Since no additional construction would be required during operations, soil disturbances during port operations would primarily be limited to dredge material stockpile expansion from maintenance dredging. At a minimum, half of the material dredged for channel construction and maintenance (approximately 325,000 cubic yards) would be disposed of on-shore in a bermed facility. Soil disturbance impacts associated with the dredge material stockpile could range from the direct burial of existing soils, to potential acute or obvious changes associated with any stockpiled marine sediment in an upland environment.

AMERICAN OVERSIGHT
EPA-0135-0002782

Soil Quality

Impacts to soil quality along the transportation corridor under Alternative 3 would be the same as described for the corridor under Alternative 1.

Erosion

Most hydraulic erosion mechanisms, nature of impacts, and mitigation and control measures during construction, operations, and closure of port facilities would be comparable to those described under Alternative 1. Since coarse alluvium outwash and shallow bedrock conditions at the port site are less susceptible to erosion, the period of greatest ground disturbance during port facility construction would generally result in less erosion than Alternative 1. However, unique conditions specific to this alternative that could potentially increase erosional susceptibility or require additional design and mitigation measures throughout construction, operations, and post-closure include the following:

- Uplands disposal of dredge material
- Topographic relief and slope stability
- Stream channel diversion, or other method of stream channel flow mitigation through the port footprint [see placeholder above.]

Hydraulic erosion of stockpiled dredge materials would be mitigated through proper impoundment and drainage design. Stockpiled materials could be susceptible to wind erosion depending on the physical attributes of dredge materials (particle size distribution and cohesion); interim surface stabilization measures; constructed dimensions; and frequency and magnitude of coastal and seasonal winds. Physical conditions that are considered less susceptible to wind erosion include high moisture contents or frozen conditions; larger particle sizes; presence of surface cover, and lower slope angles to reduce wind shear. Mitigation measures that may reduce the potential for wind erosion include wind breaks, snow fencing, reduced slope angles, or watering during increased periods of susceptibility. Final closure of the stockpile would include drainage and surface stabilization. Typical measures that could facilitate stockpile surface stabilization include slope and top cover engineering, tracking (rolling), seeding, and repurposing of material as growth media.

The topographic relief located immediately inland of the eastern port footprint (to the jetty/causeway) is characteristic of an environment where natural hydraulic erosion and slope failure processes are likely to be more prevalent. Sloped ground conditions bordering the port footprint has a greater potential for increased surface water runoff, which could result in greater rates of scouring or aggradation. This could potentially include slope failure processes that indirectly impact port infrastructure. Recent slope failure occurrence (e.g., landslide) is present along the access road extending from the port to the jetty. These conditions would require additional design and mitigation measures; however, the potential for slope failure to compromise discrete portions of port infrastructure would likely persist. This would also include infrastructure located at the base of headwall cuts in bedrock. Additional discussion regarding slope failure processes and occurrence are presented in Section 4.15, Geohazards.

4.14.3.4 Natural Gas Pipeline Corridor

The pipeline under Alternative 2 would come ashore at Ursus Cove. The pipeline would be constructed below grade along a valley floor and eventually resurface at the Diamond Point port site after a short marine crossing of Cottonwood Bay. The 5.5 miles of uplands pipeline along this segment coincides with shallow bedrock and coarse soil textures (e.g., boulder and cobble) in rough mountainous terrain; however, it is likely that an appreciable gravelly sand colluvium is

AMERICAN OVERSIGHT

present along the valley floor. The pipeline from the port would follow a shared road corridor towards the Pile Bay ferry terminal. The stand-alone pipeline (no road) between the Pile Bay and Eagle Bay road off-takes, would be 36 miles in length.

Soil Disturbance

Acreages of upland ground disturbance associated with stand-alone pipeline components under Alternative 2 include the following:

- Standalone pipeline construction ROW – 503 acres / 41.5 miles
- Material sites and access roads – XX acres
- Operation infrastructure – XX acres
- Temporary construction access – XX acres
- [Placeholder: pipeline ROW acreage estimated based on a 100-foot construction ROW, and subject to change with further information. Additional pipeline infrastructure acreage estimates forthcoming for Alternative 2 and 3 soil disturbance comparison.]

Although the pipeline construction corridor would be 100-feet wide during construction to accommodate trench spoils and heavy equipment traffic, complete removal of the overlying vegetative mat would be limited to an 8 foot span directly above the trench. The total acreage of vegetative mat that would be completely removed during construction is approximately 40 acres. Shallow soil on the spoils and working sides of the trench would mostly be limited to disturbances from working equipment resulting in ground compaction, rutting or tearing of ground surfaces.

Construction would occur year round along simultaneous or overlapping construction efforts on segments; construction would include preliminary ROW clearing and preparation followed by pipeline installation, and rehabilitation/commissioning. Temporary pipeline camps and material sites would be required.

Soils that are more susceptible to surface disturbances (e.g., wetlands) would incorporate additional mitigation measures and best management practices. Working pads constructed of swamp mats along the working ROW would be used to minimize surface disturbances during summer months and frost packing of the entire construction ROW during winter months. Frost packing would involve clearing the snow from the ROW to achieve a frost depth of 2 feet below ground surface. Although no other mitigation and restoration activities have been specified, common practices that can be used during construction include salvaging of timber for corduroy matting or ice pad construction. To the extent practicable, backfilling would occur as soon as possible to minimize additional equipment efforts or soil disturbances. Temporary impoundment of saturated spoils and/or drainage control measures for water accumulation in the trench may be required for construction in wetlands.

Most mitigation and restoration measures would be conducted during and immediately after construction; however, follow up measures may be required on a case-by-case basis particularly after winter construction activities. Surface disturbances are expected to recover within the first few years following construction. Soil disturbances during operations would be significantly less than the construction period. The permanent pipeline ROW may require periodic brush clearing to accommodate routine and non-routine pipeline monitoring and maintenance over the operational period. Disturbances may result from intermittent corrective maintenance activities or additional surface stabilization measures on a case-by-case basis.

AMERICAN OVERSIGHT

Erosion

Similar to other project components, mitigation and control measures would incorporate structural and non-structural BMPs to address erosion and stormwater runoff. ESS soils corresponding to standalone segments of pipeline are summarized in Table 4.14-4:

Table 4.14-4: Alternative 2 Standalone Pipeline Soil Types

ESS Soil Type	Percent Total Alignment	Miles
IA7[1]	41%	(~36.4 miles)
IA9[2]	6%	(~5.2 miles)
RM1[3]	21%	(~18.7 miles)
SO1[4]	<1%	(~0.5 miles)
SO11[5]	32%	(~28 miles)

Notes:

ESS - Exploratory Soil Survey of Alaska, Rieger et al., 1979)

< - less than

1. IA7: Typic Cryandepts – Very gravelly, nearly level to rolling association.
2. IA9: Typic Cryandepts – Very gravelly, hilly to steep association.
3. RM1: Rough Mountainous Land – Steep rocky slopes.
4. SO1: Typic Cryorthods – Silty loess to fibrous organic soils over gravelly till, nearly level to hilly.
5. SO11: Humic Cryorthods – Silty volcanic ash over gravelly till, hilly to steep association.

Source: Rieger et al. (1979); PLP (2018)

[Placeholder: Final access acreages to be provided with forthcoming information. However, planned lengths are provided for partial comparison]

The potential for hydraulic and wind erosion impacts would be most significant along pipeline segments in moderate to rough terrain where finer grained silty loess or volcanic ash materials are present at shallow depth. The segment of stand-alone pipeline from the port road to Canyon Creek west of Pedro Bay generally coincides with finer grained silty volcanic ash soils (shallow) overlying glacial till (SO11, Table 4.14-4). Slopes range from hilly to steep, and slightly less than half of this segment (12.3 miles) may require some blasting. Based on the presence of rougher terrain (e.g., blasting), steeper slopes, and finer grained shallow soils, this segment is considered more susceptible to erosion relative to other sections of the pipeline route to the Mine site.

Effective erosional management during and immediately after construction is anticipated through applied erosional control measures and BMPs; however, post-construction or operations phase, inspections may identify localized conditions requiring installation of long-term surface stabilization controls. Areas considered more susceptible to erosion where longer term surface stabilization controls may be required to promote recovery include sloped topography, wetlands, and waterbody crossings.

The least amount of anticipated erosion would occur during closure and post-closure. The pipeline would be abandoned in-place and areas requiring more intensive surface stabilization measures would likely be addressed over the period of operation. Surface facilities associated with the pipeline would be removed and reclaimed.

AMERICAN OVERSIGHT

4.14.3.5 Action Alternative 2 – Summer-Only Ferry Operations Variant

The Alternative 2 summer-only ferry operations variant would have the same impact at the mine site as Alternative 1. The Alternative 2 variant would require approximately 28.8 additional acres at the port as compared to the Alternative 1 summer only ferry operations variant. The additional disturbances would remain throughout the period of mine operations, and be reclaimed during closure. No other pipeline, transportation corridor, or mine site infrastructure would change under this variant.

4.14.3.6 Action Alternative 2 – Pile Supported Dock Variant

Impacts to soil resources under this variant would be the same as those described for Alternative 1.

4.14.4 Action Alternative 3 – North Road Only

A continuous overland access road would connect the Diamond Point port to the mine site. Impacts to soil resources at the mine site would be the same as Alternative 1, and those at the port would be the same as those described under Alternative 2.

Since the natural gas pipeline would be commonly aligned with the transportation corridor under this alternative, both all are collectively evaluated together for soil disturbance and erosion impacts. The following section describes impacts for the transportation corridor that would be appreciably different under Alternative 3.

4.14.4.1 Transportation Corridor

Soil Disturbance

The gas pipeline trench would be located adjacent to the road (road bed prism) to facilitate construction, maintenance, and inspection. The pipeline(s) would use vehicle bridges to span major stream crossing, and HDD drilling or trenching across smaller drainages as appropriate. No Iliamna Lake ferry infrastructure would be required under this alternative based on the continuous overland route to the mine site. Estimated acreages of transportation corridor (and pipeline) ground disturbances under this alternative include the following:

- Road corridor/pipeline(s) – 1,029 acres
- Material sites and access roads – 755 acres

[Placeholder: Acreage estimates subject to change with further information.]

The total acreage of ground disturbance from material sites and shared road and pipeline under this alternative is approximately 58 percent greater than Alternative 1, and approximately XX% greater than Alternative 2. The permanent need for transportation corridor access throughout post-closure would create a permanent ground disturbance in the footprint unlike the 500 acres of stand-alone pipeline corridor ground disturbance under Alternative 2 that would be expected to recover to pre-disturbance conditions during the operations phase.

[Placeholder: Additional pipeline infrastructure acreage estimates forthcoming for Alternative 2 and 3 soil disturbance comparisons. Section will be revised accordingly.]

Erosion

ESS soil types corresponding to transportation corridor terrain under Alternative 3 are summarized in Table 4.14-5.

AMERICAN OVERSIGHT

Table 4.14-5: Alternative 3 Approximate Road/Pipeline(s) Terrain and Soil Types

ESS Soil Type	Gentle to Moderate Terrain	Moderate to Rough Terrain
IA7[1]	42% (~34.7 miles)	4% (~3.5 miles)
IA9[2]	6% (~5 miles)	< 1% (0.36 miles)
RM1[3]	11% (~8.7 miles)	6% (~4.5 miles)
SO11[4]	15% (~12.3 miles)	16% (~13.5 miles)
Percent Total Terrain Type[5]	74% (~60.7 miles)	26% (~22 miles)

Notes:

< - less than

1. IA7: Typic Cryandepts – Very gravelly, nearly level to rolling association.
2. IA9: Typic Cryandepts – Very gravelly, hilly to steep association.
3. RM1: Rough Mountainous Land – Steep rocky slopes.
4. SO11: Humic Cryorthods – Silty volcanic ash over gravelly till, hilly to steep association.
5. Terrain type classification associated with planned blasting requirements (segments) for road construction.

Source: Rieger et al. (1979); PLP (2018)

Mitigation and control measures for erosion and stormwater runoff would incorporate structural and non-structural BMPs common to transportation and pipeline construction practices described under Alternatives 1 and 2. The greatest potential for hydraulic and wind erosion impacts would correspond with invasive ground disturbance during construction. Disturbed surfaces would remain susceptible to erosion until concurrent or follow up stabilization is achieved. Permit required mitigation measures and BMPs are anticipated to alleviate most conditions throughout or immediately after construction.

More robust mitigation and follow-up stabilization measures during and after construction are likely to be required in areas of moderate to rough terrain where fine grained soil conditions exist. This coincides with the segment of stand-alone pipeline from the port road to Canyon Creek west of Pedro Bay under Alternative 2 (SO11 soils). The least amount of erosion would likely occur during operations, when stabilization of disturbed surfaces would be achieved through natural or applied restoration and stabilization measures, and continued (i.e., real time) monitoring along the corridor. Erosion throughout post-closure would likely be greater than the operations phase based on an indefinite need for transportation corridor access; a reduced erosion monitoring frequency; and reduced access to equipment and resources.

Summary of Erosion Impacts

Enhanced design and mitigation measures would be required along discrete segments, in particular the segment of coastline road through rugged terrain from Diamond Point port (2.5 miles) under Alternatives 2 and 3. More robust mitigation and restoration measures may be needed in moderate to rough terrain with finer grained soil conditions (iSO11 soils). The duration of erosion would vary from completion of the activity (e.g., construction or reclamation), to an indefinite period in post-closure. The extent of erosion effects would be mostly limited to the immediate vicinity of disturbance or footprint.

The overall magnitude, extent and potential for erosion under this alternative is considered to be greater than the transportation corridor for Alternative 2 based on total footprint acreage,

AMERICAN OVERSIGHT
EPA-0135-0002787

presence of fine grained soils in moderate to rough terrain, and increased frequency of waterbody crossings. The duration would be comparable to Alternative 2 since both alternatives indefinitely retain transportation corridor infrastructure.

4.14.4.2 Alternative 3 – Concentrate Pipeline Variant

This variant includes an HDPE[1]-lined steel pipeline that would convey slurried copper and gold concentrates from the mine site to the port facility (PLP 2018-RFI 066). The pipeline would be predominantly buried sub-grade in the same trench as the gas pipeline, with approximately 36-inches of top cover. Impacts to soil resources at the mine site and port would be the same as those described under Alternative 2; however, a small soil disturbance increase would be anticipated due to a concentrate pipeline pump house (e.g., 1 acre), and pipeline booster station (0.7 acres).

The shared transportation and concentrate pipeline corridor would increase the road corridor width by less than 10 percent; resulting in a proportional soil disturbance increase. The duration and geographic extent of soil disturbance and erosion would be the same as Alternative 3; however, there would be an appreciable increase in erosion magnitude and potential based on the additional acreage of disturbance associated with transportation corridor widening.

4.14.5 Key Issues/Impacts Summary

Table 4.14-6 provides summary statements of key issues and impacts from the project on soil resources.

Table 4.14-6: Summary of Key Issues for Soil Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Soil disturbance	~8,129 acres (total) *Summer-Only Variant* ~8,167 acres (total)	*Alternative 2* ~119 additional acres (downstream TSF construction) *Summer-Only Variant* No change	*Alternative 3* No change from Alternative 1 *Concentrate Pipeline Variant* ~1.7 additional acres
Soil quality	Magnitude and potential: Negligible or no adverse change to surface soil chemistry from fugitive dust deposition relative to existing baseline conditions. Extent: mine site (ambient air) boundary. Duration: Throughout post-closure. *Summer-Only Variant* No change	*Alternative 2* No change *Summer-Only Variant* No change	*Alternative 3* No change *Concentrate Pipeline Variant* No change
Erosion	Magnitude: Within project design and permit	*Alternative 2* Potential erosion increase	*Alternative 3* No change from

	shallow fine grained soils. May require some enhanced design and mitigation measures. Duration: Temporary to indefinite Extent: Project footprint Potential: Inherent, but greatest potential along south access road, with a low potential for other transportation components. *Summer-Only Variant* Potential erosion increase due to greater road usage during ice free months. *East Ferry Variant* Comparable but potentially less erosion based on shorter road length.	types and gentler terrain. Duration: No change (temporary to indefinite) Potential: Increased along 2.5 mile coastline segment of port access road where unique road design and mitigation measures will be required to minimize erosion potential; however, erosion potential will likely persist (e.g., topography and maritime conditions). *Summer-Only Variant* Potential erosion increase due to greater road usage during ice free months, but less than Alternative 1 variant based on shorter road length.	crossing frequency. However, magnitude and potential may be comparable to Alternative 1 (at a minimum) based on less moderate to rough terrain that coincides with shallow fine grained soil types. Duration: No change (temporary to indefinite) *Concentrate Pipeline Variant* Magnitude and potential: Greatest amongst all action alternatives and variants due to less than 10% increase in transportation corridor width (i.e., Alternative 3). Duration: No change (temporary to indefinite) Extent: Comparable to Alternative 3.
Port Site			
Soil disturbance	~15 acres (total) *Summer-Only Variant* ~42.5 acres (total) *Pile-Supported Dock Variant* Reduced fill material demand and acreage.	*Alternative 2* ~39.7 acres (total) (~24.7 additional acres) *Summer-Only Variant* ~68.5 acres (total)	*Alternative 3* Same as Alternative 2 *Concentrate Pipeline Variant* Same as Alternative 2
Soil quality	Magnitude: Negligible or no adverse change to surface soil chemistry from fugitive dust deposition. No PAG material from locally sourced material sites, seasonal emission mitigation/suppression through watering. Concentrate transfer from sealed bins to bulk carriers conducted off-shore below deck. Calculated concentrate total emissions is approximately 4 pounds per year. Duration: Indefinite based on continued post-closure	*Alternative 2* No change *Summer-Only Variant* No change	*Alternative 3* No change *Concentrate Pipeline Variant* No change

AMERICAN OVERSIGHT
EPA-0135-0002790

Table 4.14-6: Summary of Key Issues for Soil Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
	port needs Potential: Low; however, greatest during the operational period during concentrate storage and handling. *Summer-Only Variant* No change		
Erosion	Magnitude: Low and within project design and permit requirements. Duration: Indefinite and up to several years into post-closure Extent: Project footprint Potential: Inherent – low *Summer-Only Variant* Increased erosion potential *Pile-Supported Dock Variant* Reduced erosion potential	*Alternative 2* Magnitude and Extent: Increased based on larger acreage of ground disturbance/infrastructure, terrain, and dredge material stockpile. Duration: No change Potential: Increased based on larger acreage of ground disturbance, terrain, and dredge material stockpile. *Summer-Only Variant* Increased erosion magnitude and potential *Pile-Supported Dock Variant* Same as Alternative 1 variant.	*Alternative 3* Same as Alternative 2 *Concentrate Pipeline Variant* Same as Alternative 2
Natural Gas Pipeline (Stand-alone)			
Soil disturbance	~6 acres (total) *East Ferry Variant* Shorter 3 mile pipeline length but negligible change based on shared Transportation Corridor.	*Alternative 2* ~503 additional acres	*Alternative 3* The pipeline under this alternative is considered part of the commonly aligned/shared Transportation Corridor. See Alternative 3, Transportation Corridor key issues for soil disturbance. *Concentrate Pipeline Variant* Same as above
Erosion	Magnitude: Negligible based on limited ground disturbance and shared transportation corridor; within project design and permit requirements Duration: Indefinite	*Alternative 2* Magnitude, extent, and potential: Increased during construction and operations based on larger acreage of ground disturbance, length, and reduced accessibility.	*Alternative 3* Although the pipeline under this alternative is considered part of the commonly aligned transportation corridor for evaluation, the following key issue is considered:

AMERICAN OVERSIGHT

Table 4.14-6: Summary of Key Issues for Soil Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
	Extent: Project footprint Potential: Inherent but low *East Ferry Variant* Decreased erosion potential	Magnitude and extent are considered comparable to Alternative 1 during post-closure based on stabilization, ground surface restoration and in place abandonment. Potential: Increased during post-closure. Duration: Comparable based on shared transportation corridor segments.	The potential for increased erosion susceptibility of shallow fine grained soils in moderate to rough terrain from the port road to Canyon Creek west of Pedro Bay under Alternative 2 (stand-alone pipeline) would be reduced under Alternative 3 immediately after construction and throughout operation. This is due to continuous road access for monitoring and maintenance of surface stabilization and restoration measures. *Concentrate Pipeline Variant* Same as above

4.14.6 Cumulative Effects (Soil)

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to soil disturbance and erosion impacts. Section 4.1 details the past, present, RFFAs considered for evaluation. Several of the RFFAs detailed in Section 4.1 are considered to have no negligible cumulative impact on soil resources. These would include off-shore based developments such as oil and gas lease sales, in-river hydroelectric projects, or non-industrialized point source activities that are unlikely to result in any appreciable soil impact beyond a temporary basis (e.g., subsistence, tourism, recreation, hunting, and fishing). Other RFFAs removed from further consideration include those considered to be sufficiently distant to eliminate infrastructure co-use by other parties, and distant geographic variability of soil conditions not considered representative of soil resources affected by the project (e.g., Donlin, Copper Joe). The following RFFAs identified in Section 4.1 were carried forward in this analysis based on their potential to impact soil resources in the analysis area:

- Pebble project buildout- develop 55 percent of the resource over 78-year period
- Pebble South/PEB*
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Diamond Point Rock Quarry
- Lake and Peninsula Transportation and Infrastructure

**Indicates exploration activities only.*

AMERICAN OVERSIGHT

The most important potential future actions included in this analysis are those that are likely to contribute to ground disturbances or soil erosion and are regionally common to the project. Since development at remote locations can be financially prohibitive, RFFAs in proximity to the project that could potentially minimize costs through co-use of project infrastructure are also considered important in this analysis.

The project buildout is the only mineral deposit RFFA considered for exploration and development. All other mineral deposit RFFAs are considered for exploration only. Project buildout would result in additional soil disturbance acreages not included under Alternative 1:

- Increased pit footprint
- Increased TSF and waste rock storage capacity
- Additional processing infrastructure
- Construction of a new port site with diesel fuel and concentrate pipeline(s) extending to the mine site

The additional acreage of disturbance to wetlands at the mine site would in the combined Koktuli and Upper Talarik Creek watersheds. The buildout would correspond to an increase in magnitude and local extent of disturbance impacts.

RFFAs associated with exploration activities would have some appreciable soil disturbance impacts (e.g., drill pads, camps); however, they would be seasonally sporadic, temporary, and localized based on remoteness. Erosion would vary on a case-by-case basis, and would likely be mitigated through permit required conditions. Although exploration activities are considered to have minimal cumulative impacts to soil resources, it should not preclude the potential for greater soil impacts from future development that could be incentivized through reduced infrastructure costs (e.g., transportation infrastructure co-use).

The footprint of the Diamond Point rock quarry coincides with the Diamond Point port footprint under Alternatives 2 and 3. Upland soil disturbances and erosion impacts would be limited to coarse soils occurring in rocky mountainous terrain. The increase in soil disturbance and erosion impacts e.g., magnitude and geographic extent) would be comparable to those identified under to Alternatives 2 and 3. Cumulative impacts would likely be negligible under Alternatives 2 and 3 due to commonly shared project footprints with the quarry site.

Transportation development in the Lake and Peninsula Borough would have a cumulative impact on soils in the impact study area. Development may include new transportation corridors and road improvements. Other infrastructure improvements (e.g., power) would incorporate existing footprints or alignments. Improvements to the Williamsport-Pile Bay Road may result in an appreciable soil disturbance increase; but would likely result in a net decrease of erosion through improved design. Other new road corridor developments (e.g., Iliamna River road, Kaskanak road) would appreciably increase the magnitude and local extent of soil disturbance impacts and erosion potential. Soil disturbance impacts would be permanent in road bed footprints; however, erosion is expected to be minimal based on permit required mitigation and proven industry construction practices

The magnitude of cumulative impacts to soil from RFFAs would vary from temporary soil disturbance to permanent soil removal. Similarly, erosion would vary from minimal surface stabilization efforts to indefinite erosion maintenance (e.g., roads, mine site infrastructure). All RFFA impacts to soil would likely be limited to the footprint occurrence. Furthermore, soil types and conditions affected by RFFAs in the geographic study area are most likely to be usual or ordinary and prevalent throughout the region.

K3.8 HISTORIC PROPERTIES

K3.8.1 Mine Site

SRB&A (2013a) reports on the identification of 43 cultural resource sites in Pebble Limited Partnership's (PLP) mine study area that are entered into the Alaska Heritage Resource Survey (AHRS) database. The mine study area is geographically larger than the mine operations footprint. Of these sites, two are currently within the mine operations footprint (ILI-00218 and ILI-00251, in **bold**).

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00013	Newhalen Upper Rapids	Townsend observed this site, from a plane, in a grassy area with apparently no secondary growth. It seems to be situated on several terraces and is about 100 yards long.	Prehistoric
ILI-00031	Newhalen Middle Rapids	This site was observed by Townsend, form a plan, at the top of a single terrace. Four or five house pits were noted.	Prehistoric
ILI-00106	NPS Using	No Description in AHRS database	Unknown
ILI-00193	ILI-00193*	119 surface artifacts were collected and a 50cm x 50cm test unit on the margin of the blowout was excavated. This test unit contained 13 flakes, one used flake fragment and one possible blade in the top 10cm. Collected surface artifacts include bifaces, blade fragments, and debitage. There is cultural material in a soil context and there may be charcoal or other datable material in stratified context in the area.	Prehistoric
ILI-00194*	South Fork Koktuli River Site 4	The site consists of lithic artifacts from the surface and subsurface context. Lithic artifacts include three biface fragments and debitage.	Prehistoric
ILI-00196	ILI-00196	Site consists of an isolated artifact. Testing of the surrounding area failed to locate further cultural material.	Prehistoric
ILI-00209	Isolated Find	A possible bifacially reduced cobble was discovered on the surface. The biface was not collected and no other tools were located in the vicinity.	Prehistoric
ILI-00212	Rock Stand and Circle Site	A one meter diameter circle of cobbles with a very large cobble in the center. The rocks appear to be larger and rounder than the rocks in the surrounding area, which are fractured and heavily covered with black lichen. Nearby (50m) is a collapsed stack of similar stones.	Prehistoric / Protohistoric
ILI-00214	Wiggly Lake Camp 2	This site consists of two rock features, a deposit of rifle cartridges of two different calibers, and some antler and bone pieces. The fire ring is a circle nearly a meter in diameter with a line of rocks bisecting the circle down the center. Some burned material was visible beneath the rocks. Nearby to the southeast was an area with numerous cartridges including .223, .338 and 7mm magnum rounds and a tent ring about 12 feet in diameter consisting of 5-8 cobbles resting on the surface of the tundra. Possible stakes made from antler and bone fragments are also nearby. In 2012, SRB&A conducted subsurface testing at the site and did not locate any subsurface cultural material.	Historic

AMERICAN OVERSIGHT

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00215	Wiggly Lake Camp 3	SRB&A recorded this site in 2008 as a ring of cobbles that measured approximately 12 feet in diameter. When SRB&A revisited the site in 2012, the field crew mapped in the identified faunal remains, a hearth, and rifle cartridges and mapped these features using a Trimble GPS, and conducted multiple subsurface tests in the area. The field crew did not relocate the ring of cobbles. None of the subsurface tests in 2012 produced any cultural material.	Unknown
ILI-00217	Wiggly Lake Camp 5	This site is a relatively large camp that includes a tent ring approximately 20 feet in diameter consisting of large cobbles. A plastic water container with bear bite marks, a kerosene can, a firewood stockpile and a stacked pile of caribou antlers were found below the esker on a flat area of tussock tundra. Nearby on the tussock flats a horseshoe pitch with horseshoes and rebar pins were::found. A few fire pits were on the flats toward the lake in tussock tundra. SRB&A relocated the site in 2012 and mapped it with a Trimble GPS. Multiple subsurface tests were conducted, all of which were negative for cultural materials. However, personal communication with the makers of the horseshoes, Regent Sports Corporation, allowed SRB&A to determine that the set of horseshoes identified were made during the 1960's.	Historic / Modern
ILI-00218	**Isolated Lithic Find**	**This site consisted of one used flake. The used flake was found on the surface of the tundra. No other artifacts were found on the surface or in test pits excavated nearby.**	**Prehistoric / Protohistoric**
ILI-00221	ILI-00221	Site consists of three cultural surface depressions and intact subsurface cultural strata. The cultural surface depressions are in the SW part of the site and consist of two rectangular features measuring 3.5-4m x 2.5-3m x 0.3-0.4m and one circular feature measuring 4.5m in diameter and 50cm deep. One rectangular feature has a narrow depression off the NW corner, possible an entry tunnel. Thirty-six positive shovel tests yielded 607 flakes, five shatter, six biface fragments, one grooved stone, two used flakes, one small unidentified faunal fragment, and charcoal. Cultural material was from between 0-25cm below surface.	Prehistoric
ILI-00222	ILI-00222	Surface lithic scatter on a lag deposit. Pedestrian walkover identified less than 20 flakes, a bluish green chert scraper with some polish, and at least one incomplete biface. There is potential for buried cultural material in vegetated areas adjacent to the lag deposit. Artifacts were not collected. No tests were excavated at the site.	Prehistoric
ILI-00223	ILI-00223	Site consists of an isolated straight stemmed biface with rounded shoulders found on the surface of an exposed lag deposit. The biface is made of an opaque black cryptocrystalline material with white vein inclusions and broken transversely through the midsection. A circle of large stones, about 2m in diameter (ILI-00232), was found approx. 20m S of the biface. The broken point was collected, no tests were excavated at the site.	Prehistoric
ILI-00224	ILI-00224	Site is a lithic reduction site measuring approx. 6.5m x 5m and consisting of at least 85 lithic artifacts. Artifacts consist of a large cobble core and flake core, one microblade fragment, one retouched flake, one used pebble, one hammerstone, and 79 pieces of debitage. Debitage consisted of 26 complete flakes, 25 broken flakes, and 28 shatter. Both cores and the debitage are of basalt. Two tests were excavated and both were negative. No artifacts were collected.	Prehistoric

AMERICAN OVERSIGHT

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00225	ILI-00225	The site consists of lithic debitage and a tool from both on and below the surface. One positive shovel test was excavated and yielded 10 flakes from 0-5cm below surface. SRB&A also identified a large biface preform and one piece of chalcedony shatter on the surface, about 20m S of the positive test. When field crews revisited the site in 2012, they mapped it with the Trimble GPS and conducted several subsurface tests, none of which located additional cultural materials	Prehistoric
ILI-00226	ILI-00226	Site consists of lithic debitage recovered from a subsurface context. Two shovel tests yielded 13 flakes, cultural material was 0-20cm below surface. SRB&A has begun processing a bulk hearth sample collected from the 2009 testing. Processing of the bulk sample has yielded small bone fragments, one flake, and burned botanical remains.	Prehistoric
ILI-00227	ILI-00227	Site consists of lithic debitage recovered from a subsurface context. One positive shovel test yielded one flake. Cultural material was 5-10cm below surface. This site is considered an isolated find. SRB&A collected a charcoal sample from a negative test near the positive test.	Prehistoric
ILI-00228	ILI-00228	Site consists of an isolated used flake (broken into two fragments that refit) found on the surface. The used flake was identified on an exposed surface on a tussock tundra floodplain. One negative shovel test was excavated near the surface-find. The used flake was collected.	Prehistoric
ILI-00230	Tent Ring	ILI-00230 is a campsite which included numerous pieces of cut wood and discarded sawn antlers, possibly indicating hunting for food rather than sport. The site characterized by a large glacial erratic boulder with at least three tent rings, a fire ring, several antler piles and a caribou skull pointed towards Newhalen. A local elder, mentioned having used this particular camp site with other local Native hunters as recently as last winter, mentioning the boulder as a wind block and cover that allowed hunters to shoot caribou grazing on exposed moss on the opposite side of the lake.	Historic / Modern
ILI-00231	ILI-00231	The site consists of about eight cobbles in a vegetated, relatively flat area next to the lakeshore. ILI-00231 appears to be a deconstructed tent ring or linear array of rounded cobbles well-seated in the tundra vegetation. The linear formation may reflect the use of a tarp, rather than a tent proper, or could also represent a single event of tents being weighted against a direction of wind with the lee sides allowed to flap.	Historic
ILI-00232	ILI-00232	Site includes two separated tent rings. One tent ring consists of 3.8-3pprox. 8 lichen-covered rocks embedded into the tundra it also included a metal tent peg and polypropylene twine as well as a circle of rounded cobbles. SRB&A returned to the site during 2012 cultural resource fieldwork to map it in using the Trimble GPS. The field crew was not able to relocate the tent ring that was embedded into the tundra. Due to the lack of sediment, no subsurface tests were conducted in the area, although additional ground survey was conducted in an attempt to identify previously unidentified cultural materials. No new cultural materials were identified.	Historic / Modern
ILI-00234	ILI-00234	There are at least two tent rings, several pieces of cut wood and an adjacent patch of cut willow and alder stumps, and one fire ring. The fire ring, which contains carbon staining and dead vegetation, also served as a midden for cans, plastic wrappers and bottles.	Historic / Modern

AMERICAN OVERSIGHT

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00235	ILI-00235	Cobbles arranged in two circles and are well-incorporated into the surface vegetation. SRB&A tentatively interpreted the cobble circle as two tent rings and a camp stove use area, where cobbles were like used to shield and support a camp stove. SRB&A revisited the site at the end of the 2012 field season to map the site boundary with the Trimble GPS. The field crew was not able to relocate the second tent ring. No subsurface tests were conducted at this site due to the density of cobbles directly underneath the vegetated surface. Additional ground survey of the area was conducted to ensure that all cultural materials had been identified and recorded during the 2009 field season.	Historic
ILI-00236	ILI-00236	Midden of cut antler, bone, and wood was discovered in a swale. All the wood and bone showed evidence of having been cut with a saw and was well incorporated into the surface vegetation. A tent ring on the raised ground is likely connected to the midden in the swale below, although it is difficult to determine if it represents one long episode of camp supported hunting and processing of caribou or a series of events over time with the site reused for more than one harvest episode. The presence of the antlers indicates that the purpose of the hunt was meat, rather than trophies.	Historic
ILI-00237	ILI-00237	Site includes up to two tent rings located in low-lying tussock tundra. This area was likely well-sheltered from winds, but would have been a damp and uneven place to camp. No fire rings, middens, or wood caches were located near the site.	Historic
ILI-00238	ILI-00238	Site consists of about six cobbles in a circle, measuring 6m in diameter. The cobbles are small, around 10cm diameter, with one larger boulder.	Historic
ILI-00239	ILI-00239	This site consists of two large flat boulders, near a caribou skull, with smaller rocks lying on top of the vegetation. This configuration of rocks suggests that the rocks were purposefully stacked by humans.	Historic
ILI-00240	ILI-00240	Site consists of a knoll with exposed bedrock with fracture zones filled with clear quartz crystal to opaque or milky white material, and chalcedony geodes. SRB&A found no manufactured tools or debitage on the surface or in three subsurface tests, the site has good potential as a raw material source and as such the distribution of unused materials on the surface may reflect the selective use of the materials made by prehistoric users. One fragment resembled a possible tool in form but was left in situ.	Unknown
ILI-00241	ILI-00241	Site is a prominent knoll with bedrock outcroppings with veins of quartz and chalcedony. This site is smaller than the similar site ILI-00240, with two outcrop mounds surrounded by an area of bare bedrock. The knoll is surrounded by a litter of quartz fragments including clear, milky, and fractured pieces. This distribution of material may indicate that the site had been used by prehistoric toolmakers, with the fragments examined and the unusable ones discarded.	Unknown
ILI-00242	ILI-00242	Pile of intentionally stacked rocks of unknown purpose. The stack consists of boulder-sized rocks measuring 3.8-4pprox. 1m in diameter and 0.5m high. The stack was not likely a “pretend person” but could have been a rock cache or claim mark. No indications of the reason for its construction were found.	Unknown
ILI-00249	ILI-00249	Site is a lithic scatter. The surface is un-vegetated rounded pebbles to cobbles with patches of tundra vegetation. Twenty large flakes and one unifacially worked piece were located on the deflated surface of the terrace and slumping down the stream bank.	Prehistoric

AMERICAN OVERSIGHT

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00250	ILI-00250	ILI-00250 is a lithic scatter. The site consists of three artifacts found on the un-vegetated cobble to pebble surface in the interstices between hummocks and patches of vegetation. The artifacts consist of two flakes and one core.	Prehistoric
ILI-00251	**ILI-00251**	**Site consists of two flakes of green silicified mudstone on an eroded blowout surface. One flake is blade-like. The location is an excellent hunting area with game trails below the site.**	**Prehistoric**
ILI-00252	ILI-00252	Site includes artifacts consisting of numerous small fragments of charcoal and debitage likely resulting from pressure flaking of larger pieces. The area of the cultural deposit is relatively small and consists of a distinctly colored soil deposit beneath the root mat. There was no surface indication of cultural resources deposits.	Prehistoric
ILI-00253	ILI-00253	The site consists of a single dark gray igneous flake recovered from a subsurface test, but there is potential for the recovery of further subsurface artifacts. Viewshed is excellent to the south and west. Most of the northeast tributary valley is visible from the site area. A portion of the Upper Talarik Creek valley is visible to the southwest as well.	Historic
ILI-00254	ILI-00254	ILI-00254 is a modern to historic winter fur trapping camp located in a cottonwood patch on the south side of Groundhog Mountain along a tributary of Upper Talarik Creek. The creek drains a lake higher up on the mountain which is located in a steep walled canyon. The site consists of two square flat areas that were leveled out to approximately the size of a 10x10 foot wall tent, with the downhill area cut into the root bed of a large cottonwood tree. The uphill area was leveled with less cutting into the soil. Near these tent footprints, cottonwood tree limbs were removed with an axe in the past while one tree in the patch had an axe cut blaze on it to indicate where the camp was. On the surface was a well rusted steel round gasoline can with a Chevron logo still visible where it lay. Local person indicated that the site probably belonged to either "Butchy" Hobson or one of the Koktelash family from Nondalton and was a winter fur hunting camp at least 30 years in age.	Historic/ Modern
ILI-00260	ILI-00260	SRB&A originally identified this site in 2011 based one test that yielded over 50 lithic debitage and charcoal from between 0 and 5cm. Three other subsurface tests on the landform did not reveal additional cultural materials. The position of the site suggests the site was used as a hunting lookout. In 2012, SRB&A identified two possible stone tent rings within the AHRS site boundary. Vegetation obscures more than 90 percent of both possible tent rings. The field crew mapped in the two potential features but did not conduct any testing in or near either of the possible tent rings because they are located within the site boundary.	Prehistoric
ILI-00261	ILI-00261	The ground surface is up to 50 percent exposed till and gravel. The cultural materials at the site consist of one piece of lithic debitage observed on the surface among the gravel. Pedestrian survey and two subsurface tests yielded no other artifacts.	Prehistoric
ILI-00268	ILI-00268	The site consists of SRB&A identified the site based on artifacts from two test that yielded 11 lithic flakes, one piece of lithic shatter, one lithic core and charcoal. The area is sparsely vegetated on the terrace with increasing vegetation near the river. The subsurface lithic materials and the charcoal were collected.	Prehistoric

AMERICAN OVERSIGHT

Table K3.8-1: Known AHRS Sites near the Mine Study Area

AHRS No.	Site Name	Summarized Description	Period
ILI-00269	ILI-00269	This site consists of one stone feature. This feature consists of a collection of cobbles. These cobbles are stacked in a semi-circular pattern with the opening facing down-slope to the N. The view shed is comprised of the valley with one of the Talarik's tributaries. The stones appear to have been settling into the ground for at least 20 years.	Unknown

Note: Descriptions of known sites as provided are verbatim from the AHRS database and have not been edited.

K3.8.2 Transportation Corridor

There are no reported AHRS resources in the transportation corridor. The data gap assessment report prepared by ASRC (2017) reports on the following AHRS sites near the corridor. It is expected that this list will grow through ongoing consultation and incorporation of data from additional investigations regarding cultural resources and historic properties in the transportation corridor.

Table K3.8-2: Known AHRS Sites near the Alternative 1 Transportation Corridor

AHRS No.	Site Name	Summarized Description	Period
ILI-00008	Old Kakhonak, Kakonak, Kokhanok	Eskimo village, with a population of 28, listed in the 1890 census. The site was apparently abandoned as residents moved to the present village during the 1940-1950s. Yarborough, in two surveys, noted two or three graves, upright poles from an apparent cache, the remains of a 4m x 5m log cabin, a 2m x 1.1m x .6m deep depression, and a shallow 2m x 5m rectangular feature. Site is near south ferry terminal.	Historic
ILI-00009	Napaimute, Napai, Naapaimiut	Former Eskimo village or camp reported in the 1890 Census as "Napaimiut," with a population of 11. Sue Woods, who owns an allotment on the S side of Lake Illiamna, reported graves at this locality. Graves would tend to confirm this as the location of a village. Site is near south ferry terminal.	Historic
ILI-00025	Saints Peter and Paul Chapel, Kakhonak	Russian Orthodox church built about 1940. Consists of a 25'-6" x 15' nave and sanctuary and an attached 8'-1" x 9'-2" vestibule. The exterior is shingle and corrugated metal. A 2011 survey by THRC stated that the condition of the church was "dilapidated" and a new church has been built (1984) to the SE. [NATREG] Russian Orthodox Church built about 1940. Consists of a 25'6"x 15' nave and sanctuary and an attached 8'1"x 9'2" vestibule. The exterior is shingle and corrugated metal. Site is in Kakhonak Village near south ferry terminal.	Historic

AMERICAN OVERSIGHT

Table K3.8-2: Known AHRS Sites near the Alternative 1 Transportation Corridor

AHRS No.	Site Name	Summarized Description	Period
ILI-00056	Gibraltar Lake Village	BIA investigators noted some 12-15 house pits within a 70m x 120m site area on the north bank of the outlet of Gibraltar Lake. The pits, which are poorly defined, appear to cluster on two adjacent mounds, separated by about 45m. A shovel test in the westernmost loci revealed cultural material (beneath the sod and a thin layer of Katmai Ash) consisting of burnt bone, charcoal, and fire cracked rock in a sandy silt matrix, to a depth of about 75cm. A single basalt flake was noted and a C14 date of BP 860+/-60 was obtained. On the north end of Gibraltar Lake, near the south access road.	Prehistoric
ILI-00126	Henry Olympic Allotment Cemetery on Kakhonak Bay	Site consists of a small cemetery containing 3 graves, all marked with Russian Orthodox crosses. One of the coffins was eroding out of the ground. No other archaeological remains were located on the property.	Historic
ILI-00127	Pottery and Stone Beads	No Description	Prehistoric
ILI-00128	Stone Tools, Possible AsST	No Description	N/A
ILI-00262	Kokhanok BIA School	The building is currently a single-story frame building measuring 68ft x 18ft in plan, a ridgeline at 11ft and a very low-slope roof, with a satellite dish abutting the W facade. Built ca. 1957 the Kokhanok BIA building served as a school from the late 1950s into at least the 1980s. The building contains basic attributes found in some period BIA schools in Alaska, but has undergone substantial alterations since 1973. Comparison of the 1973 building with the current makes evident an addition built on to the original N end as well as the removal of some of the original fenestration and removal of the original siding. The building currently houses administrative offices.	Historic

K3.8.3 Amakdedori Port

Recent work completed by HDR (2018) archaeologists on behalf of PLP resulted in the identification of one new archaeological site in the Amakdedori port facility boundaries (HDR-AMK-01). The GPS locational data for the Amakdedori Village (ILI-00044) was also corrected, and that site is now within the southern boundary of the facility footprint. The desktop analysis completed by ASRC (2017) listed another five sites in the vicinity, but outside the port boundaries. One other site, ILI-00291, is the AGRAM shipwreck, and is also within the boundaries of the offshore development. Sites in the facility boundary are in **bold**.

AMERICAN OVERSIGHT

Table K3.8-3: Known AHRS Sites near Amakdedori Port

AHRS No.	Site Name	Summarized Description	Period
HDR-AMK-01	N/A	Surface Lithic Scatter	Prehistoric
ILI-00007	Chenik	Site of Eskimo village; Eskimo name reported by USGS (Brooks, A.H., et al. 1925). In 1997 Janet Klein and Donna Redding, noted several collapsed structures at this site.	Prehistoric
ILI-00044	**Amakdedori Village**	**Village site consisting of five house pits of two rooms each, with connecting passages and five smaller square pits. All are located on the second and third vegetated beach ridges, which are being eroded by the creek. Testing of two house features by Reger (1980) identified historic artifacts and floor deposits dating to AD 1883-1912.**	**Prehistoric**
ILI-00104	Chenik Midden	The prehistoric midden on Chenik Head contains shells which indicate the presence, use, and variety of invertebrates. (An invertebrate checklist has not been compiled.)	Prehistoric
ILI-00136			
ILI-00218	Isolated Lithic Find	This site consisted of one possible microblade or blade core. The core was found on the surface of the tundra. No other lithics were found on the surface or in test pits excavated nearby. Near mine access road.	Prehistoric/ Protohistoric
ILI-00291	**AGRAM Shipwreck**	**On October 12, 1923 at 8:45 am the wooden gas screw cannery tender AGRAM was washed ashore and became a total wreck on a beach between Chinik Bay and Amakdedori Native Village. […] According to Doug Reger, who surveyed this stretch of the coast in 1980, no shipwreck remains were visible beyond the large amount of debris on Amakdedori beach, which is known for drift debris. The ship's remains may still be present below the waterline, although the high energy environment has likely compromised the wreck's structural integrity.** **References: U S Customs Wreck Report; The H W McCurdy Marine History of the Pacific Northwest (1966) , p. 344; "Wrecked tars live on weird edibles" The Helena Daily Independent, November 24, 1923, p.2.**	**Historic**

Note: Descriptions of known sites as provided are verbatim from the AHRS database and have not been edited.

K3.8.4 North Route Alternatives

The discussion of the northern route applies to Alternatives 2 and 3. A preliminary review of the AHRS data indicate that there are several AHRS sites in or near the road corridor between Diamond Point and the mine site. There are no recorded AHRS resources in the overland portion of the pipeline route from Ursus Cove to Cottonwood Bay. No fieldwork specific to survey of this project's components has occurred in the transportation corridor, with the exception of limited investigations cited above by SRB&A near Iliamna, and along the Newhalen River.

AMERICAN OVERSIGHT

Table K3.8-4: Known AHRS Sites near the Alternative 2 Transportation Corridor

AHRS No.	Site Name	Summarized Description	Period
ILI-00027	White Rock Site	Three large, single room, slightly semi-subterranean house on a ridge above a dry marsh. One house was partially excavated by Townsend in 1969. The site apparently equates in time with ILI-003. Yarborough noted that the site consists of two house pits and six cache pits on a south sloping ridge between two small streams. Both of the house pits have only a single room and only the smaller has an obvious entry way. The larger depression, the southern third of which Townsend excavated, measures 7.4m x 6.5m x .6-.7m deep (two possible entryways were later noted in its west wall). The other, smaller and shallower, depression measures 4.3m x 3.5m, with a 1.1m wide entry. Five of the six cache pits are rectangular to almost square, while the sixth is nearly round. They range in size from 1.35m x .9m to 3.2m x 3m and are .45-1m deep. The largest may be the feature that Townsend counted as a house pit.	Historic
ILI-00049		Yarborough located four large multi-room house pits and five cache pits surrounded by a fairly thick growth of black spruce and alders. House 1 has a 7m x 5m main room, a 3.5m x 3m room off its east wall, and an entry way in its west wall. House 2 has a 9m x 7m mian room, a 3m x 2m room to the east, and a 4m x 3m room at its northwest corner. House 3 has a 7m x 6m main room, a 3m x 4m room off its southwest wall, and an entry way in its northwest wall. House 4 has a 7m x 6m main room, a 3.5m x 3m room off its west wall, and an entry way in the east wall. Two small round cache pits are adjacent to House 2; three larger rectangular cache pits were noted adjacent to House 3, adjacent to House 2, and between House 1 and House 2. A test in the center of House 1 revealed an approx. 20cm thick layer of charcoal and fire cracked rock, with some animal bone, under 9cm of humus and 4cm of ash. [DOE] Site ILI-049 consists of four large, multi-roomed house pits and several smaller cache pits.	Prehistoric
ILI-00132	Williamsport to Pile Bay Road	The Williamsport to Pile Bay Road is a 1 lane, 15.5mi. seasonal road that provided the shortest surface route for six communities around Iliamna Lake. The road follows a traditional Den'aina Athabascan trail portage over the Chigmit Mountains and was originally built in the 1930s by the Alaska Road Commission. By 1932, the road supported small truck traffic. With the installment of the Iliamna River Bridge in 1946, the portage terminus changed from the Iliamna River at Foss's Landing to Pile Bay at Lake Iliamna. Lyle and Carl Williams subsequently began a truck freighting business, with Lyle at Pile Bay and Carl at Williamsport. The road expansion combined with the Williams' freighting operations provided an opportunity that allowed boats direct overland access to Lake Illiamna and Bristol Bay. Carl took the first Bristol Bay fishing boat over the Portage around 1938. Near the summit the dirt road is less than 11' wide with a 750' drop. Improvements began in 1917 to the trail. In 1937 the W terminus of the road was rerouted to Pile Bay.	Historic
ILI-00197	O'Hara House	This rectangular, front-gabled home is 1-, or perhaps 1 1/2 stories (photos show an upper story, or loft, within the roof), built in the early 1950s. It was built from lumber milled locally by Carl Williams, as well as from lumber collected from a house that had been demolished in the late 1940s or early 1950s. The earlier residence was built in the early 1940s by Lyle Williams, just N of where the O'Hara house is now. A depression and some scattered debris (bottles, cans) are the only remnants on the property.	Historic
ILI-00198	Pile Bay Townsite Historic District	N/A	Historic

AMERICAN OVERSIGHT

Table K3.8-4: Known AHRS Sites near the Alternative 2 Transportation Corridor

AHRS No.	Site Name	Summarized Description	Period
ILI-00199	Antenna	The site consists of a 4" diameter iron pipe erected by Carl Williams and used as the base of his HF radio antenna. The antenna wire originally strung between pipes is no longer present. In 2007 the pipe was erect and well supported by tight guy wires.	Historic
ILI-00200	Powerplant	Power plant built by Jack Vantrease in the early 1950s. In 2007 it was located adjacent to the Vantrease warehouse/store but was originally erected across the portage road from Seversen's warehouse. It was skidded to the present location circa 1957 and used to provide electricity to the Vantrease buildings. The structure is a frame building covered with corrugated metal sheets. It measures 8' x 16.5' and rests on large wood beams laid on grade. The rear wall is hinged, it opens and swings down to form a ramp.	Historic
ILI-00211		Referencing USS 7804, the BIA crew located a 6.71m x 4.57m depression on an E-W axis. The maximum depth of the depression is approx 1.8m. The berms are well defined and overgrown with grasses, moss and shrubs. Four well developed trees are present within the depression. On the E side of the depression, two 55-gal drums are 3/4 buried and upon inspection, hints of a possible entrance way to the cabin. Debris is scattered around the premises. Tin can, plastic shelving, and fuel cans were identified. Remnants of a prefabricated aluminum storage building/shed measuring 2.44m x 3.05m were adjacent to the depression on the N side. The underlying organic mat of sod was removed before the shed was place on the surface. Two wall are intact but failing. The interior contained failed roof panels and cut wood.	Historic
ILI-00244	ARC Camp	ARC CAMP ADJACENT TO WILLIAMSPORT-PILE BAY ROAD	Historic
ILI-00247	Williamsport Historical Occupation/Land Use Area	Cultural remains located at Williamsport on the Williams family property include the former cement foundation of Carl Williams' home. A modern cabin has been built on the 1940s cement foundation, although three sides of the foundation are sill visible. The original foundation is estimated to have been about 20 ft X 20 ft. Also present are the remains of the log cabin lived in by Ed McCammet and later by the Williams family. It is possible that this log cabin was once the ARC cabin at Williamsport, given that Ed McCammet was reported to have lived in the ARC cabin. The cabin has collapsed and the remaining timbers are largely embedded in river sediments and gravels and in poor condition. A gravesite is also present. The property currently contains gravel roadpads, numerous storage and staging areas, and a standing building.	Historic

Note: Descriptions of known sites as provided are verbatim from the AHRS database and have not been edited.

3.7 CULTURAL RESOURCES

Section 3.7 provides definitions of cultural resources considered under the National Environmental Policy Act (NEPA) regulations (40 Code of Federal Regulations [CFR] 1500-1508), and describes the current status of information known about these resources to characterize the affected environment. Section 3.8 defines and discusses "historic properties" as defined by Section 106 of the National Historic Preservation Act (NHPA) and its implementing regulations (36 CFR 800).

