping or level transportation infrastructure would be less susceptible to erosional processes. These would include the ferry terminal sites and access roads constructed over glacial fluvial and moraine soil types (Table 4.14-2). Physical conditions more susceptible to hydraulic erosion along the transportation corridor include poorly drained, fine-grained loess or colluvium on sloped topography, waterbody crossings, road prism drainages (e.g., swales), higher-gradient slopes, and sidehill cuts. Approximate access road lengths traversing moderate and rough terrain requiring rock cuts are detailed in Table 4.14-2.

Table 4.14-2: Alternative 1 Road Lengths, Terrain, and Soil Types

Road Segment	Gentle Terrain	Moderate Terrain	Rough Terrain	Approximate Percent Soil Map Unit
South Access Road	3.9 miles (10%)	9.8 miles (26%)	23.6 miles (63%)	20% (IA72), 80% (IA173)
Mine Access Road	26.7 miles (92%)	2.3 miles (8%)	None (0%)	59% (IA7), 37% (IA94), 4% (HY4)
Iliamna Spur Road	2.9 miles (41%)	4.1 miles (59%)	None (0%)	47% (IA7), 53% (IA9)
Percent Total Access Roads Terrain Type1	46%	22%	32%	

Notes:

1. Kokhanok Airport Spur Road is not included in the evaluation due to the comparatively short road length and similar conditions to other project access roads.

2. IA7: Typic Cryandepts – Very gravelly, nearly level to rolling association.

AMERICAN OVERSIGHT

3. IA17: Dystric Lithic Crandepts – Loamy, hilly to steep association.
4. IA9: Typic Cryandepts – Very gravelly, hilly to steep association.
5. HY4: Pergelic Cryofibrists – Nearly level association.

Source: Rieger et al. (1979); PLP (2018)

Construction phase activities that would potentially cause or contribute to erosion include:

- Removal and clearing of vegetation for access roads, material sites, and terminal facilities.
- Overburden clearing and vegetative mat removal for cut and/or fill placement of engineered materials (e.g., aggregate, substrates).
- Overburden management that would include stockpiles or windrows of organic-rich materials and vegetation, or excavated substrates considered unsuitable for infrastructure construction.
- Development of material sites and material site access roads.
- Blasting of bedrock to support roadbed construction.

The intensity of erosion during construction would vary along project road segments depending on soil types and physical conditions present, seasonal conditions, and construction requirements. Potential erosion may be localized at susceptible locations, such as waterbody drainages and crossings (e.g., culverts, bridges, and swales), wetlands, or intermittent sloped topography. Broader areas considered more susceptible to runoff and erosion would include continuous segments of road through rough terrain, and to a lesser extent moderate terrain. These conditions would require steeper roadbed grades and side-hill cuts that could result in greater erosion potential from runoff (i.e., greater energy) and slope failure.

Terrain and substrates along the south access road correspond with conditions that are considered most susceptible to erosion along the corridor. About 63 percent of the south access road would be predominantly constructed over rough, variable terrain (Table 4.14-1), where fine-grained soil types reportedly overlie shallow bedrock. Although conditions along the south access road appear most vulnerable to hydraulic erosion processes, the evaluation is based on generalized soil descriptions provided in the Exploratory Soil Survey of Alaska (Rieger et al., 1979) (ESS), and does not account for local variations in soil conditions or bedrock outcrops where no soil horizon may exist. With the exception of the northernmost 4 to 6-mile portion of the south access road route, blasting will be required for most roadbed construction, supporting the prevalence of shallow bedrock and moderate to rough terrain conditions (PLP 2018-RFI 084).

No rough terrain requiring rock cuts is present along the Iliamna spur road or the mine access road; however, each traverses approximately 59 percent and 8 percent of moderate terrain, respectively. The mine access road would be least susceptible to hydraulic erosion, based on terrain types traversed and soil conditions. Construction methods along the mine access road would require less backslope cuts (i.e., layback), foreslope contouring, and variation in roadbed grade, compared to other access roads. In addition, surficial glacial deposits and gravel fractions in existing soils along the mine access road and Iliamna spur road would be less susceptible to hydraulic erosion, compared to the south access road.

Similar to access roads, the potential for hydraulic erosion at material sites would also vary based on source material competency (e.g., shot bedrock or aggregate) and conditions unique to each borrow site location. Construction of material sites and transportation corridor infrastructure would use structural and non-structural BMPs, and employ erosion control measures adequate to satisfy appropriate ADEC discharge permit requirements and coverage under an SWPPP (PLP 2018).