NEPA does not specifically define the term "cultural resources." The law requires that agencies consider the effects of their actions on all aspects of the "human environment," which NEPA interprets to include the natural and physical environment and the *relationship of people with that environment* (emphasis added) (40 CFR 1508.14). Humans relate to their environment through culture, requiring the consideration of effects on cultural aspects of the environment in NEPA analyses. NEPA defines effects as changes "on the quality of the human environment," which includes alterations to the "aesthetic, historic, cultural, economic, [and] social" aspects of the environment. Analyses need to assess a project's impacts on an area's "historic and cultural resources" and on "districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places (NRHP)" and on "significant scientific, cultural, or historical resources." Importantly, though, cultural resources do not need to be eligible or listed on the NRHP for consideration under NEPA.

Cultural resources under NEPA can be generally defined as archaeological, historical, or architectural resources and locations of traditional cultural or religious importance to specific social and/or cultural groups. This may include, and is not limited to, Traditional Cultural Properties (TCPs); cultural landscapes (both historic and prehistoric); locations with indigenous place names; locations important in conveying oral histories; sacred and/or ceremonial sites; resource gathering and subsistence areas; or other sites of cultural importance to the continued identity and spirituality of living communities in or near the project area.

3.7.1 Data Gap Summary

Information presented herein is currently based on a review of data on file at the Alaska Heritage Resources Survey (AHRS), and the series of cultural resources survey reports prepared for the Pebble Limited Partnership (PLP) between 2004 and 2013 by Stephen R. Braund and Associates (SRB&A). Other reports have informed this section, including Boraas and Knott (2013) and data sets from subsistence harvest areas (SRB&A 2011b). Data and analytical gaps will be addressed through the ongoing Section 106 process and will allow for additional characterization of the affected environment for cultural resources in the Final EIS. For example:

- SRB&A's field work scope was limited to investigating areas where ground disturbance would occur during mineral exploration; there has not yet been a comprehensive analysis of cultural landscapes, TCPs, or other cultural resources in or near the proposed project components.
- SRB&A collected and consolidated place name data, and developed a place name database which will be integrated into this analysis. [Note to reader: Data is pending receipt of RFI 097.] The place name data cover the mine study area and the Extended Cook Inlet Basin Study Area (ECIBSA). Additional data will be collected through the NHPA Section 106 consultation process.
- SRB&A researched routes and trails, but was limited to investigating if any of the reported routes and trails intersected the project area as then defined. No

AMERICAN OVERSIGHT

comprehensive assessment of routes and trails has occurred for this undertaking, but may be informed by the NHPA Section 106 process.

- SRB&A completed interviews and noted the location of approximately 1,600 cultural resource sites based on informant knowledge but only limited field work has been completed to determine if there are physical manifestations of these interview-identified sites.
- Consultation with agencies and consulting parties, including Alaska Native villages and corporations, was initiated via letter on August 22, 2018. While an initial consultation meeting under Section 106 has occurred, direct input from Alaska Native groups and other consulting parties concerning cultural resource locations in or near the project area has not been completed. This will be incorporated into the Final Programmatic Agreement (PA).
- Assessment for off-shore cultural resources (and historic properties) has not yet been completed for project components and alternatives. This will occur during the 2019 field season and be incorporated into the Final EIS.
- The transportation corridor, pipeline, and Diamond Point components have not been surveyed or otherwise investigated for cultural resources. It is not uncommon for linear features to be investigated for cultural resources during final project design. The PA will address the process for avoidance, minimization, and mitigation of potential impacts.
- See Section 3.8, Historic Properties, for a discussion on the limitations and information gaps related to the status of archaeological site surveys, site evaluations under Section 106, predictive modeling outputs, and incorporation of results of recent (SRB&A 2018b) cultural resource reports completed by PLP.

It is expected that the USACE will be addressing data gaps throughout the Section 106 consultation process. The procedures detailing further work beyond the issuance of the Final EIS (e.g., the process for additional identification research and surveys, evaluation, and mitigation measures) will be established through the development of a PA.

3.7.2 Area of Analysis

The area of analysis for cultural resources under NEPA is the claim block of the project at the mine site and the viewshed of the project footprint when data are available. The permit area as defined by Appendix C (of 33 CFR 325) has not yet been formally delineated. It is expected that ongoing consultation with agencies and other consulting parties through the NHPA Section 106 process (see Section 3.8, Historic Properties) and NEPA-driven public involvement may likely result in gathering needed input regarding the identification of cultural resources in the area of analysis. The affected environment described below is broad in order to provide regional context. The area of analysis includes the primary project components and all the alternatives (mine site, transportation corridors, natural gas pipeline corridors, and port locations). The Final EIS will include a summation of the consultation and resultant delineation of the final area of analysis for cultural resources, as appropriate.

3.7.3 Cultural Context

The area of analysis for cultural context covers a broad and complex range of prehistoric traditions, ethnographic regions, land uses, and historic-era themes. The cultural context for prehistoric archaeological traditions, ethnographic, and historic themes is presented in the archaeology survey summary reports prepared by SRB&A (SRB&A 2011a; 2015a; 2015b), and the reader is referred to those reports. Boraas and Knott (2013) also offer a detailed prehistoric

AMERICAN OVERSIGHT

cultural chronology based on known archaeological site data. Archaeological artifacts clearly demonstrate that the area has been continuously occupied as early as 10,000 years ago, with evidence of salmon fishing by Yup'ik or proto-Yup'ik people for at least 4,000 years. A well-developed salmon-based culture emerged in the Norton tradition, dating from approximately 300 B.C. to A.D. 1000, as evidenced by the presence of sedentary villages and net fishing artifacts. The contexts in these reports cover prehistoric archaeology traditions, ethnographic studies of the Dena'ina, Yup'ik, and Alutiiq peoples that occupy the region, and offer a chronology of the regional history from contact through the Russian, and then American, periods. Tribal consultation under Section 106 of the NHPA has been initiated, and information obtained from this process, as well as data gleaned from other sources, will be incorporated into an updated context presented in the Final EIS.

3.7.3.1 Previous Cultural Resource Research

Prior to SRB&A's archaeological field surveys, only two archaeological field surveys occurred within the PLP claim boundary; and no archaeological or historic-era sites were identified. SRB&A's report details the results of the nearest cultural resources surveys in each direction from the claim boundary; and the Environmental Baseline Documents (EBDs) and annual reports each provide a bibliography of these earlier surveys that generally date between 1968 and 2011.

SRB&A's annual survey work commenced in 2004, and involved yearly surveys until 2012. Initial work focused on the mine analysis area, and was limited to locations within PLP's claim boundary, with a few exceptions, including several surveys in adjoining claim boundaries and a brief survey along a section of the Newhalen River. SRB&A's first surveys in the ECIBSA occurred in 2005, and focused on proposed port site locations. SRB&A returned in 2007 to survey a revised port site location, and has conducted surveys in the ECIBSA every year through 2013. However, aside from the small surveys near Amakdedori port (see below), the complete Amakdedori port site and the transportation corridor have not been surveyed. Details of previous research are provided in SRB&A 2011a and 2015a, and include references and a narrative of previous studies throughout the region. The SRB&A reports primarily discuss archaeological compliance surveys, but also offer a discussion of historic and ethnographic sources, including historic documents, ethnographic and linguistic studies, and oral interviews that help better characterize the affected environment. SRB&A reports also contain information on interview-identified cultural resources throughout the region, including both Bristol Bay and Cook Inlet drainages (SRB&A 2011a, 2015a, and 2018b). The reports include tables and figures summarizing the results of these interview-identified cultural features.

Ethnographic works about the Dena'ina, Yup'ik, and Alutiiq contribute models of normative behavior, subsistence food storage practices, land use traditions, place names, and many other points of data with bearing on defining cultural resources and the affected environment. Analyses of oral history interviews, when available, are informative, because they are told from the perspective of those who lived according to the practices being studied. These reports, in conjunction with consultation, contribute more detail to the characterization of the affected environment beyond archaeological and historic-era sites.

In July 2018, HDR completed an archaeological survey of the Amakdedori port site on behalf of PLP. One new archaeological site was identified (temporary site number. HDR-AMK-01), and an NRHP-evaluation report is pending.

PLP retained ASRC Energy Services to complete a desktop study of the proposed transportation corridor (ASRC 2017). This desktop study was limited to a review of the AHRS

AMERICAN OVERSIGHT

database and did not investigate other types of cultural resources beyond sites and historic-era buildings already identified in the database. The results of the ASRC study are discussed below.

3.7.4 Action Alternative 1

3.7.4.1 Mine Site

The mine site has been the primary focus of the cultural resource investigations completed by SRB&A on behalf of PLP to date; and details regarding research, survey, and archaeological site recordation methodology are available in summary reports (e.g., SBR&A 2011a and 2015a). The geographic areas investigated for the reports include lands within the "claim block boundary," which was defined as mining claims owned or leased by PLP and Kaskanak, Inc., and represents a larger area than the current mine site location. The claim block analysis area covered lands from Iliamna Lake in the south to the Nikabuna Lakes in the north and west from the Newhalen River towards the Mulchatna River. Background and place names research covered the entirety of this area, whereas field work was targeted to where PLP had proposed ground-disturbing areas.

Known AHRS Resources

Prior to SRB&A's archaeological surveys for PLP, the AHRS database included three sites in the mine analysis area: ILI-00013, ILI-00031, and ILI-00106. The first two are prehistoric sites near the Newhalen River, and ILI-00106 is a number reserved for use by the National Park Service, and may not be associated with an actual site. The AHRS database is a data repository with information on reported cultural resources, and site significance is not a consideration when assigning AHRS numbers. It is intended to be an inclusive data set, and not all sites have been field verified, nor are all sites in Alaska listed.

SRB&A archaeologists documented an additional 52 sites in the claim block area and added them to the AHRS database. In 2011, SRB&A revisited six AHRS sites (ILI-00201, ILI-00202, ILI-00205, ILI-00219, ILI-00220, and ILI-00252) that SRB&A originally identified in 2007, 2008, and 2010. Subsequently, SRB&A recommended ILI-00201, ILI-00202, ILI-00205, ILI-00219, and ILI-00220 should not retain their AHRS designation because four of the sites were based on naturally modified stones, and one site was modern in age. After site revisits in 2012, SRB&A recommended that an additional seven AHRS sites (ILI-00203, ILI-00204, ILI-00207, ILI-00208, ILI-00213, ILI-00229, and ILI-00233) that SRB&A identified in 2006, 2007, and 2009 should be removed from the AHRS because the sites are likely modern, or are based on naturally modified stones. In total, 12 AHRS sites were removed from the AHRS database.

In summary, there are currently 43 reported cultural resources sites with an AHRS designation in PLP's larger mine study area, as reported in SBR&A 2011a, 2015a, and 2015b. None of the 43 AHRS sites in the claim block area have been evaluated for NHRP eligibility. As of 2012, SRB&A has surveyed 14,912 acres in the larger mine study area, and excavated 1,103 subsurface tests. Additional analysis of the geographic extent of these surveys and site tables is presented in Section 3.8, Historic Properties, and Appendix K3.8.

Place Names

SRB&A also reviewed place name data sources, and compiled a place name database and corresponding map of known place names for the Bristol Bay and Cook Inlet areas based on these sources and SRB&A interviews (Evanoff 2010; Krieg et al. 2003, Kari, Kari, and Balluta 1986; Kari and Kari 1982). Table 22-3 and Figures 22-20 through 22-22 of the SRB&A 2011a report show the location of documented place names in the Bristol Bay drainages, mine study

AMERICAN OVERSIGHT

area, and the Cook Inlet drainages, which are also all listed in Appendix 22A of that report. Table 22-8 in the supplemental EBD (SRB&A 2015a) conveys related information about Dena'ina and Yup'ik place names in the PLP mine study area; and Figure 22-7 in that report shows Native place names in the vicinity of the claim block boundaries. The figure does not depict place names directly in the general deposit location indicated on the map, but place names are noted near the deposit on the South Fork Koktuli River, Upper Talarik Creek, and points north, west, and south of the claim block area, particularly along the Newhalen River to the east and near Nikabuna Lakes to the north. Further analysis is in progress to investigate the location of these place names relative to the current project component footprints. It is expected that additional information on place names will be learned during consultation and further analysis may be incorporated into the Final EIS.

Cultural Resources

Boraas and Knott (2013) note that the "Yup'ik and Dena'ina consider the land and waters to be their scared homeland," and census data presented in their reports also note Alutiiq populations in Igiugig and Kokhanok, the latter village being near the proposed south ferry terminal and terminus of the access road from Amakdedori port. Salmon, and the waters that support them, are crucial elements of this homeland, and therefore may be considered as part of the cultural resource landscape. Interrelated to salmon are the wild foods and harvest areas (e.g., upland subsistence areas, fishing and hunting camps). Further research and analysis is ongoing regarding these types of cultural resources, and identifying specific locations in or near the current project through further consultation. The 1,154 cultural resource features identified by SRB&A based on interviews are presented in Table 22-9 (SRB&A 2011a), displayed on Figures 22-23 through 22-25d, and listed in Appendix 22B of that report. Recent data provided by PLP in October 2018 (SRB&A 2018b) provide tables and maps for an additional 537 cultural features identified during the 2013 interviews.

Although additional research will occur during the NHPA Section 106 consultation process, the development of the PLP Cultural Resource Management Plan, and state and federal permit application review. Current data support the likelihood of a wide variety of cultural resources being present across the mine site (and other project components) that may be affected by the project, and must be taken into consideration during the NEPA analyses. A sample of cultural resource types identified by interviewees from Nondalton includes cabins, camps, graves, harvest locations, villages, spiritually important places, battlegrounds, material sources, routes, trails, and traplines. Subsistence maps demonstrate overlap with the mine site area, and harvest areas for resources such as, but not limited to berries, upland game birds, waterfowl, caribou, and moose supporting communities such as Newhalen, Nondalton, Iliamna, and Kokhanok. Additional information on subsistence harvests is presented in Section 3.9, Subsistence, and Appendix K3.9.

Boraas and Knott (2013) also detail Yup'ik and Dena'ina spirituality. Cultural relationships with the wild animals and fish are of primary importance, and some places have taken on special importance as sacred sites and landscapes, including known travel routes and traditional use areas. The Boraas and Knott report tells of one travel route, the Dena'ina trail connecting Old Iliamna and Kamishak Bay on Cook Inlet (and locations along the route), as being culturally and spiritually significant. No TCPs or cultural landscapes have been formally identified in the mine site area (or in other project components). However, there is clear potential throughout the project area for the presence of sacred sites, spiritual places, indigenous routes and trails, cultural landscapes, and TCPs. SRB&A also reports on oral interviews they conducted for cultural resources in Kokhanok, Newhalen, Nondalton, and Port Alsworth; and subsistence interviews in 19 Bristol Bay drainages study communities (SRB&A 2011a); and the results

AMERICAN OVERSIGHT

(e.g., notes, transcripts, and maps) of that work may contain information regarding the identification and location of additional cultural resources. It is expected that ongoing consultation will result in the identification of additional cultural resource locations.

Specific to routes and trails, Figures 22-17 and 22-20 (SRB&A 2014) show interview-identified routes and trails investigated in 2011 and 2012, respectively. The maps show five routes and trails in the claim block area for the 2011 investigations, and 19 routes and trails identified and investigated in 2012 that intersect the claim block area. GIS analysis and supplemental research identifying routes in the cultural resource analysis area is in progress to verify where identified trails intersect project component areas. SRB&A did not find any physical evidence of these trails, but only investigated areas where trails intersected areas where ground-disturbing actions were proposed. Evanoff (2010) also documents access routes and seasonal travel locations for subsistence use that will inform a closer examination of routes and trails and their cultural significance.

3.7.4.2 Transportation Corridor

The transportation corridor includes the overland route from Amakdedori port to the south ferry terminal near Kokhanok; ferries across Iliamna Lake to a north ferry terminal; with an access road leading north of the lake to the mine site and spur road to Iliamna. Figure 22-1 (SRB&A 2015a) depicts the study area boundaries used by SRB&A for cultural resource investigations in support of the EBD. The mine study area boundary encompasses the portion of the transportation corridor north of Iliamna Lake, and the discussion of cultural resources above for the mine site is applicable to this section of the transportation corridor. Additional work may be necessary to identify other undiscovered cultural resources in the transportation corridor north of Iliamna Lake, because the field efforts by SRB&A focused primarily on the mine site. However, the background research, including the ethnographic and traditional knowledge reports (Evanoff 2010; Boraas and Knott 2013), place name data, and interview-identified cultural features (SRB&A 2011a, 2015a, and 2015b) cover the region through which the northern portion of the transportation corridor crosses. For example, Figures 22-24a, and 22-25d (SRB&A 2011a) show trails/routes, camps, traplines, cabins, reindeer stations, battle sites, burial areas, locations with indigenous place names, villages, caches, and other cultural features throughout the mine site area and this northern portion of the transportation corridor. Appendix 22B (SRB&A 2011a) lists and describes each of the features identified on these maps. Further GIS analysis is in progress to determine if there are specific AHRS sites and cultural resource locations in this portion of the transportation corridor.

Known AHRS Resources

A cultural resources desktop analysis completed by ASRC (2017) indicated that the transportation corridor from Amakdedori port to the mine site has not been subject to archaeology survey or broader cultural resources investigations. That report summarizes 13 known AHRS sites composed of archaeological sites, village sites, cemetery, and historic buildings. None of the listed AHRS sites are in the footprint of the transportation corridor, although the proposed spur road to Kokhanok leads to AHRS sites, such as ILI-00008, Old Kakhonak, and historic buildings in Kokhanok (ILI-00025 Saints Peter and Paul Chapel). Five of these sites are discussed below under sites near Amakdedori port (ILI-00007, ILI-00044, ILI-00104, ILI-00136, and ILI-00291). The remaining eight sites are detailed in Section 3.8, Historic Properties, and Appendix K3.8. These sites include a cluster of sites in and around Kokhanok Village near the southern ferry terminal, and along the southern shore of Iliamna Lake. The other sites are more isolated. Further work is required to identify potential cultural resources sites within the transportation corridor, including predictive modeling, more detailed literature

AMERICAN OVERSIGHT

review, field survey, and consultation, which may result in the identification of additional archaeology sites, historic buildings, and cultural resources. This work may be addressed in the Section 106 PA, the PLP Cultural Resources Management Plan, and conditions of approval of state and federal permits associated with the project.

Place Names

The transportation corridor has not been subject to specific place names research or more detailed ethnographic or traditional ecological knowledge investigations. This area largely falls outside the study areas used to guide previous PLP surveys. Data from other sources cited above in the mine site section would contribute to understanding the location of native place names in this component. The SRB&A place name map shown as Figure 22-20 (SRB&A 2011a) does not reveal many place names in this area in comparison to the research completed for the mine site, transportation corridor, and ECIBSA (note that the transportation study area used by SRB&A is east of the mine site, and not applicable to this corridor).

Cultural Resources

This area remains in the homeland of the Dena'ina and Yup'ik, and the discussion above in the mine site section regarding the status of knowledge about cultural resources is applicable here. A data gap for other cultural resources in the transportation corridor remains, and additional research and analysis, would facilitate more detailed characterization of the affected environment of this project component. For example, cultural features, particularly from informants in Kokhanok, are shown throughout the transportation corridor (SRB&A 2018b). These features include villages, graves/burials, cabins, material sources, harvest location areas, camps, spiritually important places, battlegrounds, trails/routes, traplines, and materials sources across the landscape. GIS analysis will facilitate which of these features occur in the project footprint. Traditional land use is further evidenced in this area by current subsistence use throughout the area. Community subsistence data show harvest areas for plants, moose, caribou, brown bear, and other resources supporting the nearby villages, such as Iliamna, Kokhanok, Igiugig, and Newhalen. This land use, coupled with the location of known AHRS sites in the vicinity, such as the Gibraltar Lake Village and Amakdedori Village (see below), and the interview-identified data, demonstrate a high likelihood of cultural resources located throughout the transportation corridor, including the possibility of places of traditional religious and cultural significance, cultural landscapes, and TCPs.

3.7.4.3 Amakdedori Port

Amakdedori port falls within the ECIBSA used by SRB&A to frame the background research and characterize cultural resources in broader areas of interest in the lower Cook Inlet region (SRB&A 2015b). Much of the specific field work and research initially focused on the "original" Cook Inlet drainages study, which included the coast north of Ursus Cove to south of Tuxedni Bay, with an emphasis on the Knoll Head Offshore Area and Diamond Point Area. Field work was completed at Y Valley and along Sunday Creek in this region, and place name research also focused on this area, particularly along the existing overland route (Williamsport-Pile Bay Road) from the Diamond Point port site to Pile Bay. The result is that a more limited set of data is available for characterizing the affected environment at Amakdedori, and many of the data gaps discussed earlier apply to this area as well.

Known AHRS Resources

SRB&A's review of the AHRS database identified 58 previously documented AHRS sites within the entirety of the ECIBSA, two of which (ILI-00185 and ILI-00186) were documented by

AMERICAN OVERSIGHT

SRB&A during the 2005 field season. The 58 AHRS sites identified prior to SRB&A's 2012 surveys in the ECIBSA, as well as the three sites identified by SRB&A in 2012, total 61 documented sites across the ECIBSA. SRB&A crews surveyed a proposed weather station and separate repeater tower location near Amakdedori port, but did not identify any new archaeological sites (SRB&A 2014). Specifically related to offshore cultural resources, SRB&A reviewed two online databases of shipwrecks, including the National Oceanographic and Atmospheric Administration, Automated Wreck and Obstruction Information System database, and the Bureau of Ocean Energy Management, Alaskan Shipwreck Database.

There are only two known sites reported in the vicinity of the Amakdedori port (see Section 3.8, Historic Properties, and Appendix K3.8). Archaeologist Douglas Reger (1980) reported Amakdedori Village (ILI-00044) as dating to the turn of the twentieth century, and composed of several house and cache pits at the mouth of Amakdedori Creek. The other site, (ILI-00291) is the reported location of the AGRAM shipwreck dating to 1923. In addition to these known sites, PLP retained HDR to complete a cultural resource survey of the proposed port location. The full report is still in progress, but the interim memorandum describes an additional prehistoric site (HDR-AMK-01), a lithic surface scatter near the northern end of the port facilities where the transportation corridor enters the port. The report also corrected GPS data for ILI-00044, moving the village further north and within the southern boundary of the port facility. Further work on site delineation would likely occur as part of the NRHP eligibility evaluation process, which is discussed further in Section 3.8, Historic Properties.

Place Names

As noted above, data pertaining to native place names along the transportation corridor and at Amakdedori port have not yet been provided, collected, or assessed. The place names research is incomplete, because it focused on the northern portion of the ECIBSA, and does not extend to the port facility or the beginning of the transportation corridor.

Cultural Resources

In addition to the known AHRS sites discussed above, feedback received during the EIS scoping period suggests that there are known grave locations at Amakdedori, although specific locational information has not yet been attained. Residents of the Lake and Peninsula Borough also refer to "old cabins, trails, and [the] village" as having personal meaning to many who reside in the borough." This feedback suggests that there are more cultural resources near Amakdedori port, and indicates that further consultation and field studies could result in the identification of more cultural resources in this area. Interview-identified sites also mention a village with graves/burials and house pits at Amakdedori, and one trail from the head of Sid Larson Bay to the Cook Inlet coast that crosses near Amakdedori (SRB&A 2018b). In progress GIS analysis of the interview-identified data could help better demonstrate the proximity of these cultural features to the port site.

The presence of graves, trails, cabins, and known prehistoric and historic resources indicates the potential for a broad range of resources to be located at Amakdedori port. The GIS analysis demarks the coastline near Amakdedori as favorable beach lands for the harvest of coastal subsistence resources, which suggests a higher potential for identifying cultural in the general area (Figures 50-5 and 50-7; SRB&A 2015b). Additional research could result in the identification of more cultural resources, including routes and trails, and other land use areas significant to the local villages and others. Additional research may include identification and analyses of TCPs, cultural landscapes, and other types of cultural resources.

AMERICAN OVERSIGHT

3.7.4.4 Natural Gas Pipeline Corridor

No work has been done regarding marine archaeology or historic maritime archaeology for the Iliamna Lake crossing or Cook Inlet crossing, so there is currently no information regarding the affected environment for this portion of the natural gas pipeline route. Similarly, additional research and interdisciplinary research would characterize the affected cultural environment as it relates to coastal (Iliamna Lake and Cook Inlet) resource gathering and any associated traditional use areas or other cultural resources. The natural gas pipeline corridor is adjacent to the transportation corridor from the Amakdedori port site to mine site, and is described above.

There are no sites currently listed in the AHRS in the area where the compressor station would be constructed on the Kenai Peninsula.

3.7.5 Action Alternatives 2 and 3

Cultural resources at the mine site would be the same as described for Alternative 1.

3.7.5.1 Transportation Corridor

These alternatives fall in the northern portion of the ECIBSA, and as a result, represent an area that was subject to comparatively more background research for cultural resources by SRB&A than the southern portion of the transportation corridor near Amakdedori port. SRB&A conducted limited field work in this area's transportation corridor study area, which involved examinations of land along the western side of the Newhalen River between Nondalton and Iliamna, as well as a drilling-core storage area in Iliamna, both visited in October 2006 (SRB&A 2011a). SRB&A also completed field work along Sunday Creek and in Y Valley, near Knoll Head (SRB&A 2015b); however, this field work is not near any portions of the currently proposed project footprint, and is not directly applicable to the present analysis.

Alternatives 2 and 3 would cross an area that is also closer to Lake Clark National Park and Preserve than Alternative 1; there have been ethnographic/place name studies and cultural landscape analyses completed for the park that are generally applicable to Alternatives 2 and 3. Analysis is ongoing, and the discussion below is preliminary. Initial research indicates that the existing Williamsport-Pile Bay Road and the new road and/or pipeline from Diamond Point to Pile Bay, and then from Eagle Bay to the mine site, have not been surveyed for archaeological sites, nor been subject to specific research for other cultural resources along the footprint of the currently proposed corridor. The area does fall within the original transportation study area (SRB&A 2011a), so there are data gathered for place names and interview-identified cultural features.

Known AHRS Resources

More detailed analysis of AHRS sites and document references are in progress. [Note to reader: Data is pending receipt of RFI 097.] A review of AHRS data indicates six AHRS sites in the project footprint between Diamond Point and Pile Bay along the Williamsport-Pile Bay Road. No further known AHRS sites are in the road corridor from the Eagle Bay ferry terminal to the mine site. AHRS sites include the Pile Bay Townsite Historic District (ILI-000198) and associated historic-era resources at Pile Bay, such as the O'Hara House (ILI-00197), The Vantrease Power Plant (ILI-00200), and the base of a radio antennae used by Carl Williams (ILI-00199). The Williamsport-Pile Bay Road itself is a historic linear feature (ILI-132), and there is an Alaska Road Commission camp adjacent to the road (ILI-00244). Near the Cook Inlet shore is the Williamsport Historical Occupation/Land Use Area (ILI-00247).

AMERICAN OVERSIGHT

Five miles of the proposed road from Diamond Point to Pile Bay would overlap with the existing Williamsport-Pile Bay Road, resulting in essentially new construction (including features such as material sites and staging areas). There is no ferry terminal at Eagle Bay, and the road from that location to the mine site would also be new construction. Further information collection is in progress through a GIS analysis and the NHPA Section 106 consultation process.

Place Names

Figure 50-11 in SRB&A (2015b) depicts over 60 place names around Iliamna Bay on Cook Inlet and along the current road to Williamsport-Pile Bay Road. A GIS analysis is in progress to compare place name data for the proposed project. There may be more place names present along the road from Eagle Bay to the mine site, particularly because this road crosses the Newhalen River and a number of other tributary creeks along the northern shore of Iliamna Lake. Many place names in Figure 50-11 (SRB&A 2015b) are located on the existing road or in the viewshed of the current road, and would be intersected by the project. If ongoing studies result in the identification of additional place name data, this information will be integrated into further analyses.

Cultural Resources

In addition to place names, the presence of archaeology sites coupled with subsistence data, suggest the potential for cultural resources throughout Alternatives 2 and 3. Iliamna Lake and the coastal areas are used for marine resource harvests (e.g., freshwater seals, salmon), and the upland areas are used for hunting upland game birds, waterfowl, caribou, moose, and other small mammals; and harvesting berries, wood, and other plant resources (see Section 3.9, Subsistence).

The discussion for the transportation corridor for Alternative 1 also applies here with respect to the review of coastal-oriented cultural resources along Cook Inlet and Iliamna Lake. The SRB&A GIS Coastal Subsistence Resource Analysis (Figure 50-5, SRB&A 2015b) defines favorable beach types for harvest in Iliamna Bay, and the model identifies Iliamna Bay as having concentrated resources (i.e., greater than or equal to 10 resources).The land use based on subsistence activities, coupled with known archaeological sites evidencing prehistoric, proto-historic, and historic occupations, collectively suggest that a number of other cultural resources exist throughout the Alternatives 2 and 3 areas. SRB&A reports on interview-identified sites in the original transportation corridor (Figure 22-25s, SRB&A 2011a) that included battle sites, reindeer stations, villages, other sites, caches, trails/routes, traplines, camps, burials, and locations with indigenous place names. More recent (SRB&A 2018b) interview-identified sites, particularly from informants in Pedro Bay, identify over 50 cultural resource features, including places of spiritual importance. Boraas and Knott (2013) tell of a significant site, the Giant's Rock (Dzelggezh) along the Williamsport-Pile Bay Road, that held spiritual significance and was later dynamited in 1955 as part of road construction (Boraas and Knott 2013). The report also indicates the Williamsport-Pile Bay Road follows an old Dena'ina trail. Additional analysis is required to better characterize these resources, and to identify TCPs, cultural landscapes, and other cultural resource site types in the affected environment for each alternative. [Note to reader: Data is pending receipt of RFI 097.]

3.8 HISTORIC PROPERTIES

The US Army Corps of Engineers (USACE) applies the Procedures for the Protection of Historic Properties (33 Code of Federal Regulations [CFR] 325, Appendix C) to guide its process of complying with Section 106 (54 US Code [USC] 306108) of the National Historic Preservation Act (NHPA) (54 USC 300101 et seq.). Appendix C offers specific definitions of historic properties, such as "a property which has historical importance to any person or group. This term includes the types of districts, sites, buildings, structures, or objects eligible for inclusion, but not necessarily listed, on the National Register" (33 CFR 325 (1)(b). Appendix C also defines "Designated Historic Properties" as "historic propert[ies] listed in the National Register of Historic Places (National Register) or which have been determined eligible for listing in the National Register. A historic property that, in both the opinion of the [State Historic Preservation Officer] and the [US Army Corps of Engineers] district engineer, appears to meet the criteria for inclusion in the National Register will be treated as a designated historic property" (33 CFR 325 (1)(a)). Federal agencies must consider impacts to all types of cultural resources, including those that do not meet the definition of historic properties as set forth in the NHPA, and Appendix C and its implementing regulations. Please refer to Section 3.7, Cultural Resources for National Environmental Policy Act (NEPA) based definitions and analyses. Permitting the construction, operations, and closure of the Pebble Project would require the USACE's compliance with Appendix C.

Under 36 CFR 800, there are different definitions in Appendix C for historic properties and the geographic area where identification, evaluation, and effects assessments are needed. Also under 36 CFR 800, the federal agencies must carry out all the steps of the Section 106 review in consultation with the SHPO and other consulting parties, including Alaska Native tribes, which—for purposes of Section 106—includes Alaska Native Regional or Village Corporations. The scope of the identification effort, determinations of eligibility and effect, and steps to resolve adverse effects must be informed by the traditional knowledge of Tribes who ascribe value to such properties.

Appendix C does not involve the same consultation process as 36 CFR 800 outlines. 33 CFR 325(8) states that, "at any time, the district engineer may consult with the involved parties to discuss and consider possible alternatives or measures to avoid or minimize the adverse effects of the proposed activity." Consultation with involved parties was initiated by the USACE on August 17, 2018.

3.8.1 Data Gap Summary

Information in this section is currently based on data derived from the Alaska Heritage Resources Survey (AHRS) and the series of cultural resource reports prepared for the Pebble Limited Partnership (PLP) by Stephen R. Braund and Associates (SRB&A) between 2004 and 2013, particularly the summary reports included in the Environmental (and Supplemental) Baseline Documents (EBDs) for cultural resources covering the Bristol Bay and Cook Inlet Regions (SRB&A 2011a, 2015a and 2015b). A detailed review of other resources referenced in the AHRS document repository is currently underway and results from that review will be incorporated into this analysis. [Note to reader: Data is pending receipt of RFI 097.] In addition to the information gaps and resultant status of research and analysis, there are particular data gaps pertinent to the identification and evaluation of historic properties. These include:

- Preliminary review of the AHRS sites within the project footprint suggests that none of the sites have been evaluated for inclusion in the National Register. The sites are

AMERICAN OVERSIGHT

presumably important to any person or group, but it remains unclear if these sites meet the National Register Criteria.

- The proposed transportation and pipeline corridors for each alternative and Diamond Point have not been systematically surveyed for historic properties. These studies will be conducted in accordance with the NHPA Section 106 process, and the results incorporated into the ongoing analysis. Results reported herein are based on currently available information and will be revised as appropriate to incorporate additional findings. The need for and scope of additional survey will be defined in a Programmatic Agreement (PA).
- Analysis of survey coverage for areas that have been surveyed remains in progress at this time. For example, the mine site has been largely surveyed, but geographic information system (GIS) data are being calculated to determine acreage of surveyed versus unsurveyed lands in that project component.
- GIS modeling used to delineate areas of low potential (as developed and implemented by SRB&A) is in the process of being analyzed to determine how many acres of high-potential lands exist versus low-potential lands in the project components.
- Consultation with involved parties was initiated by the USACE via letters distributed to potentially involved entities on August 17, 2018. While underway, the Draft EIS and Section 106 processes have not yet produced additional information regarding the identification and evaluation of historic properties in the permit area. Guidance for ongoing identification and evaluation of historic properties will be incorporated into the PA.
- The permit area has not yet been geographically defined. The analysis in this section focuses on the footprint of the proposed facilities for each alternative. The permit area will be determined during the NHPA Section 106 consultation process.

It is expected that the USACE will be addressing these data gaps throughout its Section 106 consultation process. The procedures detailing further work beyond the issuance of the Final EIS (e.g., the process for additional identification research and surveys, evaluation, and mitigation measures) will be established through the development of a PA.

3.8.2 Permit Area

Appendix C defines the term "permit area" as the geographic extent of the USACE's responsibility for considering effects on historic properties, which varies from the Area of Potential Effect as defined by 36 CFR 800.16(d). Permit area defines "those areas comprising the waters of the United States that will be directly affected by the proposed work or structures and uplands directly affected as a result of authorizing the work or structures" (33 CFR 325 (1)(g). Three tests must be satisfied for inclusion in the permit area:

1. Such activity would not occur but for the authorization of the work or structures in the waters of the US;
2. Such activity must be integrally related to the work or structures to be authorized in waters of the US. Or, conversely, the work or structures to be authorized must be essential to the completeness of the overall project or program; and
3. Such activity must be directly associated (first order impact) with the work or structures to be authorized.

The permit area for the project has not yet been formally adopted and will be finalized during the NHPA Section 106 consultation process and development of the PA. The site tables and

AMERICAN OVERSIGHT

information presented in Appendix K3.8 are based primarily on AHRS sites identified within the project component footprints. This Draft EIS and initial reliance on AHRS data for defining potential historic properties will be addressed through ongoing consultation as part of the Section 106 process. Methods and approaches to completing determinations of eligibility will be provided in the PA.

GIS data are in the process of being analyzed for interview-identified routes and trails, areas with indigenous place names, and a multitude of other cultural resource features to allow for a comparison of those locations to the project footprint (as presented in SRB&A 2011a, 2015a, and 2015b). As noted in Section 3.7, Cultural Resources, the mine site, transportation corridor, and Expanded Cook Inlet Baseline Study Area areas do contain interview-identified routes and trails, subsistence use areas, place names, and other cultural resources features that may qualify as historic properties under Appendix C. It is expected that the GIS data and additional information gleaned through the Section 106 consultation process will further refine the extent and nature of other historic properties and the consideration of effects on historic properties.

As noted by SRB&A (2014) and until further National Register evaluations take place, it may be recommended that any cultural resources (including archaeological sites, trails and routes, traditional cultural properties, cultural landscapes, locations with indigenous place names, burial areas, resource-gathering areas, or other sites of religious or cultural significance) be considered as potentially eligible properties for the consideration of additional identification, evaluation, and effect assessments. Currently, there are no National Register eligible sites in the project footprint; however, research on AHRS resources in the study areas for the action alternatives is ongoing, and there may be eligible sites in those components. There are numerous cultural resource features spread across the landscape (See Section 3.7, Cultural Resources) that represent a wide range of site types. Many of these may warrant additional analysis as potential historic properties. Further identification efforts under Section 106 may also involve the analysis of cultural landscapes, traditional cultural properties, and/or archaeological or historic districts in the permit area.

3.8.3 Action Alternative 1 – Applicant's Proposed Alternative

3.8.3.1 Mine Site

As presented in Section 3.7, SRB&A (2015a) reports on the identification of 43 cultural resource sites in PLPs mine study area, which are now entered into the AHRS database. The mine study area is geographically larger than the mine operations footprint. Refer to SRB&A 2015a for detailed information on the 43 sites identified. Of these sites, two are currently in the mine operations footprint (ILI-00218 and ILI-00251). Sites are listed in Appendix K3.8.

3.8.3.2 Transportation Corridor

There are no reported AHRS resources in the transportation corridor. The data gap assessment report prepared by ASRC (2017) reports on AHRS sites near the corridor (see Section 3.7, Cultural Resources). As with the mine site, it is expected that this list will grow through ongoing consultation and incorporation of data from additional investigations regarding cultural resources and historic properties in the transportation corridor. Sites are listed in Appendix K3.8.

3.8.3.3 Amakdedori Port

Recent work completed by HDR (2018) archaeologists on behalf of PLP resulted in the identification of one new archaeology site in the Amakdedori port facility boundaries (HDR-AMK-01) (see Section 3.7, Cultural Resources). The GPS data for Amakdedori Village (ILI-00044)

AMERICAN OVERSIGHT

was also corrected, and that site is now within the southern boundary of the facility footprint. The desktop analysis completed by ASCR (2017) listed another five sites in the vicinity, but outside the port boundaries. One other site, ILI-00291, is the AGRAM shipwreck, and is within the boundaries of the offshore development. Sites are listed in Appendix K3.8.

As noted in Section 3.7, Cultural Resources, public feedback from involved parties indicates the presence of graves, cabins, trails, and the village, suggesting that additional investigations may lead to the identification of other cultural resources in the port area that may qualify as historic properties under Appendix C, and also will be assessed under NEPA.

3.8.3.4 Natural Gas Corridor

There are currently no AHRS sites identified in the natural gas pipeline corridor; and for Alternative 1, this gas pipeline is co-located with the transportation corridor, and the discussion above applies here. As noted in Section 3.7, Cultural Resources, no work has been completed to research and investigate the potential for marine archaeology or historic-era maritime archaeology sites along the corridor, with the exception of the previously identified AGRAM shipwreck (ILI-00291). This aspect of needed identification efforts will be addressed through the ongoing Section 106 process.

3.8.4 Action Alternatives 2 and 3 – North Road and Ferry or North Road Only

The discussion of the northern route applies to Alternatives 2 and 3 (see Section 3.7, Cultural Resources). A preliminary review of the AHRS data indicate that there are several AHRS sites in or near the proposed road corridor between Diamond Point and the mine site, including the Williamsport-Pile Bay Road itself, and the historic-era sites and buildings on each end of the existing road (listed in Appendix K3.8). There are no recorded AHRS resources in the overland portion of the pipeline route from Ursus Cove to Cottonwood Bay. No fieldwork specific to survey of this project's components has occurred in the transportation corridor, with the exception of limited investigations by SRB&A near Iliamna and along the Newhalen River, which involved examinations of land along the western side of the Newhalen River between Nondalton and Iliamna, as well as a drilling-core storage area in Iliamna, both visited in October 2006 (SRB&A 2011a).

As noted previously, the incorporation of additional data (e.g., interview-identified cultural resources in SRB&A 2015a), review of AHRS site references, further identification efforts through consultation, research, and fieldwork will add to the list of known cultural resources that may be potentially eligible for the National Register in Alternative 2 and Alternative 3.

4.7 CULTURAL RESOURCES

This section discusses the environmental consequences that construction, operation, and closure of the project would have on cultural resources. Section 4.8, Historic Properties, focuses specifically on the consideration of effects on Historic Properties as defined by Appendix C (of 33 Code of Federal Regulations 325) and the National Historic Preservation Act (NHPA). For the purposes of this section, the broad definition of cultural resource types is maintained as described in the affected environment (Section 3.7, Cultural Resources). Cultural resources may range from prehistoric archaeology sites, traditional cultural properties, place names, traditional resource collecting areas (subsistence), sacred or religious sites, and historic-era sites such as cabins or shipwrecks. Currently, the project footprints for the mine site, the transportation corridor, Amakdedori port, and the natural gas pipeline guide the analyses of environmental consequences on cultural resources. When cultural resources are identified within a part of the project footprint, direct, indirect, and cumulative effects that may result are considered. The potential for indirect effects is also considered, particularly visual impacts on cultural resources outside of the project footprint.

4.7.1 Analytical Limitations

Not all of the current locations of project components have been inventoried for cultural resources during the previous baseline studies completed by the Pebble Limited Partnership (PLP) between 2004 and 2013, and summarized in the Environmental Baseline Reports (SRB&A 2011a, 2015a and 2015b). Only the current configuration of the mine site has been subjected to more systematic cultural resource field investigations. The previous PLP investigations completed background literature and file reviews for a broader regional area, and conducted interviews to identify cultural resources, place names, and land use areas in and near the project as it was proposed at the time. These data are supplemented by other sources of ethnographic, traditional knowledge, and subsistence investigations that cover all or portions of the study area (see Section 3.7, Cultural Resources, for a preliminary list of these additional sources). The information contained in them is integrated into the Draft Environmental Impact Statement (EIS) analysis to the extent feasible. Further investigation is occurring through the National Historic Preservation Act (NHPA) Section 106 process (see Section 3.7, Cultural Resources), which may result in the identification and analysis of additional resources.

The current data and analytical gaps allow for a limited discussion of the environmental consequences, and the ability to compare the relative impacts of one alternative over another is currently constrained, because the number and types of resources that may be impacted are not fully known. Where site-specific surveys have not been completed, site-specific impacts are undeterminable at this time, as is the ability to quantify the number of resources affected or impacted by the proposed project and alternatives. Based on interview-identified cultural resource features and initial review of other ethnographic and place names data, it is assumed that a wide range of cultural resources exist across the landscape, and are within the project footprint. Additional gaps in data and analysis are reviewed in Section 3.7, Cultural Resources, and Section 3.8, Historic Properties. As is usual where systematic cultural resources field studies have not been completed at the time of submittal of permit applications, the qualitative and quantitative impacts discussion will be refined through consultation and additional studies. In addition, it is not atypical during the National Environmental Policy Act (NEPA) process that field surveys by the applicant focus solely on the proposed action and have not been conducted for alternatives. Specifically, the US Army Corps of Engineers (USACE) will be addressing these data gaps throughout its Section 106 process. The procedures detailing further work beyond the issuance of the Final EIS (e.g., the process for additional identification research and surveys,

AMERICAN OVERSIGHT

evaluation, and mitigation measures) will be established through the development of a Programmatic Agreement (PA).

4.7.2 Impacts to Cultural Resources

All of the action alternatives have the potential for direct impacts to cultural resources from the construction, operation, reclamation, and closure of the project. Necessary ground-disturbing actions involved with constructing and operating the mine and its facilities (i.e., transportation corridor, natural gas pipeline, and port facilities) can destroy, remove, or otherwise damage cultural resources. These types of direct effects are irreversible and permanent. For example, an archaeological site or spiritual object cannot be reconstructed once gone, and the significance (both cultural and scientific) is lost.

Indirect impacts are those that occur later in time or that are further removed in distance from the initial and primary action. For example, the presence of new visual elements, noise, and pollution can impact aspects of a cultural resource from which they derive their significance. There is potential for permanent visual effects that alter the viewshed to or from a cultural resource, particularly where setting and feeling are important aspects of the site's importance. Access restrictions, noise, pollution, lack of privacy, and visual intrusions can all negatively impact cultural landscapes, traditional cultural properties, and sites of religious or ceremonial significance, including burial grounds. Increased access to archaeology sites resultant from constructing the mine access road could lead to inadvertent or purposeful negative effects on cultural resources, such as looting, vandalism, or trespass in culturally sensitive areas.

Subsistence, as a way of life, would apply to the context of cultural resources throughout the analysis area, so they are broad in geographic scope and applicable at a regional level. The construction of the project and related infrastructure could impact the availability and access to subsistence resources, which would alter the manner in which people interact with their natural surroundings, although the highest intensity of impacts would occur nearest to the project and would diminish in intensity with distance (see Section 4.9, Subsistence). These impacts would last through the project operations, and would cease when subsistence resources are re-established after closure. Although there is a time horizon for the mine and subsequent closure and reclamation actions that might restore the visual and natural environments, the damage to other types of cultural resources that may have occurred may not be able to be restored to their status prior to project implementation.

Avoidance, minimization, and mitigation for potential impacts to cultural resources are a focus of the PA that would result from the NHPA Section 106 consultation process. PLP would also develop a Cultural Resources Management Plan to address the process for managing effects to cultural resources, and ensure that agreed upon protocols and procedures are established and followed. In general, NEPA and NHPA mitigation measures involve strategies such as modifying the project to avoid impacts to sites potentially in the project footprint and addressing sites in the area of potential effects. It is expected that the NEPA public process and the NHPA Section 106 consultation process will result in gathering information and perspectives on potential mitigation measures. These will be incorporated into the Final EIS and the PA.

In an area where the manner of how people interact with the natural environment is at the core of cultural beliefs, impacts of the project would be heightened, typically adverse, and may be permanent. Impacts on lifeway patterns, cultural and spiritual interactions with the environment, physical or indirect changes to archaeology sites, and other cultural resource types represent disruptions to the relationship between the people, and natural and cultural resources, and could impact the current and long-term health and vitality of their cultures.

AMERICAN OVERSIGHT

4.7.3 No Action Alternative

Under the No Action Alternative, the project would not be constructed; however, PLP would still be permitted to perform exploratory activities and research at the mine site and would be expected to do so. There would likely be no new impacts to known Alaska Heritage Resources Survey (AHRS) sites, and existing activities that impact place names or other types of cultural resources would continue at the current intensity.

4.7.4 Action Alternative 1 — Applicant's Proposed Action

4.7.4.1 Mine Site

As noted in Section 3.7, Cultural Resources, there are a number of cultural resources in or near the mine site area that may include AHRS-listed resources, routes/trails, resource gathering areas, place names, battle sites, reindeer stations, and camps. A complete survey of the project footprints, however, has not yet been conducted. Consequently, additional resources may be identified during additional surveys conducted in compliance with the Section 106 process.

Cultural resources in or near the mine site may be directly or indirectly impacted by construction and operation activities. Two known AHRS sites are in the mine site footprint. ILI-00251 is a small lithic scatter composed of two flakes, and falls within the proposed seepage collection system. This site would be destroyed by construction activities at that location. ILI-00218, a single microblade core, is within the footprint of the road along the eastern side of the water management pond, and would also be permanently destroyed as a result of construction activity.

Other cultural resources have been identified in the mine footprint, and Geographic Information System (GIS) analysis is ongoing to determine which of these resources intersect the footprint. There are no locations with native place names currently identified in the mine footprint, but interview-identified sites are present and consist primarily of trails/routes and traplines that cross through the area; and traditional use areas for fishing, trapping, caribou and moose hunting near Sharp Mountain, the headwaters of the Koktuli River, Frying Pan Lake, and Groundhog Mountain. Maps do not show any other types of interview-identified cultural resources (e.g. battlegrounds, camps and cabins, burial grounds, other culturally important areas). Stephen R Braund & Associates (SRB&A) did not find physical evidence of trails/routes during field inventory, and there may be no physical manifestation of this resource type in the mine area. Construction and placement of mine facilities would directly impact use of these trails/routes by interrupting and creating obstacles to the continuity of these linear features. To the extent these areas are used for hunting and trapping, mine construction and operation would disrupt the subsistence use patterns of the area, but physical disruption of cultural features on the ground (e.g., camps) is unlikely, because none are identified in the footprint. The impacts on traditional use areas would last for the duration of the mining operation, but would not be permanent.

Indirect impacts may include visual, atmospheric, and audible intrusions as a result of construction and operation activities, or disruptions to the subsistence lifestyle and increased presences of people in culturally sensitive areas. Analysis of sites that fall within the viewshed area is ongoing. Traditional use areas for fishing and hunting fall within the geographic extent of the mine site, and there are camps, cabins, and trials/routes surrounding the mine site. Archaeological and cultural sites identified in the claim block area, but outside of the mine footprint, include hunting camps composed of modern and historic rock features (e.g., tent rings), refuse (e.g., shell casings, plastic, food wrappers), and caribou antlers or bones. Other sites include isolated artifacts and lithic scatters. Indirect effects related to visual, audible, or atmospheric changes on archaeological sites are unlikely. Indirect effects on archaeological

AMERICAN OVERSIGHT

sites may occur due to increased population and use of the area that may result in site looting or trampling of site features—both purposefully, or inadvertently. Noise, the introduction of new visual elements in the landscape, and dust from construction and operation of the mine may impact use of traditional harvest areas identified near the mine, and this impact would decrease with distance from the mine site, but would last through the life of the mine and into closure. The camps, cabins, and sites would not be subject to indirect impacts as much as the use of the area due to resource displacement.

[Note to reviewer: A GIS analysis is being conducted to determine the extent that the mine site would directly impact cultural resources. Data will be part of RFI 097.]

4.7.4.2 Transportation Corridor

The southern transportation corridor is the component with the least amount of information from previous surveys. The transportation corridor (including the overland pipeline route and ferry terminals) would potentially subject cultural resources to the direct and indirect effects as characterized above. Direct impacts from road, pipeline, and ferry terminal construction are one aspect of the potential consequences for cultural resources. For example, any archaeological sites and cultural resources identified within the road, ferry terminal, and pipeline footprints would be permanently destroyed by construction activity. No AHRS sites have been identified in the footprint to date.

Part of the southern transportation route includes a spur road to Kokhanok, a village site that contains historic-era buildings identified in the AHRS (e.g., ILI-00025 Saints Peter and Paul Chapel and ILI-00262 Kokhanok BIA School). Direct or indirect impacts on these buildings or Old Kokhanok (ILI-0008) are not likely from the construction of a new access road to the village. The other previously identified sites in the vicinity of Kokhanok, such as the sites along the coast that include stone tools (ILI-00128) and the Napaimute village site (ILI-00009), are outside the project corridor and would not be subject to direct effects.

Indirect effects are primarily associated with the visual changes of introducing a new road and the potential for increased people, noise, and dust that would result from constructing a new road in a currently roadless area. Archaeological sites in the vicinity of the road could be subject to increased visitation and damage from use, vandalism, and trampling. Noise and visual impacts are less likely on archaeological sites.

There are a number of interview-identified cultural features north of Iliamna Lake to the mine site and south of Iliamna Lake and Amakdedori port, particularly those identified by informants in Kokhanok. For the portion between the port and Kokhanok, including spur roads and variants, these include points and lines/trails (e.g., the trail connecting Kokhanok to Gibraltar Lake and the walking/dog team trail from Sid Larson Bay to the Cook Inlet Coast). There are no points directly in the footprint (SRBA 2018); however, points in the vicinity include sites such as burials near Kokhanok and Gibraltar Lake village. The significance of these sites would be determined through the Section 106 process. The sites are subject to indirect effects, because noise and visual intrusions may affect qualities of these sites that contribute to their cultural significance and use. Burial sites and other spiritual sites may be impacted by traffic noise and visual intrusions of a new road in the vicinity. The discussion of impacts from disruption of traditional use areas in the mine site also applies here, although no specific traditional use areas are currently delineated on maps showing the interview-identified cultural resources. Indirect effects would last through operation of the transportation corridor.