AMERICAN OVERSIGHT
EPA-0135-0002777

Ground disturbances would be progressively restored throughout construction until stabilization and restoration are achieved. Most disturbances would likely be stabilized during construction or several years thereafter, at locations considered less susceptible.

The least erosion would likely occur during operations, when stabilization of disturbed surfaces would be achieved through natural recovery, applied restoration measures, and long-term or permanent stabilization measures. Material sites and access roads would be progressively reclaimed. Typical reclamation BMPs at material sites include benching or sloping of sidewalls to suitable grades, based on material types (e.g., aggregate or bedrock); distribution of salvaged overburden growth media on pit floors and slopes; and tracking and seeding.

Continuous feedback from truck traffic during operations and/or prescribed follow-up inspections would identify areas of acute or persistent erosion. Areas of concern would be identified, and additional or more robust measures applied to meet local site-specific conditions. This would most likely be required along rough terrain associated with the south access road, and/or areas requiring permanent drainage controls (e.g., culverts, bridges, swales).

Erosion during closure and post-closure would likely be greater than during operations. Some erosion may be cause by the removal and reclamation of long-term facilities (e.g., ferry terminals) before complete restoration and surface stabilization objectives are met. However, most erosion would likely be associated with permanent roads to the mine site. Monitoring frequencies in post-closure would typically be less than during operations, and there would be reduced access to equipment and resources. Required permanent transportation corridor access would result in an indefinite potential for erosion monitoring and maintenance.

4.14.2.4 Natural Gas Pipeline Corridor

This section describes potential effects on shore-based upland soils from pipeline infrastructure on the eastern side of Cook Inlet. Pipeline impacts for segments of the pipeline coincident with the transportation corridor are addressed above. Pipeline activities resulting in disturbances to wetlands and submerged ocean and lake sediment are detailed in Section 4.22, Wetlands, and Section 4.18, Water and Sediment Quality, respectively.

Soil Disturbance

The cumulative total acreage of shore-based soil disturbances from pipeline infrastructure on the eastern side of Cook Inlet is approximately 6 acres. This would include the compressor station, laydown area, access road, metering pad, and horizontal directional drilling (HDD) work area.

Erosion

Similar to other project components, mitigation and control measures would incorporate structural and non-structural BMPs to address erosion and stormwater runoff (PLP 2018). The topography associated with the pipeline infrastructure on the eastern side of Cook Inlet is gently sloping or nearly level. Silty loam soils associated with these conditions are considered to have a low hazard of erosion by water, and severe hazard of erosion by wind, assuming the top cover is removed. Use of HDD would provide a sufficiently wide setback distance between the project footprint and Cook Inlet bluff (about 200 feet); project activities are not expected to contribute to ongoing natural erosion in this area (Section 3.15, Geohazards).

AMERICAN OVERSIGHT

4.14.2.5 Action Alternative 1 – Summer-Only Ferry Operations Variant

This variant would require a proportionally small increase in soil disturbances associated with the construction of designated concentrate container storage areas at the mine site and Amakdedori port. Approximately 37.5 acres of additional storage area would be required at the mine site, and approximately 27.5 acres at Amakdedori port. The additional disturbances would remain throughout the period of mine operations, and be reclaimed during closure.

This variant would also temporally compress road traffic during ice-free months, which could result in a greater potential for hydraulic and wind erosion along the transportation corridor.

4.14.2.6 Action Alternative 1 – Kokhanok East Ferry Terminal Variant

Despite a shorter transportation route and reduced ferry terminal footprint, the total acreage of soil disturbance under this variant would be greater than Alternative 1. This is attributed to greater material quantities required for road construction, resulting in 125 additional acres of disturbances from material sites. The total acreage of soil disturbance associated with the Kokhanok east ferry terminal variant is approximately 60 acres greater than Alternative 1.

Although soil disturbance acreage is greater under this variant, the potential for erosion is likely to be less. A greater potential for erosion is associated with roads relative to material sites. Roads traverse a broader expanse of terrain and soil types (e.g., waterbodies, cross slopes, inclines) that have a greater point source potential for erosion. Roads typically require a greater diversity of erosion control measures. Engineered fill material sites inherently consist of coarser grained materials (or bedrock) that are less susceptible to hydraulic and wind erosion. Furthermore, sediment runoff is often retained in the footprint of disturbance (e.g., depressions).

4.14.2.7 Action Alternative 1 – Pile-Supported Dock Variant

A pile-supported dock constructed at Amakdedori port would reduce the volume of fill material needed for dock access/construction; therefore, less surface disturbance is anticipated at material sites. The magnitude of surface disturbance impacts would be less under this Alternative 1 variant; the duration, extent, and potential would be comparable to Alternative 1.

4.14.3 Action Alternative 2 – North Road and Ferry

The following section describes impacts to soil resources under Alternative 2. Infrastructure descriptions, usage, physical reclamation and closure would be the same as Alternative 1, but would occur at the locations described under this alternative.

4.14.3.1 Mine Site

The bulk TSF dam at the mine site would be constructed using different methods under this alternative (i.e., downstream method with buttress). The construction method would result in an increased impoundment footprint of 119 acres compared to Alternative 1. Overall, the duration and extent of impacts to soil from ground disturbances would be comparable to Alternative 1; however, there would be greater impact magnitude based on the increased acreage of disturbance. Erosion impacts would be the same as Alternative 1; however, there would be an increased potential for erosion based on infrastructure build out.

AMERICAN OVERSIGHT

4.14.3.2 Transportation Corridor

Soil Disturbance

Transportation corridor components under Alternative 2 would also incorporate two ferry terminals on Iliamna Lake and road access to either from the mine or port (i.e., Diamond Point port). The road would bypass all but 5 miles of the existing Williamsport-Pile Bay Road; however, these sections would require upgrades to accommodate larger vehicles. Soil disturbance acreages associated with Alternative 2 transportation infrastructure (including the co-located portion of roadbed pipeline) include the following:

- Mine site access road: mine site to Eagle Bay ferry terminal site – XXX acres / 36 miles
- Port access road: Pile Bay ferry terminal to Diamond Point port site – XXX acres / 18 miles
- [Placeholder: Access acreages to be provided by PLP. This section will be revised once information is received. However, total planned lengths are available for comparison and provided here.]
- Eagle Bay ferry terminal site – 6.7 acres
- Pile Bay ferry terminal site – 17.6 acres
- Material sites and access roads –XX acres

[Placeholder: Information is to be provided to differentiate transportation corridor and pipeline alignment material site needs. List will be completed when information is received.]

Although disturbance mechanisms, nature of impacts, and erosion mitigation and control measures during construction, operations, and closure of transportation corridor infrastructure would be comparable to those described under Alternative 1, the overall magnitude of soil disturbance would be less. This is based on a comparatively smaller transportation corridor soil disturbance acreage required under this alternative. The total road length under this alternative would require approximately 37 less miles of road compared to Alternative 1. The total footprint of ferry both terminals would also be approximately 1 acre less.

Soil Quality

Impacts to soil quality along the transportation corridor under Alternative 2 would be the same as described for the corridor under Alternative 1.

Erosion

Soil types and general terrain descriptors present along the Alternative 2 transportation corridor are summarized in Table 4.14-3. Terrain descriptors are based on the presence of shallow bedrock or terrain requiring blasting to accommodate road construction.

Table 4.14-3: Alternative 2 Approximate Road Terrain and Soil Types

ESS Soil Type	Gentle to Moderate Terrain	Moderate to Rough Terrain
IA7[1]	51% (~27 miles)	6% (~3 miles)
IA9[2]	9% (~4.8 miles)	< 1% (0.36 miles)
RM1[3]	15% (~8 miles)	9% (~4.5 miles)
SO11[4]	8% (~4.3 miles)	2% (~1 mile)

AMERICAN OVERSIGHT

Table 4.14-3: Alternative 2 Approximate Road Terrain and Soil Types

ESS Soil Type	Gentle to Moderate Terrain	Moderate to Rough Terrain
Percent Total Terrain Type[5]	83% (~44.1 miles)	17% (~9 miles)

Notes:

ESS - Exploratory Soil Survey of Alaska (Rieger et al., 1979)

< - less than

1. IA7: Typic Cryandepts – Very gravelly, nearly level to rolling association.
2. IA9: Typic Cryandepts – Very gravelly, hilly to steep association.
3. RM1: Rough Mountainous Land – Steep rocky slopes.
4. SO11: Humic Cryorthods – Silty volcanic ash over gravelly till, hilly to steep association.
5. Terrain type classification associated with planned blasting requirements (segments) for road construction.