North of Lake Iliamna and including the spur road to Iliamna, the transportation corridor also intersects interview-identified cultural resource locations, and there are cultural resources surrounding the corridor. These include harvest locations, spiritually important places (burials),

AMERICAN OVERSIGHT

camps, portages, cabins, and trails/routes. Traditional hunting grounds may be disrupted by traffic noise adjacent to the corridor, and this impact would diminish with distance from the road. Sites of spiritual significance may have the viewshed altered, and noise and dust may affect the setting and experience of these places. These impacts would last through construction and operation of the transportation corridor.

[Note to reviewer: A GIS analysis is being conducted to determine the extent that the transportation corridor would directly impact cultural resources. Data will be part of RFI 097.]

4.7.4.3 Amakdedori Port

The port facility area would also be subject to the direct and indirect effects, as characterized above. In addition to the three known sites (one village, one lithic scatter, one historic shipwreck), interview-identified data and public input suggest more cultural resources exist in this area; including, but not limited to, burials, cabins, and trails/routes. Additional consideration of the impacts on maritime archaeology would also need to be assessed for the port location in the PA.

Two archaeological sites are subject to direct impacts, because they all fall within the footprint, and would be permanently damaged or destroyed as a result of constructing the port facility. The revised location of Amakdedori Village (ILI-00044) places it in the southwestern portion of the main port facility near the water extraction site. The lithic scatter (HDR-AMK-01) is along the road north of the main port facility.

A limited number of additional cultural resources have been identified in the port facility. As noted in Section 3.7, Cultural Resources, locals report cabins, graves, and trails in this area; and one route, the trail to Sid Larsen Bay, is also identified in this location. The specific location and analysis of the extent of impacts on these sites is ongoing. These cultural resources are subject to indirect effects, including the introduction of new visual and audible elements in the vicinity that may disrupt setting and contemporary use of these cultural resources. These effects would last through the life of the project, based on the operation of the facility and use of the access road.

[Note to reviewer: A GIS analysis is being conducted to determine the extent that the port would directly impact cultural resources. Data will be part of RFI 097.]

4.7.4.4 Natural Gas Pipeline Corridor

The discussion about the environmental consequences of other project components also applies to the natural gas pipeline, particularly the direct and indirect impacts associated with the transportation corridor, because the pipeline is co-located with this corridor from Amakdedori port to the mine site. Regarding the Cook Inlet Crossing, no underwater archaeology or historic maritime investigations have occurred for the submerged portion of the pipeline. Any archaeological sites or shipwrecks in the alignment would be directly affected by construction. Cultural resources adjacent to the pipeline route under Cook Inlet may be subject to indirect effects from subsurface wave action and sediment disturbance.

4.7.5 Action Alternatives 2 and 3 – North Road and Ferry or North Road Only

Alternatives 2 and 3 would have the same potential for direct and indirect impacts on cultural resources at the mine site as discussed above for Alternative 1. The transportation corridor, Diamond Point port, and the natural gas pipeline would have the same types of potential effects as Alternative 1, but in different locations. They each involve construction of new roads, ferry terminals (Alternative 2 only), and overland pipeline routes between Diamond Point and the

AMERICAN OVERSIGHT

mine site. A review of AHRS data indicates six AHRS sites in the project footprint between Diamond Point and Pile Bay along the Williamsport-Pile Bay Road that would be permanently impacted by construction. The Williamsport-Pile Bay Road itself is a historic linear feature that would be permanently impacted in terms of potential modification and setting. These components cross through areas where there are known locations with indigenous place names, and interview-identified cultural features are present across the landscape.

[Note to reviewer: A GIS analysis is being conducted to determine the extent that the alternatives would directly impact cultural resources. Data will be part of RFI 097.]

4.7.6 Summary of Key Issues

Table 4.7-1 provides a summary of key issues.

Table 4.7-1: Summary of Key Issues for Cultural Resources

Project component	Alt 1 (+variants)	Alt 2 (+variants)	Alt 3 (+variants)
Mine Site			
AHRS sites (identified to date)	2 known sites in the footprint would be permanently impacted.		
Place names	No locations with place names in the footprint, but interviews identified trails/routes and traplines through the area. Construction and placement of mine facilities would directly impact trails/routes by interrupting the continuity of these linear features.		
Cultural resources	Traditional use areas for fishing, trapping, and hunting near Sharp Mountain, the headwaters of the Koktuli River, Frying Pan Lake, and Groundhog Mountain. Use of those areas for traditional purposes would cease through the life of the mine and into post-closure, although the mine site is not identified as a high frequency overlapping area for subsistence users.		
Transportation Corridor			
AHRS sites (identified to date)	None identified to date in footprint.	6 known sites in the footprint would be permanently impacted. The Williamsport-Pile Bay Road itself is a historic linear feature that would be permanently impacted.	
Place names	None identified to date in the area.	Over 60 known place names in the area from Iliamna Bay to the mine site.	
Cultural resources	Interview-identified cultural features in the area include trails from Kokhanok to Gibraltar Lake and Sid Larson Bay, and burial sites.	The same types of potential effects as Alternative 1, but in a different location. Traditional use areas include Iliamna Lake, and upland areas along the mine access roads and/or pipeline ROW.	
Amakdedori Port and Diamond Point Port			
AHRS sites (identified to date)	1 known site in the footprint would be permanently impacted, and 1 in the vicinity would be indirectly impacted.	None identified to date in footprint.	
Place names	None identified to date in the area.	Place names identified around Iliamna Bay.	
Cultural resources	Interviews suggest cultural resources in this area, including—but not limited	The same types of potential effects as Alternative 1, but in a different location. Iliamna Bay is a traditional use area.	

AMERICAN OVERSIGHT

Table 4.7-1: Summary of Key Issues for Cultural Resources

Project component	Alt 1 (+variants)	Alt 2 (+variants)	Alt 3 (+variants)
	to—burials, cabins, and trails/routes.		
Natural Gas Pipeline			
AHRS sites (identified to date)	Same as transportation corridor, except for the pipeline crossing Cook Inlet. No investigations have occurred for this portion of the pipeline. Any archaeological sites or shipwrecks in the alignment would be directly affected by construction.		
Place names			
Cultural resources			

4.7.7 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) have the potential to contribute cumulatively to effects on cultural resources, detailed in Section 4.1. These potential future actions are similar to the proposed actions in that each may result in direct and indirect effects on cultural resources, as discussed above. The following RFFAs identified in Section 4.1 apply to the consideration of cumulative effects on cultural resources.

- Pebble Project Expansion—develop 55 percent of delineated resources over a 78-year period
- Pebble South/PEB
- Big Chunk South
- Big Chunk North
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*
- Donlin Gold
- Diamond Point Rock Quarry
- ASAP
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Hydrocarbon Exploration
- LPB Transportation Projects
- LPD Capital Improvement Projects
- USDA Rural Development Projects
- LBP Renewable Energy Projects
- Nushagak Intertie Project
- Subsistence Activity
- Tourism, Recreation, Hunting, Fishing
- Scientific Surveys and Research

**Indicates exploration activities only.*

Each of these RFFAs would contribute to the increased potential for impacts on a wide range of cultural resources, because each involves some aspect of ground-disturbing activity that can lead to the irreversible destruction of cultural resources or affect the cultural context at those locations. Many of the mining exploration activities would have minimal ground disturbance, but would include helicopter overflights that can disturb cultural activities and the context of a cultural resource site.

The Pebble Project expansion would affect an area encompassed by and impacts similar to both Alternatives 1 and 3 across a greater footprint and over an extended period (from 78 to 98 years, depending on duration of additional milling after mining has ceased). Once a cultural resource feature, archaeological site, or historic site is destroyed, its value is gone and cannot be restored. Actions that expand mineral development near the Pebble deposit and around

AMERICAN OVERSIGHT

Iliamna Lake contribute to landscape-level effects, where there is continuous introduction of intrusive visual elements, increased noise and atmospheric pollution, and an increased volume of people. These lead to inadvertent and purposeful destruction of cultural resource features, invasion of privacy and solace at spiritual and ceremonial sites, adverse impacts on natural resources that are central to cultural belief systems, and subsequent degradation of these cultural belief systems that have far-reaching social and physical health impacts. Effects such as habitat fragmentation, noise, and increased access for recreational hunting and fishing also disrupt subsistence activity, and may result in impacts to resource gathering areas and other cultural features.

These types of effects are also applicable to an increase in resource development and marine traffic along the Cook Inlet coastline, which may impact marine mammals and the associated cultural resources, such as ceremonial and harvest sites and religious and spiritual practices centered on the health and relationship of people to the land they inhabit.

AMERICAN OVERSIGHT

4.8 HISTORIC PROPERTIES

Section 4.8 discusses the effects that construction, operation, and closure of the mine would have on historic properties. However, at this time, there are no historic properties identified in the analysis area (see below). Therefore, Section 4.7, Cultural Resources, offers a discussion of the effects on cultural resources that includes known AHRS sites, archaeological sites, place names, and interview-identified cultural resources. There are four sites discussed in Section 4.7, Cultural Resources, for which eligibility is not determined. This section considers the process for assessing effects on historic properties as defined by 33 Code of Federal Regulations (CFR) 325 Appendix C and National Historical Preservation Act (NHPA) Section 106 requirements for considering the project's potential to cause effects on historic properties in the permit area. For the purposes of this section, the definition of historic properties is as described in Section 3.8, Historic Properties. At this time, the project footprint is guiding the analyses of environmental consequences on historic properties, and the direct and indirect effects that may result. Some nearby communities may have historic properties, but impacts would likely be indirect and associated with setting.

4.8.1 Analytical Limitations

Adjustments to the number of historic properties affected would be anticipated, because additional properties are identified during the course of additional research and studies conducted under consultation currently under way as part of the NHPA Section 106 compliance process and development of the Programmatic Agreement (PA). The permit area (defined under Appendix C) in which the US Army Corps of Engineers (USACE) will analyze direct and indirect effects has not yet been established for NHPA compliance purposes. Because identified cultural resources features are considered as potential historic properties, the quantity of historic properties may increase, and expand the content and scope of analysis. The consultation process is ongoing between the USACE, the Alaska State Historic Preservation Office (SHPO), and other consulting parties regarding the definition and delineation of the permit area for the project. The USACE initiated Section 106 consultation with agencies and involved parties via letter on August 17, 2018, and held an introductory meeting on October 30, 2018.

Eligibility for inclusion in the National Register of Historic Places (NRHP) defines a historic property, and the process of evaluation can occur concurrent with the National Environmental Policy Act (NEPA) process. Not all of the project components were inventoried for historic properties during the baseline studies completed by PLP between 2004 and 2013 (SRB&A 2011, 2015a, and 2015b), and none of the sites identified in those studies were evaluated for eligibility for inclusion in the NRHP. The evaluation step has not yet been taken for any archaeological sites, historic buildings, or cultural resource features identified in the project components, which may lead to eligibility. The AHRS research for Alternatives 2 and 3 is ongoing, and Alaska Heritage Resources Survey (AHRS)-listed resources with National Register eligibility determinations may exist in the footprint of those alternatives.

[Note to reviewer: A GIS analysis is being conducted to determine the extent that the mine site would directly impact historic properties. Data will be received as part of RFI 097.]

Only the mine site has been subjected to systematic cultural resource field investigations. However, previous PLP investigations did complete background literature and file reviews for a broader regional area, and conducted interviews to identify cultural resources, place names, and land use areas in and near the project footprint. These data are supplemented by other sources of ethnographic, traditional knowledge, and subsistence investigations that cover portions of the study area (see Section 3.7, Cultural Resources, for a preliminary list of these

AMERICAN OVERSIGHT

additional sources). It is likely that many of the identified cultural resource features (approximately 1,600) may also be considered as historic properties, and be evaluated for inclusion to the NRHP. Archaeological and historic districts, and specific types of significance ascribed to certain areas, such as traditional cultural landscapes or traditional cultural properties, have also not been considered for eligibility.

4.8.2 Effects on Historic Properties

Per Section 106 of the NHPA, an adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion on the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association (36 CFR 800.5 (a)(1)). All of the action alternatives have the potential to cause adverse effects resultant from the construction, operation, reclamation, and closure of the mine. The discussion of types of effects and environmental consequences provided in Section 4.7, Cultural Resources, applies to the types of effects that would be anticipated on historic properties, and is not repeated here. The number of known AHRS resources in each project component is also covered in Section 3.7, Historical Properties, and listed in Appendix K3.8.

Additional identification and evaluation of each project component would occur through the NHPA Section 106 process to quantify the number and types of historic properties present prior to assessing types of effects that may occur. This process can occur concurrent with the NEPA process and is currently underway. The USACE will address effects on historic properties through application of Appendix C through a PA, and tie the completion of this process to the action of issuing a final permit for mine operation.

The steps and processes that the USACE will employ to complete the identification, evaluation, and mitigation of effects on historic properties will be captured in the PA. Per 36 CFR 800.14(b), the agency official (USACE) may negotiate a PA to govern the implementation of a particular program or the resolution of adverse effects from certain complex undertakings. The following applicable criteria for the use of a PA are met by the PLP project (36 CFR 800 14 (b)(1)(i, ii, and v):

- When effects on historic properties are similar and repetitive or are multi-state or regional in scope
- When effects on historic properties cannot be fully determined prior to approval of the undertaking
- When other circumstances warrant a departure from the normal Section 106 process.

The USACE intends to confer with consulting parties through the NHPA Section 106 process to develop the PA. The PA will record the terms and conditions agreed on to resolve the potential adverse effects, and to include consideration of mitigation measures and the ongoing strategies to identify and evaluate historic properties pre- and post-permitting. The PA will be part of the Record of Decision, and permits will be conditioned with reference to completing the project in accordance with the PA. Compliance with the procedures established by the approved PA would satisfy the USACE's NHPA Section 106 responsibilities for the project.

4.8.3 Mitigation

Site-specific mitigation measures will be developed through the Section 106 and PA process to avoid or minimize effects on historic properties, to the extent practicable. The following are typical mitigation measures:

AMERICAN OVERSIGHT

- Avoidance, which could be accomplished by shifting the footprint away from the resource, limiting activities in the vicinity of the resource, monitoring construction activities near the resource to inform whether additional actions are warranted, or through any combination of these techniques.
- Minimization, which would reduce the effects on the resource through avoidance measures as described above, but would not completely eliminate the effects.
- Mitigation, which may involve data recovery, protections of similar resources in nearby areas, contributions to local heritage programs in affected communities, interpretive exhibits, education curricula, or a host of other measures that would be decided on through consultation with the agencies and involved parties.

AMERICAN OVERSIGHT

APPENDIX E – LAWS, PERMITS, APPROVALS, AND CONSULTATIONS REQUIRED

The Pebble Project would be required to follow numerous federal laws and executive orders, and obtain permits and approvals from federal, state, and local governments. The key federal laws and Executive Orders pertaining to this Environmental Impact Statement (EIS) are described below. Table E-1 lists the permits, approvals and consultations typically required for development and operation of a hardrock mine in Alaska.

E1.1 NATIONAL ENVIRONMENTAL POLICY ACT OF 1969

The National Environmental Policy Act (NEPA) of 1969 (42 United States Code [USC] 4321 et seq.) applies to all federal agencies and their decisions that have the potential to affect the environment. It establishes the procedures that federal agencies follow to make major decisions in a public forum, while disclosing the environmental implications of the potential decision.

The president's Council on Environmental Quality (CEQ) has issued NEPA regulations and guidance for all agencies. NEPA requires implementation of the appropriate level of NEPA process (public involvement and document preparation) to be conducted with respect to a major federal action that has the potential to significantly affect the human environment.

This EIS was prepared according to the US Army Corps of Engineers (USACE) regulations implementing NEPA (33 Code of Federal Regulations [CFR] Part 230), which state that an EIS must provide detailed information regarding the proposed action and alternatives, the environmental impacts of the alternatives, potential mitigation measures, and any adverse environmental impacts that cannot be avoided if the proposal is implemented. This EIS includes analysis of measures to avoid and minimize impacts to fish, wildlife, habitats, and other resources and also addresses compensatory mitigation for impacts which cannot be avoided or minimized. It must be demonstrated that these factors have been considered by decision makers prior to undertaking actions such as issuing permits.

E1.2 CLEAN WATER ACT (1972)

Section 404 of the Clean Water Act (CWA) requires that a USACE permit be obtained for the placement or discharge of dredged and/or fill material into Waters of the US (WOUS), including jurisdictional wetlands (33 USC 1344). The USACE defines wetlands as areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. The USACE evaluates proposed actions for compliance with the Section 404(b)(1) Guidelines, which were developed by the Environmental Protection Agency (EPA) in conjunction with the Secretary of the Army. The EPA reviews and comments on permit applications for compliance with Section 404(b)(1) Guidelines and other statutes and authorities under their jurisdiction.

Under Section 402 of the CWA, discharges to surface waters from construction, operations, and reclamation of the Pebble Project would require compliance with the National Pollutant Discharge Elimination System, administered by the Alaska Department of Environmental Conservation (ADEC) as the Alaska Pollutant Discharge Elimination System (APDES). The EPA provides oversight of the state-issued wastewater permits subject to the requirements of the APDES. During construction, the Alaska Construction General Permit would require a Storm Water Pollution Prevention Plan (SWPPP). During operations, the discharges from advanced pit dewatering would also be subject to the APDES program and depending on the method of disposal domestic wastewater could require APDES coverage.

AMERICAN OVERSIGHT

E1.3 RIVERS AND HARBORS ACT (1899)

Section 10 of the Rivers and Harbors Act (RHA) of 1899 requires that a USACE permit be obtained for construction of structures, or work in and/or affecting navigable waters of the US (NWUS) (33 USC 403), which includes excavation or deposition of material in navigable waters, or other actions that could affect the course, location, condition, or capacity of these waters.

E1.4 ALASKA NATIONAL INTEREST LANDS CONSERVATION ACT (1980)

The Alaska National Interest Lands Conservation Act (ANILCA), Public Law 96-487 (16 USC 3101–3233) added 106 million acres to federal conservation system units in Alaska. ANILCA includes a number of provisions intended to allow for infrastructure and economic growth in general, travel and access in conservation system units, and pursuit of a subsistence lifestyle while protecting resource values. ANILCA helps provide context for evaluation of potential effects to the landscape, but ANILCA provisions do not apply beyond designated federally managed land boundaries and do not apply to the lands for the proposed Pebble Project.

ANILCA is a multifaceted law; two titles of particular note to this EIS include:

- Title VIII of ANILCA defines subsistence as customary and traditional uses of wild renewable resources by rural Alaska residents (Section 803), establishes a subsistence priority on federal public lands and waters (Section 804), and provides for a system of regional advisory councils to ensure the participation of rural residents in subsistence management (Section 805). Section 810 of ANILCA requires analysis of impacts to subsistence from federal land use decisions. Section 811 ensures reasonable access to subsistence resources on federal public lands, including the use of snowmachines, motorboats, and other means of surface transportation traditionally employed for subsistence purposes, subject to reasonable regulation.
- Title IX of ANILCA clarifies the implementation of ANCSA and the Alaska Statehood Act Section 906(k) requires state concurrence on selected lands prior to granting a right-of-way (ROW).

E1.5 ALASKA NATIVE CLAIMS SETTLEMENT ACT (1971)

Alaska Native regional and village corporations own lands and minerals in the project area under the provisions of Alaska Native Claims Settlement Act (ANCSA) (43 USC 1601, et seq.).

The Pebble Project transportation corridor connecting the Amakdedori port to the mine site crosses both state land and land patented under ANCSA. ANCSA corporations were invited to participate in the National Historic Preservation Act (NHPA) Section 106 process for cultural resource identification and mitigation.

E1.6 PIPELINE SAFETY, REGULATORY CERTAINTY, AND JOB CREATION ACT OF 2011

The Pipeline Safety, Regulatory Certainty, and Job Creation Act (49 USC 60101) was enacted to improve and examine the state of pipeline safety regulations. Enforcement falls under the jurisdiction of the Pipeline and Hazardous Materials Safety Administration (PHMSA), the agency that regulates and enforces the operations of pipeline transportation systems in the US and oversees pipeline infrastructure. The PHMSA has the primary responsibility for the issuance of Department of Transportation special permits and approvals for hazardous materials and for natural gas and hazardous liquid pipelines. Special permits authorize a person to perform a function outside of PHMSA regulations or to not perform a function currently required under the

AMERICAN OVERSIGHT

PHMSA regulations. Approvals authorize the transportation of designated hazardous materials (i.e. explosives) or the performance of a designated hazardous materials function (i.e. cylinder retester) under the PHMSA regulations.

E1.7 CLEAN AIR ACT (1970)

The Clean Air Act (CAA) of 1970, with amendments in 1990, addresses standards for many categories of air pollutants and defines how the EPA implements its regulatory authority for air quality (42 USC 85). The requirements of this law encompass many pollution sources, provide health-based standards, and identify control methods to reduce the emission of common air pollutants. The potential construction and operations of a mine and power plant would introduce activities that are associated with particle pollution and ground-level ozone pollution. Both of these forms of air pollution, and others, have known health effects and would be subject to further evaluation under federal- and state-implemented air quality management programs. Implementation of the CAA has been delegated to the State of Alaska; therefore, the ADEC would issue any air permits associated with this project. EPA provides oversight of the state-issued air permits.

E1.8 ENDANGERED SPECIES ACT (1973)

The Endangered Species Act (ESA) of 1973 was enacted to conserve species that have been found to be at risk of extinction in all or a substantial portion of their ranges, and to conserve the ecosystems and habitats upon which they rely. The US Fish and Wildlife Service (USFWS) and National Oceanic and Atmospheric Administration (NOAA)-Fisheries/National Marine Fisheries Service (NMFS) have regulatory authority for implementing the ESA. In general, USFWS is responsible for managing the terrestrial animal and plant species listed as endangered and threatened, and generally coordinates related issues for terrestrial and freshwater species, while NOAA-Fisheries/NMFS is responsible for most marine mammals and anadromous fish species. Some marine mammals, including the northern sea otter, are managed by USFWS. Pebble Project vessel traffic would traverse areas where threatened or endangered species occur.

E1.9 HISTORIC PRESERVATION LAWS

The National Historic Preservation Act (NHPA) of 1966 (as amended), the Archaeological Resources Protection Act of 1979, the Antiquities Act of 1906, and the Alaska Historic Preservation Act (1971) guide the management of cultural resources and historic properties. Under Section 106 of the NHPA (36 CFR Part 800), federal agencies are required to consider the effect of their actions on historic properties listed on, or eligible for, the National Register of Historic Places (National Register). The NHPA allows sites of traditional religious and cultural significance to Native Americans or Alaska Natives to be considered eligible for the National Register. Section 106 requires a process of consultation with the Advisory Council on Historic Preservation (ACHP), State Historic Preservation Office (SHPO), Indian (or Alaska Native) tribes, local governments, and other interested parties to identify historic properties and determine the effects of the action on those resources. If historic properties would be adversely affected by a project, the agency must, again in consultation, resolve the effects through appropriate mitigation. The Pebble Project has the potential to affect cultural resources and historic properties. 36 CFR 800.14 allows for the resolution of adverse effects from complex projects through negotiation of a programmatic agreement between federal agencies and the ACHP. Inventory, documentation, and preservation of cultural resources and traditional cultural properties and mitigation of adverse impacts from the Pebble Project would be based on a programmatic agreement that is currently under development with consultation among PLP, the USACE, ACHP, Alaska SHPO, and tribal representatives.

AMERICAN OVERSIGHT

E1.10 NATIVE AMERICAN GRAVES PROTECTION AND REPATRIATION ACT

Native American Graves Protection and Repatriation Act (NAGPRA, 25 USC 3001) requires that discovery or disturbance of any human remains on federal or tribal lands in the project area must be accounted for and protected and/or properly returned to the tribe of origin. The potential for impacts from the Pebble Project to resources protected under NAGPRA must be evaluated in the EIS.

E1.11 AMERICAN INDIAN RELIGIOUS FREEDOM ACT OF 1978

The American Indian Religious Freedom Act of 1978 (42 USC 1996) requires federal agencies to consider Native American religious concerns when a federal management decision has the potential to impact an Indian religious practice or a spiritually significant site (on both federal and non-federal lands affected by the federal action). The potential for impacts from the Pebble Project to activities protected under this act is evaluated in the EIS.

E1.12 MARINE MAMMAL PROTECTION ACT (1972)

The USFWS and NOAA-Fisheries/NMFS have regulatory authority for implementing the Marine Mammal Protection Act (MMPA) (16 USC 1361-1407), which prohibits the harassment, hunting, capture, or killing of marine mammals, or the attempt to harass, hunt, capture, or kill marine mammals. The law provides exceptions for authorized scientific research and subsistence uses by Alaska Natives. Actions that have potential to take marine mammals must be reviewed and approved by the regulating agencies. Pebble Project vessel traffic would traverse areas where marine mammals occur.

E1.13 MIGRATORY BIRD TREATY ACT (1918)

The Migratory Bird Treaty Act (MBTA) of 1918 (16 USC 703-712) implements several international conventions to protect migratory birds. Following treaty amendments in 1997, regulations for subsistence bird harvests were established under the purview of the Alaska Migratory Bird Co-Management Council, operating under authority of the MBTA, as amended. Under the MBTA, takings are prohibited unless expressly authorized or exempted. This EIS addresses potential impacts of the project and associated infrastructure on all birds protected under the MBTA.

E1.14 BALD AND GOLDEN EAGLE PROTECTION ACT (1940, 1962)

The Bald and Golden Eagle Protection Act (16 USC 668, et seq.) provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the take, possession, and commerce of such birds. Eagle take permits may be necessary for activities that result in removal of nests, loss of habitat, and disturbance of birds during construction, operations, and maintenance of the project. This EIS identifies the presence of eagles or their nests in the project area (along with associated infrastructure routes), and analyzes potential impacts of the project on both bald and golden eagles as protected under the Bald and Golden Eagle Protection Act. Alaska-specific information can be found at: http://alaska.fws.gov/eaglepermit/index.htm.

E1.15 FISH AND WILDLIFE COORDINATION ACT (1980)

The Fish and Wildlife Coordination Act (FWCA), as amended, (16 USC 661, et seq.), requires the agency that is authorized to permit or license changes in a water body to first consult with USFWS and the appropriate state fish and game agency. The FWCA provides that wildlife conservation receive equal consideration, and be coordinated with other features of the development project.

AMERICAN OVERSIGHT

The FWCA authorizes the USFWS to conduct surveys and investigations to determine the possible damage of proposed developments on wildlife resources, in order to make recommendations for preventing their loss or damage. The USFWS incorporates the concerns and findings of state and other federal agencies, including NOAA-Fisheries/NMFS, into a report that addresses wildlife factors and provides recommendations for mitigating or enhancing impacts to wildlife affected by a federally constructed, permitted, or licensed water development project. The term wildlife resources is explicitly defined to include "birds, fishes, mammals, and all other classes of wild animals and types of aquatic and land vegetation upon which wildlife is dependent" (16 USC 666 (b)). Additionally, the FWCA states that reports determining the possible damage to wildlife resources and an estimation of wildlife loss be made an integral part of any report prepared or submitted the agency with permitting authority (16 USC 662 (b),(f)).

E1.16 NATIONAL WILDLIFE REFUGE SYSTEM ADMINISTRATION ACT OF 1966, AS AMENDED

The National Wildlife Refuge System Administration Act (16 USC 668dd-668ee), as amended by the National Wildlife Refuge System Improvement Act of 1997 (Public Law 105-57), established a unified mission for the National Wildlife Refuge System and a compatibility standard for assessing proposed uses within a refuge. The refuge system is dedicated to the conservation of fish, wildlife, and plant resources and their habitats in the refuge. Although the proposed project would not install infrastructure on a refuge, the activities of the Pebble Project have the potential to affect refuge land and resources.

E1.17 MAGNUSON-STEVENS FISHERY CONSERVATION AND MANAGEMENT ACT

To provide for the conservation and management of sustainable fisheries, the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA) sets forth a mandate for NOAA-Fisheries/NMFS, regional fishery management councils, and other federal agencies to identify and protect important marine and anadromous fish habitats (16 USC 1801-1883). Federal agencies must consult with NOAA-Fisheries/NMFS on actions or proposed actions authorized by the federal agency that may adversely affect Essential Fish Habitat (EFH). EFH includes habitats necessary to a species for spawning, breeding, feeding, or growth to maturity. The Pebble Project has potential to affect EFH.

E1.18 RESOURCE CONSERVATION AND RECOVERY ACT OF 1976

Under this act, the EPA develops and implements regulatory programs to manage hazardous waste from generation until ultimate disposal, including issuing an identification number for any entity that generates hazardous wastes. Construction, operations, and reclamation of the proposed Pebble Project would generate wastes subject to Resource Conservation and Recovery Act (RCRA) rules (40 CFR 239 through 282).

E1.19 TOXIC SUBSTANCES CONTROL ACT OF 1976

Under the Toxic Substances Control Act (TSCA) of 1976 (15 USC 2601), the EPA develops and implements regulatory requirements for the testing of new and existing chemical substances and regulates the treatment, storage, and disposal of certain toxic substances. Construction, operations, and reclamation of the Pebble Project would involve chemical substances subject to TSCA rules.

AMERICAN OVERSIGHT

E1.20 THE FEDERAL MINE SAFETY AND HEALTH ACT OF 1977

The Mine Safety and Health Administration (MSHA) administers the provisions of the Mine Act (30 USC. 22) to enforce compliance with mandatory safety and health standards as a means to eliminate fatal accidents, to reduce the frequency and severity of non-fatal accidents, to minimize health hazards, and to promote improved safety and health conditions in the nation's mines. Operations of the Pebble Project would require compliance with MSHA standards.

E1.21 COMPREHENSIVE ENVIRONMENTAL RESPONSE, COMPENSATION, AND LIABILITY ACT

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) (43 USC 103), sometimes referred to as Superfund, provides federal funding to clean up uncontrolled or abandoned hazardous-waste sites as well as accidents, spills, and other emergency releases of pollutants and contaminants into the environment. Through CERCLA, EPA has authority to assure cooperation in the cleanup from responsible parties.

EPA cleans up orphan sites when potentially responsible parties cannot be identified or located, or when they fail to act. Through various enforcement tools, EPA obtains private party cleanup through orders, consent decrees, and other small party settlements. EPA also recovers costs from financially viable individuals and companies once a response action has been completed.

E1.22 EMERGENCY PLANNING AND COMMUNITY-RIGHT-TO-KNOW ACT OF 1986

Authorized by Title III of the Superfund Amendments and Reauthorization Act (SARA), the Emergency Planning & Community Right-to-Know Act (EPCRA) (42 USC 116) was enacted by Congress as the national legislation on community safety. This law is designed to help local communities protect public health, safety, and the environment from chemical hazards.

To implement EPCRA, Congress requires each state to appoint a State Emergency Response Commission (SERC). The SERCs are required to divide their states into emergency planning districts and to name a Local Emergency Planning Committee (LEPC) for each district.

Broad representation by firefighters, health officials, government and media representatives, community groups, industrial facilities, and emergency managers ensures that all necessary elements of the planning process are represented.

E1.23 SAFE WATER DRINKING ACT OF 1974

The Safe Drinking Water Act (42 USC. 300 (f) et seq.) was established to protect drinking water in the US. This law focuses on all waters actually or potentially designed for drinking use, whether from above ground or underground sources. This act authorizes the EPA to establish minimum standards to protect tap water and requires all owners or operators of public water systems to comply with these primary (health-related) standards. State governments, which can be approved to implement these rules for the EPA, also encourage attainment of secondary standards (nuisance-related). Under the act, the EPA also establishes minimum standards for state programs to protect underground sources of drinking water from endangerment by underground injection of fluids.

E1.24 OIL POLLUTION ACT OF 1990

The Oil Pollution Act (OPA) of 1990 (33 USC 40) streamlined and strengthened the EPA's ability to prevent and respond to catastrophic oil spills. The OPA requires oil storage facilities and vessels to submit plans detailing how they will respond to large discharges to the federal

AMERICAN OVERSIGHT

government. The OPA also requires the development of area contingency plans to prepare and plan for oil spill response on a regional scale.

E1.25 PORTS AND WATERWAYS SAFETY ACT OF 1972

The Ports and Waterways Safety Act (PWSA) of 1972 (33 USC 25) authorizes the US Coast Guard to establish vessel traffic services and separation schemes (VTSS) for ports, harbors, and other waters subject to congested vessel traffic. The VTSS apply to commercial ships, other than fishing vessels, weighing 300 gross tons (270 gross metric tons) or more. The OPA amended the PWSA to mandate that appropriate vessels must comply with the VTSS.

E1.26 OUTER CONTINENTAL SHELF LANDS ACT OF 1953

The Outer Continental Shelf Lands Act (OCSLA) of 1953 (43 USC 1331) requires the Department of Interior (DOI) to manage the orderly leasing, exploration, development, production, and decommissioning of oil and gas resources on the federal Outer Continental Shelf (OCS), while simultaneously ensuring protection of the human, marine, and coastal environments and assuring receipt of fair market value for the lands leased and the rights conveyed by the federal government. OCSLA also requires coordination with state and local governments affected by OCS development activities.

Under the OCSLA, the Bureau of Environmental Safety and Environmental (BSEE) is responsible for regulating and monitoring oil and gas operations on the federal OCS, promoting safety, and protecting the environment. BSEE approves ROW authorization for pipelines in federal OCS waters, and is responsible for approving ROW authorization for the subsea natural gas pipeline proposed in the Pebble Project EIS.

E1.27 EXECUTIVE MEMORANDUM OF APRIL 29, 1994, ON GOVERNMENT-TO-GOVERNMENT RELATIONS WITH NATIVE AMERICAN TRIBAL GOVERNMENTS, AND EXECUTIVE ORDER 13175 – CONSULTATION AND COORDINATION WITH INDIAN TRIBAL GOVERNMENT

Federal agencies are instructed to operate within a government-to-government relationship with federally recognized tribes; tasked with consulting with potentially affected tribal governments prior to taking actions that affect federally recognized tribal governments; and must also evaluate the impact of federal government plans, projects, programs, and activities on tribal trust resources; and assure that tribal government rights and concerns are considered during the development of such plans, projects, programs, and activities. The USACE, as the lead federal agency for this EIS, is required to consult with federally recognized tribes potentially affected by the Pebble Project.

E1.28 EXECUTIVE ORDER 11514 – PROTECTION AND ENHANCEMENT OF ENVIRONMENTAL QUALITY

This order requires the EPA to review and evaluate the Draft and Final EIS for compliance with CEQ Guidelines.

E1.29 EXECUTIVE ORDER 11988 – FLOODPLAIN MANAGEMENT

This order requires federal agencies to establish procedures ensuring that the potential effects of flood hazards and floodplain management are considered for actions undertaken in a floodplain.

AMERICAN OVERSIGHT

Impacts to floodplains are to be avoided to the extent practicable. The Pebble Project has the potential to impact floodplains.

E1.30 EXECUTIVE ORDER 11990 – PROTECTION OF WETLANDS

This order requires federal agencies to avoid short- and long-term adverse impacts to wetlands whenever a practicable alternative exists. This EIS analyzes impacts to wetlands.

E1.31 EXECUTIVE ORDER 12898 – FEDERAL ACTIONS TO ADDRESS ENVIRONMENTAL JUSTICE IN MINORITY POPULATIONS AND LOW-INCOME POPULATIONS

This order instructs federal agencies to develop environmental justice (strategies to identify and address disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations (including Native American and Alaska Native tribes).

E1.32 EXECUTIVE ORDER 12962 – RECREATIONAL FISHERIES

This order instructs federal agencies to evaluate proposed federal actions for potential effects to aquatic systems and recreational fisheries. The quantity, function, sustainable productivity, and distribution of aquatic resources are to be improved to the practicable extent permitted by law. This EIS analyzes potential impacts to aquatic systems and recreational fishing opportunities.

E1.33 EXECUTIVE ORDER 13007 – INDIAN SACRED SITES

This order requires federal agencies to accommodate access to and ceremonial uses of Indian sacred sites located on federal property by Indian religious practitioners, and to avoid adversely affecting the physical integrity of such sacred sites. This EIS analyzes the potential for impacts to Indian sacred sites.

E1.34 EXECUTIVE ORDER 13045 – PROTECTION OF CHILDREN FROM ENVIRONMENTAL HEALTH RISKS AND SAFETY RISKS

The order applies to economically significant rules under Executive Order 12866 (Regulatory Planning and Review) that concern an environmental health or safety risk that the EPA has reason to believe may disproportionately affect children. This EIS analyzes potential impacts to human health, including children.

E1.35 EXECUTIVE ORDER 13112 – INVASIVE SPECIES

This order instructs federal agencies to prevent the introduction of invasive species, control those that are introduced, and provide for the restoration of native species.

E1.36 EXECUTIVE ORDER 13186 – RESPONSIBILITIES OF FEDERAL AGENCIES TO PROTECT MIGRATORY BIRDS

This order requires federal agencies to avoid or minimize the impacts of their actions on migratory birds and take active steps to protect birds and their habitats.

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Federal		
Federal Laws and Executive Orders Common To Multiple Federal Agencies		
National Environmental Policy Act (NEPA) (42 USC 4321)	NEPA (1969) requires all federal agencies to prepare a detailed statement of the environmental effects of proposed major federal actions that may significantly affect the quality of the human environment.	• Environmental Impact Statement
National Historic Preservation Act (NHPA) of 1966 (54 USC 300101 et seq.).	Prior to the issuance of a federal permit, federal agencies are responsible for taking into account the effect of the undertaking on historical, cultural, and archaeological sites and resources.	• NHPA Consultation, Section 106 Programmatic Agreement
US Army Corps of Engineers		
Clean Water Act (CWA) of 1972 (33 USC 1344)	Discharge of dredged or fill material into WOUS, including wetlands.	• Department of the Army (DA) Permit
Rivers and Harbors Act (RHA) of 1899 (33 USC 403)	Work and/or construction of structures in, over, or under navigable WOUS, or which affects the course, location, condition, or capacity of such waters.	• DA Permit
BSEE		
Title 30 Mineral Lands and Mining (30 CFR Part 250.1000-1019, Subpart J – Pipelines and Pipeline Rights of Way) Title 33 Navigation and Navigable Waters, Section 1321 – Oil and Hazardous Substance Liability (30 CFR Part 254.20-.30)	The Bureau of Safety and Environmental Enforcement (BSEE) is responsible for regulating and monitoring oil and gas operations on the federal OCS, promoting safety, and protecting the environment. BSEE approves ROW authorization for pipelines in federal OCS waters.	• ROW Authorization for subsea natural gas pipeline in OCS waters.

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
US Coast Guard		
Ports and Waterways Safety Act (PWSA) of 1972 Title 33 Navigation and Navigable Waters, Subchapter P, Ports and Waterways Safety (33 CFR 160 through 169) Title 33 Navigation and Navigable Waters, Subchapter J, Bridges (33 CFR 114 through Parts 118)	US Coast Guard (USCG) and Department of Homeland Security approve safety features in ports and waterways. USCG has authority over locations and clearances of bridges and causeways in or over navigable waters of the US (NWOUS).	• Application for Cargo Transfer Operations • Port Operations Manual Approval • Facility Response Plans (FRPs) • Private Aids to Navigation Authorization • Vessel Inspections • Notice to Mariners • Bridge permits
Environmental Protection Agency		
Clean Air Act (CAA) of 1967, Amended 1977 (42 USC 7401 et seq.)	The EPA conducts a review and evaluation on the environmental impact and adequacy of the Draft and Final EIS as authorized by Section 309 of the CAA. The EPA has oversight responsibilities of state-issued air permits.	• Section 309 evaluation
Clean Water Act of 1972, Amended 1977 (33 USC 1251 et seq.) (40 CFR Parts 110 and 112)	Section 311 – The EPA requires owners/operators to prepare and implement spill prevention, control, and counter-measure (SPCC) plans for facilities that store more than 1,320 gallons in aggregate in above-ground tanks with capacity of 55 gallons or more. Section 402 - The EPA oversees draft APDES permits and can object to proposed permit decisions. Section 404 – The EPA reviews and comments on permit applications for compliance with Section 404(b)(1) Guidelines and other statutes and authorities within their jurisdiction.	• Oversight of SPCC Rule Requirements • Review of APDES permit applications • Review of DA permit applications pursuant to Section 404
Comprehensive Environmental Response, Compensation, and Liability Act.	Provides federal funding to clean up uncontrolled or abandoned hazardous-waste sites as well as accidents, spills, and other emergency releases of pollutants and contaminants into the environment.	• Authority to assure cooperation in the cleanup from responsible parties.
Oil Pollution Act (OPA) of 1990 (40 CFR Part 112.20)	Section 4202 of the OPA amended CWA Section 311(j) by requiring owners or operators of tank vessels, offshore facilities, and certain onshore facilities to prepare and submit Facility Response Plans (FRPs).	• Review of FRPs

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Resource Conservation and Recovery Act (RCRA)	Establishes criteria governing the management of hazardous waste. Any hazardous waste generated at a facility associated with the proposed project is subject to the hazardous waste regulations administered by the EPA.	• Permits for the transportation and storage of hazardous waste material
Safe Drinking Water Act of 1974 (42 USC 300 (f) et seq.)	Requires EPA to set limits for maximum allowable levels of contaminants in public drinking water systems.	• Sets standard for public drinking water quality
Toxic Substances Control Act (TSCA) of 1976 (15 USC 2601),	Develops and implements regulatory requirements for the testing of new and existing chemical substances and regulates the treatment, storage, and disposal of certain toxic substances.	• Reporting requirements
Pipeline and Hazardous Materials Safety Administration		
Pipeline Safety Regulations (49 CFR Parts 190-199) Pipeline Inspection, Protection, Enforcement, and Safety Act of 2006 Public Law 109-468 The Pipeline Safety Statute (49 USC 60101-60301)	Pipeline transportation and pipeline facilities must meet the minimum safety standards as regulated and enforced by the PHMSA.	• Meet minimum safety standards
Hazardous Materials Transportation Act (49 USC 1801-1819)	Hazardous materials must be transported according to US Department of Transportation regulations.	• Hazardous materials registration
US Federal Aviation Act (14 CFR 61, 91, 119)	Federal Aviation Administration regulates air navigation facilities and air traffic control.	• Notice of Landing Area Proposal (existing airstrip) • Notice of Controlled Firing Area for Blasting • Notice of construction, activation, and deactivation of airports
US Fish and Wildlife Service		
Bald and Golden Eagle Protection Act (16 USC 668)	USFWS permits relocation of bald and golden eagle nests that interfere with resource development or recovery operations.	• Permits to take, haze, relocate or destroy birds or their nests, for public safety purposes

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Marine Mammal Protection Act (MMPA) (16 USC 1361 et seq.)	USFWS has regulatory authority for implementing the Marine Mammal Protection Act (MMPA) which prohibits the harassment, hunting, capture, or killing of marine mammals, or the attempt to harass, hunt, capture, or kill marine mammals. Requires Incidental Take Authorizations (ITAs) under Section 101(a)(5)(A) or (D) of the MMPA. Incidental Take Authorizations (ITAs) may be issued as either: 1) regulations and associated Letters of Authorizations, or 2) Incidental Harassment Authorizations (NOAA-Fisheries/NMFS also administers the MMPA).	• ITAs (as necessary); Letters of Authorization or Incidental Harassment Authorizations.
Migratory Bird Treaty Act (MBTA) (16 USC 703)	USFWS implements provisions of the MBTA.	• MBTA consultation
Endangered Species Act of 1973 (ESA) (16 USC 1531)	USFWS provides consultation on effects to threatened or endangered species, and to designated critical habitat, and issues incidental take authorizations. Species include terrestrial mammals, plants, birds, and several marine mammals (NOAA also administers the ESA).	• ESA consultation, USACE Issuance of Biological Assessment, USFWS issuance of concurrence or Biological Opinion.
National Oceanic and Atmospheric Administration-Fisheries/National Marine Fisheries Service		
Magnuson-Stevens Fishery Conservation and Management Act (16 USC 1801-1883)	NOAA-Fisheries/NMFS provides consultation on the effects on EFH. EFH includes habitats necessary to a species for spawning, breeding, feeding, or growth to maturity.	• EFH consultation
Marine Mammal Protection Act (MMPA) (16 USC 1361 et seq.)	NOAA-Fisheries/NMFS has regulatory authority for implementing the MMPA, which prohibits the harassment, hunting, capture, or killing of marine mammals, or the attempt to harass, hunt, capture, or kill marine mammals. Requires ITA under Section 101(a)(5)(A) or (D) of the MMPA. ITAs may be issued as either: 1) regulations and associated Letters of Authorizations, or 2) Incidental Harassment Authorizations (USFWS also administers the MMPA).	• Incidental Take Authorization; Letters of Authorization or Incidental Harassment Authorizations.
Endangered Species Act of 1973 (ESA) (16 USC 1531)	NOAA-Fisheries/NMFS provides consultation on effects to threatened or endangered species, and to designated critical habitat, and issues incidental take authorizations. Species include most marine mammals (see USFWS species exceptions), and anadromous fish species (USFWS also administers the ESA).	• ESA Consultation, USACE Issuance of Biological Assessment, NOAA-Fisheries/NMFS issuance of concurrence or Biological Opinion

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
US Department of the Treasury		
Treasury Department Order No. 120-1	US Department of the Treasury, Bureau of Alcohol, Tobacco, Firearms, and Explosives requires that applicants obtain a Permit to Purchase Explosives for blasting prior to the purchase, storage, and use of explosives for conducting blasting activities.	• License to transport explosives • Permit and license for use of explosives
Federal Communications Commission		
Communications Act of 1934 (47 USC 151 et seq.)	Federal Communications Commission (FCC) regulates interstate and international communications by radio, television, wire, satellite and cable, including radio licensing.	• Radio license
US Department of Homeland Security		
Aviation and Transportation Security Act	Transportation Security Administration (TSA) oversees security for airports.	• TSA Inspection Program at Airport • Chemical Facility Anti-Terrorism Standards
State		
Alaska Department of Environmental Conservation		
Clean Air Act of 1967, Amended 1977 (42 USC 7401 et seq.) Air Quality Control (18 Alaska Administrative Code (AAC) 50 et seq.)	ADEC issues Air Quality Control permits to construct and to operate. ADEC issues Title V Operating permits and prevention of significant deterioration (PSD) permits for air pollutant emissions under the CAA Amendments (Title V).	• Air Quality PSD Permit • Title V Operating Permit • Air quality construction permit
Clean Water Act of 1972, Amended 1977 (33 USC 1251 et seq.)	Section 401 requires (for the USACE permit pursuant to Section 404) that ADEC certify that discharges into WOUS will comply with the CWA, the Alaska Water Quality Standards (18 AAC 70), and other applicable state laws.	• Section 401 Water Quality Certification

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Clean Water Act of 1972, Amended 1977 (33 USC 1251 et seq.) Wastewater Disposal (18 AAC 72) Alaska Pollutant Discharge Elimination System (18 AAC 83) Water Quality Standards (18 AAC 70) Drinking Water Standards (18 AAC 80)	ADEC provides approval for domestic wastewater collection, treatment, and disposal plans for domestic wastewaters. ADEC requires a permit for disposal of domestic and non-domestic wastewater. ADEC is fully authorized to administer the EPA's NPDES program through the APDES overseen by EPA. Existing regulations at 18 AAC 15 (Administrative Procedures) and 18 AAC 72 were amended to comply with the CWA. New regulations, 18 AAC 83, were also promulgated in addition to amending the existing regulations. ADEC provides approval for treatment and disposal plans for industrial wastewaters.	• APDES permits • Review Storm Water Discharge Pollution Prevention Plans • Plans review of treatment systems • Plan Review for Non-Domestic Wastewater Treatment System • Plan Review and Construction Approval for Domestic Sewage System • Domestic wastewater disposal permit • Non-domestic wastewater disposal permit
Solid Waste Management (18 AAC Chapter 60) (AS 46.03.100)	ADEC reviews and approves solid waste processing and temporary storage facilities plans for handling and temporary storage of solid waste and landfills.	• Integrated Waste Management Permit/Plan Approval
Food Permit and Registration Requirements (18 AAC 31.020)	ADEC may issue permits for persons seeking to operate a food establishment.	• Food Establishment Permit
Drinking Water System Classification and Plan Approval (18 AAC 80.200)	ADEC may issue approval of public drinking water plans.	• Potable water well logs • Approval to Construct and Operate a Public Water Supply System • Public Water System Identification Number
Open Burning (18 AAC 50.065)	ADEC enforces air quality requirements for open burning, and requires a permit for controlled open burning of forest land, vegetative cover, fisheries, or wildlife habitat in excess of 40 acres annually.	• Air Quality Permit to Open Burn

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Oil and Hazardous Substances Pollution Control Regulations (18 AAC 75) (AS 46.04.040, 050)	ADEC requires production and terminal facilities having an effective above-ground or below-ground storage capacity of greater than 10,000 barrels (420,000 gallons) of refined petroleum products to prepare an Oil Discharge Prevention and Contingency Plan and provide Proof of Financial Responsibility.	• Oil Discharge Prevention and Contingency Plan • Operation of vessels and petroleum product barges on state waters • Oil terminal/storage facility capable of storing 10,000 barrels or more • Above-ground Storage Tank Program (>420,000 gallons)
Alaska Department of Fish and Game		
The Fish and Wildlife Conservation Act (FWCA) of 1980 (16 USC 2901) The Fish and Wildlife Conservation Act of 1980 (16 USC 661 et seq.)	The Alaska Department of Fish and Game (ADF&G) consults with USFWS about fish and wildlife resources to conserve or improve wildlife resources. ADF&G provides comments and recommendations to federal agencies pursuant to the FWCA.	• Wildlife consultation • Fish habitat permits
Anadromous Fish Act (Alaska Statute [AS] 16.05.871)	An individual or governmental agency notifies and obtains authorization from ADF&G for activities that could use, divert, obstruct, pollute, or change natural flow of specified anadromous fish streams.	• Fish passage permits
Fishway Act (AS 16.05.841)	The Fishway Act requires that an individual or government agency notify and obtain authorization from the ADF&G for activities in or across a stream used by fish if it is determined that such uses or activities could represent an impediment to the efficient passage of resident or anadromous fish.	• Fish passage sufficiency determination
Activities Requiring a Special Area Permit (5 AAC 95.420)	A special area permit must be obtained from the ADF&G for activities (except for lawful hunting, trapping, fishing, viewing, and photography) occurring in state game refuges, state recreation areas, across designated wild and scenic rivers, or through state parks.	• Special area permits for designated areas
License, Permit, and Tag Fees; Surcharge; Miscellaneous Permits to Take Fish and Game (AS 16.05.340)	The ADF&G may issue a permit to collect fish and game, subject to limitations and provisions that are appropriate, for a scientific, propagative, or educational purpose.	• Permit to collect fish and game
Permit for Scientific, Educational, Propagative, or Public Safety Purposes (5 AAC 92.033)	The ADF&G may issue a permit for the taking, possessing, importing, or exporting of game for scientific, educational, propagative, or public safety purposes.	• Fish collection permits for field studies

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Alaska Department of Natural Resources		
Alaska Historic Preservation Act (AS 41.35.010-.240) NHPA of 1966 (16 USC 470 et seq.) (36 CFR 800.106-.110) Archaeological Resources Protection Act of 1979 (16 USC 470)	Section 106 of the NHPA requires consultation with the SHPO and, when there are effects on cultural resources listed on or eligible for inclusion in the National Register of Historic Places (NRHP), with the ACHP. SHPO issues a Field Archaeology Permit for archaeological fieldwork on state lands. The SHPO would also be consulted by the USACE. ADNR Office of History and Archaeology (OHA) issues a Cultural Resources Concurrence for developments that may affect historic or archaeological sites.	• Section 106 Programmatic Agreement • Archaeology collection permit • Field archaeology permit
Material Sales (AS 38.05.550-565) Permits (AS 38.05.850) Mining Sites Reclamation Plan Approvals (AS 27.19) Plan of Operations Approval (11 AAC 86.800)	ADNR issues a Material Sales Contract for mining and purchase of gravel from state lands. ADNR issues ROW and land use permits for use of state land, ice road construction on state land, and state waters. ADNR approves mining reclamation plans on state, federal, municipal, and private land and water. ADNR approves the plan of operations for non-coal mines, and is required for all mining projects on state land. ADNR's Division of Mining, Land and Water, Mining Section issues this approval. ADNR requires a Millsite Lease for mine project facilities on state land. This lease gives the applicant a surface property right for the associated facilities. ADNR's Division of Mining, Land and Water, Mining Section issues this lease. ADNR requires a tideland lease for use of state-owned tidelands for marine facilities such as docks. For use of state-owned uplands, a lease is required for facilities such as transportation and staging facilities. The Pebble Project includes port structures below high tide lines. ADNR requires a permit from Division of Mining, Land and Water, Lands Section before constructing snow or ice roads on state land, or conducting overland travel. Crossings of fish-bearing water bodies by snow or ice roads also require authorization by The Alaska Department of Fish and Game, Division of Habitat prior to construction.	• Material sales contract • Mining license • Reclamation plan approval • Land use permits and leases • Bonding and financial assurance approval • Plan of Operations approval • Millsite Lease approval • Upland or Tideland Lease approval • Snow or ice road approval.
Right-of-Way Leasing Act (AS 38.35.020)	The ADNR State Pipeline Coordinator's Office issues pipeline ROW leases for new pipeline and pipeline related construction and operation across state lands. The ADNR Commissioner signs the leases and the State Pipeline Coordinator manages the leases.	• ROWs

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Water Use (AS 46.15)	ADNR issues a temporary water use permit for water use necessary for construction and operations. ADNR issues a water rights permit for appropriation of a significant amount of water on other than a temporary basis.	• Temporary Water Use permits • Appropriation of Water Permit/ Certificate to Appropriate Water
Duties and Powers of Department of Natural Resources, Limitations (AS 41.21.020) Section 6(f) of the Land and Water Conservation Fund (LWCF) (16 USC 4601 et seq.)	ADNR has the responsibility for outdoor recreation planning and administering the LWCF program within Alaska.	• Administer LWCF program
Water Management, Article 3 (Dam Safety) (11 AAC 93.150 - 201)	ADNR Dam Safety and Construction Unit issues certificates to construct and operate dams in Alaska	• Certificate of Approval to Construct, Modify, Remove, or Abandon a Dam • Certificate of Approval to Operate a Dam
Alaska Department of Public Safety (ADPS), Division of Fire and Life Safety		
General function of the Department of Public Safety with respect to fire protection (AS 18.70.010) Alaska Fire and Life Safety Regulations (13 AAC 50-55)	The Division of Fire and Life Safety has statewide jurisdiction for fire code enforcement and plan review authority, except in communities that have received deferrals—including the municipality of Anchorage, Fairbanks, University of Alaska Fairbanks, and Wasilla/Lakes.	• Approval to transport hazardous materials • Life and Fire Safety Plan checks • Plan Review Certificate of Approval for each building • Fire Marshal permits
2009 International Fire Code (IFC)	All fuel systems being developed to support port and airport operations during pipeline construction and operations must be reviewed and found to conform to the 2009 IFC requirements. Although explosive blasting is not anticipated to be used in the project, if used, the storage magazine type, location, and any barricade requirements must meet IFC requirements.	• 2009 IFC requirements
Alaska Department of Transportation and Public Facilities		
Chapter 25 Operations, Wheeled Vehicles: Oversize and Overweight Vehicles (17 AAC 25.300)	Alaska Department of Transportation and Public Facilities (ADOT&PF) issues permits for oversize or overweight vehicles.	• Oversize or overweight vehicle permits

AMERICAN OVERSIGHT

Table E-1 : Permits, Approvals, and Consultations Required

Legal Authority	Agency	Role
Chapter 25 Operations, Wheeled Vehicles: Transportation of Hazardous Materials, Hazardous Substances, or Hazardous Waste (17 AAC 25.200)	ADOT&PF regulates the transportation of hazardous materials, hazardous substances, or hazardous waste by vehicles.	• Compliance with the transportation of hazardous materials, hazardous substances, or hazardous waste regulations.
Utility Permits (17 AAC 15.011)	ADOT&PF issues permits authorizing applicants to construct or install utility facilities in a department ROW.	• Utility permits
Alaska Department of Labor, Standards and Safety		
Health Safety and Housing (AS 18.60.180), (8 AAC)	The Alaska Division of Labor Standards and Safety enforces Occupational Safety and Health Administration regulations, and ensures that project related activities meet standards and regulations for occupational health and safety.	• Certificates of Inspection for Fired and Unfired Pressure Vessels • Occupational Safety and Health (inspections and certificates) • Employer Identification Number
Alaska Department of Health and Social Services		
Alaska Best Management Practices, Alaska Health Impact Assessment (HIA) Program	The HIA program evaluates the potential human health effects of new policies, programs, or development projects in Alaska through the use of existing public health surveillance data, medical literature reviews, and field studies.	• HIA
Alaska Department of Military Affairs		
Emergency Planning Districts and Committees, Plan Review (AS 26.23.073, .077)	Planning and reporting requirements for facilities that handle, store, and/or manufacture hazardous materials.	• Hazardous chemical inventories
Alaska Division of Homeland Security & Emergency Management		
Hazardous Chemicals, Materials, and Wastes (AS 29.35.500)	The State Emergency Response Commission enforces reporting and planning requirements for facilities that handle, store, and/or manufacture hazardous materials.	• Hazardous chemical inventories

AMERICAN OVERSIGHT

All,
This is the first a chain of emails where USACE will be sending the following:
11 Word files, the review drafts of:

Sec3.2, 4.2 - Lands. This is one figure set for Sec3.2 (two PDFs, figures 1A and figures 1B-E, attached). There are no technical appendices. CAs include Curyung Tribal Council, Nondalton Tribal Council, Lake and Peninsula Borough, State of Alaska.

Sec3.6, K3.6, 4.6-Commercial and Recreational Fisheries. There are no separate figure PDFs. There is only one technical appendix (K3.6). CAs include USFWS, State of Alaska.

Sec 3.9, 4.9, K4.9-Subsistence. There are 7 separate PDF files for 3.9 figures and 12pdfs- to be sent later. There is only one technical appendix (K4.9). CAs include Curyung Tribal Council, Nondalton Tribal Council, Lake and Peninsula Borough, NPS, USFWS, State of Alaska.

Sec3.20, 4.20, K4.20-Air Quality. There are no separate figure PDFs. There is only one technical appendix (K4.20). CAs include State of Alaska .

K3.6 COMMERCIAL AND RECREATIONAL FISHERIES

K3.6.1 Area N, P, S, and T Freshwater Guide Logbook Data

The table below summarizes 2011-2014 data from the Alaska Department of Fish and Game's (ADF&G) Freshwater Guide Logbook program, which requires fishing guides in the state of Alaska to record the location, number of clients, and catch/harvest for every guided trip. Included in Table K3.6-1 is the average number of businesses reporting for a waterbody, the average annual number of trips taken, and the average number of days fished. In addition, the table shows the number of times in the 4-year span that the ADF&G reported program data. For example, Upper Talarik Creek appears in the data 3 out of 4 years between 2011 and 2014. On average, five businesses reported a total of 16 trips and 48 fishing days there a year. The table highlights waterbodies that could be affected by an aspect of the project or unanticipated releases.

K3.9 SUBSISTENCE

This section briefly summarizes the most recent available comprehensive subsistence harvest surveys for the 13 communities that would not be located near the mine site, transportation corridor, or port site locations. A summary of the subsistence harvest surveys for the six communities closest to the project area are discussed in Section 3.9, Subsistence. The results include those communities around Iliamna Lake area communities, more distant communities down the Kvichak River drainage and Nushagak River drainage, as well as a pair of Cook Inlet communities. Communities for which there were older data or no data were not included.

Figure K3.9-1 through Figure K3.9-12 show the search and harvest areas that communities use for large land mammals, fish, vegetation, marine mammals, marine invertebrates, birds, and small mammals. Large land mammals include caribou, moose, brown bear, black bear, and sheep or goats. Fish figures are divided by salmon and non-salmon, and vegetation combines plants, wood, berries, and fungi. Marine mammals refers to seals, sea lions, sea otters, and whales and marine invertebrates include clams, mussels, scallops, crabs, octopus, and shrimp. Upland game birds include grouse and ptarmigan, and waterfowl refers to ducks and geese. Eggs primarily come from ducks, geese, and seabirds. The figures for small land mammals include beaver, muskrat, river otter, foxes, hares, weasels, wolf, wolverine, squirrels, porcupine, and lynx.

AMERICAN OVERSIGHT

K3.9.1 Port Alsworth

Port Alsworth is a majority Euro-American community on Lake Clark. It is the location of the Lake Clark National Park and Preserve headquarters and is also home to many hunting and fishing guide services and lodges. In 2004, Port Alsworth had an estimated year-round population of 109 people in 30 households. Port Alsworth residents harvested an estimated 14,489 pounds of wild food (133 pounds per capita) in 2004 a lower total compared to the Iliamna Lake area communities. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Port Alsworth residents in 2004 in terms of edible weight are shown in Figure K3.9-13. Port Alsworth households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (100 percent of households) followed by large land mammals (91 percent), plants and fungi (86 percent), non-salmon fish (73 percent), marine invertebrates (50 percent), birds and eggs (46 percent), and small land mammals (41 percent). Sharing and distribution of subsistence foods was widespread. In 2004, 91 percent of Port Alsworth households received wild resources and 73 percent of households gave resources away. Some of the resources received by Port Alsworth residents came from non-local hunters who dropped off meat for people in the community (Fall et al. 2006).

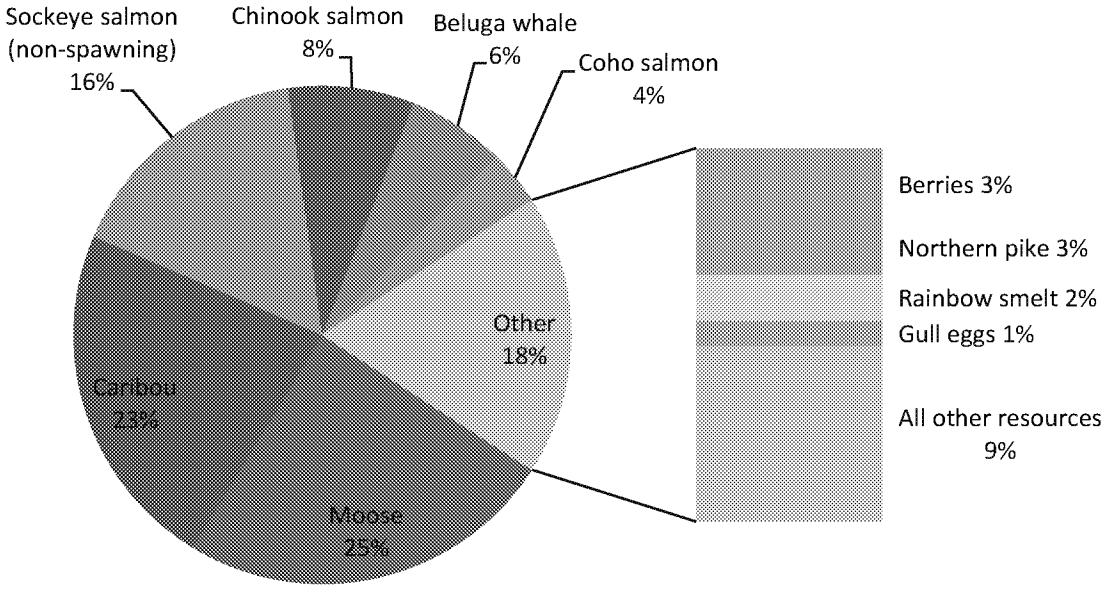
AMERICAN OVERSIGHT

K3.9.2Koliganek

Koliganek is a primarily Yup'ik community on the Nushagak River 65 miles northeast of Dillingham. In 2005, Koliganek had an estimated year-round population of 150 people in 42 households. Koliganek residents harvested an estimated total of 134,779 pounds of wild food (899 pounds per capita) in 2005, a notably high level of food production among communities in the project area. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Koliganek residents in 2005 in terms of edible weight are shown in Figure K3.9-14. Koliganek households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (100 percent of households) followed by plants and fungi (96 percent), non-salmon fish (96 percent), large land mammals (96 percent), birds and eggs (93 percent), small land mammals (64 percent), and marine mammal (64 percent). Sharing and distribution of subsistence foods was widespread. In 2005, 89 percent of Koliganek households received at least one subsistence resource and 93 percent gave away at least one resource (Krieg et al. 2009).

Figure K3.9-14: Composition of Koliganek Subsistence Harvest by Estimated Edible Weight, 2005

Source: Krieg et al. 2009



Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.3 Levelock

Levelock is a mixed Alutiiq and Yup'ik community on the Kvichak River. In 2005, Levelock had an estimated year-round population of 34 people in 19 households. Levelock residents harvested an estimated total of 17,871 pounds of wild foods (527 pounds per capita) in 2005. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Levelock residents in 2005 in terms of edible weight are shown in Figure K3.9-15, with a distinctively high level of reliance on large land mammals. Levelock households reported high levels of participation in subsistence activities. Large land mammals were the most widely used resource category (100 percent of households) followed by plants and fungi (93 percent), salmon (93 percent), birds and eggs (88 percent), non-salmon fish (86 percent), small land mammals (57 percent), and marine mammals (50 percent) Sharing and distribution of subsistence foods was widespread. In 2005, 93 percent of Levelock households received at least one subsistence resource and 86 percent of households gave away at least one resource (Krieg et al. 2009).

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.4 New Stuyahok

New Stuyahok is a Yup'ik community on the Nushagak River 52 miles northeast of Dillingham. In 2005, New Stuyahok had an estimated year-round population of 421 people in 96 households. New Stuyahok residents harvested an estimated total of 163,927 pounds of wild foods (389 pounds per capita) in 2005. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by New Stuyahok residents in 2005 in terms of edible weight are shown in Figure K3.9-16, with characteristically high level of reliance on salmon, but also on large land mammals. New Stuyahok households reported high levels of participation in subsistence activities. In 2005, all New Stuyahok households used plants and fungi, as well as large land mammals. Other widely used resource categories included salmon (90 percent of households), birds and eggs (90 percent), non-salmon fish (88 percent), small land mammals (59 percent), and marine mammals (51 percent). Sharing and distribution of subsistence foods was widespread. In 2005, 98 percent of households received at least one subsistence resource and 74 percent gave away at least one resource (Krieg et al. 2009).

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.5 King Salmon

King Salmon is a predominantly Euro-American community on the Naknek River. King Salmon's Alaska Native population is a mix of Alutiiq, Yup'ik, and Dena'ina people. In 2007, King Salmon had an estimated year-round population of 246 people in 88 households. Holen et al. (2011) surveyed residents about their 2007 subsistence activities and found that King Salmon residents harvested an estimated total of 77,020 pounds of wild foods (313 pounds per capita), with very high reliance on salmon. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by King Salmon residents in 2007 in terms of edible weight are shown in Figure K3.9-17. King Salmon households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (86 percent of households) followed by plants and fungi (78 percent), non-salmon fish (57 percent), and large land mammals (47 percent). Sharing and distribution of subsistence foods was less widespread than in most communities within the project area. In 2007, 59 percent of households received at least one subsistence resource and 53 percent gave away at least one resource (Holen et al. 2011).

Figure K3.9-17: Composition of King Salmon Subsistence Harvest by Estimated Edible Weight, 2007

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.6 Naknek

Naknek is located on the northern bank of the Naknek River and is a mix of Yup'ik, Alutiiq, Dena'ina, and non-Native people. Naknek's economy is largely driven by the salmon industry (Deur 2008). In 2007, Naknek had an estimated year-round population of 533 people in 206 households. Just over half of the population was Alaska Native. Naknek residents harvested an estimated total of 140,757 pounds of wild foods (264 pounds per capita) in 2007. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Naknek residents in 2007 in terms of edible weight are shown in Figure K3.9-18. Naknek households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (93 percent of households) followed by plants and fungi (92 percent), non-salmon fish (76 percent), large land mammals (60 percent), birds and eggs (57 percent), and marine invertebrates (51 percent). Sharing and distribution of subsistence foods was widespread. In 2007, 91 percent of households received at least one subsistence resource and 73 percent gave away at least one resource (Holen et al. 2011).

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.7 South Naknek

South Naknek is located on the southern bank of the Naknek River across from the community of Naknek. South Naknek is predominantly a mixture of Alutiiq and Yup'ik people. Today, many of the Alutiiq people who reside in South Naknek are descendants of people displaced by the Mount Katmai and Novarupta volcanic eruptions of 1912. In 2007, South Naknek had an estimated year-round population of 52 people in 26 households. South Naknek residents harvested an estimated total of 13,909 pounds of wild foods (278 pounds per capita) in 2007, with characteristically high reliance on salmon, but a distinctive level of reliance on beluga whales. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by South Naknek residents in 2007 in terms of edible weight are shown in Figure K3.9-19. South Naknek households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (95 percent of households) followed by plants and fungi (91 percent), non-salmon fish (86 percent), large land mammals (67 percent), and marine mammals (48 percent). Sharing and distribution of subsistence foods was widespread. In 2007, 91 percent of households received at least one subsistence resource and 76 percent of households gave away at least one resource (Holen et al. 2011).

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.8 Aleknagik

Aleknagik is a predominantly Yup'ik community at the head of the Wood River on the southeast end of Aleknagik Lake. In 2008, Aleknagik had an estimated year-round population of 175 people in 47 households. Holen et al. (2012) surveyed residents about their 2008 subsistence activities and found that Aleknagik residents harvested an estimated total of 51,738 pounds of wild foods (296 pounds per capita). See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Aleknagik residents in 2008 in terms of edible weight are shown in Figure K3.9-20. Aleknagik households reported high levels of participation in subsistence activities. Plants and fungi, as well as salmon, were used by every household in Aleknagik. Other widely used resource categories included large land mammals (94 percent of households), birds and eggs (88 percent), non-salmon fish (78 percent), and marine mammals (56 percent). Sharing and distribution of subsistence foods was widespread. In 2007, 97 percent of households received at least one subsistence resource and 84 percent gave away at least one resource (Holen et al. 2012).

AMERICAN OVERSIGHT

K3.9.9Clark's Point

Clark's Point is a predominantly Yup'ik community on Nushagak Bay, 15 miles from Dillingham. In 2008, Clark's Point had an estimated year-round population of 38 people in 18 households. Clark's Point residents harvested an estimated total of 45,543 pounds of wild foods (1,210 pounds per capita) in 2008, a notably high level of subsistence food production among communities in the project area. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Clark's Point residents in 2008 in terms of edible weight are shown in Figure K3.9-21. Clark's Point households reported high levels of participation in subsistence activities. All households in Clark's point used salmon, non-salmon fish, birds and eggs, and large land mammals. Other widely used resource categories included plants and fungi (91 percent of households), small land mammals (82 percent), marine mammals (73 percent), and marine invertebrates (46 percent). Sharing and distribution of subsistence foods was widespread. Every household received and gave away at least one subsistence resource (Holen et al. 2012).

AMERICAN OVERSIGHT

K3.9.10 Manokotak

Manokotak is a Yup'ik community on the Igushik River. In 2008, Manokotak had an estimated year-round population of 379 people in 96 households. Manokotak residents harvested an estimated total of 113,196 pounds of wild foods (298 pounds per capita) in 2008. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Manokotak residents in 2008 in terms of edible weight are shown in Figure K3.9-22. Manokotak households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (97 percent of households), followed by plants and fungi (95 percent), birds and eggs (95 percent), non-salmon fish (93 percent), large land mammals (87 percent), marine invertebrates (82 percent), marine mammals (75 percent), and small land mammals (54 percent). Sharing and distribution of subsistence foods was widespread. In 2008, 93 percent of Manokotak households received at least one subsistence resource and 90 percent of households gave away at least one resource (Holen et al. 2012).

AMERICAN OVERSIGHT

K3.9.11 Dillingham

Dillingham is located at the northern end of Nushagak Bay at the confluence of the Wood and Nushagak rivers. Historically a Yup'ik area with Russian influences, Dillingham is now a diverse community with a mix of non-Native and Native people. In 2010, Dillingham had an estimated year-round population of 2,294 people in 726 households. Evans et al. (2013) surveyed residents about their 2010 subsistence activities and found that Dillingham households harvested an estimated total of 486,533 pounds of wild foods (212 pounds per capita). See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Dillingham residents in 2010 in terms of edible weight are shown in Figure K3.9-23. Dillingham households reported high levels of participation in subsistence activities. Salmon was the most widely used resource category (91 percent of households) followed by plants and fungi (89 percent), large land mammals (77 percent), birds and eggs (73 percent), and non-salmon fish (69 percent). Sharing and distribution of subsistence foods was widespread. In 2010, 91 percent of Dillingham households received at least one subsistence resource and 79 percent of households gave away at least one resource (Evans et al. 2013).

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

AMERICAN OVERSIGHT

K3.9.12 Ninilchik

Ninilchik is a predominately Euro-American community that lies on the eastern shore of Cook Inlet on the Sterling Highway. The Alaska Native population of Ninilchik is a mix of Alutiiq, Aleut, and Dena'ina people. Recent data is limited for this community (a comprehensive harvest survey has not been conducted since 1998) (Fall et al. 2000). In 1998, Ninilchik had an estimated population of 1,075 people in 400 households. Ninilchik residents harvested an estimated total of 175,817 pounds of wild foods (164 pounds per capita) in 1998. See Section 3.9, Subsistence, for per capita harvest by resource category. The top ten resources harvested by Ninilchik residents in 1998 in terms of edible weight are shown in Figure K3.9-24. Non-salmon fish was the most widely used resource category (92 percent of households), followed by salmon (90 percent), plants and fungi (83 percent), marine invertebrates (78 percent), and large land mammals (63 percent). Sharing and distribution of subsistence foods was widespread. In 1998, 92 percent of households received at least one subsistence resource and 73 percent of households gave away at least one resource (Fall et al. 2000).

AMERICAN OVERSIGHT

K3.9.13 Seldovia

Seldovia is a majority Euro-American community located on the Kenai Peninsula on the south shore of Kachemak Bay. The Alaska Native population of Seldovia is a mix of Alutiiq, Dena'ina, and Aleut people. In 2014, Seldovia (including Seldovia city and Seldovia Village) had an estimated year-round population of 278 people in 126 households. Seldovia residents harvested an estimated total of 38,455 pounds of wild foods (138 pounds per capita) in 2014, a comparatively low level among communities in the project area. See Section 3.9, Subsistence, for per capita harvests by resource category. The top ten resources harvested by Seldovia residents in 2014 in terms of edible weight are shown in Figure K3.9-25. Seldovia households reported high levels of participation in subsistence activities. Plants and fungi were the most widely harvested resource category (95 percent of households) followed by salmon (94 percent), non-salmon fish (90 percent), marine invertebrates (68 percent), and large land mammals (61 percent). Sharing and distribution of subsistence foods was widespread. In 2014, 97 percent of Seldovia households received at least one subsistence resource and 76 percent of households gave away at least one resource (Jones and Kostick 2016). Although located on the Kenai Peninsula, harvest areas of the Seldovia Village Tribe greater traditional use area include Kachemak Bay, Chinitna Bay, Tuxedni Bay and the western side of Cook Inlet including Kamishak Bay.

K4.20 AIR QUALITY

This Technical Appendix supports discussion and explanation of analysis of impact to air quality during the project, as described in Section 4.20, Air Quality, of the Environmental Impact Statement (EIS). Direct and indirect air quality impacts from all phases of the project are evaluated using project emissions, and where applicable, air modeling results.

K4.20.1 Methodology for the Analysis of Air Quality Impacts

Table K4.20-1 lists the Prevention of Significant Deterioration (PSD) Class II increments and Alaska Ambient Air Quality Standards (AAAQS) criteria used to evaluate project impacts, based on the results of dispersion modeling. The comparison of impacts using PSD Class II increments has been provided for informational purposes only, and does not represent a regulatory PSD increment consumption analysis. PSD increment consumption would be assessed as part of a formal increment consumption analysis during the permitting process, if required. The closest PSD Class I increments are not included as it is anticipated that the closest Federal Class I areas are far enough from the project components to not be impacted by the project. Also, for the purpose of this assessment, not all ambient standards and increments are addressed. The modeled cumulative and project-only impacts are compared to the ambient standards and increments based on likely air quality permits requirements once the project is operational.

Table K4.20-1: Prevention of Significant Deterioration Increments and Alaska Ambient Air Quality Standards

Pollutant	Averaging Period	PSD Class II Increment		AAAQS	
		Value ($\mu g/m^3$)	Form	Value ($\mu g/m^3$)	Form
CO	8 hours	N/A	N/A	10,000	Not to be exceeded more than once per year
	1 hour	N/A	N/A	40,000	Not to be exceeded more than once per year
NO_2	Annual	25	Annual mean	100	Annual mean
	1 hour	N/A	N/A	188	98th percentile of annual distribution of the maximum daily 1-hour concentrations averaged over 3 years
$PM_{2.5}$	Annual	4	Annual mean	15	Annual mean, averaged over 3 years
	24 hours	9	Not to be exceeded more than once per year	35	98th percentile, averaged over 3 years
PM_{10}	Annual	17	Annual mean	N/A	Annual mean
	24 hours	30	Not to be exceeded more than once per year	150	Not to be exceeded more than once per year on average over 3 years
SO_2	Annual	20	Annual mean	80	Never to be exceeded

AMERICAN OVERSIGHT

Table K4.20-1: Prevention of Significant Deterioration Increments and Alaska Ambient Air Quality Standards

Pollutant	Averaging Period	PSD Class II Increment		AAAQS	
		Value ($\mu g/m^3$)	Form	Value ($\mu g/m^3$)	Form
	24 hours	91	Not to be exceeded more than once per year	365	Not to be exceeded more than once per year
	3 hours	512	Not to be exceeded more than once per year	1,300	Not to be exceeded more than once per year
	1-hour	N/A	N/A	196	98th percentile of the annual distribution of the maximum daily 1-hour concentrations averaged over 3 years

Notes:

$\mu g/m^3$ = micrograms per cubic meter

AAAQS = Alaska Ambient Air Quality Standards

CO = carbon monoxide

N/A = not applicable

NO_2 = nitrogen dioxide

$PM_{2.5}$ and PM_{10} = particulate matter with an aerodynamic diameter less than or equal to 2.5 and 10 micrometers, respectively

PSD = prevention of significant deterioration

SO_2 = sulfur dioxide

Source: Alaska Administrative Code Title 18, Section 50.010

K4.20.2 Alternative 1 – Applicant's Proposed Alternative

The approach and results of the assessment of emissions and impacts of Alternative 1 are addressed for each project component by project phase (construction, operations, and decommissioning) in the following sections.

The modeling impacts are presented for the project-only concentrations and cumulative concentrations, which are the background concentrations plus the project-only concentrations. All modeling was conducted without offsite emissions sources. So, the project-only impacts can be inferred from the modeling results tables presented in the following sections by eliminating the background concentrations. The background concentrations presented in the modeling results tables are representative background conditions that are part of the ambient environment include the concentrations from nearby sources that are part of the ambient environment. Therefore, the background concentrations vary depending on the project component because the ambient environment of each component is different.

K4.20.2.1

Mine Site

The potential mine site impacts for mine construction activities and mine operations activities were developed by completing a cumulative near-field and far-field impacts assessment. The emissions from the mine site construction, operations, and decommissioning are provided in Section 4.20, Air Quality.

AMERICAN OVERSIGHT

Mine Site Construction

The representative air quality impacts related to the construction of the mine site were assessed using a near-field model. The concentration of particulate matter attributed to the increase in emissions from construction activities of a new source lasting less than 24-months are excluded from PSD increment consumption analysis under 18 Alaska Administrative Code (AAC) 50.306(b)(2). Therefore, particulate matter with an aerodynamic diameter less than or equal to 10 micrometers (PM_{10}) and particulate matter with an aerodynamic diameter less than or equal to 2.5 micrometers ($PM_{2.5}$) PSD increments were not part of the dispersion modeling assessment. However, in accordance with potential future permit requirements, dispersion modeling was conducted to demonstrate compliance with the nitrogen dioxide (NO_2), PM_{10} and $PM_{2.5}$ AAAQS and the NO_2 increment. Table K4.20-2 and Table K4.20-3 present the modeling results relative to AAAQS and PSD Class II increments, respectively. The maximum modeled impacts are presented for modeled AAAQS in Figure K4.20-1, and the modeled PSD Class II increments are presented in Figure K4.20-2. Additional details regarding the near-field modeling configuration, emissions, and assessments are provided in PLP 2018-RFI 009. Compliance with modeled concentrations compared to the air quality standards and PSD Class II increment is demonstrated. Minimal, localized, and short-term impacts would occur during the construction of the mine site. Impacts would dissipate once the construction was complete (PLP 2018-RFI 009).

Table K4.20-2: Mine Site Construction Maximum Modeled Cumulative Impacts Compared to the AAAQS

Pollutant	Averaging Period	Maximum Project-only Predicted Concentration (µg/m³)	Background Concentration (µg/m³)	Maximum Cumulative Concentration (µg/m³)	AAAQS (µg/m³)	Percent of the AAAQS

AMERICAN OVERSIGHT

Figure K4.20-2: Mine Site Construction Maximum Modeled Project-Only Impacts – PSD Class II Increments

Mine Site Operations

A near-field assessment was conducted based on the emissions presented in Section 4.20, Air Quality, and an analysis of modeling needs based on likely air quality permits required once the mine is operational. The full permit applicability analysis is provided in PLP 2018-RFI 007. In the future, the mine site would undergo a complete permitting analysis.

Near-field Impact Assessment

A near-field modeling assessment was completed, consistent with Alaska Department of Environmental Conservation (ADEC) air quality permitting requirements. It was prepared to address the potential air quality impacts related to the operation of the mine site. Table K4.20-4 and Table K4.20-5 present the modeling results relative to the AAAQS and PSD Class II increments, respectively, likely required for the air quality permits. The maximum modeled impacts are presented for modeled AAAQS in Figure K4.20-3, and the modeled PSD Class II increments are presented in Figure K4.20-4. Additional details regarding the near-field modeling configuration, emissions, and assessments is provided in PLP 2018-RFI 009. Compliance with modeled air quality standards and PSD Class II increments is demonstrated. No substantial short-term impacts are predicted to occur under the mine site operations, and air quality long-term impacts would be negligible.

AMERICAN OVERSIGHT

Far-field Impact Assessment

A far-field impact assessment included an analysis of impacts to air quality–related values (AQRVs). The US Forest Service, National Park Service, and US Fish and Wildlife Service, collectively the Federal Land Managers (FLM), define an AQRV as "a resource, as identified by the FLM for one or more federal areas that may be adversely affected by a change in air quality. The resource may include visibility or a specific scenic, cultural, physical, biological, ecological or recreational resource identified by the FLM for a particular area" (FLAG 2010). The FLAG 2010 document provides guidance on methods used to assess the potential AQRV impacts from the project. Because the mine site operations would have the potential to trigger PSD permitting, an assessment of the visibility, ambient ozone, and deposition impacts was completed. Far-field AQRV impacts from the mine site are anticipated to be minimal at any nearby Federal Class I areas.

The Plume Visual Impact Screening Model (VISCREEN) was used to determine whether air pollutant emissions from the mine site would cause visibility impacts at Federal Class I areas in the general vicinity of the mine site. Based on the combination of inputs, distances modeled, and conservative model assumptions, the model-predicted impacts show that the visibility screening criteria established for Federal Class I areas would not be exceeded at any Federal Class I area obviating the need for a cumulative impact analysis to demonstrate this project will not contribute to visibility impairment. Further details of this assessment are provided in PLP 2018-RFI 012.

The mine site is not in an ozone nonattainment area. Additionally, there are minimal nearby anthropogenic sources of oxides of nitrogen (NO_x) and volatile organic compounds (VOCs), which are ozone precursors. The mine site would have very few sources of anthropogenic ozone. The area surrounding the mine site has naturally occurring VOCs. As demonstrated in Section 3.20, the ambient NO_x concentrations are low surrounding the mine site. This results in a NOx-limited ozone environment, meaning ozone formation is capped the reactions that result in ozone are limited by the amount of available NO_x. Because the mine site potential to emit NOx would be low mine site air pollutant emissions would result in minimal ozone formation, if any formation would occur. This would result in no adverse ozone impacts at mine site or nearby National Park or National Wildlife Refuge Federal Class I areas.

Although near-field deposition impacts from the mine site were not directly evaluated, potential deposition impacts can be infer using the predicted NO_x and SO_2 impacts. NO_x and SO_2 contribute to deposition when these compounds are converted into other compounds that are readily removed from the atmosphere and deposited to soils, vegetation, and waterbodies. SO_2 impacts were not modeled for the mine site since the emissions are below the modeling requirement based on the likely permitting needs. Therefore, it is unlikely that the SO_2 emissions from the mine site would be large enough to contribute to sulfur deposition impacts. The annual NO_2 modeling impacts from the mine are less than one percent of the PSD increment and AAAQS. The nitrogen deposition impacts are calculated from the annual modeled ambient NO_2 impacts using a Level I Analysis of Long Range Transport and Depositional Impacts (EPA 1993). This calculation assumes the total conversion of all NOx emissions to depositional nitrogen, which results in a conservatively high nitrogen deposition impact of 0.5 kilograms per hectare per year (kg/ha/yr).

The National Park Service has developed nitrogen deposition critical load values for Federal Class I areas based on the amount of deposition that could lead to harmful changes within an ecosystem. As presented in Section 3.20, the nitrogen deposition critical loads for Denali National Park and other nearby Federal Class I areas are between 1.2 and 17 kg/ha/yr. The critical loads are for total (wet plus dry) deposition, while the project nitrogen deposition impact

AMERICAN OVERSIGHT

is representative dry deposition for the project-only. Measured wet and dry deposition values at Denali National Park can be added to the project-only nitrogen deposition impact to provide an estimated cumulative dry deposition. As presented in Table 3.20, for 2015, the nitrogen dry deposition value was 0.3 kg/ha/yr while the wet deposition was 0.4 kg/ha/yr (1.5 micro-equivalent per liter)., When added to the project-only deposition, the total cumulative deposition is 1.2 kg/ha/yr. This estimated cumulative deposition is equal to the lowest critical load for Denali National Park and other nearby Federal Class I areas. Although, the calculated cumulative nitrogen deposition value is a conservatively high estimate, the deposition value indicates that nitrogen deposition impacts could occur in the Federal Class I areas.

Transportation Corridor

For analysis of impacts to air quality, the transportation corridor includes all-season gravel roads, ferry terminals on Iliamna Lake, port, and spur roads, and the onshore pipeline segment at the port because the pipeline and road would be constructed jointly. The transportation corridor would be operational through the life of the project.

K4.20.2.2

The emissions are presented in Section 4.20, Air Quality. It is anticipated that the construction and operations of the transportation corridor would have similar or lower near-field impacts, as presented for the mine site, as well as far-field impacts.

Amakdedori Port

K4.20.2.3

The potential near-field impacts are presented for Amakdedori port operations. It is anticipated that the construction of the Amakdedori port would have similar near-field impacts as presented for the mine site in Section 4.20, Air Quality; therefore, they are not further evaluated. The emissions from the construction and operations phases of the Amakdedori port and offshore pipeline portions in the Cook Inlet and Iliamna Lake are presented in Section 4.20, Air Quality.

Port Operations

A near-field assessment was conducted based on the emissions presented in Section 4.20, Air Quality, and an analysis of modeling needs based on likely air quality permits required once the mine is operational. The permit applicability analysis is provided in PLP 2018-RFI 007. In the future, the port would undergo a complete permitting analysis.

Near-field Impacts Assessment

Based on the air quality permitting assessment, a minor source permit could be required for NO_x emissions. A near-field modeling assessment was completed, consistent with Alaska Department of Environmental Conservation (ADEC) minor air quality permitting requirements, which uses dispersion modeling to determine the annual NO_2 impact of the NO_x that would occur from the Amakdedori port. Table K4.20-6 presents the modeling results relative to the modeled AAAQS. Figure K4.20-5 presents the maximum modeled impacts for modeled AAAQS. Additional details regarding the near-field modeling configuration, emissions, and assessments are provided in PLP 2018-RFI 009. Compliance with potentially modeled air quality standards is demonstrated. The modeled AAAQS would not be exceeded under the port operations, and would result in minimal adverse impacts, which would be localized and remain while the operation is occurring..

AMERICAN OVERSIGHT

Far-Field Impacts Assessment

Per the FLAG 2010 guidance, a screening assessment was conducted to determine if the emissions from the port would affect the AQRVs in the nearby Federal Class I area. Q/D[1] value is calculated by dividing the port's total stationary potential NO_X, total suspended particulate matter (PM), and sulfur dioxide (SO_2) emissions by the distance to closest boundary of a Federal Class I area. A Q/D value of greater than or equal to 10 would indicate possible AQRV impacts to the Federal Class I from the port. The Q/D values for the port are all less than 2. As a result, AQRVs would not likely be affected at any of the Federal Class I areas.

Natural Gas Pipeline Corridor

The potential for near-field impacts are presented for compressor station operations. It is anticipated that the construction of the compressor station would have similar near-field impacts K4.20-24 as presented for the mine site. Section 4.20, Air Quality, addresses emissions from the construction air impacts of the Kenai compressor station on the eastern landfall of the natural gas pipeline corridor, as well as the air impacts from operations and decommissioning of the entire pipeline corridor.

Pipeline Corridor Operations

During the operations of the pipeline corridor, the emissions and associated impacts from the onshore and offshore pipelines would be negligible. The Kenai compressor station would have emissions and possible air impacts. For the operations phase, only the compressor station is assessed.

A near-field assessment was conducted based on the emissions presented in Section 4.20 and an analysis of modeling needs based on likely air quality permits required once the mine is operational. The full permit applicability analysis is provided in PLP 2018-RFI 007. In the future, the compressor station would undergo a complete permitting analysis.

Near-field Impact Assessment

A near-field modeling assessment for the operation of the compressor station was completed to address possible air quality impacts. Because a requirement to obtain a minor air quality permit might be triggered, a dispersion modeling assessment consistent with ADEC minor air quality permitting requirements was prepared. Per those requirements, dispersion modeling was used to determine the annual NO_2 impact of the NO_X emissions that would occur from the Kenai compressor station, based on the estimated emissions. Table K4.20-8 presents the modeling results relative to the AAAQS. Figure K4.20-7 presents the maximum modeled impacts presented for the modeled AAAQS. Additional details regarding the near-field modeling configuration, emissions, and assessments are provided in PLP 2018-RFI 009. Compliance with modeled air quality standards is demonstrated. If near-field impacts occur from the compressor station, those impacts would be minimal and localized.

[1] Q/D = sum of certain pollutant emissions (tons per year) divided by distance (km) from Class I area

3.2 LAND OWNERSHIP, MANAGEMENT, AND USE

This section describes the regulatory setting, along with the baseline conditions of land ownership, land management, and existing land use patterns in the Environmental Impact Statement (EIS) analysis area. Relevant land use plans are discussed and land status maps display land ownership for the EIS analysis area, which is the project footprint for land ownership and management, and the broader area around it for land use (Figure 3.2-1A through Figure 3.2-1E). Indirect effects to lands adjacent to the project are discussed under specific resources. Additional details on recreational, subsistence, and cultural uses of lands in the EIS analysis area are found in the related analyses in Section 3.5, Recreation, Section 3.7, Cultural Resources, and Section 3.9, Subsistence.

3.2.1 Land Ownership

Land ownership was determined using general land status data, which are accurate to the scale of 1 square mile (one section), and data of the project footprint.

The entire project area would be on lands owned by the State of Alaska, or privately owned by an Alaska Native Claims Settlement Act (ANCSA) Native regional or village corporation. Land ownership is shown in Table 3.2-1. The transportation corridor includes spur roads to communities under Alternative 1.

Alternative 1 would not bisect any Native Allotments. The Alternative 2 natural gas pipeline would bisect one Native Allotment (AKA 063274A). The Diamond Point port and facilities would be located on two Native Allotments (AKAA 4592a and AKAA 4225b) (Alternatives 2 and 3).

3.2.1.1 Legal Access

In the EIS analysis area, there are mechanisms to ensure consistent surface access to public lands, and in some instances, private parcels or traditional use areas. These mechanisms for access include Revised Statute (R.S.) 2477 Rights-of-Way (ROWs), ANCSA Section 17(b) Easements, Alaska National Interest Lands Conservation Act Sections 811 and 1110, State Section Line Easements, and State Public Access Easements.

Revised Statute 2477 Rights-of-Way

Section 8 of the 1866 Mining Act that states, "the right-of-way for the construction of highways over public lands, not reserved for public uses, is hereby granted." In 1873, the provision was separated from the Mining Act and re-enacted as Revised Statute (R.S.) 2477. In 1938, it was re-codified as 43 United States Code (U.S.C.) Section 932. In 1976, the Federal Land Policy and Management Act repealed both the 1866 Mining Act and R.S. 2477, but all ROWs that existed on the date of the repeal (October 21, 1976) were preserved under 43 USC Section 1769 through a savings provision for prior established rights.

Through statute or administrative action, the State of Alaska recognizes approximately 6,750 R.S. 2477 routes throughout the state (Alaska Statute 19.30.400). However, the validity of the grant is not dependent on those state recognitions.

There are no state-recognized R.S. 2477 easements in the footprint of Alternative 1. Alternatives 2 and 3 would cross the Iliamna-Pile Bay R.S. 2477 ROW, as listed in Table 3.2-2.

AMERICAN OVERSIGHT

Table 3.2-2: Revised Statute 2477 Rights-of-Way in the Project Area

ID	Name	Alternative	Project Component(s)
RST 396	Iliamna-Pile Bay	2	Mine Access Road
RST 396	Iliamna-Pile Bay	2	Natural Gas Pipeline (crosses in two locations)
RST 396	Iliamna-Pile Bay	2	Transportation Corridor (Pipeline Construction Access)
RST 396	Iliamna-Pile Bay	3	Transportation Corridor / Natural Gas Pipeline (crosses in four locations)

Source: ADNR 2018 (GIS)

Note: Project components cross the ROW in one location, unless otherwise noted.

Section Line Easements

Section line easements are state-recognized easements for highway purposes that run along a surveyed section line of the rectangular survey system (11 Alaska Admin Code [AAC] 51.025). Lands acquired by the state after March 26, 1951, including some lands in the project area, are subject to a section line easement that remains in existence unless vacated by proper authority. Easements are public ROWs, 33-, 50-, 66-, 83-, or 100-feet wide. The state asserts that all 33- and 66-foot wide section line easements were acquired under R.S. 2477, regardless of whether trails have ever been developed along them. Section line easements are authorized in law and may be established when the rectangular survey of a section line occurs. Prior to survey, the state asserts the easements exist centered on the protracted section line; however, the easement must be surveyed before it can be used. Section line easements are used primarily for transportation. The project area would encompass several section line easements.

Alaska Native Claims Settlement Act Section 17(b) Easements

Under Section 17(b) of ANCSA, the United States reserves linear access easements to public land and water on lands that have been or will be conveyed to Alaska Native Village and Regional corporations (ADNR 2013b). Easements can take the form of 60-foot wide roads, 25- and 50-foot trails, or 1-acre site easements for vehicle parking, temporary camping, or loading/unloading. These easements are reserved to allow for public access through ANCSA lands to reach public lands and waterways. They do not authorize public access to the private land that the easement crosses (BLM 2009). The BLM has management authority for the United States for these easements unless that authority has been otherwise delegated.

Section 17(b) easements have specific allowable uses that are stated in the conveyance document. They cannot be reserved or retained for recreational purposes, but can provide access to recreational opportunities on publicly owned land or for change in mode of transportation. Uses beyond those expressly granted should be approved by the property owner to avoid trespass issues between the user and the property owner.

Alternative 1 would intersect 1 Section 17(b) easement, on the southern shore of Lake Iliamna. Alternative 2 and Alternative 3 would intersect 2 Section 17(b) easements; both begin at the northern shore of Iliamna Lake and continue north (Table 3.2-3).

AMERICAN OVERSIGHT

Table 3.2-3: ANCSA Section 17(b) Easements in the Project Area

ID	Description	Alternative(s)	Project Component

Source: ADNR 1990, BLM 2018 (GIS reference)

State Public Access Easements

Five 100- to 400-foot wide State Public Access Easements exist on state land along the proposed pipeline route. Under these easements, the State of Alaska reserved public access for present and future needs along the corridors as well as authorization for trail improvements, trail maintenance and safety cabins. The State Public Access Easements in the project area are listed in Table 3.2-4.

Table 3.2-4: State Public Access Easements in the Project Area

ID	Description	Alternative	Project Component(s)
ADL 230875	United Utilities, Inc. exclusive ROW for hybrid fiber optic cable and microwave broadband communications network. In the project area, it would bisect in Iliamna Lake and Cook Inlet.	1, 2, 3	Transportation Corridor (ferry route, Alternatives1 and 2 only)[2], Transportation Corridor, Natural Gas Pipeline
ADL 218329	Pedro Bay Improvement Corporation, Inc. (obsolete).	2, 3	Transportation Corridor (Alternative 3 only), Natural Gas Pipeline
ADL 232949	Alaska Department of Transportation and Public Facilities design and construction ROW, central region (obsolete).	2, 3	Transportation Corridor, Natural Gas Pipeline

Notes:

Project components cross the easement in one location, unless otherwise noted.

1. Crosses in two locations under the proposed action. Under the Kokhanok east ferry terminal variant, the pipeline would cross in two locations, and the ferry route would cross in three locations.

2. Crosses in nine locations.

Source: LM 2010, ADNR 2018 (GIS reference)

AMERICAN OVERSIGHT

3.2.2 Land Management

3.2.2.1 Federal Management

The project footprint for any of the alternatives would not intersect with federal land. Under Alternative 1, the mine access road and natural gas pipeline corridor would be within 9 miles of Lake Clark National Park and Preserve (NPP), within 8 miles from Katmai NPP, and more than 20 miles from Alagnak Wild River. The natural gas pipeline corridor would pass near a portion of the Alaska Maritime National Wildlife Refuge and the Kachemak Bay National Estuarine Research Reserve (NERR). The mine access road would be within 1 mile of lands that are selected by the State and managed by the Bureau of Land Management (BLM).

Under Alternatives 2 and 3, the transportation corridor and natural gas pipeline would be within 5 miles of Lake Clark NPP, and within approximately 1 mile of lands that are selected by the State or Native corporations and managed by the BLM. The natural gas pipeline corridor would pass near a portion of the Alaska Maritime National Wildlife Refuge and the Kachemak Bay NERR.

National Park Service

The National Park Service (NPS) manages Lake Clark NPP, Katmai NPP, and the Alagnak Wild River. The transportation corridor and the mine site components would occur in the vicinity of, but not on, these lands. These project components would therefore not be subject to the NPS's land management jurisdiction. Section 3.5, Recreation, includes more information about management in each NPS unit.

US Fish and Wildlife Service

The US Fish and Wildlife Service (USFWS) manages the Alaska Maritime National Wildlife Refuge, a portion of which would be within 10 miles of the natural gas pipeline corridor, and some refuge islands would be within 20 miles of the Amakdedori port site. These project components would not be subject to USFWS's land management jurisdiction, as the project components would be near, but not on, USFWS land. Section 3.5, Recreation, includes more information about management in the refuge.

Bureau of Land Management

The mine access road would occur within 1 mile of, but not on, BLM-managed lands under Alternative 1. This project component would therefore not be subject to BLM's land management jurisdiction. The project alternatives would cross one or more ANCSA Section 17(b) easements, discussed below.

National Oceanic and Atmospheric Administration

The Kachemak Bay NERR is a state/federal partnership with the Alaska Department of Fish and Game (ADF&G) and the National Oceanic and Atmospheric Administration (NOAA); it was designated to promote informed management of the nation's estuaries and coastal habitats (KBNERR 2011). The pipeline compressor station would be located approximately 4 miles from the reserve and would therefore not be subject to the NOAA or ADF&G land management jurisdiction.

AMERICAN OVERSIGHT

3.2.2.2 State Management

The Alaska Department of Natural Resources (ADNR), under AS 38.04.065 Land Use Planning and Classification and 11 AAC 55.010-.030, "shall, with local governmental and public involvement under AS 38.05.945, adopt, maintain, and, when appropriate, revise regional land use plans that provide for the use and management of State of Alaska-owned lands." Plans applicable to the EIS analysis area include the Bristol Bay Area Plan (ADNR 2013a), the Nushagak and Mulchatna Rivers Recreation Management Plan (2005), and the Kenai Area Plan (ADNR 2001).

All resource and land uses, including mining and recreation, are considered and evaluated under state management. Unless closed by the legislature, or a less-than-640-acre tract closed by administrative order, all state land is open for multiple uses. The State of Alaska's Generally Allowed Uses on State Land provides a general explanation of the state's use management framework.

The proposed natural gas pipeline and Amakdedori port would be within 2 miles of the boundary of (but would not occupy) the McNeil River State Game Refuge and Sanctuary, which is managed by the ADF&G in accordance with the McNeil River State Game Refuge and Sanctuary Management Plan (ADF&G 2008). Section 3.5, Recreation, includes more information about management in the refuge and sanctuary.

Bristol Bay Area Plan

The Bristol Bay Area Plan was the outgrowth of a cooperative federal-state land use planning process mandated by the Alaska National Interest Lands Conservation Act. It was developed during the early 1980s, and was revised in 2005 to address the outstanding municipal entitlements of the three boroughs in the planning area (i.e., Bristol Bay, Lake and Peninsula, and Aleutians East), revise the tideland designations, address regional economic changes and changing land use patterns, and to allow ADNR to lease portions of the area for oil and gas development.

The plan was substantially revised again in 2013 after litigation, which focused on the concern of loss of protection to important habitat and recreation areas when much of the plan area was re-designated for general use. The 2005 plan was revised in response to an agreement with the plaintiffs in Nondalton Tribal Council et al. v. State of Alaska, which dismissed the litigation in exchange for ADNR's agreement to address the issues raised in the lawsuit through the existing administrative process for amending area land use plans and reclassifying land.

The Bristol Bay Area Plan divides the Bristol Bay area into 20 regions with management units. The mine site would be located in Region 6, and the transportation corridor would be in regions 6, 9, and 10 under Alternative 1 and 6, 8, and 9 under Alternatives 2 and 3. Region 6 is designated for mineral development, and managed to ensure that impacts to the anadromous and high value resident fish streams are avoided or reduced as appropriate in the permitting processes. Additionally, impacts to moose wintering habitat are to be taken into consideration during mine permit review, and the upper Koktuli River is managed for recreation. Regions 8, 9, and 10 are managed for a variety of uses including mineral exploration and development, public recreation and tourism, and protection of anadromous fish and wildlife resources and habitat. Region 8 is also managed for settlement. State-owned lands within these regions are identified to be retained in public ownership and managed for multiple use. The state selected much of the land in the planning area because of its mineral potential. Most of the area of mine itself is designated with the primary use of mineral development. An additional goal for this region is for the state to provide support for mining by aiding in the development of infrastructure, such as ports and roads (ADNR 2013a).

AMERICAN OVERSIGHT

Iliamna Lake is managed under Region 9, co-designated under Public Recreation and Tourism-Dispersed and Habitat land designations. The navigable waters of this lake are to be managed so that its public recreation and habitat values are maintained. Development authorizations in these waters may be appropriate insofar as essential habitat and public recreation values are maintained. Authorizations in these waterbodies should not interfere with navigability, important habitat values, or recreational uses (ADNR 2013a).

Nushagak and Mulchatna Rivers Recreation Management Plan

The Nushagak and Mulchatna Rivers Recreation Management Plan is a component of the Bristol Bay Area Plan. This plan is superseded by the management intent of the Bristol Bay Area Plan 2013 revision. In response to previous plans and to public concern about subsistence use and increased recreational use in the region, ADNR, ADF&G, and the Bristol Bay Coastal Resource Service Area entered into a cooperative agreement to manage these rivers. No project components would be covered by the plan, but the mine site is approximately 20 miles upriver of units 16, 17, 18, and 19 of the plan.

The Bristol Bay Area Plan includes goals that identify the need to manage land; protect fish, wildlife, and water; and provide a diversity of commercial and non-commercial public use opportunities. To meet goals in the Bristol Bay Area Plan, state land in the Nushagak and Mulchatna planning area is to be managed to provide a mix of commercial and non-commercial public use opportunities, ensure availability of public use sites to meet the needs of all users, protect habitat and other natural resources, and maintain options for future recreation management. Units 16, 17, 18, and 19, are managed as primitive or semi-primitive and some permanent and temporary facilities may be prohibited (ADNR 2005).

Kenai Area Plan

The Kenai Area Plan divides the Cook Inlet area into 12 regions with management units. Amakdedori port would be located in Region 12, and the natural gas pipeline component would be in Region 7 and Region 12. State-owned lands in these regions are identified to be retained in public ownership and managed for multiple uses. The area around Amakdedori port is managed as habitat for bear spring feeding, moose, Dolly Varden, Arctic char, ducks, and geese. Cook Inlet waters at Amakdedori are managed for recreation. The plan has management guidelines for the development of transportation and utilities, which include cultural surveys, and protection of hydrologic systems and roads near wetlands. The plan also provides guidelines for waterfront development for soil erosion and fuel storage (ADNR 2001).