Source: Rieger et al. (1979); PLP (2018)

A greater proportion of coarse-grained materials are present along the transportation corridor route based on generalized soil descriptions provided in the ESS, whereas the occurrence of finer grained silt/sand loam mixtures are reportedly less prevalent than Alternative 1 (Table 4.14-3). A lower potential for wind erosion is anticipated under this alternative based on the prevalence of coarser grained substrates along the transportation corridor; a comparatively smaller acreage of soil disturbance that would reduce the potential for wind shear on disturbed surfaces; and a reduced vehicle travel distance for dust dispersion. Since the proposed route under this alternative is also lower in elevation than Alternative 1, overall wind driven forces (e.g., velocity) are also likely to be less. However, this would not preclude occurrence of episodic high wind processes that are commonly associated with valley features present along the port access road.

Most hydraulic erosion mechanisms; nature of impacts; and mitigation and control measures during construction, operations, and closure of transportation corridor infrastructure would be comparable to those described under Alternative 1. Similar to Alternative 1, hydraulic erosion susceptibility under this alternative would be greatest along the southernmost port access road segment.

Heavy precipitation and flooding during fall months has previously resulted in significant hydraulic erosion losses along the Williamsport-Pile Bay Road (USACE 2007a; KPB 2014). Specific conditions that resulted in impassable erosion washout at multiple points along the Williamsport-Pile Bay Road in the fall of 2003 included culvert and bridge crossings, and surface water erosion in drainages aligned adjacent (e.g., swale or ditch) to the road (USACE 2007).

Although the proposed route is commonly aligned with five miles of the existing Williamsport-Pile Bay Road, the remaining roadway would be newly constructed roadway to minimize conditions historically susceptible to erosional processes along the current Williamsport-Pile Bay Road alignment. The southernmost uplands road segment has comparatively less cross cuts along toe-slopes in areas of greater vertical relief, and traversed terrain is considered to be more gentle and moderate in character (Table 4.14-3). Rock cuts along the southernmost uplands segment and other discrete segments would require blasting; however, it would be comparatively less than the south access road under Alternative 1. Furthermore, roadway commonly shared with the existing Williamsport-Pile Bay Road would be improved to accommodate large trucks. These improvements would foreseeably account for historical erosion occurrence through road design and condition specific mitigation and control measures.

AMERICAN OVERSIGHT

Approximately 2.5 to 3 miles of road extending from the Diamond Point port site would follow the coastline of Iliamna Bay. This coastline road segment is considered most susceptible to erosion under all action alternatives. The coastal road is situated along the toe slopes of mountainous terrain, and would likely be subjected to marine driven processes. The topographic relief located immediately adjacent to the road from the port is characteristic of a high energy environment where natural hydraulic erosion and slope failure processes are likely to be more prevalent. Portions of roadway along this coastline segment could also be more susceptible to tidal action; ice scour/rafting, storm surge, and wave action. Additional discussion regarding slope failure processes and occurrence are presented in Section 4.15, Geohazards.

The greatest potential for transportation corridor erosion under Alternatives 1 and 2 are located along the port access routes. Erosion along the port access route under Alternative 2 would likely be less based on a smaller acreage of soil disturbance and presence of terrain types that are associated with a reduced erosion potential. However, the initial 2 miles of road extending from the port under Alternative 2 could be the most erosion susceptible segment of road. This nearshore segment of road is unique to Alternatives 2 and 3, and would require enhanced design and mitigation measures to account for the high energy environment.

4.14.3.3 Diamond Point Port

Soil Disturbance

Soils in the port footprint are reportedly associated with rough mountainous land (RM1) consisting of sparsely vegetated soil over shallow bedrock or stones/boulders. The port terminal facility and dredge material stockpile would result in the greatest soil disturbances. The total acreage of soil disturbances at Diamond Point port is 39.7 acres. The estimated acreage of disturbance includes the footprints of the port terminal facility and uplands disposal of dredged materials (e.g., stockpile).

[Placeholder: A revised layout for the Diamond Point port is being considered to avoid in-stream construction per PLP 2018-RFI 099. Section will be revised once information is received.]

Most soil disturbance mechanisms and impacts during construction, operations, and closure at the port would be similar to those described under Alternative 1; however, disturbances unique to this alternative include the following:

- Blasting of shallow bedrock at discrete locations to accommodate port infrastructure
- Uplands disposal of dredge material
- Stream channel diversion, or other method of stream channel flow mitigation through the port footprint [see placeholder above]

Soil disturbances during construction would involve grading and contouring of ground surfaces, and extensive blasting of shallow bedrock to accommodate port construction. Removal of soil considered unsuitable for construction purposes would be limited due to prevalent shallow bedrock and coarse alluvium outwash. The bermed dredge material stockpile would be built immediately adjacent to the port terminal to receive spoils from dredge channel clearance.