3.2.2.3 Borough Management

Lake and Peninsula Borough

The mine site, the natural gas pipeline, and the transportation corridor would be within the boundaries of the Lake and Peninsula Borough (LPB). The LPB, as a non-unified home rule borough, is required to provide for planning, platting, and land use regulations on an area-wide basis (both inside and outside of cities) in the borough but not necessarily in accordance with AS 29.40.

The LPB's planning commission was established to perform the area-wide functions of planning, platting, and zoning. The commission's recommendations are then transmitted to the LPB assembly, a body of elected district representatives that sets policy and exercises legislative power in the borough (LPB n.d.). The commission prepares and revises the LPB

AMERICAN OVERSIGHT

Comprehensive Plan (LPB 2012). The LPB Comprehensive Plan provides general goals and policy recommendations to address pressing issues in the region.

The plan includes the following strategies for planning for wise land use and environmental protection: periodically review (and if appropriate improve) enforceable development standards (e.g., stream setbacks), and periodically review (and if appropriate, improve) the LPB's large project review process. Unlike some comprehensive plans, it does not make land use regulations, but is linked to community action plans for each of the LPB's communities, including those in the EIS analysis area. In addition to the LPB Comprehensive Plan, the LPB has prepared Village Strategic Plans for the following communities: Port Alsworth, Nondalton, Newhalen, Pedro Bay, Kokhanok, and Levelock. These brief plans outline core values, an envisioned future, and strategic direction for the period of 2017 to 2022.

LPB permits include Chapters 9.07 Development Permit and 9.08 Large Project Permits of the LPB code, and have requirements that apply to local approval of the Pebble Project. The Large Project Permit requires that the project comply with socioeconomic and with fiscal impact criteria that are outlined in the ordinance. These include activities within 100 feet of an anadromous stream, reclamation plans, and socioeconomic and fiscal impact reports.

Kenai Peninsula Borough

A portion of the proposed natural gas pipeline would be within the Kenai Peninsula Borough (KPB). The Amakdedori and Diamond Point ports and southern portions of the transportation corridor mine access roads would be within the KPB boundaries. As a second-class borough, the KPB is required to provide for planning, platting, and land use regulations on an area-wide basis (both inside and outside of cities) in the borough in accordance with AS 29.40. Land use in the KPB is guided by the KPB Comprehensive Plan (KPB 2005, 2017). The Code of Ordinances dictates the KPB's powers and operations.

Zoning in the KPB is unrestricted outside of the KPB's cities and Local Option Zone Districts, none of which are located in the EIS analysis area. However, the KPB does regulate floodplain development, and development near certain anadromous fish streams throughout the borough, including Amakdedori Creek, near the proposed port site.

The KPB Comprehensive Plan recognizes the borough's vicinity to the project area and acknowledges that proposed infrastructure would be located in the borough, although the plan does not contain goals, objectives, or implementation actions specific to development for the project on lands in the KPB.

3.2.2.4 Alaska Native Regional and Village Corporations

In 1971, President Richard Nixon signed ANCSA into law. Under ANCSA, aboriginal land claims were settled in exchange for $962.5 million in compensation, as well as approximately 40 million acres of land (Norris 2002). ANCSA established 12 for-profit Alaska Native regional corporations and 225 Alaska Native village corporations to administer the settlement lands and compensation funds. A 13th regional corporation was later added for Alaska Natives living outside the state. Alaska Natives enrolled as shareholders in the village and regional corporations where they lived at the time of enactment. The regional and village corporations land entitlement was generally proportionate to the population of these corporations at the time of enrollment. In most cases, the surface estate is owned by the village corporations, with the subsurface estate owned by the associated regional corporations.

Alaska Native corporation land is often held in large tracts and used for subsistence purposes or developed/sold to generate revenue. Alaska Native corporation-owned lands in the proposed

AMERICAN OVERSIGHT

transportation corridors and natural gas pipeline corridors consist of parcels with surface and subsurface rights owned by Bristol Bay Native Corporation (BBNC) and Cook Inlet Region Inc. (CIRI), and surface rights owned by Iliamna Natives Ltd. and Alaska Peninsula Corporation and other village corporations. Complete ownership for all alternatives is listed above in Table 3.2-1.

As private land, uses on land owned by Alaska Native corporations are subject to approvals of the surface and subsurface landowners. The BBNC manages their lands to uphold three primary values: fiscal, environmental, and social, in order to protect the fish that have sustained the culture of the people through history (BBNC 2018). Some of the project components would be located on CIRI property. CIRI manages their lands to strike a balance between sustainably developing resources to improve opportunities for shareholders, and protecting the land for future generations (CIRI 2018). The Alaska Peninsula Corporation mission is "to preserve and enhance the quality of life of Alaska Peninsula Corporation shareholders and to protect our culture while managing our assets in a manner which enhances their value" (APC 2018). Parts of the mine access road would be located on Alaska Peninsula Corporation property. Village corporation missions often include protection for the natural and cultural environment, and allowance of some development.

3.2.2.5 Native Allotments

Native allotments are parcels of land up to 160 acres that are owned by an individual issued under the 1906 Native Allotment Act. The lands are held in trust by the federal government and generally require the Bureau of Indian Affairs oversight for sales, gift deeds, leases permits, partitions, ROWs, and sand and gravel leases.

3.2.2.6 Local Management

Some communities in the project area have developed community plans including comprehensive, capital improvement, land use, strategic, transportation, vision, and other planning documents. Such planning exercises determine community goals, objectives, and management strategies for enacting public policy on transportation, utilities, land use, recreation, housing, and other topics of importance to the community. No physical, project-related infrastructure would be developed on lands that are in local jurisdiction, but indirect effects could occur from management on adjacent lands.

3.2.3 Land Use

The prevalent land uses around the EIS analysis area are fish and wildlife habitat, low-intensity recreational activities, and subsistence, which do not require developed facilities. Land development in the Bristol Bay area is generally limited to the areas in and around geographically isolated communities, fish processing facilities, and small fishing and hunting lodges. Developments include roads, airstrips, and docks.

Residential and commercial land use in the vicinity of the mine site is limited and includes the communities of Newhalen (population 230), Nondalton (population 144), and Iliamna (population 100), each located approximately 17 miles from the mine site. Use around the transportation corridor is also limited and includes the community of Kokhanok (population 173) located approximately 2 miles from the Alternative 1 mine access road, or the community of Pedro Bay (population 32) located within 1 mile of the Alternative 3 transportation corridor. Many residents practice a lifestyle reliant on subsistence activities, and recreational hunting, fishing, and boating also occurs in the area (DCCED 2018) (see Section 3.5, Recreation, Section 3.6, Recreation and Commercial Fishing, and Section 3.9, Subsistence for details). There are additional mining

AMERICAN OVERSIGHT

claims near the project area filed by Northern Dynasty Minerals and other mining exploration firms. Some claims have been relinquished, while others remain active.

The Amakdedori port site is used for some subsistence activity, and cultural education for nearby communities. The Diamond Point port site is used for resource extraction. The transportation corridor under Alternatives 2 and 3 includes the Williamsport-Pile Bay road, which is used for the portage of fishing boats from Cook Inlet to the Bristol Bay fishery.

On the Kenai Peninsula, there is a higher use of the land for recreation, and scattered residential and commercial development along the Sterling Highway where the natural gas pipeline component would cross it. The highway is traveled in all seasons, but sees particularly high use in the summer when recreation and tourism activities increase. Where the natural gas pipeline corridor would cross Cook Inlet, the water is used for transportation, barging, boating, commercial fishing recreational and subsistence fishing, sightseeing, and provides habitat for wildlife.

AMERICAN OVERSIGHT

3.6 COMMERCIAL AND RECREATIONAL FISHERIES

3.6.1 Commercial Fishing

The inshore waters of Bristol Bay are home to the world's largest sockeye fishery and some of the world's largest natural salmon runs. Between 2000 and 2010, Bristol Bay provided 45 percent of the world's sockeye harvest, 7 percent of the world's wild salmon harvests and 2 percent of world salmon supply (EPA 2014a). Each year, roughly 2,840 holders of State of Alaska Area T salmon permits (shown in Figure 3.6-1) have the opportunity to harvest salmon from five major fishing districts managed by the Alaska Department of Fish and Game (ADF&G)[1]. The economic ecosystem driven by the salmon resource provides the Bristol Bay region with its largest private source of earned income and employment.

Figure 3.6-1: Bristol Bay (Area T) Salmon Fishing Districts

Source: ADF&G 2018k

In comparison to the inshore state waters salmon fishery, fisheries outside of the 3-mile limit of state waters are limited by the federally managed Nearshore Bristol Bay Trawl Closure Area. The closure area bans trawl fishing in federal Bristol Bay waters, with the exception of the seasonal opening of a very small area west of Cape Constantine and Nushagak Point.

With localized federal conservation measures in place to protect juvenile red king crab, the state Area T Bristol Bay salmon fishery is the only commercial fishery in the EIS analysis area.

[1] In Alaska, commercial fishing salmon permits are issued by the State and can be used in one specific fishery as defined by state regulations. The State assigns each fishery a letter designation. The designation for Bristol Bay is "Area T."

AMERICAN OVERSIGHT

3.6.1.1 The Bristol Bay Salmon Fishery

The Area T Bristol Bay salmon fishery (the fishery) is divided into five districts (Naknek/Kvichak, Egegik, Ugashik, Nushagak, and Togiak) encompassing nine major river systems. Only some waterbodies in the Naknek/Kvichak district and the Nushagak district are hydrologically connected to the proposed project. Across all five districts, sockeye salmon are the most commonly harvested species, representing 97 percent or more of the harvest in the Naknek/Kvichak district, the Egegik district, and the Ugashik district (see Table 3.6-1). In the Nushagak district, sockeye have represented 86 percent of the 20-year harvest with chum salmon and pink salmon representing 7 percent and 6 percent of the harvest, respectively. While Chinook salmon account for just 1 percent of annual Nushagak harvest, the number of fish harvested averages 40,000 annually, making the Nushagak district the most important Chinook salmon fishery, by volume, outside of Southeast Alaska (ADF&G 2018k). The Togiak district also harvests sizeable portions of chum salmon and pink salmon, with those species accounting for 19 percent and 8 percent of the 20-year harvest, respectively.

Over the last 20 years, the fishery's average annual harvests have equalled 23 million sockeye salmon, 950,000 chum salmon, 500,000 pink salmon, 80,000 coho salmon, and 50,000 Chinook salmon (ADF&G 2018m).

Table 3.6-1: 20-Year Average Harvest Distribution by Species (Percent)

Species	Naknek/ Kvichak	Egegik	Ugashik	Nushagak	Togiak	Total
Sockeye	97	99	97	86	71	94
Chinook	0	0	0	1	1	0
Coho	0	0	0	1	1	0
Chum	2	1	2	7	19	4
Pink	0	0	0	6	8	2

Note: Percentages may not equal 100 due to rounding

Source: ADF&G 2018m

Harvest varies significantly across the five fishing districts and in each district from year to year. On average, the most productive fishing districts are the Naknek/Kvichak district (8.2 million fish annually), followed by the Nushagak (7.3 million), the Egegik (6.8 million), the Ugashik (2.9 million), and the Togiak (0.7 million). Harvest size in each district can vary substantially due to the overall size of salmon runs. The ADF&G manages each district to ensure that the required number of salmon reach their spawning grounds to maximize long-term productivity. The number of salmon that are not harvested by the fishery is known as the "escapement number." Harvest numbers tend to vary more than escapement numbers because the escapement goal is a set range, while fishing effort is the tool used to balance between the number of fish returning and the escapement goal. In particular, the Naknek/Kvichak district in particular is known for its varying run strength. The 20-year minimum harvest in this district was 602,061 fish compared to an average of over 8 million fish, and a maximum near 17 million fish. Thus, the largest harvest was 28 times the smallest harvest. In the hydrologically connected to the project area Nushagak district, and the non-hydrologically connected Ugashik district, the largest harvest was nearly 13 times the smallest harvest. In the other districts the largest to smallest ratio was less than 5.5:1. In all districts, the average harvests from 2008 to 2017 have been larger than the average harvests from 1998 to 2007. Harvests by district are shown in Table 3.6-2.

AMERICAN OVERSIGHT

Table 3.6-2: 20-Year Annual Bristol Bay Salmon Harvest by District

	Naknek/ Kvichak	Egegik	Ugashik	Nushagak	Togiak	Total
20-Year Min.	602,061	2,369,459	526,114	2,761,086	198,926	10,721,140
20-Year Max.	16,885,517	12,143,186	6,705,869	13,334,168	1,082,937	40,592,915
20-Year Median	8,513,405	7,082,486	2,450,220	6,734,064	778,472	26,391,928
20-Year Average	8,220,622	6,829,737	2,901,849	7,263,097	764,344	26,041,124

2008-17 Average	10,830,378	7,586,138	3,610,179	7,639,353	817,879	30,438,547

Source: ADF&G 2018m

The 20-year average escapements for each of the districts are 6.4 million fish in the Naknek/Kvichak district (which contains two major river systems), 2.6 million fish in the Nushagak district, 1.3 million fish in the Egegik district, 1 million fish in the Ugashik district, and 0.2 million fish in the Togiak district (see Table 3.6-3). In all districts except the Togiak district, escapement has been higher in the past 10 years than in the 10 years between 1998 and 2007. Subsistence users and recreational anglers access the resource after salmon enter freshwater, and after the fish have escaped the commercial fishery; the ADF&G's escapement goals include a portion expected to be harvested by these users.

Table 3.6-3: Annual Bristol Bay Salmon Escapement by District

	Naknek/ Kvichak	Egegik	Ugashik	Nushagak	Togiak	Total
20-Year Min.	2,303,463	927,054	596,332	1,389,975	128,118	6,200,639
20-Year Max.	15,033,216	2,600,982	2,599,186	7,705,277	390,080	22,366,676

2008-17 Average	7,037,010	1,345,465	1,185,379	2,621,797	207,049	12,396,700

Source: ADF&G 2018m

Administration of the Bristol Bay fishery occurs through two different sets of permits: drift net permits and set net permits. Drift nets are nets attached by one end to boats, while set nets are attached to by one end to land. On average, drift net permit holders harvest four out of every five fish harvested in the fishery, but the ratio has been as low as two out of every three fish (see Table 3.6-4).

Table 3.6-4: Sockeye Drift Net and Set Net Harvest Split (Percent)

	20-Year Min.	20-Year Max.	20-Year Median	20-Year Average	1998-07 Average	2008-17 Average

Set Net Portion	34	14	19	20	20	19

Source: ADF&G 2018m

AMERICAN OVERSIGHT

Nushagak and Kvichak District Historical Harvest and Escapement

The EIS analysis area is limited to river systems hydrologically connected to the project area, which contribute to the Bristol Bay salmon fishery. Only the Naknek/Kvichak district and the Nushagak district contain some rivers that are hydrologically connected to the project area.

The Naknek/Kvichak district contains three of the nine major river systems in the Bristol Bay fishery, but only the Kvichak River is hydrologically connected to the project area. Over the last 20 years, the average return (run) to this river is roughly 6.7 million fish, which is 43 percent of the total average run strength in the district (see Table 3.6-5 and Figure 3.6-2). The Kvichak River is known for its variable run strength; the smallest return to this river in the last 20 years was just 707,000 fish, while the largest run was 15.5 million fish. At the same time, the average return to the river system from 2008 to 2017 was more than double the average return from 1998 to 2007.

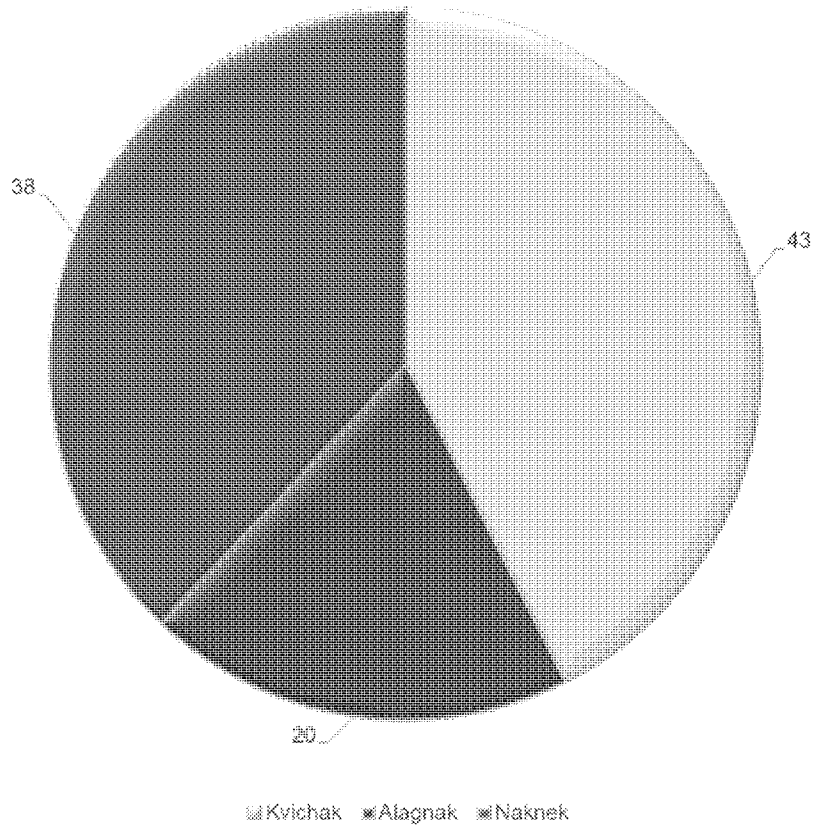

Table 3.6-5: Naknek-Kvichak District Run Distribution (Thousands of Fish)

	Kvichak	Alagnak	Naknek	Total
20-Year Min. Run Size	707	234	1,402	3,337
20-Year Max. Run Size	15,466	11,629	8,794	31,566

Figure 3.6-2: Naknek-Kvichak District 20-Year Run Distribution by River System (Percent of Run)

Source: ADF&G 2017a

The Nushagak district is also comprised of three large river systems: the Wood River, the Igushik River, and the Nushagak River. The Nushagak River is hydrologically connected to the project via the Mulchatna River system, but the other two river systems are not. The Wood River, fed by the Wood-Tikchik Lake system, is the dominant fish producer in the district and accounted for 62 percent of the estimated run strength over the last 20 years. The return to this system averaged 5.7 million fish per year. In comparison, the Nushagak River accounted for 2.3 million fish per year between 1998 and 2017, or 24 percent of the district total. The Nushagak River also experiences significant variations in run strength. While not as extreme as the variations found on the Kvichak River, the largest run in the past 20 years was nearly 12 times the size of the smallest run (see Table 3.6-6 and Figure 3.6-3).

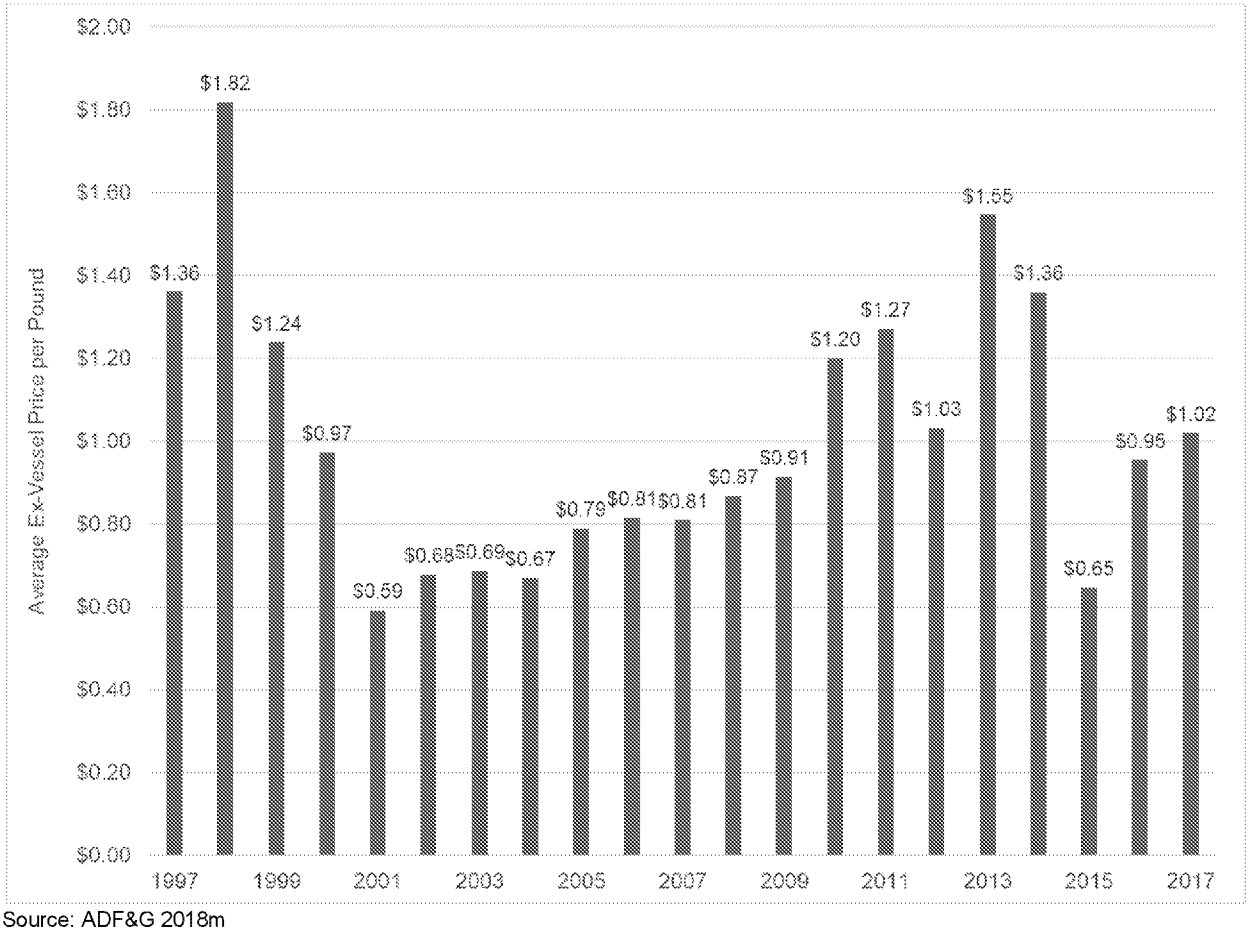
Figure 3.6-3: Nushagak District 20-Year Run Distribution by River System (Percentages)

Source: ADF&G 2017a

In the context of other Bristol Bay rivers and other Alaska rivers such as the Kenai River and the Copper River, the Nushagak River does not particularly stand out for the average size of its sockeye salmon run. The Wood River is the dominant producer of sockeye in Nushagak district. However, the Nushagak River does stand out for the size of its Chinook salmon run. Over the last 20 years, on average, the entire Bristol Bay fishery harvested 32,908 Chinook each year, and 25,623 of these fish (78 percent) came from the Nushagak district. The 20-year average Chinook run size for the Nushagak is 179,000 fish (ADF&G 2017b). Average run sizes for Chinook in other river systems in Alaska are approximately 260,000 in the Kuskokwim drainage, 166,000 in the Yukon drainage, 100,000 to 200,000 in the Susitna drainage, 56,000 in the Kenai



AMERICAN OVERSIGHT

River, and 55,000 in the Copper River (JTC 2018, Poetter and Tiernan 2017, ADF&G 2008c, ADF&G 2016a, Russell et al. 2017).

The Value of the Fishery

The average price per pound that processors pay permit holders for their salmon depends largely on the condition of world salmon markets, including salmon produced by other wild and farmed sources. Individual and collective efforts around marketing, improving product quality, and developing new markets and products can also have long-term effects on the value of salmon at harvester level. The connection to a world commodity market means that ex-vessel prices for salmon can vary markedly from year to year. In 2017, permit holders in Bristol Bay received an average of $1.02 per pound. Four years earlier they received $1.55 per pound, which was the highest average price since 1998; two years earlier they received $0.65 per pound on average (see Figure 3.6-4)[2]. Between 2008 and 2017, the average price swing from year to year was +/- 20 percent.

Figure 3.6-4: Average Price per Pound for Bristol Bay Sockeye, 2017

Source: ADF&G 2018m

With the exception of 1998 when prices for sockeye were at their modern high, the prices that Bristol Bay permit holders receive for their salmon are lower than prices received for the same species of fish caught in other major Alaskan salmon fisheries. Over the past 20 years, the ex-vessel prices for sockeye salmon in the Cook Inlet, Copper River, Prince William Sound, and Southeast Alaska fisheries averaged 50 percent, 150 percent, 60 percent, and 54 percent

[2] All prices are in $US 2017.

AMERICAN OVERSIGHT

higher, respectively, than the price paid for Bristol Bay sockeye (see Table 3.6-7). The price differential can be explained by a number of factors, including the remoteness of the Bristol Bay fishery, which increases transportation and operating costs for processors, and the historic lack of a strong brand identity for Bristol Bay fish (in comparison to the Copper River fishery, which does have a strong brand identity). In recent years, Bristol Bay permit holders have worked with processors to increase quality throughout the chain of custody and to establish a brand identity (BBRSDA 2018). The annual data show that the price gap tends to be smaller when demand for sockeye is high, and tends increase to when demand for sockeye is low.

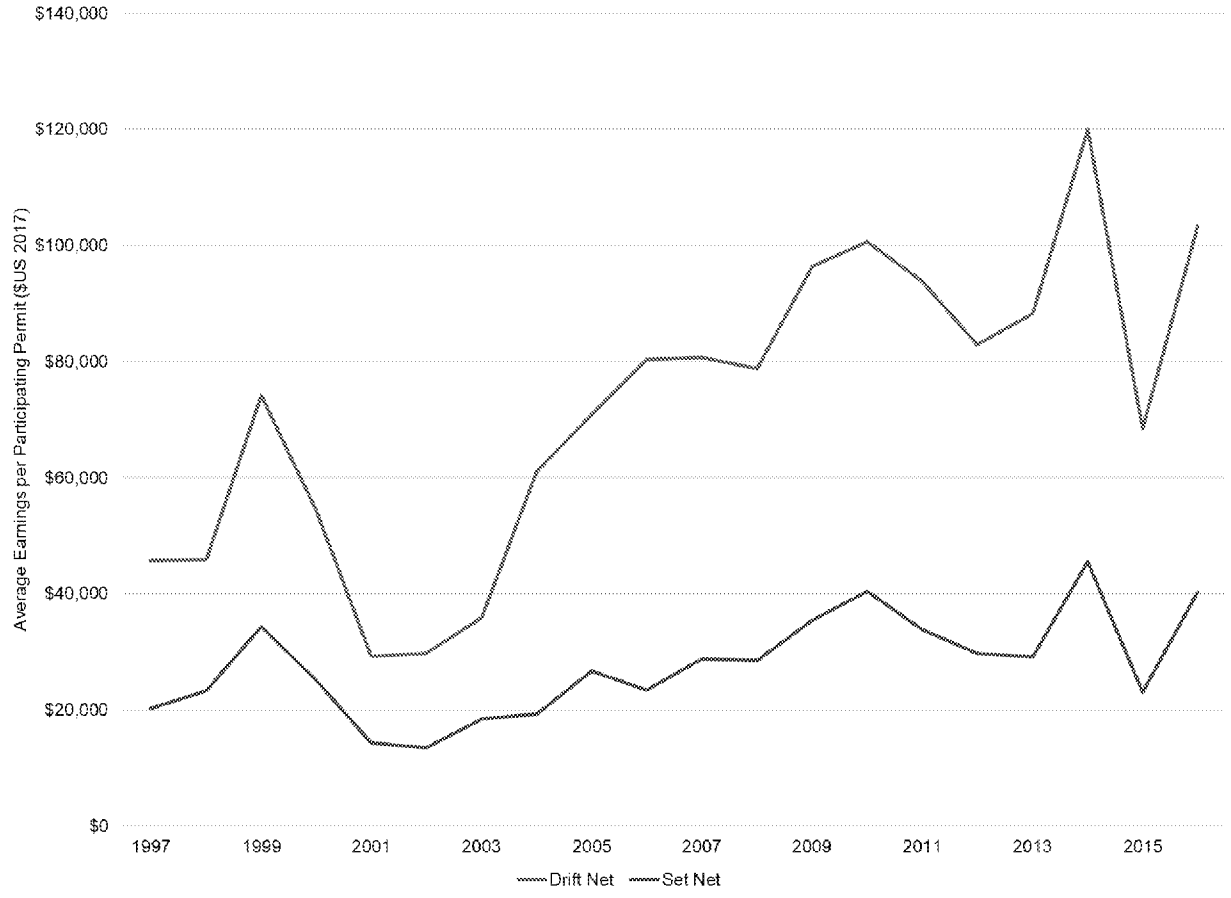
In 2017, the fishery generated $216.4 million in ex-vessel payments to all Area T permit holders, making that year the second-best year for permit holders collectively since 1997 (see Figure 3.6-5). The 20-year inflation-adjusted ex-vessel value of the fishery is approximately $134.4 million, but over the last 10 years the ex-vessel value has averaged $162.8 million.

AMERICAN OVERSIGHT

Figure 3.6-5: Total Ex-Vessel Fishery Value for Bristol Bay (Area T), $US 2017

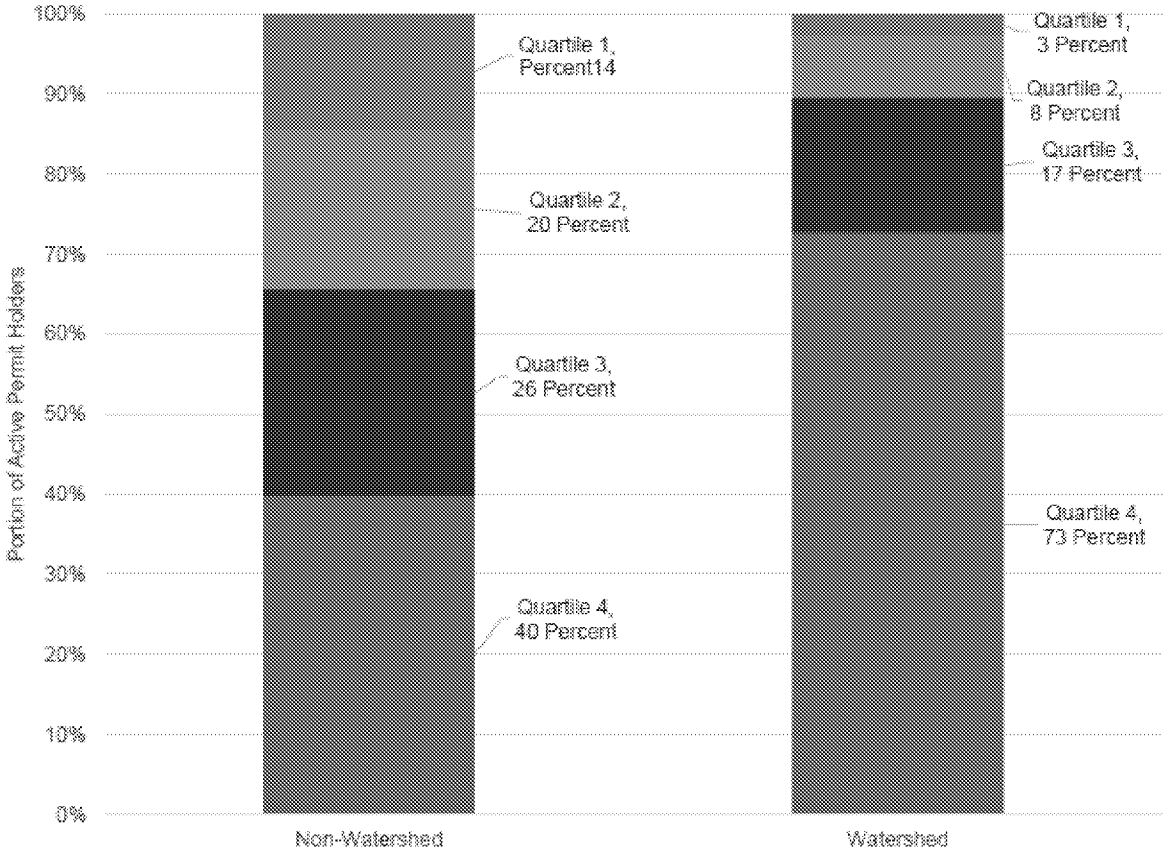


Source: ADF&G 2018m

Average permit holder gross earnings vary from year to year with run and market strength, but increased substantially in both the set net and drift net fisheries since 2001 and 2002, when the fishery generated the lowest level of ex-vessel value in the modern era (see Figure 3.6-6). In 2017, drift net permit values had an estimated value of over $103,000, while set net permits had an estimated value of roughly $40,000. The estimated values of both types of permits have risen substantially since 2001 and 2002, when smaller average run sizes and lower prices depressed the permits' expected earnings power.

AMERICAN OVERSIGHT

Figure 3.6-6: Annual Average Permit Holder Earnings per Year, 2017

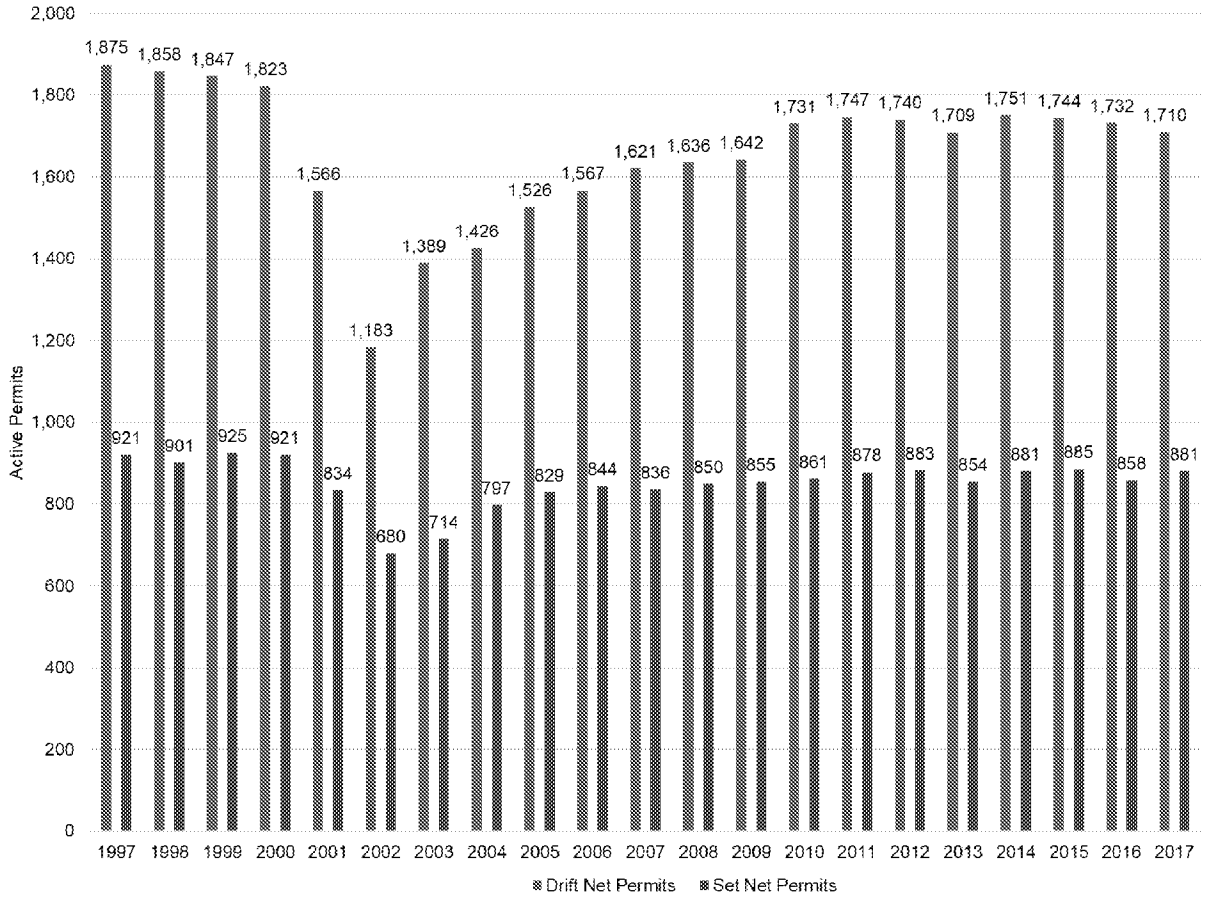


Source: CFEC 2018

Alaska Commercial Fisheries Entry Commission (CFEC) data divide permit holders into four earnings (i.e., quartiles). The cumulative amount of earnings in each group is the same, but the number of permit holders and the average earnings per permit holder is different. For example, in 2016 each quartile group earned roughly $35.5 million in aggregate, but the top group included just 170 permit holders earning an average of $232,837 each, while the bottom group included 759 permit holders earning an average of $52,044 each (CFEC 2018). Permit holders who are residents of the District T are more likely to be in the bottom quartile compared to non-residents, and 80 percent less likely to be in the top quartile (see Figure 3.6-7). Between 2002 and 2012, 73 percent of watershed residents were in the bottom earnings quartile, while 40 percent of non-watershed residents landed in the bottom quartile. In the same period for the top quartile, 3 percent of watershed resident permit holders landed in the top quartile, while 14 percent of non-watershed residents earned enough to be in that quartile (NEI 2014).

AMERICAN OVERSIGHT

Figure 3.6-7: Distribution of Quartiles in the Drift Net Fishery by Area of Residence, 2002-2012



Source: NEI 2014

Participation in the Fishery and Permit Ownership

Permit holder participation in the fishery varies from year to year depending on permit holder expectations for both prices and the size of the overall Bristol Bay salmon run. Several distinct periods define permit holder participation over the past 20 years. Between 1997 and 2000, more than 97 percent of drift net permit holders and 90 percent of set net holders participated in the fishery. Fishery participation dropped substantially in 2001 and 2002 as low prices discouraged permit holders from fishing; only 63 percent of drift net permit holders and 67 percent of set net holders participated in the 2002 fishery. As ex-vessel prices have recovered, and the fishery has become better organized with the creation of the Bristol Bay Regional Seafood Development Association and combined permit holder/processor efforts to improve the value of the fishery, a greater percentage of permit holders are fishing their permits. Since 2010, at least 1,700 (91 percent) drift net permit holders have participated in the fishery each year, while at least 830 (85 percent) set net permit holders have participated since 2007 (see Figure 3.6-8).

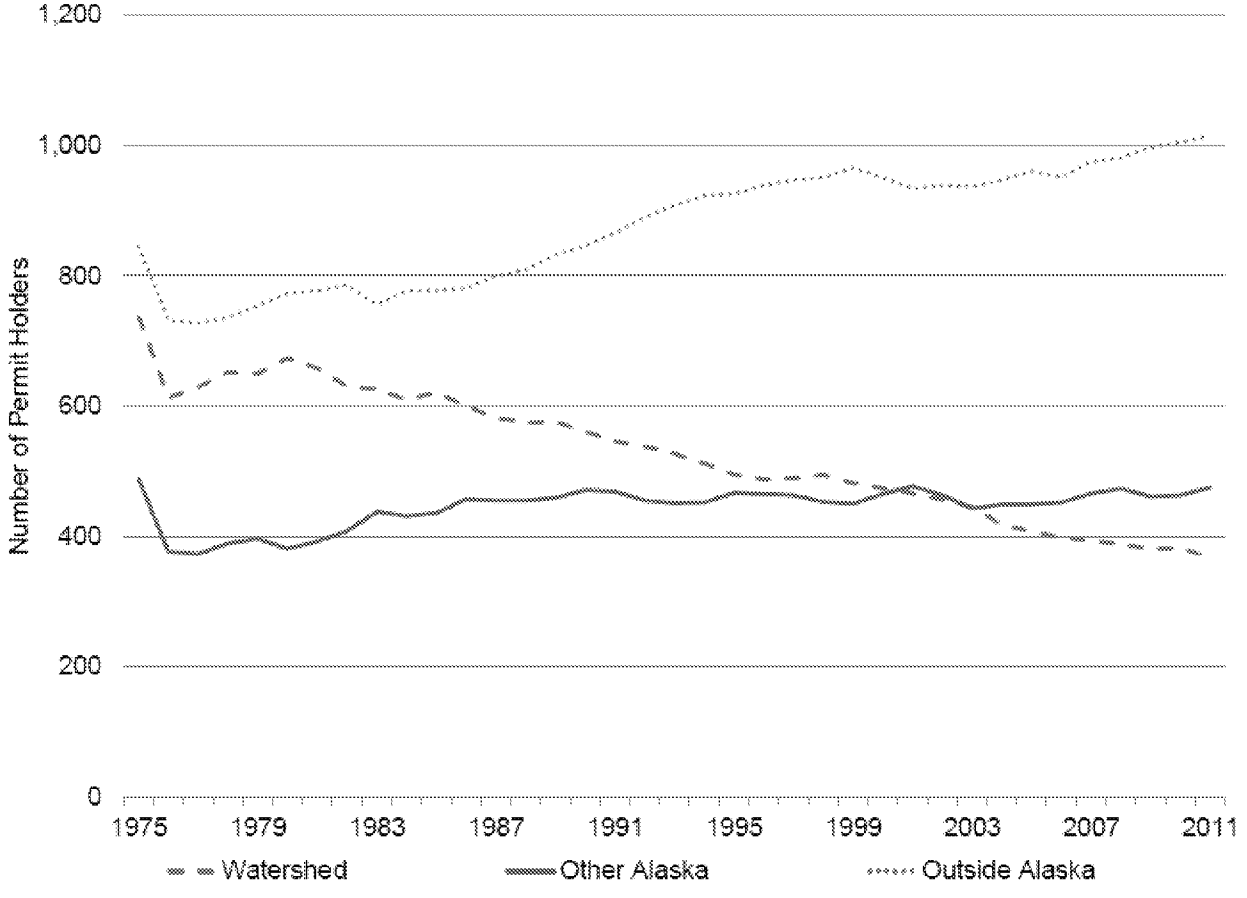
AMERICAN OVERSIGHT

Figure 3.6-8: Annual Permit Holder Participation

Source: ADF&G 2018m

The fishery has experienced a gradual out-migration of permits from Alaskans to non-Alaskans; in particular from watershed residents to non-watershed Alaskans and non-Alaskans (ADF&G 2018m). Overall Alaskan permit ownership in the drift net fishery dropped from 55 percent to 45 percent between 1990 and 2017, while in the same period Alaskan ownership of set net permits fell from 76 percent to 65 percent (see Table 3.6-8).

Table 3.6-8: Permits Owned by Alaskans and Non-Alaskans



Year	Drift Net			Set Net		
	Alaskan	Non-Alaskan	Percent Resident	Alaskan	Non-Alaskan	Percent Resident
1990	1,039	839	55	783	243	76
1995	967	921	51	762	257	75

Source: ADF&G 2018m

AMERICAN OVERSIGHT

The collective data show a loss in Alaska-owned permits, but more refined data show that out-migration of permits is really an issue specific to the Bristol Bay watershed residents, as ownership by Alaskans based outside of the watershed is stable or increasing (see Figure 3.6-9). Between 1975 (when the limited-entry program started) and 2011, non-Alaskan ownership of the permits increased from roughly 850 permits to over 1,000 permits. Permit ownership by non-watershed Alaskans dipped after initial issuance as the CFEC adjudicated temporary permits, but has risen from a low of less than 400 permits to nearly 500 permits in 2011. Permit ownership by residents of the watershed fell steadily between the late 1970s and 2011, from roughly 700 permits to less than 400 permits. As permits leave the region, so too does the associated spending resulting from fishery earnings. With average permit holder earnings of over $100,000 in 2017, the roughly 300 drift net permits that have out-migrated from the watershed represent approximately $30 million dollars in annual gross income that is not available to support the local economy.

Figure 3.6-9: Drift Net Participation in the Fishery by Permit Holder Region, 1975-2011

Source: NEI 2014

Theories as to why permits have left Bristol Bay include: lower access to, and higher cost of capital; the long-term effect of consistently earning less than non-watershed peers; financial hardship; and the relative desirability of the fishery to outsiders who want to join the fishery because of the fishery's higher earning power (Apgar-Kurtz 2012). Prior research shows that Bristol Bay resident vessels tend to be older, have less horsepower, smaller fuel and less refrigeration capacity, as shown in Table 3.6-9 (NEI 2009).

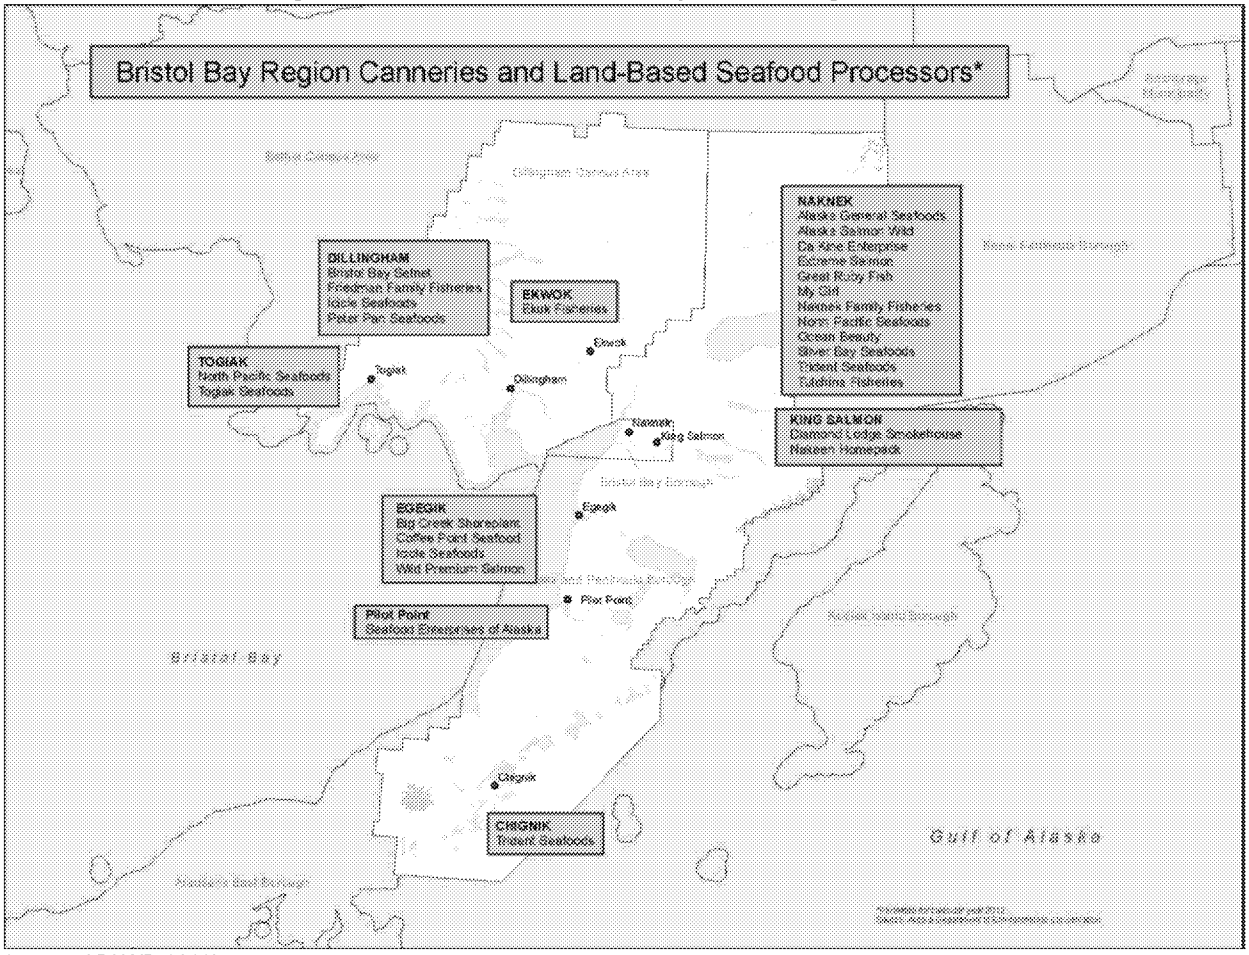
Source: NEI 2009

The rate of loss of permits is not equally spread across communities in the watershed. Apgar-Kurtz (2012) showed that the rate of permit loss was higher amongst communities who were not part of the Bristol Bay Economic Development Corporation (BBEDC) region and thus not eligible for BBEDC's permit loan program. The non-BBEDC watershed communities include those that are closest to the proposed project including Iliamna, Nondalton, Pedro Bay, Port Alsworth, and Newhalen. The group also includes communities further from the proposed project, but still in water systems hydrologically connected to the project, including Igiugig, Koliganek, Kokhanok, and New Stuyahok. When permit holders sell their permits, there are secondary effects on the community that lower earnings and the likelihood of community participation in the fishery:

1. There are now fewer opportunities for community members to obtain crew member jobs and bring a share of their earnings back to that community. Permit holders prefer to hire people that they know, and they are more likely to know people from their own community (Apgar-Kurtz 2012).



AMERICAN OVERSIGHT

2. Family is the predominant way in which people learn to fish in the bay; if a family sells their permits the next generation is less likely to be commercial fishermen (Apgar-Kurtz 2012).

3.6.1.2 The Processing Sector

After harvest, permit holders deliver salmon to processors who pay them for their catch and prepare fish for distribution and sale into the broader seafood market. The processing sector in Bristol Bay ranges from small family owned operations to business units of multi-national corporations with operations across Alaska, the United States, and the rest of the world. While the Alaska Department of Environmental Conservation documents processing facilities in seven Bristol Bay communities, the heart of processing in Bristol Bay is located in the Bristol Bay Borough community of Naknek (see Figure 3.6-10). In 2015, the last year for which data are available, the processing sector employed 3,087 people in the Bristol Bay Borough, 908 in the Dillingham Census Area, and 162 in the Lake and Peninsula Borough (LPB) (ADLWD 2018a).

Figure 3.6-10: Current Bristol Bay Processing Locations[3]

Source: ADLWD 2018b.

From 1998 to 2017, the processing sector in Bristol Bay produced $6.93 billion of first wholesale value seafood products; processors derived $6.2 billion of this value (89.5 percent) from

[3] The Chignik processing facilities service the Chignik area salmon fisheries. These runs return to their spawning grounds via the Gulf of Alaska and not via Bristol Bay.

AMERICAN OVERSIGHT

sockeye salmon (see Table 3.6-10)[4]. The next most valuable species was Pacific herring, which occur every May in the Togiak/Twin Hills region of the Bristol Bay. The remaining salmon species represented 3.6 percent, or $246.3 million, of wholesale value; other species generated $23.6 million in wholesale value.

Table 3.6-10: Bristol Bay Wholesale Values by Species and Year (millions of dollars)

Source: ADF&G 2018d

Between 2004 and 2015, the processing sector provided jobs for an average of 4,106 workers; just 2.4 percent of those workers were residents from the Bristol Bay watershed, while another 12.2 percent were Alaska residents from outside the watershed. The remaining 85.4 percent were residents from regions outside of Alaska. Collective watershed resident wages averaged $1 million per year between 2004 and 2015, while total worker wages averaged $29.4 million (see Table 3.6-11).

[4] All prices are in $US 2017.

Over the last decade, processors, the BBEDC, and the Bristol Bay Regional Seafood Development Association have focused a number of efforts to increase raw product quality in the fishery. Processors consistently identify chilling fish at the point of harvest as the most important action that permit holders can take to increase product quality and they have offered bonuses to permit holders that chill their fish. Between 2008 and 2017, these bonuses have added between 12 percent and 28 percent to the base price paid to permit holders depending on the year. Permit holders responded to these incentives by increasing the portion of Bristol Bay salmon that is chilled immediately at harvest from 24 percent in 2008, to 73 percent in 2018 (Figure 3.6-11) (NEI 2018).

AMERICAN OVERSIGHT

Source: NEI 2018

3.6.1.3 Commercial Fishery Fiscal Contributions

The fiscal contributions of the Bristol Bay salmon fishery depend on the long-term health of the fishery. The harvest and processing of salmon in the Bristol Bay region provides millions in tax revenues to federal, state, and local governments. The federal government benefits through personal and corporate income taxes, and the State of Alaska benefits from Alaska Fisheries Business Tax (AFBT) (Alaska Statute 43.75.015), while local governments benefit from general taxes such as sales taxes, real and personal property taxes, and raw fish taxes on the ex-vessel value of salmon processed within the jurisdiction (EPA 2014a). Each municipality generates revenues in different ways: the Bristol Bay Borough, home to many processing plants, relies on real/personal property taxes and raw fish taxes; the city of Dillingham does not contain as many processing plants within the city limits, but it is home to lay-down and repair yards for boats, and a major provisioning center for fishing crews and so relies on sales taxes and property taxes; the LPB lacks a centralized population area that could provide it with sales and property tax revenues, but instead relies on raw fish taxes (see Table 3.6-12). Overall, these taxes depend on the long-term value of the fishery, the attractiveness of the fishery to investors who build business around the fishery, and total employment in the fishery including processing workers.

AMERICAN OVERSIGHT

Table 3.6-12: Community Revenue Sources, 2017

Community	Sales Tax	Real Property Tax	Raw Fish Tax	Professional Guide Tax
Bristol Bay Borough	No	$4,918,466	$2,117,857	No
City of Dillingham	$2,528,395	$2,256,826	No	No
Lake and Peninsula Borough	No	No	$1,638,335	Yes
Egegik	No	No	$1,230,569	No
Nondalton	$0	No	No	No
Newhalen	$272	No	No	No

Source: ADCCED 2018

The State of Alaska shares revenues generated from the AFBT with local municipalities. As noted in EPA (2014a), the State does not break out AFBT revenue by species or fishery. However, in 2010 when the ex-vessel value of the fishery topped $180 million in nominal terms, the Institute for Social and Economic Research estimated that the processors paid a minimum of $6.38 million in AFBT taxes (EPA 2014a). In 2016 and 2017, the ex-vessel of the fishery was $156 and $216 million respectively (see Table 3.6-13). Thus, one could expect that AFBT payment was slightly less than 2010 in 2016, and slightly more than 2010 in 2017.

AMERICAN OVERSIGHT

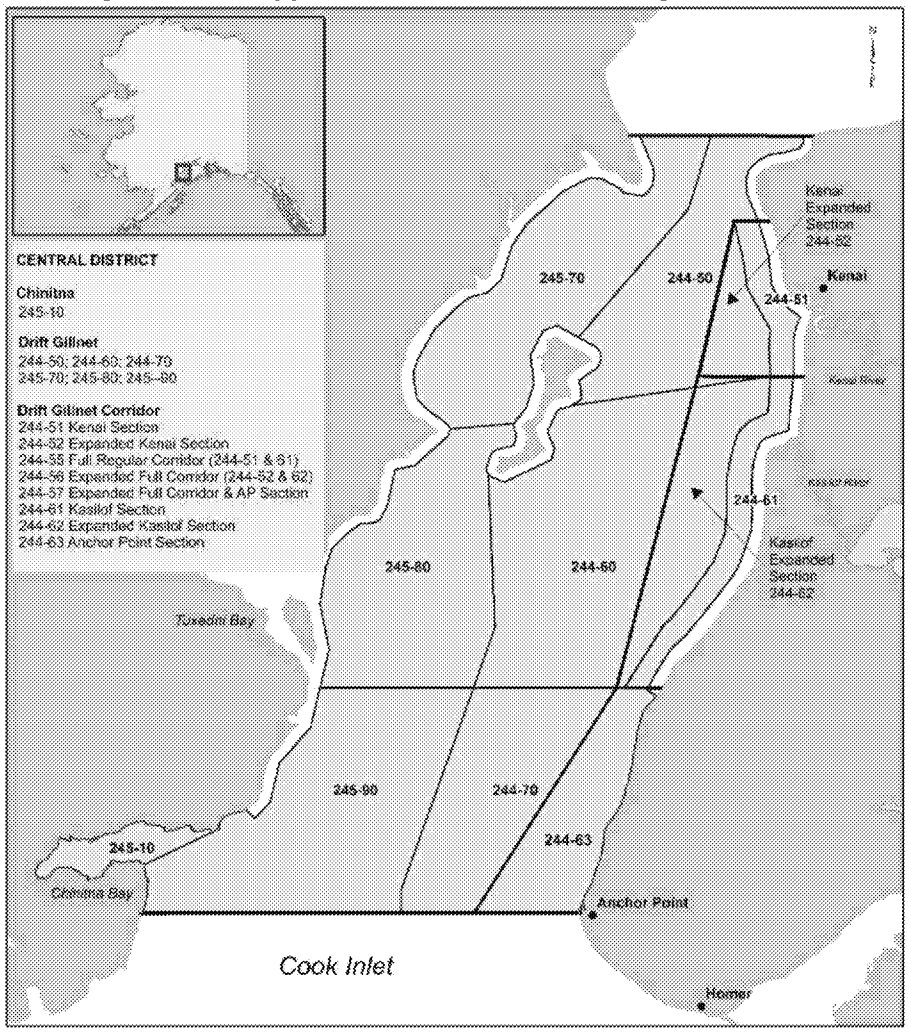
3.6.2 Cook Inlet Commercial Fisheries



The proposed project alternatives include a natural gas pipeline extending from north of Anchor Point on the Kenai Peninsula across Cook Inlet to Amakdedori port or Ursus Cove. This route crosses a complex set of fishing boundary areas including the southern edge of the Upper Cook Inlet (UCI) Management Area, the Lower Cook Inlet (LCI) Management Area, and federally managed waters more than 3 miles offshore. The Upper Cook Inlet Management Area, which includes fisheries dependent on salmon headed to the Kasilof, Kenai, Susitna, Little Susitna, and Matanuska/Knik drainages, is home to extensive oil and gas pipeline infrastructure, which has operated since the 1960s.

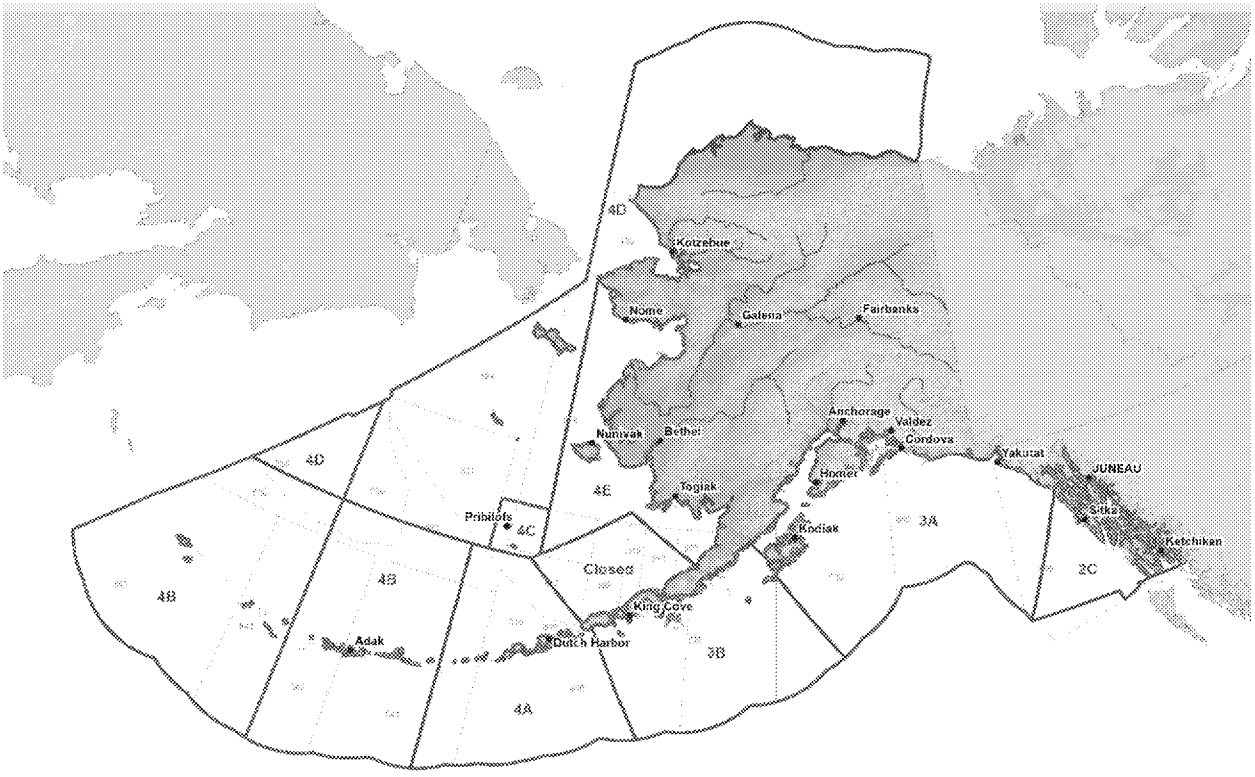
The UCI Management Area is one of the Alaska's most complex salmon management areas as management has to balance runs escape goals for multiple river systems, competing user groups including commercial set net permit holders, commercial drift net permit holders, fresh and saltwater recreational anglers and guides, and personal use fisheries. Between 2007 and 2016, commercial fisheries harvested an average of 3.48 million fish per year generating, on average, $29.8 million in ex-vessel value. The 10-year average harvests for the fishery are 2.9 million sockeye salmon, 245,000 Pink salmon, 167,000 coho salmon, 149,000 chum salmon, and 9,477 Chinook salmon (Shields and Frothingham, 2018). The project's proposed pipeline would originate from just north of Anchor Point, with the highest potential to affect drift net commercial fisheries and saltwater recreational anglers. While the UCI Management Area primarily encompasses salmon fisheries, the ADF&G also manages small commercial herring, smelt, and razor clam fisheries within the area boundaries.

The proposed project's pipeline would pass through ADF&G drift gillnet statistical areas 244-63 and 244-70 before passing into the LCI Management Area (see Figure 3.6-12). The proposed pipeline would be located south of any set net fisheries contained in ADF&G statistical area 244-21 (encompassing the unnamed white area located east of Area 244-61 in Figure 3.6-12). Unfortunately, it is not possible to determine the amount of drift fleet harvest in areas 244-63 and 244-70. The ADF&G does not collect harvest data or attempt to estimate harvest in these specific areas. Instead, harvest from areas 244-60, 245-80, 245-90, 244-70, and 244-63 are reported in aggregate as "Area 244-60" or "Area 1/District Wide." In 2016, the drift net fleet harvest 728,037 of the 1,266,696 sockeye from this aggregate area; an amount equal to 57.5 percent of all UCI Management Area drift sockeye harvests. In the same year, the aggregate areas produced 70 percent of the coho salmon harvest and nearly two-thirds of the pink salmon harvest (Shields and Frothingham, 2018). In spite of the uncertainty around the magnitude of the overlap between drift net fleet harvest activities and the project's proposed natural gas pipeline, the potential for conflict is low because of the depth of the pipeline on the sea floor and the specifications of drift gillnet gear (ADF&G 2017c).

AMERICAN OVERSIGHT

Figure 3.6-12. Upper Cook Inlet Drift Net Management Areas

Source: Shields and Frothingham, 2018



The harvest in the LCI Management Area focuses primarily on pink salmon and sockeye salmon from a combination of hatchery and wild sources, and is much smaller than UCI salmon harvests. Harvests in this area are much smaller than those in the UCI Management Area averaging $2.95 million per year in ex-vessel value between purse seine, set gillnet, and hatchery recovery operations. On average, 35 to 40 permit holders participate in salmon fisheries in these areas per year (Hollowell, Otis, and Ford 2017). The ADF&G also manages a commercial herring fishery in the LCI Management Area, but since 2000 the spawning biomass has been too small to allow the opening of this fishery.

The proposed pipeline would cross waters within the 3 nautical miles of shore managed by the State for groundfish fisheries for Pacific Cod, Sablefish, Rockfish, and Walleye pollock. These species are generally harvested by baited longlines or pots laid across the ocean floor, but can also be harvested using mechanical jigs or hand troll gear. ADF&G data indicate that Pacific cod is commercially the most important species of this group with Cook Inlet district harvests averaging between 1.7 and 3.0 million pounds annually; ex-vessel values average less than $2 million per year. Much of this harvest takes places inside Kachemak Bay, south and east of the proposed pipeline. Limited fishing occurs near the pipeline's western terminus (Rumble, Russ, and Russ 2016).

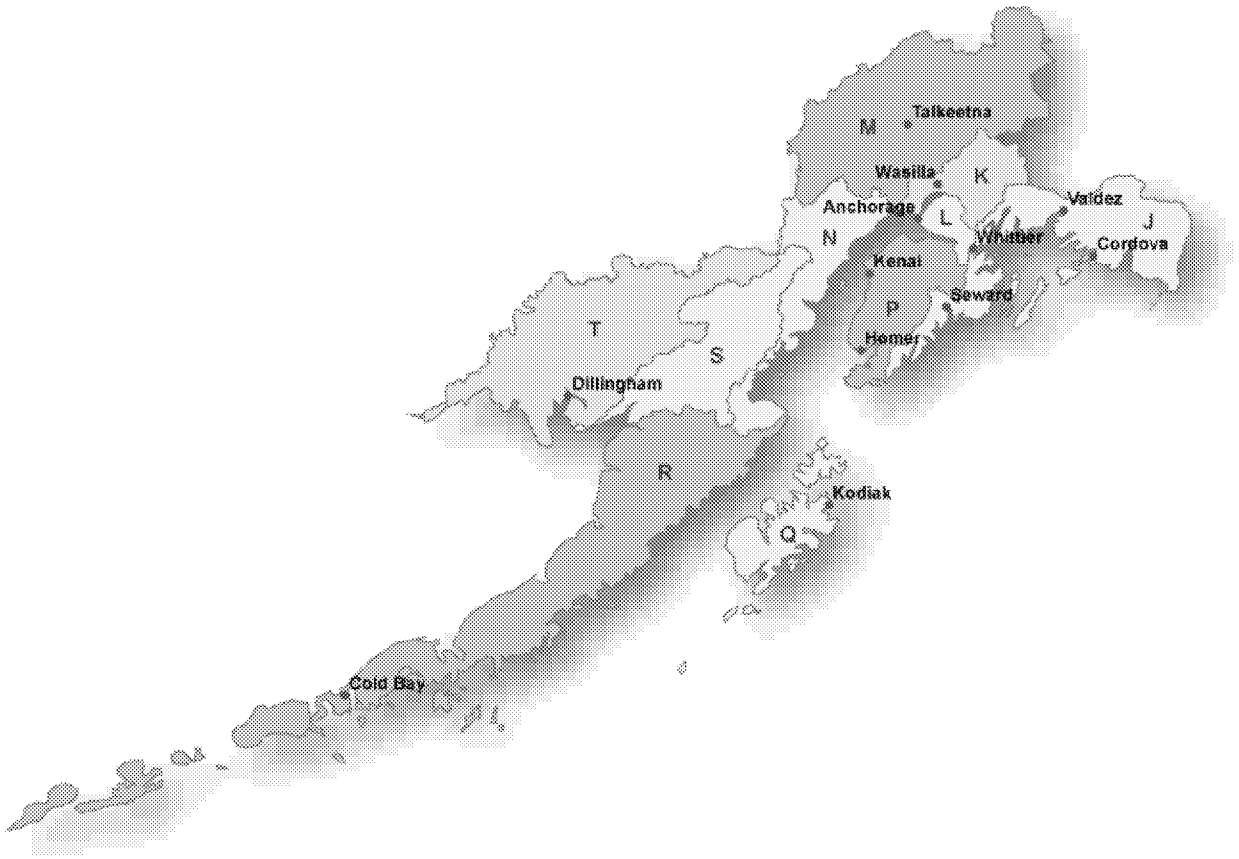
AMERICAN OVERSIGHT

The proposed pipeline would cross federally managed waters in Cook Inlet beyond 3 nautical miles from shoreline. Commercial fisheries in these areas include fisheries for Pacific Halibut, Pacific Cod, and other groundfish (Figure 3.6-13). The halibut fishery is co-managed with the State of Alaska and the federal government and operates under limits established by the International Pacific Halibut Commission. The fishery for halibut uses longlines consisting of bait hooks laid on the ocean floor, while the cod fishery primarily uses longlines and pots. Federal management areas are much larger than state management areas; thus, fishermen have greater flexibility to avoid fixed assets such as buried pipelines and undersea cables. For example, halibut fishermen holding halibut quota for International Pacific Halibut Commission Area 3A, which includes Cook Inlet, can fish anywhere in the 3A managed area.

Figure 3.6-13. Federal Halibut Fishery Management Areas

Source: NOAA, 2018d

3.6.3 Guided and Unguided Recreational Fishing



The project area hosts numerous freshwater fishing resources that anglers use primarily to target Chinook salmon, sockeye salmon, rainbow trout, and other salmonid species. They value the area's low angler density, catch rates, and wilderness fishing conditions (EPA 2014a). In turn, these well-known fisheries resources support sport fishing lodges, fishing guides and related services such as air taxis, and generate revenue for the state of Alaska and local municipal governments.

The ADF&G measures recreational fishing effort via the annual Statewide Harvest Survey (SWHS). The SWHS measures effort and catch (i.e., harvest plus catch and release) across a set of geographic statistical areas via a mail survey distributed to a sample of individuals who purchased an Alaska fishing license in the year being surveyed. Each year, the ADF&G mails 47,000 SWHSs to anglers who bought licenses; it divides anglers into four sample frames: Alaskans, non-Alaskan US citizens, Canadian residents, and all other anglers. In 2016,

AMERICAN OVERSIGHT

response rates across the frames varied between 26 percent and 50 percent; each year the ADF&G expects approximately 17,000 responses (ADF&G 2017m).

Figure 3.6-14: Map of ADF&G Recreational Fishing Areas

Source: ADF&G 2018d

The ADF&G SWHS statistical areas S, T, and N contain the waterbodies hydrologically connected to the project area; Area S contains the Kvichak River drainage while Area T contains the Nushagak, Wood, and Togiak river drainages (see Figure 3.6-14). In 2016, the ADF&G estimated that anglers fished just over 27,000 days in Area S, nearly 28,000 days in Area T, and 11,600 days in Area N; the vast majority of these days were freshwater fishing days. In comparison, the ADF&G estimates that anglers spent 497,000 days fishing the freshwaters of the Kenai Peninsula and 52,000 days in the Anchorage Bowl[5].

Each year, the ADF&G publishes estimates of angler counts, fishing days, and harvest for those waterbodies that they have received enough completed surveys; this is in order to generate results of a certain statistical reliability. The SWHS combines all waterbodies for which there are not enough responses into an "other" category. Thus, busier waterbodies generate enough angler survey responses for ADF&G to create effort estimates every year, while some less busy

[5] Area P includes the eastern terminus of the proposed natural gas pipeline, where the pipeline would connect with the existing natural gas supply system on the Kenai Peninsula. The primary facility would be a new compressor station north of Anchor Point and the Anchor River, which hosted an estimated 12,699 angler days in 2016. The facility would not be expected to affect angling in the area; thus, Area P is not discussed in further detail in this section.

AMERICAN OVERSIGHT

waterbodies may only generate enough results a couple of times in a 10-year period. The absence of an estimate in a particular year for one of these waterbodies does not indicate the absence of effort in that year, but rather a lack of angler survey responses. Therefore, for these waterbodies it is particularly important to look at effort across time get a truer sense.

In Area T, between 1997 and 2016, angler responses allowed the SWHS to estimate angling effort for eight distinct waterbodies, drainages, or systems. The survey identified the Nushagak River (excluding the Mulchatna drainage), the Wood River System, and the Togiak River System as the most frequently fished systems. These three systems accounted for 84 percent of estimated angling effort between 1997 and 2016, and each system received enough angler survey responses for the ADF&G to estimate effort on an annual basis. The Mulchatna River is the only system in Area S known to be hydrologically connected to the project area; the river accounted for 6.4 percent of estimated angling effort in the 20 years between 1997 and 2016. However, average annual angling effort on the Mulchatna River was 45 percent lower for the 2007 to 2016 period than it was during the 1997 to 2006 period (see Table 3.6-14).

Table 3.6-14: Area T Waterbodies, Average Annual Angling Days and SWHS Appearances

Waterbody	1997-2006		2007-2016

Freshwater Total	**39,638**	**10**	**33,137**	**10**

Source: ADF&G 2018d

*This estimate includes any activity on the Koktuli River. Data from the ADF&G from 2007-2016 indicate that on average 2.3 anglers per year return harvest surveys indicating they fish the Koktuli; a number below the threshold for estimating effort on a specific waterbody (Borden 2018). In comparison, Lower Talarik Creek responses ranged from 2 responses to 17 responses and averaged 9.5 responses per year in same period. The department only estimated effort for Lower Talarik Creek when the number of responses in a single year reached the mid-teens at a minimum. Responses indicating effort on the Koktuli are typically a fraction of the ADF&G's minimum for estimating and publishing specific waterbody effort.

Angler responses allowed the ADF&G to estimate angling effort for twice as many waterbodies in Area T as compared to Area S in the 1997 to 2016 period. However, Area S averages roughly one-quarter fewer angling days on average than Area T. The most popular waterbodies in Area S are the Alagnak/Branch River, the Kvichak River, the Copper River (tributary of Iliamna Lake), and the Lake Clark and Iliamna Lake drainages. Waterbodies that have been included in the SWHS annual report, which have the potential to be directly affected by the project, including transportation activity, are the Newhalen River, Lower Talarik Creek, the Kvichak River, the Gibraltar River, and Iliamna Lake (see Table 3.6-15).

AMERICAN OVERSIGHT

In Area N, the SWHS estimated an average of 15,102 fishing days between 1997 and 2006, and 13,113 days between 2007 and 2016. Angler effort is concentrated north of the project area for all the named sites, with the exception of the Kamishak River located north of Tuxedni Bay. The Kamishak River, which appears once as a named site in 20 years' worth of data, is located south of the project area near the McNeil River State Game Sanctuary and roughly 25 to 30 air miles from the potential Amakdedori port site (see Table 3.6-16).

In addition to the SWHS, the ADF&G collects data on guided saltwater and freshwater fishing trips via the Alaska Guide Logbook Program. Under the program, Alaska guides record data on each day they spend guiding including data and location of the trip(s), the license numbers of guided anglers, harvest, and catch. While SWHS data is superior in its breadth, including both guided and unguided angler effort, logbook data is a census of guided trips as opposed to estimates based on a survey. Appendix K3.6 summarizes 2011 to 2014 program data for SWHS areas N, P, S, and T. Table 3.6-17 shows the summarized data for "high interest" waterbodies, which would either be directly affected by the proposed project, have potential for cumulative or downstream effects, or have been mentioned in public scoping. The data provide interesting insights into guided effort in the area including:

- The vast majority (i.e., 95+ percent) of all guided Nushagak/Mulchatna effort is on the Nushagak River.
- The Copper River, which is located on the eastern shores of Iliamna Lake south of alternative leading to Diamond Point port, and north of the alternative leading to Amakdedori port, hosts an average of nearly 1,500 guided fishing days per year.
- The Gibraltar River, which would be crossed by the alternative leading to Amakdedori port, hosts an average of fewer than 300 guided fishing days per year.
- The Newhalen River, which would be crossed by the spur road to Iliamna or north route alternatives, hosts fewer than 200 guided days per year and only appeared in 3 years' worth of data out of a maximum of 4 years.
- Upper and Lower Talarik Creek host fewer than 200 guided angling days per year, combined. On average, Lower Talarik Creek is the more popular of the two waterbodies, hosting 75 percent of combined effort.
- The Koktuli River does not appear in the program data for these years.

3.6.3.1 Estimates of Economic Contribution

Sport fishing is a consistently significant economic activity in the Bristol Bay Region (EPA 2014a). Anglers spend significant sums of money on transportation, lodging and meals, equipment, and guide services, amongst other expenditure categories. These expenditures help fuel local economies and generate local tax revenues for the City of Dillingham, the LPB, and the Bristol Bay Borough (which includes the community of King Salmon). Although annual estimates of sport fishing's economic contribution are not available, EPA (2014a) and Duffield et al. (2007) provide estimates of annualized value based on 2005 sport fishing effort. The Duffield et al. (2007) estimates indicate that in 2005, per trip expenditures ranged from $426 for watershed residents to $7,933 for those staying at remote lodges. Watershed resident anglers

AMERICAN OVERSIGHT

averaged 11.54 trips per year, while ex-watershed Alaska residents and non-residents average 1.3 and 1.49 trips per year[6] (see Table 3.6-18).

Table 3.6-18: Inflation-Adjusted Estimates of per Trip Expenditures

Category	Watershed Residents	Alaska Ex-Watershed	Non-Residents	Remote Lodges
Estimated per Trip Expenditures	$426	$1,806	$4,560	$7,933
Average Trips per Year	11.54	1.30	1.49	N/A

Source: EPA 2014a. Expenditures adjusted using Anchorage CPI.

The inflation-adjusted collective expenditures in Duffield et al. (2007) associated with recreational fishing in the Bristol Bay region equal $5.5 million by watershed residents, $6.9 million by Alaska residents living outside the region, and $54.1 million by non-residents, for a total of $66.58 million (see Table 3.6-19). The inflation-adjusted estimate of statewide expenditures from Duffield et al. (2007) is $69.32 million; thus, most angler expenditures occur in-region.

Table 3.6-19: Inflation-Adjusted Estimates of In-Region Expenditures

Category	Watershed Residents	Alaska Ex-Watershed	Non-Residents	Total
Estimated Bristol Bay Expenditures	$5,564,568	$6,910,211	$54,108,115	$66,582,894

Source: EPA 2014a. Expenditures adjusted using Anchorage CPI

In 2005, the year the Duffield et al. (2007) expenditure estimates are based on, the ADF&G SWHS estimated that anglers spent 75,083 days angling in SWHS areas S and T. In 2016, the same survey estimated that anglers spent 54,882 angling days in the region; a decline of 27 percent. For the 5-year periods of 2001 to 2005 and 2012 to 2016, effort was down 15 percent from the earlier period to the later period, as shown in Table 3.6-20. Presuming that angler expenditures have stayed the same adjusted for inflation, the decline in effort would result in a reduction in regional expenditures. A 27 percent adjustment applied to the Duffield et al. (2007) estimate of $66.58 million results in an estimate of $56.54 million in regional expenditures for 2016, presuming that the distribution of angler expenditures has remained constant.

Table 3.6-20: Comparative Estimates of Sport Fishing Effort, Days

SWHS Area	Annual Counts		Five-Year Averages	
	2005	2016	2001-2005	2012-2016
Nushagak	48,751	27,786	41,670	32,807
Kvichak	26,332	27,096	26,460	25,043
Total	75,083	54,882	68,130	57,851

Source: ADF&G 2018d

[6] Duffield et al. (2007) and EPA (2014a) defined a trip as "a roundtrip visit from home and return." Given the region's remoteness, this definition means that most trips involve multiple days of activity. Remote fishing lodge packages typically range from 3 to 7 days.

AMERICAN OVERSIGHT

3.6.3.2 Local Recreational Fishery Fiscal Contribution

Anglers can contribute to the fiscal resources of local governments through taxes such as sales (City of Dillingham) and lodging (LPB, City of Dillingham, Bristol Bay Borough). The LPB also raises revenue through a direct tax on guide services where guides pay $3 per angler day to the borough.

In fiscal year 2018, the LPB generated $56,282 from 147 guides licensed to work in the borough, and $177,566 from 64 lodges in the borough. These amounts are equal to roughly 6.8 percent of all LPB tax revenue, and 4.6 percent of the all fiscal year 2018 revenue (LPB 2018b).

Table 3.6-21: Lake and Peninsula Borough Recreational Fishing Revenues

Fiscal Year	Annual Revenues	
	Guide Tax	Bed Tax
2015	39,716	262,831
2016	46,030	180,069
2017	30,948	108,895
2018	56,282	177,566

Source: LPB 2018b

The Bristol Bay Borough, which does not have a guide tax, does have transient occupancy (i.e., bed) tax revenues and real property tax revenues associated with lodges. It is very likely that these revenues are a small subset of the borough's $4.9 million in annual property tax revenues given that fish processing facilities likely make up the bulk of the borough's tax base.

3.9 SUBSISTENCE

Subsistence is the way of life for many cultural groups in Alaska, including the Dena'ina Athabascan of Southcentral Alaska, the Central Yup'ik of Southwest Alaska, and the Sugpiaq-Alutiiq of lower Cook Inlet and Alaska Peninsula. Subsistence encompasses hunting, fishing, trapping, gathering, camping, and ceremonial activities, as well as the processing, sharing, use, consumption, trade, and barter of wild resources. Subsistence resources include fish, wildlife, plants, and firewood. These renewable resources provide food, fuel, and materials to make clothing, shelter, tools, and art.

For indigenous people, subsistence activities are rooted in traditional cultural values, spirituality, and a sense of community. Subsistence activities help transmit cultural knowledge between generations, maintain the connection of people to their land and environment, and are a source of pride and identity (Boraas and Knott 2013; SRB&A 2011b). In addition to its inextricable roots in traditional Alaska Native culture, subsistence is integral to the contemporary mixed economic system in rural Alaska. For many, subsistence is a chosen lifestyle, preferred over or in conjunction with a wage-earning lifestyle. Wage employment opportunities are scarce in rural Alaska, and residents face high prices for store-bought goods; some may have to travel to other communities to visit a store. Cash incomes typically supplement and support subsistence activities, which for generations have provided considerable nutritional and economic value for rural households. Part-time work or commercial fishing can provide enough income to purchase tools for support of subsistence activities: boats, all-terrain vehicles and gear; as well as providing fuel for home and engines. For additional information on cash incomes and socioeconomic conditions, see Section 3.3, Needs and Welfare of the People—Socioeconomics.

The sharing of resources is a fundamental characteristic of the subsistence way of life. Sharing of subsistence foods within and between communities reinforces social bonds and helps the recipients meet economic, material, and nutritional needs. The percentage of households giving and receiving subsistence resources is provided below for the six communities closest to project infrastructure (Iliamna, Newhalen, Pedro Bay, Nondalton, Iguigig, and Kokhanok), and for other communities in the project area in Appendix K3.9. Sharing is an indicator of resilience of the culture to variations in household abilities to harvest and process wild foods (SRB&A 2011b).

A further indication of the importance of sharing practices in integrating communities is seen in the fact that some households are especially highly productive in their subsistence pursuits and provide a particularly large proportion of all subsistence harvest in a community. Studies conducted by the Alaska Department of Fish and Game (ADF&G) Division of Subsistence have documented a pattern in Alaska Native communities whereby 30 percent of a community's households produce 70 percent of the community's total subsistence harvest in terms of edible weight (known as the 30-70 rule) (Wolfe et al. 2005). This pattern is consistent, despite wide variation in community and household harvest profiles. The households that produce at a high level tend to be those with several older adult members who have access to cash and necessary equipment; these households are typically successful in both the subsistence and cash sectors of the mixed economy. The extra subsistence foods produced by high-harvesting households are usually shared with elders, single mothers with young children, young couples, and other segments of the community (ADF&G no date). Resources are shared widely through kinship and friendship relationships, among households in the community, and in other communities in Alaska. The 30-70 rule also illustrates the specialization in production of wild foods in the subsistence sector; particular individuals or individual households may benefit from technological ability, financial resources, or traditional knowledge. For example, although nearly all households participate in the harvest of salmon in the study area communities, there are a

AMERICAN OVERSIGHT

smaller number of individuals who have the equipment, expertise, and time necessary to harvest certain resources, such as moose. Therefore, a relatively small group of hunters meet the community need for moose meat through long-established sharing patterns.

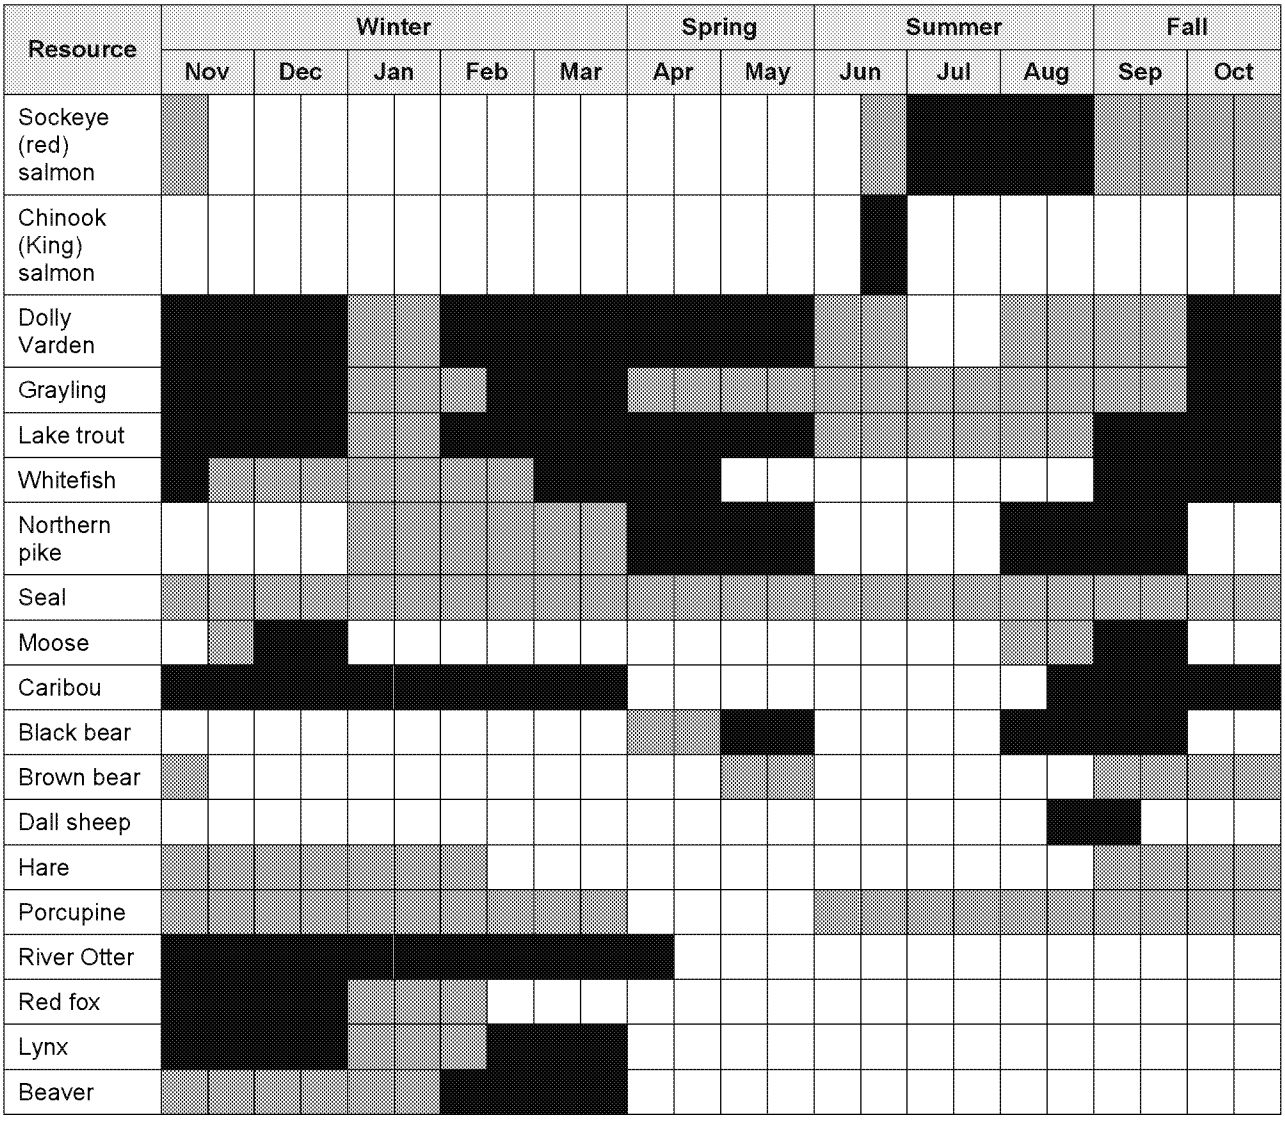
Subsistence activities in Alaska are regulated by both the federal and state governments. The Alaska National Interest Lands Conservation Act (ANILCA) passed by Congress in 1980, gives *rural* Alaskans priority for subsistence harvest of fish and wildlife on federal public lands and waters. The multi-agency Federal Subsistence Board is the decision-making body that regulates subsistence hunting and fishing on federal lands and waters, with technical support from the U.S. Fish and Wildlife Service (USFWS) Office of Subsistence Management. There would be no project components proposed on federal lands where the subsistence management provisions of ANILCA would apply (see Section 3.2, Land Ownership, Management, and Use).

On state and private lands and waters, including those affected by the proposed project, since the 1989 Alaska Supreme Court *McDowell* decision, *all* Alaskans are qualified to harvest subsistence resources. With technical support of ADF&G, the Alaska Board of Fisheries and the Board of Game have ultimate decision-making responsibility for hunting and fishing on lands within the state jurisdiction.

Harvest of certain species is also regulated by additional laws such as the Marine Mammal Protection Act and the Migratory Bird Treaty Act, and therefore these species are managed by different federal agencies. Pacific halibut and most marine mammals are managed by the National Marine Fisheries Service. Sea otter and walrus are managed by the USFWS. Migratory birds are jointly managed by the state and federal governments and a co-management body representing eligible Alaska Native tribes.

3.9.1 Traditional Ecological Knowledge

The detailed results of a study done by Steven R. Braund & Associates, in coordination with the ADF&G, are documented in SRB&A (2011b). Methods included mapping subsistence use areas, updating harvest data, and a literature review. The study also documented traditional knowledge on "changes in resource use, abundance, quality, distribution, and migration," as well as other factors like climate change and development projects (SRB&A 2011b). The data (tables, charts, and maps) used to determine the environmental baseline for this section reflect the findings of this study, and a subsequent data review of the six communities closest to the proposed project infrastructure, performed by SRB&A in 2018. Traditional Ecological Knowledge (TEK) and the culture value of subsistence as a chosen lifestyle, as described by Boraas and Knott (2013) were also reviewed during development of this section. Boraas and Knott concluded, based on elder and culture-bearer interviews, that this lifestyle has built strong networks of connected extended families in the Nushagak and Kvichak drainages based on sharing, traditional knowledge, and a respect for the environment, with salmon and clean water as the foundation of culture. A summary of specific TEK comments from Boraas and Knott (2013) is provided in Appendix K3.1. In this way, TEK regarding areas of subsistence use and harvest data, processing and sharing, and how information is transmitted over generations are incorporated into the analysis of Section 4.9, Subsistence. Scoping comments related to TEK were also considered in the analysis of impacts in Section 4.9, and are summarized in Appendix K3.1.



3.9.2 Seasonal Round

Subsistence users harvest a wide variety of resources throughout the year, and they often target specific species during certain seasons of the year, following a cyclical harvest pattern called the *seasonal round*. In general, communities in southwest Alaska share a similar

AMERICAN OVERSIGHT

seasonal round, with some variations depending on the area, available resources, and applicable hunting regulations. For example, coastal, lakeside, and riverside communities each rely on a somewhat different mixture of subsistence resources. Non-salmon fish and freshwater seals are harvested throughout the year, and many subsistence users prefer to harvest freshwater seals in the winter. In the spring, migratory birds, gull and waterfowl eggs, and Chinook salmon are harvested. Sockeye salmon are targeted in the spring or summer, depending on the run timing in different areas. Other salmon species, marine invertebrates, and green plants are harvested in summer. In late summer and into fall, spawning sockeye salmon and berries are harvested. During fall, subsistence users harvest migratory birds and upland game birds. In Dillingham, however, upland game birds are harvested year-round. Moose and caribou hunting typically occur in fall and/or winter, although hunters in Iliamna and Newhalen harvest caribou in spring. The coldest part of winter is the best time to harvest small, furbearing mammals (Fall et al. 2006; Krieg et al. 2009; Holen et al. 2011, 2012; Evans et al. 2013). The general gathering cycle of when harvests occur in the six communities closest to proposed project infrastructure is described in Table 3.9-1.

Table 3.9-1 Generalized Seasonal Round of Subsistence Activities, Project Area Communities

AMERICAN OVERSIGHT

Table 3.9-1 Generalized Seasonal Round of Subsistence Activities, Project Area Communities

Resource	Winter					Spring		Summer			Fall	
	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct

Seasonal harvest is generalized for these communities, and patterns may differ slightly from community to community.

Source: SRB&A 2011b

Residents of Cook Inlet communities (i.e., Ninilchik and Seldovia) harvest many of the same resources at the same times of year as southwest Alaska communities, with some variations. In spring, green plants, mushrooms, and kelp are harvested. In summer, subsistence users gather berries, greens, marine invertebrates, and seaweed. The moose-hunting season occurs in late summer to early fall. During fall and winter, the residents hunt for upland game birds. Winter is the typical time for gathering firewood (Jones and Kostick 2016).

Subsistence hunters have observed that habitat change in southwest Alaska is affecting the Mulchatna caribou herd harvest in the Illiamna Lake and Bristol Bay areas (Van Lanen 2018). Many respondents said that the herd has moved away from these areas, and caribou hunting often requires traveling too far to make harvest worthwhile; moose are closer and more easily accessible. Hunters have adapted to changes in species availability by switching to greater reliance on increasing numbers of moose, rather than the more difficult-to-access caribou. Moose harvest data have verified local knowledge observations that habitat change, which is benefiting moose, is occurring. It was reported that since the late 1990s, the moose harvests by local residents have increased significantly in the southern portion of game management units (GMUs) 9B, 9C, and 17; and during the current decade, in the western portion of GMU 18. Increasing range expansion of moose in Alaska's tundra areas has been linked to warming, and has increased the shrub habitat (willows) that moose prefer (Tape et al. 2016). Changing winter conditions and more recent low snow and ice conditions are creating challenges in terms of access via snowmachine travel for winter caribou and moose hunting, and efforts focus on the fall season instead of the winter season.

3.9.3 Subsistence Harvest Patterns by Community

Routine operations would primarily affect the subsistence areas of six Iliamna Lake communities near the mine site, transportation corridor, and port site locations. There would be small effects on resources in the watershed as a whole; impacts would be localized to the vicinity of the project area. This section summarizes the most recent available comprehensive subsistence harvest surveys for the six communities. A summary of the subsistence harvest surveys for

AMERICAN OVERSIGHT

other communities in the project area and nearby watersheds is provided in Appendix K3.9. The results are organized geographically from those communities closest to the proposed project around Iliamna Lake, followed by more distant communities down the Kvichak River drainage, across to the Nushagak River drainage, and includes a pair of Cook Inlet communities. Study years range from 2004 to 2014, depending on the community. Communities for which there were older data or no data were not included. For most of the communities, the data available through ADF&G technical papers were reviewed and incorporated into this analysis, instead of the ADF&G Community Subsistence Information System, where data were not as recent.

In this region, salmon is the most important subsistence food and ranges up to 82 percent of the subsistence diet, with land mammals (moose and caribou) and non-salmon fish (northern pike, Dolly Varden/char, white fish, and trout) comprising the second and third most important type of subsistence resource (Boraas and Knott 2013). Within the region, the majority of subsistence harvested food is shared, which in turn accounts for high numbers of per capita harvest, because the people harvest and gather large volumes of wild food and subsistence resources, which forms the basis of the culture (Boraas and Knott 2013).

Table 3.9-2 shows subsistence harvest amounts for eight resource groups for each community. The six Iliamna Lake communities show a particularly high level of reliance on salmon. Annual per capita harvests of salmon ranged from 205 pounds in Igiugig to 513 pounds in Kokhanok. Port Alsworth was the exception, with a reported annual per capita salmon harvest of 89 pounds. In another indicator of high reliance, salmon represent 79 percent of total subsistence harvest for Iliamna and 73 percent for Newhalen, as examples. Additional information is shown on species diversity and proportions of total harvest in subsequent community accounts.

These communities show smaller harvest amounts for non-salmon fish; although, it is important to note that these fish are often taken throughout the year, providing a fresh food resource during winter months. Harvest levels of large land mammals, such as moose and caribou, are also smaller, although they too play an important role in subsistence food diversity.

Other communities in the study area beyond Iliamna Lake show varying levels of harvest for salmon, with particularly high per capita harvest levels reported for Koliganek (565 pounds) and Clark's Point (637 pounds), and low levels of per capita salmon harvest reported for the Cook Inlet communities of Ninilchik (43 pounds) and Seldovia (48 pounds).

Another important dimension of subsistence harvest patterns is found in the rates of household hunting, harvesting receiving, and giving resources. Data on these patterns are described below in the community accounts for the communities located closest to the proposed project infrastructure.

Subsistence use areas represent another important dimension of subsistence activities. Communities have traditional use areas that represent a sophisticated cumulative body of knowledge about where animals are likely to be available and in prime condition throughout the seasons of the year. Use areas for some species are relatively constant, such as salmon fishing areas; while use areas for other species, such as moose, caribou, and fur-bearers, would vary with changes in abundance and distribution. Cumulative traditional use areas are relatively constant over long periods of time, although not all portions of the long-term use area would be used each year. Instead, harvest patterns are dynamic and strategic, as subsistence users concentrate their efforts in areas likely to be productive, with current abundance and distribution of resources. Traditional places names identify significant locations in a traditional use area, and further indicate the long-term use patterns. Figure 3.9-1 shows the subsistence use areas for all communities. Subsistence use areas for the six communities closest to the project are shown below with relevant communities.

AMERICAN OVERSIGHT

Tables 3.9-3 to 3.9-8 generally show higher levels of harvest, which is an average over all study years (SRB&A 2018), compared to the 2004 and 2005 single-year studies and information in SRB&A 2011b. This may be because earlier studies used less precise methods to evaluate the data; and in comparison to the 1980s and 1990s, the use patterns after 2000 represent a reduction in subsistence effort and success. After 2000, the economics of village communities in Alaska generally become more difficult, with declining state spending and project hires, while energy costs increased considerably.

AMERICAN OVERSIGHT

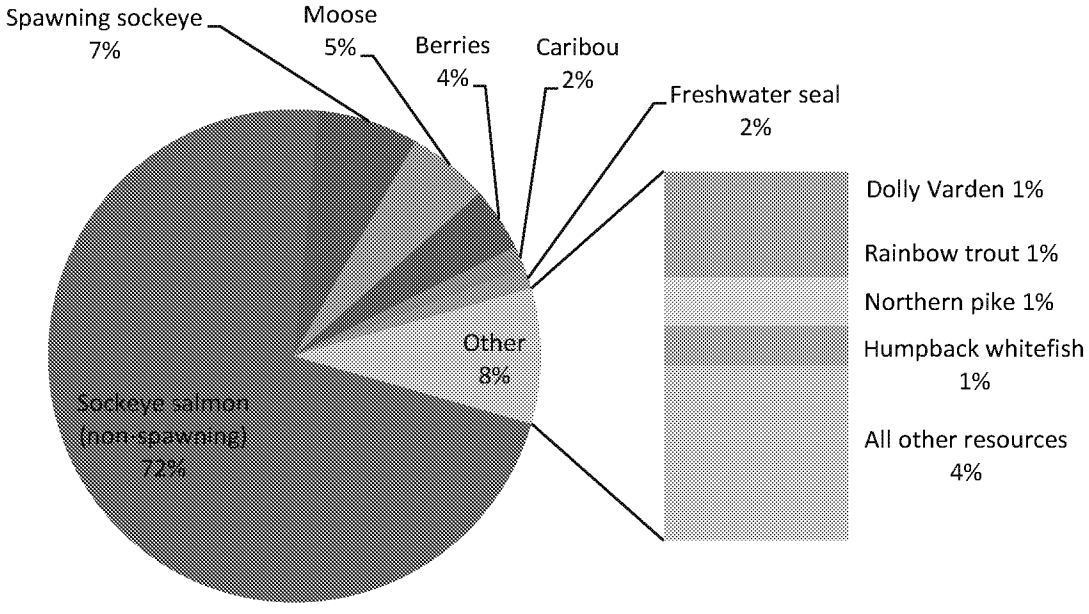
AMERICAN OVERSIGHT

Figure 3.9-1 Subsistence Use Areas

AMERICAN OVERSIGHT



3.9.3.1 Iliamna

Iliamna was established at its present location on the northern shore of Iliamna Lake when the Dena'ina Athabascan community of Old Iliamna moved from the mouth of Iliamna River in 1935. Today, this majority Alaska Native community is a cultural mosaic of Dena'ina, Yupik, Alutiiq, and Euro-American people. In 2004, Iliamna had an estimated year-round population of 73 people in 22 households. Subsistence pursuits by Iliamna residents are highly productive, resulting in an estimated total of 34,160 pounds of wild foods (469 pounds per capita), according to a 2004 survey (Fall et al. 2006). Salmon dominate the subsistence production of Iliamna residents, as seen in Table 3.9-2, which displays per capita harvests by resource category. The top ten resources harvested by Iliamna residents in 2004 in terms of edible weight are shown in Figure 3.9-2.

Iliamna households show very high levels of participation in subsistence activities and uses. Salmon was the most widely used resource category (100 percent of households) followed by non-salmon fish (92 percent), plants and fungi (85 percent), large land mammals (77 percent), birds and eggs (69 percent), and marine invertebrates (46 percent). Sharing and distribution of subsistence foods extend widely across households.

In 2004, 77 percent of Iliamna households received wild resources, and 54 percent of households gave resources away (Fall et al. 2006).

Figure 3.9-2: Composition of Iliamna Subsistence Harvest by Estimated Edible Weight, 2004

Source: Fall et al. 2006

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

Table 3.9-3 describes the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies as described by SRB&A (2018) for Iliamna. Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, large land mammals.

AMERICAN OVERSIGHT

[1]Estimated numbers typically represent individuals, except in some cases, such as vegetation, where they may represent gallons.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Source: SRB&A 2018.

Trends in Iliamna subsistence harvest over time indicate that recent overall harvests and uses in 2004 were the same as the recent past, with some notable variations among uses of specific resources. Households reported changes in the uses of individual resources, with 46 percent reporting that their use of salmon and edible plants had increased, while the percentage of harvest of large land mammals had declined. Survey respondents noted competition, weather, animal population changes, and personal reasons as explanations for changes in their use of these resources (Fall et al. 2006; SRB&A 2011b). Iliamna residents expressed concern that non-local hunters were overharvesting caribou from the Mulchatna caribou herd. They also observed that lichen had become too thin to support the formerly large herd near the Mulchatna River, and it may be a decade before they can return to this area (Fall et al. 2006).

Figure 3.9-3 illustrates the total use area for subsistence activities (all resources) for Iliamna. The primary areas used are north and west of Iliamna Lake, extending around Lake Clark to the Koktuli and Stuyahok rivers, and over the flats to the Kvichak River. High-use areas show in the Chulitna River and on the islands in Iliamna Lake. Hunting and harvesting occurs along the Nushagak, Mulchatna, and Kvichak rivers. Iliamna residents travel along the lakeshore and rivers to harvest moose, caribou, waterfowl, and plants and berries. During the winter, inland use occurs for hunting and traping small land mammals and furbearers, along with caribou, moose, and ptarmigan. Egg harvest, berry picking, and plant harvest occurs on the islands in Iliamna Lake. Boats, snowmachines and all-terrain vehicles (ATV) were the most common method of travel; there is a direct route across Iliamna Lake between Iliamna and Kokhanok.

AMERICAN OVERSIGHT

3.9.3.2 Newhalen

The Yup'ik village of Noghelingamiut was listed on the 1890 census in the location of present-day Newhalen at the mouth of Newhalen River on Iliamna Lake. Today, Newhalen is a predominantly Yup'ik community, but is also home to Alutiiq, Dena'ina, and Euro-American people. In 2004, Newhalen had an estimated year-round population of 125 people in 39 households. Newhalen residents were highly productive in subsistence activities, harvesting an estimated total of 86,607 pounds of wild foods (692 pounds per capita) in 2004. Salmon dominated the subsistence harvests, as seen in Table 3.9-2 for per capita harvests by resource category. The top ten resources harvested by Newhalen residents in 2004 in terms of edible weight are shown in Figure 3.9-4.

Household participation in subsistence activities was very high. Salmon was the most widely used resource category (100 percent of households), followed by plants and fungi (92 percent), birds and eggs (92 percent), large land mammals (92 percent), non-salmon fish (88 percent), marine invertebrates (56 percent), and marine mammals (52 percent). Sharing and distribution of subsistence foods extend widely across households. In 2004, 96 percent of Newhalen households received wild resources, and 80 percent of households gave resources away (Fall et al. 2006).

Figure 3.9-4: Composition of Newhalen Subsistence Harvest by Estimated Edible Weight, 2004

Source: Fall et al. 2006

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

Table 3.9-4 describes the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies, as described by SRB&A (2018) for Newhalen. Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, marine mammals.

Notes: Blank cells indicate no data. Source: SRB&A 2018

[1]Estimated numbers typically represent individuals, except in some cases, such as vegetation, where they may represent gallons.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Trends in Newhalen subsistence harvest over time indicate that overall harvests were similar across all study years. Sockeye salmon, spawning sockeye salmon, and caribou were the top three harvested resources. Harvest and use of wild resources in 2004 was about the same as in the preceding 5 years, but they used less furbearers and large land mammals in recent years. Changes in resource populations have caused lower harvests in 2004, especially for large land mammals. A majority (61 percent of respondents) reported that having more cash and wage-based employment reduced the time to participate in subsistence activities. Newhalen residents expressed similar concerns as Iliamna residents that non-local hunters were overharvesting caribou from the Mulchatna caribou herd. They too observed that lichen has become too thin to support the formerly large herd near the Mulchatna River (Fall et al. 2006).

Figure 3.9-5 illustrates the total use area for subsistence activities (all resources) for Newhalen. Harvest areas extend from Lime Village to Naknek, and from Tikchik Lakes to the eastern edges of Lake Clark and Iliamna Lake, with some use in Cook Inlet. The primary areas of overlapping use are near the Newhalen, Kvichak, Nushagak, and Mulchatna river drainages for hunting of caribou, moose, waterfowl, and other game; and also for fish, berries, and plants in the summer and fall. Overlapping use areas occur inland close to the community, along the northwestern shore of Iliamna Lake, and toward Nondalton and the eastern shoreline. The primary means of travel are by snowmachine, boat, ATV, and truck. Travel routes to access resources were close to the Iliamna Lake shoreline, and there is a direct route across Iliamna between Newhalen and Big Mountain, and a similar direct route from Newhalen to Kokhanok.

AMERICAN OVERSIGHT

3.9.3.3 Pedro Bay

Pedro Bay is a Dena'ina Athabascan community at the eastern end of Iliamna Lake. In 2004, Pedro Bay had an estimated year-round population of 69 in 21 households. Pedro Bay residents harvested an estimated total of 21,026 pounds of wild food (306 pounds per capita) in 2004. See Table 3.9-2 for per capita harvests by resource category. The top ten resources harvested by Pedro Bay residents in 2004 in terms of edible weight are shown in Figure 3.9-6. Salmon, as well as plants and fungi, was the most widely used resource category (100 percent of households), followed by birds and eggs (94 percent), non-salmon fish (89 percent), and large land mammals (78 percent). Sharing and distribution of subsistence foods was widespread. In 2004, all Pedro Bay households received wild resources and almost all (89 percent) households gave resources away (Fall et al. 2006).

Figure 3.9-6: Composition of Pedro Bay Subsistence Harvest by Estimated Edible Weight, 2004

Source: Fall et al. 2006

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

Table 3.9-5 describes the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies, as described by SRB&A (2018) for Pedro Bay. Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, marine mammals and large land mammals.

Notes: Blank cells indicate no data. Source: SRB&A 2018.

[1]Estimated numbers typically represent individuals, except in some cases, such as vegetation, where they may represent gallons.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Trends in Pedro Bay overall subsistence harvest over time indicate that they remained relatively unchanged over the study years. Salmon accounted for the majority of the total harvest, and large land mammals and non-salmon fish contribute to the yearly subsistence harvest. Pedro Bay residents described sociocultural changes that were affecting harvest patterns. People had stopped harvesting smaller land mammals (beaver, snowshoe, and porcupine) as a food source as the community loses elders and there is less demand. Additionally, people were not spending as much time on subsistence activities because wage labor increased, and caused people to spend less time hunting and fishing for subsistence. Residents reported that Dolly Varden in the Iliamna River were being overharvested by the sport fishery, and that motorized boats were disturbing stream habitat. They observed that moose were being adversely affected by increased populations of wolves and bears (Fall et al. 2006).

Figure 3.9-7 illustrates the total use areas for subsistence activities (all resources) for Pedro Bay, and are concentrated on the eastern end of Iliamna Lake. Lower-use areas extended to near Upper and Lower Talarik creeks and along the Chulitna, Mulchatna and Nushagak rivers. Use areas extend toward Iliamna, near Tazimina Lakes, and east to Cook Inlet. The highest numbers of overlapping use areas are close to Pedro Bay, and along the coast to the Iliamna River for moose, other large land mammals, furbearers, small land mammals, waterfowl upland birds, berries, and plants. Flat and Porcupine islands were the prime harvesting locations for moose, seal, waterfowl, berries, and plants. Salmon and trout are taken in overlapping use areas near the community and near Pile Bay. Travel routes to access subsistence areas were reported to extend west along the lake to Dillingham, and east to Pile Bay and to Williamsport.

AMERICAN OVERSIGHT

3.9.3.4 Nondalton

Nondalton is a primarily Dena'ina community on Sixmile Lake. In 2004, Nondalton had an estimated year-round population of 164 people in 43 households. Nondalton residents pursued a diverse range of productive subsistence activities, and harvested a total of 58,686 pounds of wild food (358 pounds per capita) in 2004. See Table 3.9-2 for per capita harvests by resource category. The top ten resources harvested by Nondalton residents in 2004 in terms of edible weight are shown in Figure 3.9-8. Plants and fungi was the most widely used resource category (97 percent of households) followed by salmon (92 percent), large land mammals (84 percent), non-salmon fish (82 percent), small land mammals (58 percent), and birds and eggs (50 percent). Sharing and distribution of subsistence foods was widespread. In 2004, 97 percent of Nondalton households received wild resources, and 92 percent of households gave resources away (Fall et al. 2006).

Figure 3.9-8: Composition of Nondalton Subsistence Harvest by Estimated Edible Weight, 2004

Source: Fall et al. 2006

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

Table 3.9-6 shows the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies, as described by SRB&A (2018) for Nondalton. Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, marine mammals.

[1]Estimated numbers typically represent individuals, except in some cases, such as vegetation, where they may represent gallons.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Source: SRB&A 2018.

Trends in Nondalton subsistence harvest over time indicate that fish were the most commonly used resource, and sockeye salmon were the most shared resource. Large land mammals, mostly moose, were shared with other households, and comprised 75 percent of the total large land mammals harvest in 2004. Participants commented that caribou numbers have declined, affecting subsistence resources, so that locals could not compete with non-local hunters. They also noticed that disturbance from helicopter traffic causes the caribou herd to move farther away, and they were seeing a trend of overharvest by non-locals for caribou and moose (Fall et al. 2006).

Figure 3.9-9 illustrates the total use areas for subsistence activities (all resources) for Nondalton. Use areas for caribou, moose, black bear, and brown bear hunting were from the headwaters of the Mulchatna River and towards the Koktuli River system. Residents traveled south to Iliamna, to the headwaters of Upper Talarik Creek, and to the eastern end of Little Lake Clark (Fall et al, 2006). Fishing for salmon and freshwater fish occurred primarily at the outlet of Sixmile Lake north of the community. Small game and furbearers were trapped near Nondalton, close to the headwaters of Upper Talarik Creek, and in the Chulitna River valley. Waterfowl and upland bird hunting occurred in these same areas. Fishing also occurred in the Newhalen River near Petrof Falls, and on Lake Clark in Chulitna Bay. For berry picking, the area used was around the northern and southern shores of Iliamna Lake, and into the headwaters of the Koktuli River near Groundhog Mountain and Frying Pan Lake. Wild plant harvest occurred in the area immediately around Nondalton and on islands in Iliamna Lake, including Flat Island.

AMERICAN OVERSIGHT

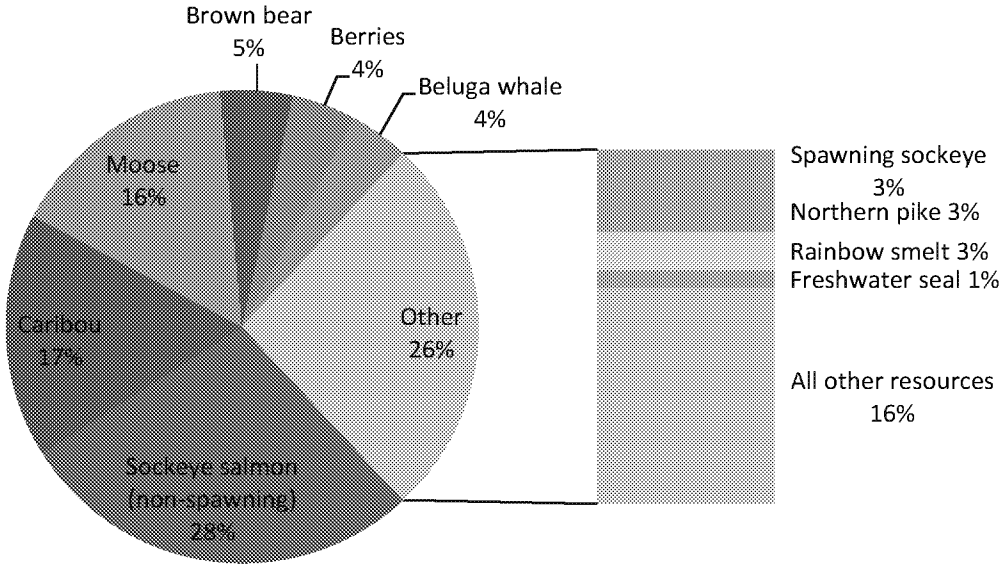

Figure 3.9-9 Subsistence Use Areas, All Resources – Nondalton

AMERICAN OVERSIGHT

3.9.3.5 Igiugig

Igiugig is on the southeastern side of Iliamna Lake at the mouth of the Kvichak River, and was formerly a portage point for a reindeer station established at Kukaklek Lake in the early 1900s (Deur 2008). It was historically a Yup'ik village, and is now home to primarily Alutiiq, Yup'ik, and Dena'ina people. In 2005, Igiugig had an estimated year-round population of 41 people in 13 households. Residents pursue a wide array of productive subsistence activities. Krieg et al. (2009) surveyed residents about their 2005 subsistence activities, and found that Igiugig households harvested an estimated total of 22,310 pounds of wild foods (542 pounds per capita). Although salmon dominate the subsistence food production of residents, moose and caribou provide a larger portion of total subsistence food when compared to the other Iliamna Lake communities for per capita harvests, as shown in Table 3.9-2. The top ten resources harvested in 2005 in terms of edible weight are shown in Figure 3.9-10. In 2005, all households in Igiugig used salmon, non-salmon fish, plants and fungi, and large land mammals. Other widely used resource categories included birds and eggs (92 percent of households), marine mammals (67 percent), and small land mammals (50 percent). Sharing and distribution of subsistence foods is widespread. All households received and gave away at least one subsistence resource in 2005 (Krieg et al. 2009). In addition to relying heavily on subsistence hunting and fishing, the community relies on commercial fishing for cash income, with some families holding commercial fishing permits, and other working in the canneries (Deur 2008).

Figure 3.9-10: Composition of Igiugig Subsistence Harvest by Estimated Edible Weight, 2005

Source: Krieg et al. 2009

Note: The term "spawning sockeye" refers to late-run sockeye salmon that have a distinctive red color and white meat, and are harvested in the fall.

Table 3.9-7 describes the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies, for Igiugig (SRB&A 2018). Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, marine mammals.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Source: SRB&A 2018.

Trends in Igiugig subsistence harvest over time indicate that overall harvests remained relatively unchanged over the study years. Salmon use decreased, and harvest of large land mammals increased (SRB&A 2011b). Reasons residents cited for changes were personal reasons and change in animal populations. It was noted that personal reasons accounted for 75 percent of households using less salmon, and 50 percent of households using fewer non-salmon fish, birds and eggs, and wild plants. Residents noted that these declines were from a need for fewer resources due to smaller families. All households reported that they were using fewer furbearers due to lower fur prices and higher costs of transportation (fuel). Competition and regulations were not the reasons given for changes in harvest and the uses (Krieg et al. 2009).

Figure 3.9-11 illustrates the total use areas for subsistence activities (all resources) for Iguigig, encompassing a large area that extends around much of Iliamna Lake, and along the entire Kvichak River to Naknek. Travel for subsistence extends into Katmai National Park and Preserve and to the Mulchatna River. The majority of high-use areas for Igiugig are close to the community along the western shore of the lake, and along Kaskanak Creek, Kvichak, and Alagnak river corridors. Medium- to low-use areas for overlapping resources for waterfowl, upland birds, berries, and plants in the summer and fall are in the vicinity of the northern mine access roads and ferry terminals. Travel routes were across the same areas, with lake route crossings occurring close to the shorelines.

AMERICAN OVERSIGHT

3.9.3.6 Kokhanok

Kokhanok is a predominantly Alaska Native community on the southern shore of Iliamna Lake. The Alaska Native population is a mix of Alutiiq, Yup'ik, and Dena'ina people. Economically, Kokhanok residents are highly dependent on subsistence fishing and hunting, with comparatively little industrial or tourist-based economic development; with subsistence hunting, fishing, and gathering representing a significant source of non-cash income (Deur 2008). In 2005, Kokhanok had an estimated year-round population of 158 people in 42 households. Kokhanok residents pursued a diverse range of productive subsistence activities, and harvested an estimated total of 107,645 pounds of wild foods (680 pounds per capita) in 2005. See Table 3.9-2 for per capita harvests by resource category. The top ten resources harvested by Kokhanok residents in 2005 in terms of edible weight are shown in Figure 3.9-12. Salmon, as well as plants and fungi, was the most widely used resource category (97 percent of households), followed by birds and eggs (91 percent), large land mammals (91 percent), non-salmon fish (74 percent), small land mammals (43 percent), and marine mammals (40 percent). Sharing and distribution of subsistence foods is widespread. In 2005, 94 percent of Kokhanok households received wild resources, and 83 percent of households gave resources away (Krieg et al. 2009).

Figure 3.9-12: Composition of Kokhanok Subsistence Harvest by Estimated Edible Weight, 2005

Source: Krieg et al. 2009

Table 3.9-8 describes the rates of household participation and harvest levels, as well as the average contribution to subsistence by resource category from inventory of subsistence studies, as described by SRB&A (2018) for Kokhanok. Salmon and large land mammals represent the higher volumes in terms of total pounds of the estimated harvest. Most households try for and harvest salmon, but a smaller proportion of households harvest several other species groups; notably, marine mammals.

Notes: Blank cells indicate no data.

[1]Estimated numbers typically represent individuals, except in some cases, such as vegetation, where they may represent gallons.

[2]Estimated pounds include only edible pounds, and therefore do not include estimates for resources that are not typically eaten by community residents (e.g., furbearers).

Source: SRB&A 2018.

Trends in Kokhanok subsistence harvest over time indicate the top three resources consistently harvested over all of the study years were salmon, non-salmon, and large land mammals. Participation in harvest of non-salmon fish and small land mammals and furbearers was noted to have declined across the study years. Birds and egg harvest and vegetation harvest had increases in participation levels, and harvest of salmon has been the same across study years.

Figure 3.9-13 illustrates the total use areas for subsistence activities (all resources) for Kokhanok. The highest-use areas for all resources was the area closest to the community along the Iliamna Lake shoreline towards Big Mountain, near the south ferry terminal, and along the south mine access road. The areas of use for all resources extend as far north as the Chulitna River, and west from Nondalton and Newhalen to the upper Koktuli River, Kaskanak Creek, and the Kvichak and Alagnak rivers. To the south of the community, use areas extend into Katmai National Park and Preserve, and east into Cook Inlet. Overlapping resource use areas are between Dennis Creek to the west near the southern ferry terminal, to the south along the south access mine road near Gibraltar Lake and east to Tommy Point, as well as the islands near Kokhanok and Intricate, Leon, and Kokhanok bays. The lands to the south of Kokhanok are overlapping use areas for caribou, moose, bear, fish, waterfowl, upland birds, berries, and plants. Travel routes occurred close to the Iliamna Lake shoreline and crossing the southern ferry terminal location, with a direct route to Igiugig along the shoreline and a route directly across Iliamna Lake between Iliamna and Kokhanok.

3.20 AIR QUALITY

This section describes the current air quality and climate for the Pebble Project area. The project area for air quality and climate analysis encompasses the mine site, Amakdedori port, the transportation corridor, and the natural gas pipeline corridor. The air quality and climate analyses presented are applicable for all alternatives, because they are generally located in the same area.

3.20.1 Regional Air Quality

Air quality is defined by the concentration of criteria pollutants and their interactions in the atmosphere, Hazardous Air Pollutants (HAPs), and the magnitude of haze and acidic deposition generally referred to as Air Quality Related Values (AQRVs). An understanding of current conditions and trends of these air quality metrics also provides a baseline for comparison of potential future impacts. Recent trends in air quality are important to consider when evaluating potential future changes, independent of an individual project.

Project area air quality is assessed through the analysis of values measured by the monitors listed in Table 3.20-1 and from the Alaska Air Monitoring Network. Criteria pollutants were analyzed using data obtained from the Alaska Department of Environmental Conservation (ADEC). Existing visibility conditions were assessed using monitors from the Intergraded Monitoring of Protected Environment (IMPROVE) network. The wet and dry deposition measurements are collected by the National Acid Deposition Program (NADP) and the Clean Air Status and Trends Network (CASTNeT), respectively. With the exception of Denali National Park monitors, all monitors are within 200 miles of the mine site.

Table 3.20-1: Monitor Name and Details Used in the Analysis

Network	Monitor Name	Monitor Period	Monitored Parameters[1]	Monitor Purpose[2]	Approximate Distance from Mine Site

3.20.1.1 Criteria Pollutants

The relative importance of criteria pollutant concentrations can be determined by comparison with the Alaska Ambient Air Quality Standards (AAAQS) which are equivalent to, or more stringent than, the National Ambient Air Quality Standards (NAAQS). Air pollutant concentrations that are lower than the AAAQS provide public health protection, including protecting the health of sensitive populations such as asthmatics, children, and the elderly. For this project, all pollutants in the region are below the AAAQS. With the exception of locations near airfields, where lead exposure from aircraft exhaust has the potential to occur, regional sources of lead are minimal. The project is far from any airfields where lead expose could occur. Given the extremely low levels of lead emissions from potential project-related air pollutant, ambient lead concentrations and comparisons to the lead AAAQS are not addressed further in this analysis.

The Alaska Air Monitoring Network measures certain criteria pollutants of interest throughout Alaska and can be used to assess the general air quality trends of the region. The nearest of these monitors are in relatively urbanized areas in and around Anchorage and are distant from the project area (ADEC 2016a). Due to the increased anthropogenic activity, measurements at these monitors are expected to be elevated compared to what should be observed in the project area; however, the long-term measurement record available from this network can provide an understanding of regional trends. The Alaska Air Monitoring Network only measures $PM_{2.5}$, PM_{10}, ozone, and carbon monoxide (CO) close enough to the project area to be relevant. For the remaining criteria pollutants, long-term trends are not available for analysis. For $PM_{2.5}$ and PM_{10}, the frequency of AAAQS exceedances has increased since 2000 (ADEC 2016a). ADEC documents that this increase is due to an increase in the frequency of wildfires near the monitors. For the more rural monitors that are more representative of the project area, the measured concentrations have remained relatively constant with average annual $PM_{2.5}$ values near 6.5 micrograms per cubic meter ($\mu g/m^3$), and well below the NAAQS. The measured CO concentrations at the Anchorage monitor have decreased to values consistently below 6 parts per million (ppm) from 2000 to 2014 (ADEC 2016a). An assessment of 4 years of ozone measurements at monitoring sites near Anchorage indicates that hourly ozone concentrations peak in the late spring, and are lowest in winter (ADEC 2016a).

Table 3.20-2 lists existing conditions measured at locations near the project study area; shown for all criteria pollutants except lead. Compared to the Anchorage monitors discussed previously, these monitors are found in more remote areas with fewer anthropogenic sources

AMERICAN OVERSIGHT

similar to the project study area. None of the monitoring programs documented in this table represent more than 1 year of data; therefore, multi-year averages that are required for the 1-hour nitrogen dioxide (NO_2), 1-hour sulfur dioxide (SO_2), and $PM_{2.5}$ AAAQS cannot be properly calculated. For those pollutants and averaging periods, the values presented in Table 3.20-2 are not directly comparable to the AAAQS, but are still a solid indicator of recent air quality and indicate if values in the vicinity of the project area are near AAAQS thresholds, keeping in mind that a single year of data could represent an anomalous event.

All values listed in Table 3.20-2 are well below the AAAQS. Unlike the measurement locations themselves, the project area is far away from large emissions sources, such as power and gas plants, with relatively sparse population. Therefore, measured concentrations in the project area are expected to be lower.

In most cases, the AAAQS are also protective of the health of plant and animal species because they are equal to or lower than the secondary NAAQS. Secondary NAAQS set limits to protect public welfare, including protection against decreased visibility, endangerment to animals and damage to crops, vegetation, and buildings. However, for some species of lichens, which can be particularly sensitive to SO_2, ADEC (2016b) recommends supplementing these standards with an annual SO_2 threshold of 13 $\mu g/m^3$. Annual SO_2 concentrations at the Alaska Liquefied Natural Gas (LNG) Nikiski monitor are reported as zero (Table 3.20-2), indicating that concentrations are less than 0.0005 ppm (1.4 $\mu g/m^3$) and well below the annual SO_2 threshold of 13 $\mu g/m^3$. Given that the project study area has limit sources of anthropogenic SO_2, it is expected that the SO_2 concentrations within the project study area would be similar to those measured at the LNG Nikiski monitor.

Table 3.20-2:Criteria Pollutant Data Complied by ADEC

Pollutant	Averaging Period	Rank	AAAQS	Monitor Name				
				Chevron Trading Bay	Chevron Swanson River	Agrium Nikiski	Alaska LNG Nikiski	Chugach International Station

3.20.1.2 Hazardous Air Pollutants

HAPs can cause serious health effects or adverse environmental or ecological effects. Concentrations of HAPs are rarely measured and not measured in the region, therefore, there are no data available to assess the current concentrations or trends. HAPs are not generally measured except in the vicinity of large sources, such as factories, refineries, or power plants. The HAPs of major concern are reactive and short-lived in the atmosphere. Therefore, absent of large regional anthropogenic sources, there is no reason to expect measureable concentrations in the project area except for what is biogenic in nature. For the same reasons, there is no reason to expect increasing or decreasing trends over time of HAPs in the project area.

3.20.1.3 Air Quality Related Values

Thresholds for AQRVs have been set to protect resources sensitive to acidic deposition and visibility degradation, which includes vegetation, soils, water, fish wildlife, and recreation. Visibility and deposition are reviewed in more detail below for the purpose of establishing baseline conditions pertinent to vegetation, soils, water, fish and recreation.

Visibility

Visibility impairment only impacts recreation and people and is not a concern for vegetation, soil, water and fish. Regional haze is a visibility impairment caused by the cumulative air pollutant emissions from numerous sources over a wide geographic area. Visibility impairment is caused by particles and gases in the atmosphere that scatter or absorb light. The primary cause of regional haze in many parts of the country is light scattering resulting from fine particles (e.g., $PM_{2.5}$) in the atmosphere. Additionally, coarse particles between 2.5 and 10 microns in diameter can contribute to both light absorption and scattering increasing regional haze. Coarse particles and $PM_{2.5}$ can be naturally occurring or the result of human activity. The natural levels of coarse particles result in some level of visibility impairment in the absence of any human influences and vary with season, daily meteorology, and geography (Malm 1999).

The US Environmental Protection Agency (EPA) and other agencies have been monitoring visibility in national parks and wilderness areas since 1988. Observations have shown that visibility at national parks and wilderness areas throughout the United States was not as good as natural background conditions (i.e., visibility is impaired relative to natural background conditions). The Regional Haze Rule was promulgated by the EPA in 1999 to established Reasonable Progress Goals for improving visibility (EPA 2018c).

AMERICAN OVERSIGHT

ADEC (2011) has determined that a primary source of visibility degradation for Alaska is short- and long-range transport of dust, and transport of combustion emissions from anthropogenic sources located in Asia and Northern Europe. The long-range transport of dust across the Pacific Ocean typically influences visibility in Alaska in spring and summer, while anthropogenic emissions from Northern Europe and Russia reach Alaska during the winter and early spring. Additionally, particulate and gaseous emissions from wildfires influence visibility throughout Alaska. Wildfire season typically starts once snow melt occurs in late spring and ends early fall (ADEC 2011).

Visibility impacts are expressed in deciviews (dv), which is a measure for describing perceived changes in visibility. Deciview values are calculated from either measured or estimated light extinction values in units of inverse megameters (Mm^{-1}); the smaller the dv value, the more pristine the atmosphere. For Tuxedni (approximately 50 miles east-northeast of the mine site), the estimated annual average natural visibility condition for the haziest days is 11.3 dv and for the clearest days is 3.1 dv measured. The natural visibility condition represents the long-term degree of visibility that is estimated to exist in a Federal Class I area in the absence of human-caused impairment and gives a sense for the magnitude of the deciview metric.

Visibility in the project area was inferred using the two closest visibility monitoring stations operated by the IMPROVE program as listed in Table 3.20-1. Visibility (in dv) for the 20 percent best days (i.e., clearest), 20 percent worst days (i.e., haziest), and natural conditions are shown in Table 3.20-3 for these two IMPROVE stations over the period from 2011 to 2016, noting that the Tuxedni monitor does not have data after 2014.

Data in Table 3.20-3 indicate that for either Tuxedni or Denali National Park, the haziest days generally have visibility values between 7 and 13 dv, while the clearest typically have visibility values less than 5 dv. When comparing the current visibility at either monitor to the estimated natural background conditions, both the haziest and clearest days are higher than natural background conditions. Overall, at the Tuxedni monitor, which is most representative of the project area, the annual average haze index is closer to the natural conditions on both the haziest and clearest days than the Denali National Park monitor; whereas the measured visibility at Denali National Park is worse compared to the natural condition for the both the haziest and clearest days. Most importantly, regardless of the location, visibility has been steadily trending toward natural conditions.

Table 3.20-3: Visibility Values by Year

Monitor Name	Type	Annual Average Haze Index (deciview)						
		2011	2012	2013	2014	2015	2016	Natural Condition
Tuxedni	Haziest Days	12.3	11.6	12.4	13.2	-	-	11.3
	Clearest Days	4.3	3.9	3.6	3.8	-	-	3.1
Denali National Park	Haziest Days	9.1	8.7	9.6	8.6	12	7.3	7.3
	Clearest Days	2.7	2.7	2.2	2.3	2.2	1.9	1.8

Deposition

Deposition can be from both wet and dry processes. Wet deposition refers to acidic rain, fog, and snow; whereas dry deposition refers to acidic gases and particles the wind blows onto buildings, cars, homes, and trees. The effects of atmospheric deposition of nitrogen and sulfur compounds on terrestrial and aquatic ecosystems are well documented and have been shown

AMERICAN OVERSIGHT

to cause leaching of nutrients from soils, acidification of surface waters, injury to high elevation vegetation, and changes in nutrient cycling and species composition. The effects of acidification through sulfur deposition are not as widespread in Alaska relative to the eastern US because sulfur deposition, which is a large source of acidification in the east, tends to be lower in Alaska. Due to the lower sulfur deposition rates in Alaska, nitrogen deposition is often the main contributor of acidification in Alaska.

In Alaska, deposition is routinely measured at Denali National Park. However, given that both SO_2 and NO_x emissions contribute to both visibility impairment and deposition, and knowing that visibility degradation in Denali National Park is slightly worse than Tuxedni, it is expected that deposition measurements in Denali National Park are conservatively representative of Tuxedni and the project area. Wet deposition measurements at Denali National Park are collected by NADP in micro-equivalent per liter (µeq/l), and dry deposition is estimated from ambient measurements collected by CASTNet in kilograms per hectare (kg/ha).. Deposition measurements in Denali National Park indicate that sulfate and nitrate deposition rates have steadily decreased since the start of the record (although for some species, the decrease is not statistically significant) (Table 3.20-4).

In the western US and Alaska, the focus is on nitrogen deposition, given low sulfur dioxide emissions and the expectation that the effects of nitrogen deposition will manifest before those from sulfur deposition. Currently, the National Park Service is recommending the use of nutrient nitrogen critical loads for the evaluation of deposition impacts in terrestrial and aquatic ecosystems. Nutrient nitrogen critical loads are a tool used to assess and understand the impacts of nitrogen deposition to ecosystems. The nitrogen critical loads are determined by amount of nitrogen deposition below, in which no harmful effects to an ecosystem are expected. This value varies based on the type of ecosystem present in an area. Estimates of nitrogen critical load values in Denali National Park range from 1.2 kilograms of nitrogen per hectare per year (kgN/ha/yr) for lichens and bryophytes to 17.0 kgN/ha/yr for forests and nitrate leaching (National Park Service 2018y). While additional information would be needed to convert the wet deposition rates into appropriate units for comparison to critical load values, the estimates of dry deposition at Denali National Park are well below the lowest critical load value of 1.2 kgN/ha/yr (Table 3.20-4). The same should be expected for the project area.

Table 3.20-4: Wet and Dry Deposition at Denali National Park Monitoring Location

Year	Wet Deposition (µeq/l)[1]		Dry Deposition (kg/ha)[2]

3.20.2 Regional Climate

The project area is in a transitional climatic zone with a strong maritime influence (Hoefler 2010a). Terrain changes and proximity to large bodies of water locally influence the climate. For example, the proximity of Cook Inlet more heavily influences the climate around the Amakdedori port site than the vicinity of the mine site. Portions of the project area that are at higher elevation are likely to experience colder temperatures and differences in precipitation patterns relative to those areas at lower elevations. Summer temperatures are moderated by the open waters of Iliamna Lake, the Bering Sea, and Cook Inlet. During winter, ice forms on these open waters, resulting in a more continental temperature pattern. Overall, the weather systems arrive from the west and southwest, bringing cool to cold air that is often saturated with moisture. These systems result in frequent clouds, rain, and snow with possible thunderstorm activity during the warm season.

Meteorological monitoring was conducted at the mine site and Cook Inlet by Hoefler (2010a, b) and SLR (2013, 2015). The Cook Inlet monitor, also called Knoll Head, is located about 30 miles northeast of the proposed Amakdedori port site. Table 3.20-5 and Table 3.20-6 present monthly and annual averages for mean temperature, mean wind speed, and total precipitation for the mine site (Pebble Site 1) and Cook Inlet (Port Site 1) monitors, respectively. The Port Site 1 monitor has slightly warmer average monthly temperatures than the Pebble 1 monitor (Table 3.20-5 and Table 3.20-6). At the Port Site 1 monitor, wind is generally from the north and northeast due to local terrain influences (Hoefler 2010b). At the Pebble 1 monitor, the wind is bimodal, generally from the northwest or the southeast (Hoefler 2010a). The differences in observations are likely due the influence of Cook Inlet and elevation of the monitors.

Monthly climate averages for Iliamna Airport are listed in Table 3.20-7. These averages are from 30 years of data collection and represent long-term averages compared to the Pebble 1 monitor, which only collected data for 7 years. The 30-year record minimizes the naturally occurring year-to-year variability that can bias a shorter term record. Overall, the Iliamna Airport has colder temperatures during the winter, and warmer temperatures during the summer with more precipitation, than the Pebble 1 and Port Site 1 monitoring sites.

AMERICAN OVERSIGHT

4.2 LAND OWNERSHIP, MANAGEMENT, AND USE

The environmental impact statement (EIS) analysis area for land ownership and management includes the project footprint, and use of those and adjacent lands. Potential direct and indirect impacts include:

- Change in/or conflict with land management as a result of the project.
- Change in land status if a lease was to be issued, an easement were to be altered or vacated, or if additional access were legally acquired.
- Change in land use from an existing or allowed land use.

4.2.1 No Action Alternative

Under the No Action Alternative, the development of the Pebble Project as proposed would not be authorized. Any existing or new land use activities at the mine site, such as exploration or cessation of field activities, would occur in accordance with the requirements of the State of Alaska as the landowner. Such activities may result in a reversion of use (i.e., cessation of activity) or continuation of the existing use (i.e., exploration). Land ownership and management of the mine site, Amakdedori port, transportation corridor, and natural gas pipeline corridor would remain the same. Because the project would not be implemented, the No Action Alternative would have no new impacts on existing land ownership, management, and use.

4.2.2 Action Alternative 1 – Applicant's Proposed Alternative

4.2.2.1 Land Ownership

For a description of land ownership under Alternative 1, see Section 3.2, Land Ownership, Management, and Use. No land in the project footprint would be conveyed or sold, although an Uplands Mining Lease and associated permits would be required for mining activities and facilities on State lands, and temporary use permits, easements, and ROWs for the transportation corridors and natural gas pipeline would be required on State and ANCSA corporation lands to construct and operate the project if approved (see Appendix E, laws, permits, approvals, and consultations required). This would result in a change in land status and an encumbrance on use at the mine site, and along the route of the mine access roads, ferry terminals, and pipeline. A tidelands lease would also be required for in-water facilities at the Amakdedori port site. These changes in land status constitute a direct impact. The impact would last through the duration of the project, and after closure as long as the project components were in use. There would be no aspects of the project developed on federal or municipal owned lands.

4.2.2.2 Land Management

Federal Management

Under Alternative 1, no physical project-related infrastructure would be developed on any federal land or in other legislatively designated areas. Therefore, project construction, operations, or closure would not result in any direct effects on the management, ownership, or use of federal lands. However, project-related activities could indirectly and cumulatively affect the environment, resources, and visitor experience of four federal management units: Lake Clark National Park and Preserve (NPP), Katmai NPP, Kachemak Bay National Estuarine Research Reserve, and the Alagnak Wild River. Some adaptation in land management may be

AMERICAN OVERSIGHT

needed in response to potential indirect impacts, such as noise and visual disturbance to recreationists and wildlife. See Section 4.5, Recreation, Section 4.11, Aesthetics, Section 4.19 Noise, and 4.23 Wildlife Values for discussions of impacts on those resources.

State Management

Mine Site. The mine site would be located on state-owned lands managed under the guidance of the state's Bristol Bay Area Plan. The State of Alaska selected much of the land mass in the Bristol Bay Area Plan planning area because of its mineral potential (ADNR 2013a). The Bristol Bay Area Plan specifies that these lands are to be retained in public ownership and managed for multiple use, which includes recreation; timber; minerals; fish and wildlife; and natural scenic, scientific, and historic values. This designation would not preclude construction of the mine or related facilities. The project would be consistent with the plan's goals for the use of subsurface resources, which call for making metallic and nonmetallic minerals available to contribute to the mineral inventory and independence of the United States generally and Alaska specifically, while protecting the integrity of the environment and affected cultures. The habitat resources of the North and South Fork Koktuli stream corridors that traverse this unit are managed for protection; in addition, the area is managed for moose wintering habitat. Active management for fish and wildlife protection would be modified as necessary in the immediate area as a result of the project. There would not be a conflict with management plans but may require permit conditions to accommodate additional plan direction related to fish and wildlife management.

Transportation Corridor and Pipeline. Some of the transportation corridor and natural gas pipeline would be located on state-owned lands managed under the guidance of the Bristol Bay Area Plan (see Section 3.2, Land Ownership, Management, and Use). The plan specifies that these lands are to be retained in public ownership and managed for a multiple use designation that would not preclude construction of the mine access roads. Active management for fish and wildlife protection would necessarily be modified in the immediate area through the life of the mine and into post-closure as a result of the project.

Iliamna Lake is managed as a navigable waterbody under the Bristol Bay Area Plan. The lake is co-designated for public recreation, dispersed tourism, and habitat. The designations allow for development insofar as essential habitat and recreation values are maintained. These designations would not preclude construction and operations of the project's proposed north and south ferry terminals, as well as the ferry route across the lake.

Amakdedori port and the pipeline compressor station on the Kenai Peninsula would fall under the management of the state's Kenai Area Plan. The plan has management guidelines for the development of transportation and utilities that include protection of hydrologic systems and roads near wetlands. The plan also provides guidelines for waterfront development with regard to soil erosion and fuel storage (ADNR 2001). These guidelines would not preclude the development of Amakdedori port or the pipeline facilities on the Kenai Peninsula.

Because the project would be in agreement with the state's planned land management of the area, project construction, operations and maintenance, or closure on state lands would not result in adverse direct or indirect effects on land management, but active management may be modified in some areas for the duration of the project and into post-closure.

Borough Management

The mine site, the majority of the transportation corridor, and a portion of the natural gas pipeline corridor would lie within the boundaries of the Lake and Peninsula Borough (LPB). Pebble Limited Partnership (PLP) would be required to obtain development permits from the LPB; however, no direct or indirect effects on land management in the LPB would occur. Any

AMERICAN OVERSIGHT

permits from a borough would likely only be issued with permit stipulations that would minimize potential land use conflicts.

Amakdedori port and a portion of the proposed transportation corridor and the natural gas pipeline corridor on the western side of Cook Inlet would be located in the Kenai Peninsula Borough (KPB). The KPB Comprehensive Plan does not contain goals, objectives, or implementation actions specific to development of the project on lands in the KPB. However, the KPB does regulate development on the floodplain, in the coastal zone, and near certain anadromous fish streams throughout the borough. No direct or indirect effects on land management in the KPB would occur.

Alaska Native Regional and Village Corporation Management

Portions of the mine access road (including the Kokhanok east ferry terminal variant) would cross surface lands owned by Alaska Peninsula Corporation, and Iliamna Natives Limited. The natural gas pipeline corridor would cross subsurface lands owned by Cook Inlet Region, Inc. and Bristol Bay Native Corporation. Uses on these surface and subsurface lands privately owned by Alaska Native corporations are subject to the approval of the landowners. Any activity would be conducted in accordance with lease and surface use agreements that PLP would establish with the landowners. Project construction, operations and maintenance, or closure would not result in adverse direct or indirect effects on management of these lands.

Local Management

Under Action Alternative 1, no physical project-related infrastructure would be developed on lands that are in local jurisdiction. Therefore, project construction, operations, or closure would not result in any direct effects on the ownership, management, or use of local lands. However, project-related activities could indirectly affect the environment and resources of local communities. Those impacts are discussed in relevant resource sections of this EIS.

Legal Access

There are no state-recognized Revised Statute (R.S.) 2477 rights-of-way (ROWs) in the footprint of Alternative 1.

The project area encompasses several section line easements. These easements do not prohibit development of a pipeline ROW or access roads across the affected section lines. Access to the easements would not be prohibited, although any future use may be conditioned by the presence of the access road and pipeline, if permitted and constructed.

The south access road would intersect one Section 17(b) easement, on the south shore of Lake Iliamna (EIN 17b C5). The road would not prevent access to the easement, and crossing points would be sign-posted, with appropriate traffic controls established to ensure public safety, if needed (PLP 2018-RFI 027). This easement would not be impacted by the Kokhanok east ferry terminal variant.

One state public access easement exists along the proposed pipeline route in Iliamna Lake (see Section 3.2, Land Ownership, Management, and Use). It is an easement for communication networks (for example, there are fiber optic cables in Iliamna Lake) and other utilities. Development of the project would not prohibit access to the easement, although PLP would need to be in contact with the easement holders to ensure that construction would not affect existing infrastructure.

AMERICAN OVERSIGHT

4.2.2.3 Land Use

As discussed in Section 3.2, Land Ownership, Management, and Use, the prevalent land uses around the EIS analysis area are undisturbed landscape and natural habitat, low-intensity recreational activities, and subsistence activity. Land development in the Bristol Bay area is generally limited to the areas in and around geographically isolated communities, fish processing facilities, and small fishing and hunting lodges.

Project construction, operations, and closure would not affect small-scale mining and exploration activities that may currently occur in the project vicinity. Residential and commercial uses in surrounding communities would not be directly affected by the project, but could expand based on employment and support service opportunities.

Mine Site. Land use at the mine site would change from minimal disturbance from exploration activities to intense industrial development. This would constitute an acute and obvious change over the life of the project. The area affected would represent only a small portion of the total land area owned and managed by the State in the Bristol Bay watershed. Subsistence activity and recreation would be excluded from the vicinity of the mine site during construction and operations. Land use would change again at closure of the mine, as the site would be restored per permit requirements and no longer used for mining. Impacts on those uses are described in Section 4.9, Subsistence, and Section 4.5, Recreation.

Transportation Corridor. Construction of the mine access roads would introduce artificial features to a previously undeveloped location, and therefore, would change the land use; associating it with heavy use of industrial trucks along the transportation corridor. The access roads would be restricted to mine-related traffic and some use by local residents and businesses, and would not facilitate land use associated with non-resident recreation and tourism activities. The ferry operating daily on Lake Iliamna would represent an addition to the watercraft currently used in open water. However, the ferry would present a new use of the lake during the winter, with the potential to interfere with other uses of the ice for local transportation and subsistence activities. Winter impacts would not occur under the summer-only ferry operations variant. The transportation corridor would remain in place upon project closure to support monitoring activities, although the intensity of use from the project would decrease substantially. Depending on any agreements between the State and LPB, some level of local use of the corridor may continue. These remaining features would constitute a permanent shift from an undisturbed landscape with low levels of intermittent use to transportation infrastructure supporting an industrial use.

Natural Gas Pipeline Corridor. The natural gas pipeline would be located in the transportation corridor from Amakdedori port to the mine site, and would not result in any foreseen additional land use changes. At the compressor station on the Kenai Peninsula, where the pipeline would connect to existing infrastructure, the land currently has some industrial development. There would be additional development from construction of the compressor station, but overall land use in that area would not change.

Amakdedori Port Site. Construction at the port site would introduce an industrial port facility to a previously undeveloped location, and therefore, would change the land use with industrial ship traffic, truck traffic and storage activities. Any use of the physical footprint of the port site would be displaced (including cultural education at the site), and adjacent use activities could be affected; however, access to the port site is limited and existing use activities are intermittent. Amakdedori port would remain in place until project closure when the port would no longer be needed to support reclamation and monitoring activities.

AMERICAN OVERSIGHT

4.2.3 Action Alternative 2 – North Road and Ferry

4.2.3.1 Land Ownership

For a description of land ownership under Alternative 2, see Section 3.2, Land Ownership, Management, and Use. No land in the project footprint would be conveyed or sold, although temporary use permits, easements, and ROWs for the transportation corridor and natural gas pipeline would be issued to construct and operate the project if approved. This would result in a change in land status and an encumbrance on use along the route of the mine access roads and pipeline, a direct impact. Impacts would generally be the same as described in Alternative 1, but affect different areas and communities along the transportation corridor and port site. Depending on the location of the port site, a new or amended tidelands lease may be required from the State of Alaska.

4.2.3.2 Land Management

Federal land management under Alternative 2 would be similar to Alternative 1; project construction, operations, or closure would not result in any direct effects on the management, ownership, or use of federal lands. The Alternative 2 transportation corridor is closer to Lake Clark NPP, where project transportation activities may be more noticeable to park users, and farther from both the Katmai NPP and the McNeil River State Game Refuge and Sanctuary. Project-related activities could indirectly and cumulatively affect the environment, resources, and visitor experience of the federal management units listed for Alternative 1.

State management at the mine site, transportation corridor, and on the Kenai Peninsula would be the same as Alternative 1, but would affect different areas and be primarily located on ANCSA corporation lands. There would be no port facilities on state-owned lands.

Land use of surface and subsurface lands privately owned by Alaska Native corporations are subject to the approval of the landowners. Any activity would be conducted in accordance with lease and surface use agreements that PLP would establish with the landowners. Project construction, operations and maintenance, or closure would not result in adverse direct or indirect effects on management of these lands.

The entirety of the Diamond Point port would be located on Native Allotments. The lands are held in trust by the federal government and generally require Bureau of Indian Affairs oversight for sales, gift deeds, leases permits, partitions, ROWs, and sand and gravel leases.

As with Alternative 1, the mine site, the majority of the transportation corridor, and a portion of the natural gas pipeline corridor would lie in the boundaries of the LPB. The Diamond Point port and a portion of the proposed transportation corridor and the natural gas pipeline on the western side of Cook Inlet would lie in the KPB. Impacts for borough management in these locations would be similar to borough management for Alternative 1.

Under Alternative 2, no physical project-related infrastructure would be developed on lands that are in local jurisdiction. Impacts would be the similar to those in Alternative 1.

Legal Access

The project area encompasses several section line easements, and impacts would be similar to Alternative 1.

There is one R.S. 2477 ROW that runs from the community of Pile Bay to the community of Iliamna (RST 396). Alternative 2 project components would bisect the ROW at several locations (see Section 3.2, Land Ownership, Management, and Use). Where a R.S. 2477 ROW is

AMERICAN OVERSIGHT

impacted from construction or operations of the project, alternate access or marked crossings would be provided as appropriate. Land ownership changes may not be measurable or apparent due to very low existing levels of use of the easement. Most local residents travel on Iliamna Lake via boat or snowmachine and not on this ROW.

The natural gas pipeline would intersect one Section 17(b) easement, on the northern shore of Iliamna Lake (EIN 30a C5 D1); the transportation corridor and natural gas pipeline would intersect one Section 17(b) easement, also on the northern shore of Iliamna Lake (EIN 15f C5). The project would not prevent access to the easements, and crossing points would be sign-posted, with appropriate traffic controls established to ensure public safety (PLP 2018-RFI 027).

Alternative 2 would intersect the same pubic access easements in Iliamna Lake as Alternative 1, although the number and locations of the crossings would be different. Impacts would be similar to Alternative 1. The natural gas pipeline under Alternative 2 would intersect two additional public access easements (one would also be intersected by the transportation corridor). The project would not prevent access to the easements, and crossing points would be sign-posted, with appropriate traffic controls established to ensure public safety (PLP 2018-RFI 027).

4.2.3.3 Land Use

Impact to land use at the mine site and the Kenai Peninsula pipeline compressor station would be the same as discussed under Alternative 1.

Impacts to land use from the transportation corridor would be similar to Alternative 1 for the mine access road from the Eagle Bay ferry terminal to the mine site, and for the ferry use across Iliamna Lake. The transportation corridor under Alternative 2 includes construction of a mine access road in the vicinity of and in places overlapping the current Williamsport-Pile Bay road, which is used for the summer season portage of fishing boats from Cook Inlet to the Bristol Bay fishery. Existing traffic would use the new road which would experience regular and heavy industrial use. The change would be high intensity and last through the life of the mine. After closure, the road would likely revert to the current level of use, although it may increase slightly, as an improved route could entice additional boat owners to use it.

At the Diamond Point port site, the area would change from active resource extraction to an industrial port. There would also be changes associated with industrial ship traffic in Iliamna Bay. The impacts would last through the duration of the project.

The natural gas pipeline from Pile Bay to the mine access road from Eagle Bay ferry terminal would introduce a land use change from a mostly undisturbed area to a utility corridor. Impacts would be low intensity and last until the pipeline was decommissioned, which could extend beyond the life of the project.

4.2.4 Action Alternative 3 – North Road Only

4.2.4.1 Land Ownership

For a description of land ownership under Alternative 3, see Section 3.2, Land Ownership, Management, and Use. No land in the project footprint would be conveyed or sold, although temporary use permits, easements, and ROWs for the transportation corridor and natural gas pipeline would be issued to construct and operate the project, if approved. This would result in a change in land status and an encumbrance on use along the route of the mine access roads and pipeline, a direct impact. Impacts would be the same as described in Alternative 1, but

AMERICAN OVERSIGHT

affect different areas and ANCSA corporation landowners; the length of the access road easement would be in the same area but longer than Alternative 2.

4.2.4.2 Land Management

Land management under Alternative 3 would be the similar to Alternative 2 for federal, State, borough, and local management. The transportation corridor would transect the same ANCSA native corporation lands as the transportation corridor and natural gas pipeline under Alternative 2, and the impacts to land management would be similar to those of the transportation corridor under Alternatives 1 and 2.

Legal Access

The project area encompasses several section line easements, and impacts would be similar to Alternative 1.

Alternative 3 transportation corridor and natural gas pipeline would bisect the same R.S. 2477 ROW (RST 396), Section 17(b) easements (EIN 30a C5 D1 and EIN 15f C5), and public access easements as in Alternative 2, and the impacts would be similar.

4.2.4.3 Land Use

Impact to land use at the mine site and the Kenai Peninsula pipeline compressor station would be the same as discussed under Alternative 1.

The impact to the transportation corridor along the Williamsport-Pile Bay road would be similar to Alternative 2. From Pile Bay to the mine site, impacts to the transportation corridor would be similar to Alternative 1 along the mine access roads. There would be no impacts to summer or winter transportation and subsistence use of Iliamna Lake, compared to Alternatives 1 and 2.

As with Alternative 2, the area at the Diamond Point port site would change from active resource extraction to an industrial port. There would also be changes associated with industrial ship traffic in Iliamna Bay.

4.2.5 Summary of Key Issues

See Table 4.2-1 for a summary of key issues.

Table 4.2-1: Summary of Key Issues for Land Ownership, Management, and Use

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Land management and ownership	The mine site would be entirely on lands by the State of Alaska and managed for multiple use, including habitat protection and mineral development.		
Land use	Land use at the mine site would change from minimal disturbance from exploration activities to intense industrial development.		
Transportation Corridor			
Land ownership	67% would be owned and managed by the State of Alaska. 33% would be owned and managed by ANCSA village corporations.	39% State of Alaska. 1% ANCSA regional corporations. 59% ANCSA village corporations.	35% State of Alaska. 3% ANCSA regional corporations. 62% ANCSA village corporations.

AMERICAN OVERSIGHT

Table 4.2-1: Summary of Key Issues for Land Ownership, Management, and Use

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
	Kokhanok east ferry terminal variant: 73% State of Alaska. 27% ANCSA village corporations.	*Summer-only ferry variant:* 100% ANCSA village corporations.	
Land management	The state would manage lands for multiple use that would not preclude a mine access road. Uses on surface and subsurface lands privately owned by Alaska Native corporations are subject to the approval of the landowners. There would be no direct effects to federal lands, but indirect impacts from the project may result in additional management considerations.		
Legal Access	R.S.2477 ROWs: 0 17(b) easements: 1 Public access easements: 1	R.S.2477 ROWs: 1 17(b) easements: 2 Public access easements: 3	R.S.2477 ROWs: 1 17(b) easements: 2 Public access easements: 3
Land use	The mine access roads would introduce a transportation system with industrial traffic to a previously undeveloped location, and would change the land use associated with industrial truck traffic. The ferry would represent increased summer traffic and an additional use to the lake during winter, with the potential to interfere with other uses that utilize the ice for local transportation and subsistence activities.	Similar to Alternative 1 except the Williamsport-Pile Bay road, which would change from intermittent, seasonal use, to heavy industrial use.	Similar to Alternative 1 for the mine access road from Pile Bay to the mine site, and similar to Alternative 2 from Diamond Point to Pile Bay.
Port Site			
Land ownership	Amakdedori port would be on lands owned by the State and managed with guidelines for waterfront development.	The Diamond Point port would be located entirely on lands privately owned on a Native Allotment.	
		Pile-Supported Dock Variant: 82% ANCSA regional corporations. 18% ANCSA village corporations.	
Land management		Uses on surface and subsurface lands privately owned by Alaska Native corporations are subject to the approval of the landowners.	

AMERICAN OVERSIGHT

Table 4.2-1: Summary of Key Issues for Land Ownership, Management, and Use

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Land use	Amakdedori port would introduce artificial features to a previously undeveloped location, changing the land use to industrial ship traffic and storage activities.	At the Diamond Point port site, the area would change from active resource extraction to an industrial port. There would also be changes associated with industrial ship traffic in Iliamna Bay.	
Natural Gas Pipeline			
Land ownership	67% State of Alaska. 33% ANCSA village corporations.	28% State of Alaska. 6% ANCSA regional corporations. 66% ANCSA village corporations.	27% State of Alaska. 6% ANCSA regional corporations. 67% ANCSA village corporations.
	Kokhanok east ferry terminal variant: 21% State of Alaska. 79% ANCSA village corporations.		*Concentrate pipeline variant:* 59% State of Alaska. 41% ANCSA village corporations.
Land management	The pipeline would cross subsurface lands owned by Cook Inlet Region, Inc. and Bristol Bay Native Corporation. Uses on surface and subsurface lands privately owned by Alaska Native corporations are subject to the approval of the landowners.		
Land use	The pipeline compressor station would add to the existing industrial development.	Same as Alternative 1 except the ROW from Pile Bay to the mine access road would introduce a land use change from a mostly undisturbed area to a utility corridor.	Impacts from the mine access roads and pipeline compressor station would be similar to Alternative 1. The impacts to the Williamsport-Pile Bay road and Diamond Point port would be similar to Alternative 2.

Note: See Section 3.2, Land Ownership, Management, and Use, for complete land ownership.

4.2.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to impacts in similar ways to land ownership, management, legal access, and use during construction, operation, and closure. All of the RFFAs identified in Section 4.1 have the potential to impact land ownership, management, or use in the analysis area.

All the RFFAs would impact land ownership and management in the ways described above, with the potential for some land conveyance and other changes in land ownership, such as encumbrance for an easement or a ROW; with those impacts would be changes to management actions.

Future actions for development of mineral deposits and oil and gas exploration and development, along with any related infrastructure, could contribute to a slow land use change in the region, from more undeveloped, pristine landscapes to more industrial use and resource extraction.

AMERICAN OVERSIGHT

The RFFA that would have the greatest cumulative impact to the immediate area would be the Pebble Project buildout, which would continue the impacts from this project for an extended amount of time, over a larger geographic area, adding intensity to activities (more traffic) and potentially more infrastructure to the Iliamna Lake area.

Expansion would affect land management, ownership and use in ways similar to the combined effects of Alternative 1 and 3, but over an operating life of 78 years then a period of closure. Effects of expansion would be similar to Alternative 3 with the concentrate pipeline variant, minus the concentrate truck traffic, and additive to the effects of Alterative 1. State permits and leases with the mine site would need to be amended and additional ROWs granted. Additional tidelands leases might also be required. The proximity of expanded facilities to federal lands management units would be similar to a combined Alternatives 1 and 3, because the expanded Pebble project would need to develop the Alternative 3 corridor for the concentrate export pipeline and would need a port at Diamond Point and/or Iniskin Bay. Some actions may be necessary to address indirect project impacts, although concentrate truck traffic would cease with the operations of the concentrate pipeline, reducing potential traffic and noise impacts on the Alternative 1 transportation corridor and not introducing those impacts along the Alternative 3 transportation corridor. The primary impacts would be the expanded industrial use at the mine site and the introduction of industrial activities in two undeveloped areas over two transportation corridors instead of one over an extended timeframe. The impacts would be partially offset with the construction of the concentrate pipeline, in that concentrate truck traffic would be eliminated. The contribution of the proposed action to cumulative impacts would be the extended duration of mining activities over an area and acreage double the size of the proposed action.

Transportation, infrastructure, energy, and utility RFFAs could contribute to a slow transition of land use to more developed movement through the area for people and utilities.

RFFAs that include current land uses (e.g., commercial fishing, subsistence, tourism, recreation, hunting and fishing, and scientific surveys and research), would continue along baseline trends as long as the resources are available to engage in those activities. These uses would be impacted cumulatively by the development RFFAs discussed above.

AMERICAN OVERSIGHT

4.6 COMMERCIAL AND RECREATIONAL FISHERIES

This section addresses the direct and indirect effects of the No Action Alternative and action alternatives on commercial and recreational fishing. As noted in Section 3.6, Commercial and Recreational Fisheries, the Alaska Department of Fish and Game (ADF&G) Commercial Salmon Fishery Area T and Area H and ADF&G Statewide Harvest Survey (SWHS) areas S, T, N and P comprise the study area for this resource. Potential impacts include:

- Long-term changes in salmon populations that reduce the number of returning adult spawners available for harvest by commercial permit holders and thus reduce:
  - wholesale fisheries value, payments to permit holders and crew, and expenditures into local economies;
  - delivery of fish to processors, revenue generated by processed fish, and employment of and payments to processing labor; and
  - generation of tax revenue to state and local governments through sales tax, real property tax, and raw fish tax.
- Reduction in consumer willingness to buy Bristol Bay salmon due to a perceived loss of quality resulting in a lower price paid to commercial fishermen.
- A reduction or displacement of recreational fishing effort associated with affected waterbodies, along with a reduction in government revenue generated by the professional guide tax.
- An increase in recreational fishing effort associated with long-term project driven population changes and/or changes in the regional transportation network.

Commercial Fisheries. The proposed project has the potential to affect the commercial fisheries sector and related fiscal contributions through two primary mechanisms: a decline in the productivity of Bristol Bay river systems, which would be reflected through a decline in total fishery harvest; and a change in market reception of Bristol Bay fish. The total value of the fishery in economic terms starts with volume (i.e., productivity) and price (i.e., what the market will pay for the fish). While the permit holders and processors are the two most frequently discussed groups associated with the fishery, the economic connections of the fishery extend to crew members, shipping companies, local businesses, utilities, and governments.

The loss of any harvestable fish from a project-induced decline in productivity would result in a lower total fishery value. Every harvested salmon has a quantifiable value to permit holders, processors, and state and local governments. This value varies from year-to-year with average ex-vessel price and average wholesale value, but it is demonstrable that every salmon lost to harvest has an economic value. This section uses estimates of lost productivity as noted in Section 4.24, Fish Values, to estimate lost ex-vessel payments, lost wholesale value, and lost fishery-related government revenues.

It is easier to connect lost productivity in the fishery to lost ex-vessel and first wholesale values than it is to connect the effect of a change in consumer willingness to pay to these same measures. As noted in Section 3.6, Commercial and Recreational Fisheries, Bristol Bay salmon is a "price-taker;" it does not have cohesive brand identification as the Copper River fishery has to help drive prices higher. Therefore, Bristol Bay prices reflect the broader market for salmon products and the market for wild Alaska salmon products. In addition, prices paid in Bristol Bay are nearly always lower than those paid in other Alaska salmon fisheries producing similar products, which reflects the higher transportation expense associated with Bristol Bay's geographic location.

AMERICAN OVERSIGHT

Recreational Fisheries. With recreational fisheries, the potential effects of the proposed project are:

- Direct loss of angling days on portions of the North and South Fork of the Koktuli River and Upper Talarik Creek, which are located in the project area.
- A reduction in angling days downstream of the project area if the project reduces fish populations in downstream waters.
- Reduction in angling days caused by the quality of opportunities on waterbodies affected by the selected transportation routes.
- An increase in angling days caused by an increase in the number of opportunities through expansion of the local road network or an increase in regional population.

The Bristol Bay watershed is renowned for the diversity of its recreational angling opportunities. Therefore, fishing effort (angling days) and the ability of anglers and guides to redirect operations to substitute sites would play a key role in determining the magnitude and duration of recreational fishing impacts.

4.6.1 No Action Alternative

Under the No Action Alternative, the Pebble Project would not be developed. No construction, operation, or closure activities would occur at the mine site, Amakdedori port, transportation corridor or the natural gas pipeline corridor. Therefore, no future direct or indirect effects on commercial or recreational fisheries would be expected. Under the No Action Alternative, the Pebble Limited Partnership (PLP) would have the same options for exploration activities that currently exist (ADNR-RFI 073). Therefore, it is anticipated that PLP would continue some level of activity in an effort to identify future opportunities.

4.6.1.1 Commercial Fishing

The total value of the Bristol Bay salmon fishery depends on two primary factors: the volume of salmon harvested, and the value per pound of that salmon. Direct and indirect effects to commercial fishing from the proposed project require a connection between any alternative and either or both of those factors.

Permit Holders and Crew Members

Under the No Action Alternative, there would be no project-associated change in the number of returning fish available for harvest, the long-term productivity from the Nushagak and Kvichak river systems, and no change in the reputational value, which could affect price. The ex-vessel value of the fishery earned by permit holders and wages paid to crew members would continue to be affected by the broader drivers of the value of the Bristol Bay salmon fishery including world protein markets, world salmon markets, the overall productivity of the fisheries, and the decisions of processors about what products to produce.

The Processing Sector

Without an effect on the value or volume of salmon produced by the ecosystem, the No Action Alternative would not have any effect on the processing sector.

Fiscal Contributions

The No Action Alternative would not negatively affect fiscal contributions to state and local governments. It is possible that the long-term attractiveness of the fishery could increase if

AMERICAN OVERSIGHT

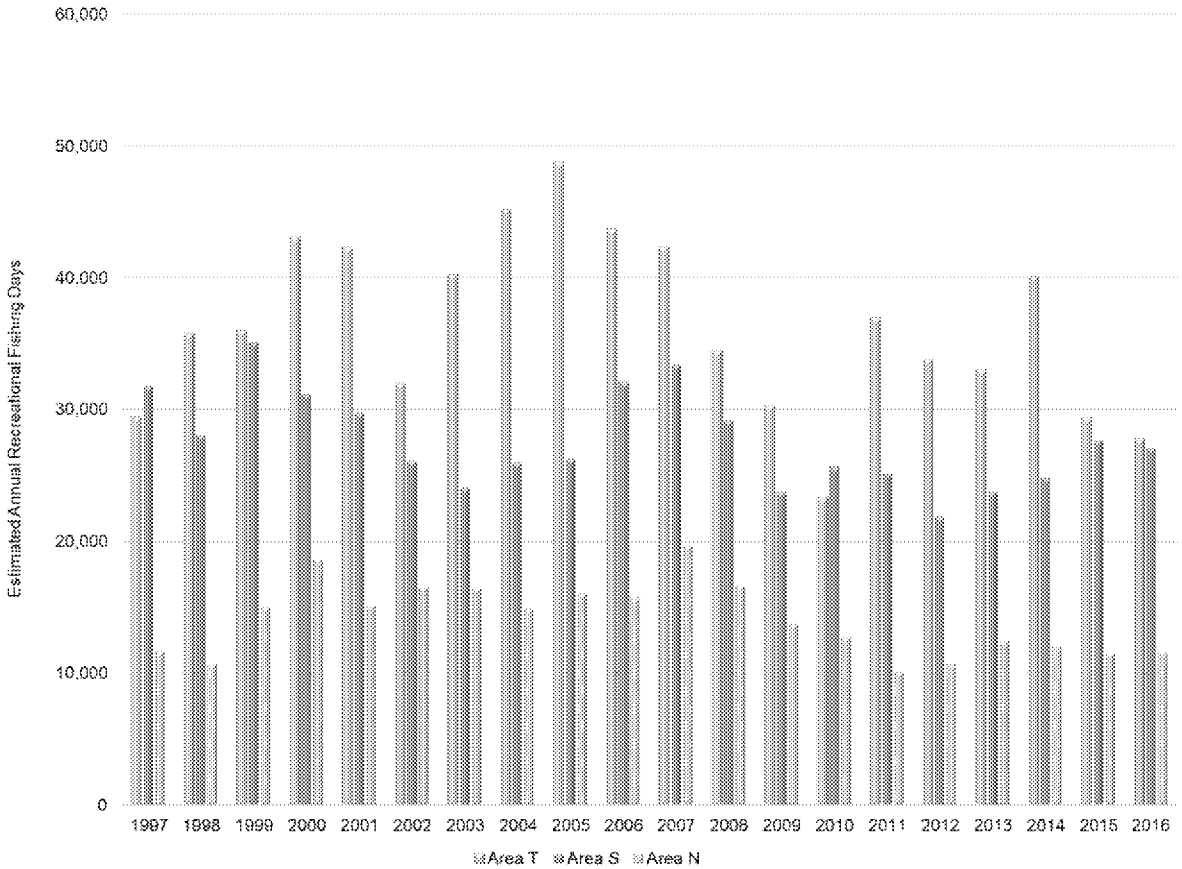
permit holders and processors had been withholding investment in recent years with the expectation that the proposed project would be built and would materially affect the fishery. There is no evidence that permit holders or processors have been withholding investment in the fishery. In 2014, Silver Bay Seafoods opened the fishery's first new major plant in several years. The company expanded the plant in 2015 and has the capability to expand more if the flexibility is needed (SBS 2018). Over the last decade, permit holders have installed refrigerated seawater systems to properly chill their salmon immediately after harvest and obtain the chilling bonuses offered by processors. The amount of slush ice in Bristol Bay, usually provided by processors, has not increased in recent years. Without growth in slush ice availability, new chilling capacity is coming from refrigerated seawater installations (NEI 2018).

4.6.1.2 Recreational and Tourism-Based Fishing

Recreational fishing is driven by two populations: resident anglers and non-watershed resident anglers, including other Alaskans. The Bristol Bay region is renowned for its productive rainbow trout, king salmon, and sockeye salmon fisheries, as well as its ability to provide an uncrowded fishing experience in a remote and "pristine" environment. Fishery effort varies with fishing conditions, the availability of tour providers/guides, and the state and world economy. Recreational fishing in areas N, S, and T declined from 2000 to 2002 and from 2007 to 2009 as the US economy experienced economic recessions (Figure 4.6-1). Recreational fishing in Area T also declined from 2014 to 2016. Effort in individual fisheries varies with the quality of the runs, and weak Chinook returns can affect participation in Chinook fisheries. For example, weak runs over the last decade have reduced the number of guided angler days on the Kenai River between Cook Inlet and the Soldotna Bridge from 34,000 angler days in 2008, to just under 22,000 days in 2016. In 2010, the Nushagak River closed to Chinooks; angler days in between the ADF&G sonar site and the mouth of the Mulchatna River declined from 8,100 days in 2009 to 3,600 days (ADF&G 2018d). Under the No Action Alternative, recreational fishing would continue under current conditions and trends.

4.6.2 Action Alternative 1 – Applicant's Proposed Alternative

Project construction and operations could have an impact on both the commercial fishing community from crew members to the processing sector, on the recreational sector via recreational fishing, and on revenue generated to state and local government. Potential impacts are influenced by project-related effects on fish population, habitat, and runs (see Section 4.24, Fish Values), as well as on real and perceived effects on the quality of the fish, environment, and fishing experience.



4.6.2.1 Commercial Fishing

As noted in Section 3.6, Commercial and Recreational Fisheries, the ADF&G manages for the long-term health of the fishery by ensuring that a minimum, but preferably optimal, number of spawners reach their home rivers. ADF&G has no control over external factors such as ocean conditions, so it largely manages the number of returning spawners by adjusting commercial and recreational fishing harvest via effort. The ADF&G restricts effort when the strength of the returning run requires less harvest to meet the optimal escapement goals (OEGs), and liberalizes harvest opportunity when run strength threatens to exceed OEGs. Beyond the scheduling of fishing openings and closures, the ADF&G also has the ability to define the geographic extent of fishery openings. For example, the points at which the Naknek and Kvichak rivers empty into Bristol Bay are just miles apart. In years when the Kvichak sockeye run has been weak, the ADF&G has restricted the fishing fleet to the mouth of the Naknek River to limit the harvest of Kvichak-bound fish. Under more normal conditions, this district is

AMERICAN OVERSIGHT

managed with less specificity. Under Pebble Project construction and operation, if the ADF&G does not adjust the OEGs to account for any lost carrying capacity associated with the project, then the reduction in returning spawners would directly translate into lost harvest opportunities for permit holders. If the ADF&G adjusts the OEGs for lost carrying capacity, then a portion of lost harvest opportunities would be captured with the adjusted OEGs, and the remaining portion would transmit to commercial permit holders as lost harvest opportunities.

Figure 4.6-1. Recreational Fishing Effort, 1997-2016

Source: ADF&G 2018d.

Crew members, permit holders, processors, and local municipalities are all dependent on the total value of the Bristol Bay fishery, which is a function of market price and harvested volume. When permit holders harvest fewer fish, the net result is that permit holders receive less net income, crew members are paid less, processors have less product to sell, and municipalities have less economic activity to tax.

This section relies on Section 4.24, Fish Values, which estimates that Alternative 1 would not reduce returning adult salmon to the Kvichak and Nushagak river systems as a result of project operations.

As noted above, the commercial fishing sector is concerned that the existence of the project could lower the perceived quality of Bristol Bay salmon and thus lower price. Prices paid in Bristol Bay are nearly always lower than those paid in other Alaska salmon fisheries producing similar products, which reflects the higher transportation expense associated with Bristol Bay's geographic location. Other salmon fisheries in Alaska exist in conjunction with non-renewable resources. For example, the Cook Inlet salmon fisheries exist in an active oil and gas basin and have developed headwaters of Anchorage and the Matanuska-Susitna areas. The Copper River

AMERICAN OVERSIGHT

salmon fishery exists in the remains of the historic Kennecott Copper Mine and the Trans Alaska Pipeline System in the headwaters of portions of the fishery. Both of these fisheries average higher prices per pound than the Bristol Bay Salmon Fishery (See Section 3.6, Commercial and Recreational Fisheries).

The Amakdedori port site would not be located near substantial commercial fishery resources. Commercial fishermen would need to be aware of increased vessel traffic in the area, but it should not affect fishing effort.

The natural gas pipeline would follow the transportation corridor and would not directly interact with the Bristol Bay salmon fishery. The pipeline would cross waters fished by the Cook Inlet salmon fishery and Cook Inlet groundfish fisheries. It would not directly interact with the salmon fishery given that the salmon fishery occurs in the top 30 feet of the water column. Groundfish commercial fishermen may need to adjust their gear placement to avoid the natural gas pipeline, but they would have flexibility to do so.

Permit Holders and Crew Members

Based on estimations of the effect to fish populations discussed in Section 4.24, Fish Values, this alternative would not result in a measureable change in permit holder revenues, crew member payments, or permits based on a change in the return of adult spawners.

The Processing Sector

Any reduction in harvest by permit holders is immediately transmitted to the processing sector as fewer fish to be processed and sold into the world sockeye market. The lost harvest results in lower total wholesale value for processors. The magnitude of the financial loss depends on the size of the harvest reduction and individual choices by processor around how to adjust their product mix. Processors make these decisions based on run size, their individual capabilities, and the needs of the world market, which means that any long-term loss in harvest would express itself differently each year based on the aforementioned factors. Based on estimates from Section 4.24, Fish Values, and the historical relationship between ex-vessel values and wholesale values, there would be no measurable change to wholesale values or processor operations expected for this alternative.

Fishery Fiscal Contributions

As noted above, the fiscal contributions of the Bristol Bay salmon fishery to state and local government depend on the long-term health of the fishery. Lost harvest value would be directly expressed through reduced Fisheries Business Tax and Raw Fish Landings Taxes. Significant reductions in long-term value of the fishery would affect property taxes, sales taxes, and use taxes. Potential effects of reductions in state and local revenue are discussed in Section 4.3, Needs and Welfare of the People—Socioeconomics. However, based on the results of Section 4.24, Fish Values, no long-term measureable change in the fishery would be expected; therefore, there would be no long-term changes expected in fishery fiscal contribution attributable to this alternative.

4.6.2.2 Recreational and Tourism-Based Fishing

Recreational fishing effort in areas S, T, N, and P is based on several different types of fisheries with different goals, attributes, and experiences. For example, a Chinook salmon angler on the Nushagak River is likely to be fishing from a boat and focused on the harvest of Chinook salmon for consumption. An angler fishing the Gibraltar River is fishing a much smaller waterbody with more shore fishing and is more likely to be targeting rainbow trout for a non-consumptive

AMERICAN OVERSIGHT

purpose. The effects of Alternative 1 on the overall recreation fishery would depend on the factors noted above and the availability of alternative opportunities. There are few worldwide alternatives to the Nushagak River, as its Chinook fishery is the largest Chinook fishery in Alaska. The Gibraltar River offers a remote fishing experience for rainbow trout, but is one of several streams offering this type of experience in the Bristol Bay region. Rainbow trout are common and angling opportunities in remote conditions are widespread throughout the region. The loss of fishing opportunities in these areas would be more likely to be experienced by select guide and lodge operators than by a substantial portion of all anglers in the Bristol Bay region. These same operators could substitute fishing on different streams, albeit at potentially higher costs to themselves and their consumers, or anglers could redirect their fishing to other sites in the Bristol Bay region or in Alaska. Anglers themselves would likely be able to find similar opportunities on other streams in the region if the effect of Alternative 1 is limited to subset of regional fishing opportunities. Impacts would extend through construction and operations, and would be very likely.

Mine facilities under Alternative 1 would directly impact portions of the tributaries of the North and South Fork Koktuli River watersheds, while support and transportation infrastructure would affect the Upper Talarik Creek Watershed, the Gibraltar River, and Iliamna Lake. As noted in Section 3.6, Commercial and Recreational Fisheries, these watersheds account for a small portion of overall recreational fishing effort in SWHS areas S, T, and N. The ADF&G SWHS estimates and Guide Logbook Program data indicate that total fishing effort on the Koktuli River and Upper Talarik Creek is less than 100 angling days per year each, while total effort in SWHS areas S and T is estimated at over 40,000 days per year. The two most important fisheries that would interact with Alternative 1 are Iliamna Lake and the Gibraltar River. Iliamna Lake and unnamed tributaries host roughly 1,900 to 2,200 angling days per year. This effort is dispersed across the lake and numerous unidentified tributaries without enough SWHS survey responses to allow for individual effort estimates. Under normal operations, the ferry across the lake would not be expected to limit or affect the quality of these fishing days. The Gibraltar River (approximately 650 angling days per year) primarily hosts fly-in wade and float anglers. The river is currently roadless and the transportation corridor would create a new road and crossing along the river. While Section 4.24, Fish Values, does not estimate measurable changes in fish populations along the river, the presence of the road and bridge crossing would change the fishing experience on the river, particularly for float anglers who would have to pass the bridge to float the length of the river. Construction activities would be disruptive, and the road and bridge would be in place through project operations and post-closure until they are no longer needed. These impacts would not exist under the east Kokhanok ferry terminal variant, which avoids crossing the Gibraltar River.

The waterbodies affected by Alternative 1 have fewer total recreational angling days than the waterbodies affected by Alternatives 2 or 3. However, the main angling waterbodies affected by Alternatives 2 and 3 (the Newhalen, Pile, and Iliamna rivers), already have some minimal road access from local communities. Alternative 1 differs from Alternatives 2 and 3 in its establishment of new road affecting a waterbody without current road access and more than 500 recreational fishing days per year; Alternatives 2 and 3 would not affect a river with these qualities. Impacts would be fairly likely to occur and would last through closure until the road is no longer used.

The Amakdedori port site is not located near recreational fisheries resources so there would be no direct or indirect impacts expected.

AMERICAN OVERSIGHT

4.6.3 Action Alternative 2 – North Road and Ferry

Under Alternative 2, commercial fishing effects would not be expected to be any different than under Alternative 1; mine operations would be the same and the different transportation corridors would not be expected to affect long-term fish populations. Alternative 2 would affect different recreational fishery resources. This alternative would avoid the currently roadless Gibraltar River area and though the mine access road and/or the pipeline right-of-way (ROW) would cross a number of waterbodies with measurable fishing pressure, including the Newhalen River and the Iliamna River.

4.6.3.1 Commercial Fishing

As with Alternative 1, Alternative 2 would not be expected to measurably affect the health or value of Bristol Bay salmon fishery including permit holder earnings, permit holder value, crew earnings, fishery first wholesale values, processor earnings, or local fiscal contributions. The Diamond Point port site is not located near substantial commercial fishery resources. Commercial fishermen would need to be aware of increased vessel traffic in the area.

4.6.3.2 Recreational and Tourism-Based Fishing

The Newhalen River drainage (approximately 1,900 angler days per year) and the Iliamna River (approximately 1,000 angler days per year) are the most frequently fished waterbodies along the Alternative 2 transportation corridor route. Transport activity may dislocate fishing effort where the corridor transects these waterbodies, but would not be expected to run along them for significant lengths. Fishing effort should not be negatively affected, as long as fish populations are unaffected, but may redistribute along the waterbodies. Iliamna Lake and unnamed tributaries host 1,900 to 2,200 angler days per year of recreational fishing effort, which is distributed across the entirety of the lake and where tributaries flow into it. Although detailed data about the geographic distribution of this effort are not available, a single transport route across the lake should not affect the number of fishing days under normal operations.

Alternative 2 would affect waterbodies with more measurable fishing effort than Alternative 1, but it would not establish new roads near waterbodies such as the Gibraltar River, which are known for the remote characteristics and have measurable fishing effort. Alternative 2 crosses fewer waterbodies along the lake's northern boundary than Alternative 3 by virtue of the ferry from Eagle Bay to Pile Bay and then the road corridor to Diamond Point port. However, the pipeline ROW would cross the same streams as discussed below for Alternative 3. Access along the ROW may increase slightly for recreational fishing, but the increase would be low intensity. The impacts would last through the duration of operations.

4.6.4 Action Alternative 3 Road Only

Under Alternative 3, commercial fishing effects would not be expected to be different than under Alternative 1, as mine operations would be the same and the transportation corridor would not be expected to affect long-term fish populations. Alternative 3 would affect different recreational fishery resources and lesser used recreational fishery resources than Alternative 2. This alternative would avoid the currently roadless Gibraltar River and would cross a number of waterbodies with measurable fishing pressure including the Newhalen River, the Pile River, and the Iliamna River.

4.6.4.1 Commercial Fishing

As with Alternatives 1 and 2, Alternative 3 would not be expected to measurably affect the health or value of Bristol Bay salmon fishery including permit holder earnings, permit holder

AMERICAN OVERSIGHT

value, crew earnings, fishery first wholesale values, processor earnings, or local fiscal contributions. The Diamond Point port site is not located near substantial commercial fishery resources. Commercial fishermen would need to be aware of increased vessel traffic in the area.

4.6.4.2 Recreational and Tourism-Based Fishing

As with Alternative 2, Alternative 3 and the transportation corridor would continue on land across Chekok, Canyon, and Knutson creeks, on to Pile Bay, across the Pile River, and then cross the Iliamna River, leading to Diamond Point port.

As noted above, the Newhalen River drainage (approximately 1,900 angler days per year) and the Iliamna River (approximately 1,000 angler days per year) are the most frequently fished waterbodies along this route. Transport activity may displace fishing effort where the corridor intersects with these waterbodies, but the corridor overlap would be short in length. Truck traffic would adversely affect the recreation experience that occurs in the vicinity of the road. Fishing effort should not be negatively affected, but may redistribute along the waterbodies as long as fish populations are unaffected. ADF&G data indicate that Chekok Creek receives some fishing pressure (less than 50 days per year), while the other waterbodies along the Alternative 3 transportation corridor do not appear in published ADF&G data.

Alternative 3 would affect waterbodies with more measurable fishing effort than Alternative 1 and Alternative 3, but like Alternative 2 it would not establish new roads near waterbodies.

4.6.5 Summary of Key Issues

The alternatives would not be expected to result in a long-term change in the health of the commercial fisheries in Bristol Bay or Cook Inlet (see Table 4.6-1). Recreational fishing effort would be displaced along the Koktuli River and Lower Talarik Creek, but ADF&G data indicate that effort along these rivers is very modest at around 110 angling days per year. Alternative 1 would result in a new road alongside, and across the Gibraltar River, which receives six times the annual recreational fishing effort of the Koktuli River and Lower Talarik Creek combined. Alternatives 2 and 3 would intersect with the Newhalen and Iliamna rivers. Both of these rivers are already connected by road to local communities and together host approximately 2,900 angling days per year (see Table 4.6-1). The road corridor intersections may result in the redistribution of some angling days along the river.

Table 4.6-1: Summary of Key Issues for Commercial and Recreational Fisheries

Impact-Causing Project Component	Action Alternative 1 – Applicant's Proposed Alternative	Action Alternative 2 – North Road and Ferry	Action Alternative 3 – North Road Only
Mine Site			
Effects to commercial fisheries	Impacts from the mine site would be the same across all alternatives. The mine site would result in loss of fish habitat in the North and South Fork Koktuli rivers and, to a small extent, the Upper Talarik Creek. As noted in Section 4.24, Fish Values, this disturbance would not be expected to result in changes to salmon populations and the long-term average number of returning adult spawners to the Nushagak and Kvichak district. The mine site area is not connected to the Togiak, Ugashik, Naknek, and Egegik watersheds and is not expected to affect fish populations or harvests from these watersheds.		
Effects to recreational fisheries	All three action alternatives would affect the North and South Fork Koktuli rivers and Upper Talarik Creek. The Koktuli River does not appear in some ADF&G SWHS publications because not enough survey respondents report fishing on the river. The		

AMERICAN OVERSIGHT

Table 4.6-1: Summary of Key Issues for Commercial and Recreational Fisheries

Impact-Causing Project Component	Action Alternative 1 – Applicant's Proposed Alternative	Action Alternative 2 – North Road and Ferry	Action Alternative 3 – North Road Only
	river also does not appear in ADF&G Guided Logbook data for 2011-2014. The unpublished ADF&G SWHS estimates for the Koktuli River for 2007-2016 average 63 angler days per year. These days would be displaced if they occurred in the project area and could be displaced if they occur near the confluence of the Koktuli and the Mulchatna rivers.		
Transportation Corridor			
Effects to commercial fisheries	This corridor would intersect with Upper Talarik Creek, Pete Anderson Creek, the Gibraltar River, Dunultak Creek, and Amakdedori Creek and cross Iliamna Lake. The east Kokhanok ferry terminal variant would avoid impacts to Gibraltar River. This alternative would not be expected to change salmon populations or the number of returning adult spawners, and therefore would have no impact to commercial fisheries.	This corridor would intersect with Upper Talarik Creek, the Newhalen River and the Iliamna River while crossing Iliamna Lake. This alternative would not be expected to change salmon populations or the number of returning adult spawners.	This corridor would intersect with Upper Talarik Creek, the Newhalen River, Chekok Creek, Canyon Creek, Knutson Creek, the Pile River, and the Iliamna River. This alternative would not be expected to change salmon populations or the number of returning adult spawners.
Effects to recreational fisheries	Only the Gibraltar River hosts a measurable amount of angling pressure (~650 SWHS angling days per year). The Gibraltar River is currently roadless and the project would change the character of the river in the immediate vicinity of the intersection. Angling pressure on the river may redistribute to other locations along waterbody or to other waterbodies. There would be no impacts to the Gibraltar River under the east Kokhanok ferry terminal variant. The corridor would cross Iliamna Lake which (with its tributaries) host 1,900-2,200 angler days per year. Transport across the lake should not affect these fisheries.	Only the pipeline ROW would intersect with the smaller creeks noted in Alternative 3. The Newhalen River drainage (~1,900 angler days per year) and the Iliamna River (~1,000 angler days per year) are the most frequently fished waterbodies along this route. Transport activity may dislocate fishing effort where the corridor intersects with these creeks, but this effort should redistribute along the waterbodies as long as fish populations are unaffected. The lake itself and unnamed tributaries, host 1,900-2,200 angler days per year of effort. Transport across the lake should not affect these days	The Newhalen River drainage (~1,900 angler days per year) and the Iliamna River (~1,000 angler days per year) are the most frequently fished waterbodies along this route. Transport activity may disrupt fishing effort where the corridor intersects with these creeks, but this effort would redistribute along the waterbodies.
Port Site

Commercial fishermen would need to be aware of increased vessel traffic in the area.	site is not located near substantial commercial fishery resources. Commercial fishermen would need to be aware of increased vessel traffic in the area.
Effects to recreational fisheries	The Amakdedori port site is located near Amakdedori Creek, which does not appear in SWHS or Guide Logbook data. The closest waterbody with measurable fishing effort Is the Kamishak River, which is more than 25 air miles to the south.	There are no recreational fishing resources of note near the Diamond Point port site. The closest waterbody with measurable fishing effort is the Iliamna River.	There are no recreational fishing resources of note near the Diamond Point port site. The closest waterbody with measurable fishing effort is the Iliamna River.
Pipeline Route			
Effects to commercial and recreational fisheries	Regardless of route, the pipeline would follow the transportation corridor and would not directly interact with the Bristol Bay salmon fishery. The pipeline would cross waters fished by the Cook Inlet salmon fishery and Cook Inlet groundfish fisheries. The pipeline would not directly interact with the salmon fishery given that the salmon fishery occurs in the top 30 feet of the water column. Groundfish commercial fishermen may need to adjust their gear placement to avoid the natural gas pipeline, but they would have flexibility to do so.		
Effects to recreational fisheries	The pipeline would follow the transportation corridor and is not expected to affect recreational fishing resources beyond those aforementioned under the transportation corridor. Cook Inlet and Anchor River fishing opportunities should be unaffected.	The pipeline ROW would cross the same streams as the mine access road in Alternative 3. Access along the ROW may increase for recreational fishing, but the increase would be low intensity.	The pipeline would follow the transportation corridor and is not expected to affect recreational fishing resources beyond those aforementioned under the transportation corridor. Cook Inlet and Anchor River fishing opportunities should be unaffected.

4.6.6 Cumulative Effects on Commercial and Recreational Fisheries

The list of Reasonably Foreseeable Future Actions (RFFAs) in Section 4.1, Introduction to Environmental Consequences, includes a number of potential mineral projects are likely to be subjected to continued exploration and study (i.e., Big Chunk South, Big Chunk North, Fog Lake, Groundhog, Johnson Tract, and Copper Joe), and a pair of projects that are reasonably foreseeable as future developments within the RFFA time frame (i.e., Pebble 78-year expansion, Pebble South, Shotgun). In addition, the RFFAs include transportation improvements and utility improvements spurred by economic activity in the area. Each project has the potential to impact fish population numbers, contributing to the cumulative effects to commercial and recreational fisheries in the region.

AMERICAN OVERSIGHT

4.6.6.1 Cumulative Effects- Commercial Fisheries

This study does not estimate fish population changes associated with cumulative effects of the RFFAs. It is clear that changes in the number of returning salmon spawners have a direct effect on the value of the Bristol Bay salmon fishery. The ADF&G is obligated to manage for the long-term health of the resource, which means that if escapement goals remain unchanged, reductions in returning spawners are directly transmitted as lost harvest opportunities for the commercial fleet. Cumulatively, the more development, the greater likelihood of declining number of fish. Between 1998 and 2017, the average individual salmon (of all species) harvested in Bristol Bay generated $5.16 (2017 US dollars) in ex-vessel value, and an additional $7.22 in first wholesale value to processors. Ex-vessel earnings are used to pay crew members, pay for boat maintenance and storage fees, cover the cost of supplies, and generate income for permit holders. Processor gross earnings pay permit holders, local and state taxes, utilities, and material suppliers as well as generate net earnings for processors. Any reduction in returning spawners and harvest opportunities has a value that can be calculated. Between 1998 and 2017, permit holders in Bristol Bay harvested an average of 60.4 to 60.7 percent of all returning sockeye salmon (Elison, T. et al. 2018). Presuming that the 20-year average real prices and historical harvest trends continue, each decline of 1,000,000 returning adult spawners (all species) in a year results in permit holders losing approximately $3.1 million in ex-vessel value, and processors losing another $4.3 million. Long-term declines in productivity would expand these losses across the duration of the fishery and the decline and the value of losses in real terms would change with the value of the fishery's products in real terms.

4.6.6.2 Cumulative Effects- Recreational Fisheries

Cumulative effects on recreational fisheries are harder to quantify than those on commercial fisheries. In addition to salmon, recreational anglers in the region primarily target rainbow trout and dolly varden, which depend on salmon eggs and salmon flesh for a good portion of their annual caloric intake. Fewer salmon means fewer eggs and carcasses on which to feed. In addition, cumulative effects can take their toll on the size and health of populations by degrading in-stream and near-stream habitats. Mineral development could contribute cumulatively to the reduction of the undeveloped nature of the region, and thereby reduce opportunities available for recreation activities fishing in remote areas. However, recreational anglers are more mobile and have the option to select similar substitute experiences. The most likely effect is a redistribution of days to different locations rather than a large reduction in total days. Lodges are not mobile and providers who frequent rivers that may no longer provide the same experience they once did may choose to change the services that they offer, access different locations via air, and/or lose a portion of their clientele. Changes in angler demand for trips in the region would depend on the magnitude of changes in the angling experience, angler preferences, and the type of responses by trip providers.

AMERICAN OVERSIGHT

4.9 SUBSISTENCE

This section describes potential impacts of the Pebble Project on subsistence in communities near Iliamna Lake, in the Kvichak and Nushagak river drainages, and on the southwest coast of Kenai Peninsula. The magnitude, geographic extent, and duration of impacts are assessed for each project phase. Potential impacts include:

- Changes in resource availability – construction and operation of project facilities may impact fish and wildlife habitat, and decrease or displace fish, wildlife, and vegetative resources used for subsistence.
- Changes in access to resources – project facilities and transportation corridors may open or remove areas from subsistence activities, or facilitate or restrict access to subsistence resources. In addition to physical access, project activity may change the character of the subsistence activities.
- Changes in competition for resources – changes to local population from direct and indirect employment and construction of project transportation access corridors may result in increased competition for subsistence resources.
- Changes in sociocultural conditions – direct/indirect employment opportunities for local residents and the presence of new large scale industrial facilities may have adverse and beneficial sociocultural effects.

4.9.1 No Action Alternative

Under the No Action Alternative, the mine would not be constructed; however, Pebble Limited Partnership (PLP) would still be permitted to perform exploratory activities and research at the site and would be expected to do so. Resource availability would not change from the conditions present during exploration activity and environmental studies at the action alternatives' proposed mine site. Local employment from exploration would be minimal. Potential effects to sociocultural aspects of subsistence (see below for an explanation of sociocultural dimensions of subsistence) would include a loss of income for a small number of people to fund subsistence activities (see Section 4.3, Needs and Welfare of the People—Socioeconomics), while labor and time available for subsistence would increase for those individuals. There would be no additional direct or indirect effects on subsistence. Existing trends in subsistence activities and resources would continue.

4.9.2 Alternative 1 – Applicant's Proposed Alternative

4.9.2.1 Changes in Resource Availability

During the 4-year construction phase, project activities would, in varying degrees, affect the availability and abundance of traditional and subsistence resources through habitat loss; behavioral disturbance and displacement resulting from increased noise, vehicle/aircraft/ferry traffic, and human activity; fugitive dust deposits on vegetation; concerns about contamination of resources; avoidance of traditional use areas; and increased costs and times for traveling to more distant areas (see Section 4.23, Wildlife Values, Section 4.24, Fish Values, Section 4.25, Threatened and Endangered Species, and Section 4.26, Vegetation, for discussions of project impacts on fish, wildlife, and vegetation).

During the operations phase, the effects of project activities would be similar. However, the effects would last for 20 years, and occur with less intensity along the transportation corridor than during construction because operations activities would be less disruptive than

AMERICAN OVERSIGHT

construction activities, although regular vehicle and ferry traffic and the physical presence of transportation corridor elements would continue to affect availability of subsistence resources. At the mine site, effects could occur with more intensity, associated with mining activity, noise, and expansion of the open pit and the waste rock and tailings storage.

Resources and species of concern that have been identified through the scoping process and environmental baseline documents include salmon, caribou, moose, seal, berries, small mammals, and firewood. With regard to the mine site, displacement and individual mortality of fish would occur in the upper portions of the North and South Fork Koktuli Rivers directly affected by mine facilities, but given the limited number of fish observed in that area and the quality of fish habitat, impacts would not be noticeable downstream from the affected channels (see Section 4.24, Fish Values). Similarly, there would be displacement of any moose, caribou, small land mammal, and upland birds that use the proposed mine site, but this would represent a small percentage of available habitat. These impacts to fish and wildlife would not be expected to impact harvest levels, since there would be no population-level decrease in resources and alternative, and in many cases more productive, habitats are available.

With regard to transportation facilities such as access roads and Iliamna Lake ferry operations, there would be loss of habitat from the facility footprint, potential displacement of individual fish and wildlife from human activities and noise, and potential injury and mortality from strikes with truck traffic (large and small land mammals) (see Section 4.23, Wildlife Values). However, the facility footprint would be small with regard to the total habitat available, and culverts would be required on the access road to allow for fish passage. Vehicle collisions with large and small land mammals would not have a population-level effect. There would be some site specific habitat fragmentation from project facilities, causing behavioral disturbance to terrestrial wildlife and birds and localized changes in distribution.

There would be direct loss of resource availability for berries and firewood in the project footprint and the immediate area of mine and transportation facilities; but these resources are commonly available in the project area, and there are alternative gathering areas available that are traditionally used.

Fugitive dust impacts would occur within a narrow corridor on either side of the roadways as described in Section 4.26, Vegetation. The heaviest dust deposition would be anticipated to occur within 35 feet of the road and vegetation and berry picking activity may avoid dusted areas. Some localized impacts of dust settlement in stream channels where fishing occurs may be noticeable, but implementation of dust suppression and enforcement of slow speed limits at all stream crossings would minimize dust-related impacts to aquatic ecosystems. Impacts would be expected to extend through the life of the project and would be localized to the area of disturbance. Fugitive dust from construction, roadways, and mining activities deposited in streams and on berries, other traditionally used plants, plants that animals eat, and water, would discourage subsistence users from harvesting these resources near the areas affected by the mine site and the transportation corridor. Subsistence users also may avoid harvesting waterfowl because of concerns about birds becoming contaminated from landing on and using open water at mine site facilities.

The communities closest to project infrastructure and transportation activities, including the mine site, transportation corridor, the ferry and terminals, port, and airports, would be the most affected by changes in resource availability. These communities include Nondalton, Iliamna, Newhalen, Pedro Bay, Igiugig, and Kokhanok. In contrast, communities in the Nushagak River drainage and in the Kvichak River drainage below Igiugig would experience little to no impact on resource availability as the potential impact on fish is small. Residents in Port Alsworth use an area in the vicinity of the mine site and along the north mine access road to harvest caribou,

AMERICAN OVERSIGHT

moose, other land mammals, waterfowl, upland birds, and berries though the areas closer to and surrounding this community see higher concentrations of use and it is expected that there would be little to no impact on resource availability in the concentrated use areas closer to the community during operations. On the east side of Cook Inlet, the construction and decommissioning of the natural gas pipeline would disturb a small area near the Sterling Highway but distant from communities traditionally pursuing subsistence activities, and would have a very low potential to impact subsistence users.

During construction and operations, the effects of project activities on resource availability would be primarily localized in the vicinity of project facilities and activities. While the mine site is within subsistence harvest areas used by five communities, it provides relatively poor fish and wildlife habitat and is not within the area of highest intensity overlapping subsistence users. Portions of the transportation corridor, primarily in the vicinity of Upper Talarik Creek and Gibraltar Lake and River are more heavily used (see Section 3.9, Subsistence). Truck traffic along these portions of the transportation corridor could displace moose and other land mammals in the immediate vicinity of the transportation corridor. Subsistence users that harvest resources in the immediate vicinity of the transportation corridor, particularly those from Iliamna, Newhalen, and Kokhanok, would likely need to make some adjustments to where they might traditionally harvest some subsistence resources to target resources that would be less affected by project activities. These adaptive approaches would likely sustain harvest levels for affected communities, but may increase the expenses and time needed to harvest subsistence resources.

Many project features would be removed or reclaimed, or both, during closure. Once restoration activities have been completed, impacts on the availability of subsistence resources would be reduced as these areas become revegetated and return to a more natural state than their condition during operations. The pit lake at the mine site would fill during the decades after mine closure. This would introduce a new standing waterbody, and concern about contamination of waterfowl was expressed during scoping. While there would be exceedance of water quality standards for specific metals, during the phases of closure (see Appendix K 4.18) risks to wildlife and birds from potential contaminants exposure would be limited and short-term, since the pit lake is anticipated to not support habitat that is attractive to many species of waterfowl and shorebirds and alternate habitat, including open water for staging, is available in the area. Some project facilities, including the pipeline, power plant, limited camp and storage facilities, access roads, and mine water treatment plant, would remain in use after mine closure as long as needed to support closure activities. Impacts on resource availability would be localized, in the vicinity of remaining infrastructure and activities (see Section 4.26, Vegetation, and Section 4.23, Wildlife Values, for discussions on vegetation restoration and impacts to wildlife).

The likelihood of impacts to subsistence resource availability in the project area during construction and operations would be high but have the highest intensity in the immediate vicinity of the project components. Disturbance, displacement, individual mortalities such as vehicle collisions with large land mammals and physical loss of stream habitat, and the loss of acres of habitat from project components would be the primary impacts to subsistence resources, but would be of low magnitude based on lack of population-level effects to fish and wildlife and the general availability of similar habitat to that affected by the project footprint. Impacts from the transportation corridor and associated uses would be intermittent to prolonged over the construction period and 20 year operations period. The duration of impacts would extend beyond the life of the mine but would decrease in intensity after closure and would cease when project restoration is complete.

AMERICAN OVERSIGHT

4.9.2.2 Changes in Access to Resources

During the construction phase, access to the area in the immediate vicinity of the project components would be impaired or restricted. Such restrictions would affect communities located near project infrastructure that use this land for or to access subsistence fishing, hunting, gathering, education of youth on subsistence traditions, and other customary practices. Construction of linear features, such as the roads and pipeline, could interrupt travel to resources or communities on the other side of the right-of-way (ROW). For example, construction of the natural gas pipeline and south access road could inconvenience residents of Kokhanok accessing subsistence areas south and west of the community during 1 of the 4 years of construction. Additionally, construction-related vessel traffic crossing Iliamna Lake could inconvenience other vessel traffic and subsistence activities. Safety considerations and presence of project equipment and personnel may restrict hunting activities in proximity to project facilities, and would be subject to consultation with potentially affected communities.

During the operations phase, the project footprint of the mine site, Iliamna Lake ferry terminals, access roads areas, and Amakdedori port would not be available for subsistence uses. Hunting may be restricted in the vicinity of those areas, and a raised gravel road may present a barrier to snowmachine and all-terrain vehicle (ATV) crossing. However, such restrictions would have minimal impact on access to subsistence resources because these project components would occupy a relatively small portion of the nearby communities' harvest areas, and because mitigating measures would be in place to minimize or avoid impact, such as providing marked crossing points across the transportation corridor and around the ferry terminals (PLP 2018-RFI 027). However, crossing at designated points may add travel time for subsistence users.

PLP would work with local communities to identify safe, practicable ways for residents to use the access roads, such as scheduled escorted convoys for private vehicle transport, and address hunting guidelines in proximity to project facilities. Trails and crossing points would be sign-posted and appropriate traffic controls would be established to ensure public safety (PLP 2018-RFI 027). Once constructed, the transportation corridor roads and the natural gas pipeline corridor ROW could have a positive effect on access to subsistence resources (depending on the level of access agreed to between the State, PLP, and the Lake and Peninsula Borough [LPB]) because these cleared routes could facilitate some overland travel by ATVs and snowmachines.

The Iliamna Lake ice-breaking ferry would disrupt winter travel over the frozen lake by creating a corridor of open water and potentially adding to travel time and increasing fuel expenditures by subsistence users. In addition, the open water in the ferry's wake would present a safety hazard for subsistence users. However, the project would work with communities (and supply funding) to provide for the marking and maintenance of snowmachine trails between communities across Iliamna Lake when lake ice is thick enough to support such traffic (PLP 2018-RFI 071a) (see Section 3.12 Transportation and Navigation). For the Kokhanok east ferry terminal site variant, snowmachine access to Iliamna Lake would be provided to the east of the terminal to enable access to the Sid Larson Bay area without crossing the ferry route (PLP 2018-RFI 078). PLP would work with local communities to find solutions for ferry transportation use (PLP 2018-RFI 027). The summer-only ferry variant would have no impact to winter access across Iliamna Lake.

At closure, roads in the transportation corridor would remain for monitoring purposes and so could continue to facilitate overland travel for subsistence access. The ferry facilities would be removed and supplies would be transported across the lake using a summer barging operation; thus, there would be no impacts from ice-breaking ferries after closure. Many of the other

AMERICAN OVERSIGHT

project features would be removed and/or reclaimed; therefore, adverse impacts on access to subsistence resources would be greatly reduced.

Impacts of access in the transportation corridor to subsistence users in the EIS analysis area would be of medium magnitude and localized geographic extent due to the ability to access other areas for harvest of resources. This is primarily because the Upper Talarik Creek portion of the transportation corridor is identified as a high overlapping area for subsistence users for two communities (Iliamna and Newhalen) and used by two others (Nondalton and Igiugig), and the Gibraltar River and Lake portion of the transportation corridor is a high overlapping subsistence use area for Kokhanok that is also used by Igiugig. Impacts of the transportation corridor and associated uses would be intermittent to prolonged over the 24 year period of construction and operation. The duration of impacts would be long-term, extending beyond the life of the mine. The likelihood of impacts is high.

The following sections evaluate project impacts on access to subsistence resource harvest areas for the six communities located closest to the project components, as project facilities and activities may restrict access in areas of overlapping subsistence use by these communities. It is based on reported and historical use of these areas as described by SRB&A (2011b), Fall et al. (2006), and Krieg et al. (2009) and presented in Section 3.9, Subsistence. For most of the communities, the contemporary use areas mirror the traditional use of the lands used to harvest subsistence resources, while in some communities the movement of animals (e.g., the Mulchatna caribou herd) to different areas has changed patterns of use and hunters have focused attention on different areas or resources. The figures in Section 3.9, Subsistence, show the multi-year subsistence use areas and the relative number of subsistence users for the six communities closest to the project components. It is possible that some downriver communities in the Kvichak and Nushagak River drainages may occasionally use the project area for subsistence activities, but their high frequency use areas are closer to the location of their communities (see Appendix K3.9).

The impacts to use areas and access to these areas from construction and operations of the natural gas pipeline would be the same as described for the transportation corridor.

The mine site would impact all six of the listed communities in similar ways. Construction, operations, and closure may affect access to subsistence hunting and fishing on these lands. Project-related activities, such as blasting and operation of heavy equipment and helicopters, would adversely restrict access. Lake community residents that may have otherwise traveled through the mine site area to reach subsistence resources further north and west would have to take alternative routes and potentially travel farther distances to avoid the mine site and infrastructure. However, the mine site is not shown as a high frequency overlapping use area for any of the six communities.

Impacts to accessing the mine site for subsistence use and harvest would be most concentrated near the mine site area and would diminish with distance. The effects would be localized in geographic extent; there is availability of alternate areas in traditional subsistence areas for activities. Impacts of the mine site and associated uses would be intermittent to prolonged. The duration of impacts would extend beyond the life of the project, with diminishing intensity as the site is reclaimed during closure. The likelihood of impacts would be high.

Iliamna

Construction and operations of the mine access roads (including a bridge over the Newhalen River) and the north ferry terminal under Alternative 1 would likely disrupt access to a portion of the overall harvest areas near Upper and Lower Talarik creeks, which are medium- to high-use areas for Iliamna subsistence users, particularly for moose and other land mammals. While

AMERICAN OVERSIGHT

there are other areas shown as medium to high uses areas for moose and other land mammals, hunters who traditionally use the Upper and Lower Talarik creeks areas would be affected. The south ferry terminal, Kokhanok east ferry terminal variant, and south mine access road would be located in lower overlapping use areas that Iliamna residents' access for resources.

Under the summer-only ferry variant the volume of haul trucks on the access roads would double in the summer, which could result in a greater impact in terms of access to resources in the use areas near the ferry terminals and access roads. Summer ferry traffic would also double, increasing from one daily round-trip to two; however, that impact would be low intensity, as boat traffic by subsistence users would only be minimally affected by the increase.

Until Iliamna Lake is connected to Cook Inlet through the transportation corridor at the southern ferry terminal, the Williamsport-Pile Bay Road may be used to transport supplies to Iliamna Lake during construction (PLP 2018-RFI 037). If this route were to be used, the volume of traffic on Williamsport-Pile Bay Road would increase during construction, which could affect access to resources, though this would be in an area accessed by a low to moderate number of subsistence users.

Newhalen

Construction and operations of the mine access roads (including a bridge over the Newhalen River) and the north ferry terminal under Alternative 1 and the variants may disrupt access to a portion of the overall harvest areas near Upper and Lower Talarik creeks, which are medium- to high-use areas for Newhalen subsistence users. Impacts to access would be similar to those described above for Iliamna. The south ferry terminal and south mine access road and variants are located in an area with lower overlapping uses that Newhalen residents access for resources. Under the summer-only ferry variant, the volume of haul trucks on the access roads would increase, which could result in a greater impact in terms of access to resources in the use areas near the ferry terminals and access roads. Ferry traffic would also double, increasing from one daily round-trip to two; however, that impact would be low intensity, as boat traffic would only minimally be affected by the increase.

If the Williamsport-Pile Bay Road is used during construction, the volume of traffic on this route would increase, which could affect access to resources though this would be in an area accessed by a low number subsistence users.

Pedro Bay

Construction and operations of the mine access roads and ferry terminals under Alternative 1 and the variants may displace access to a small portion of the overall harvest areas near the Upper and Lower Talarik creeks, which show low overlapping uses for Pedro Bay harvesters.

If the Williamsport-Pile Bay Road is used during construction, the volume of traffic on this route would increase, which could affect access to resources; this would be in an area accessed by a moderate to high number of residents.

Nondalton

Construction and operations of the mine access roads (including a bridge over the Newhalen River) and ferry terminals under Alternative 1 and variants may impact access to the use areas near the Upper and Lower Talarik creeks, which are used by a low to moderate number of Nondalton subsistence users. Impacts on access in this area would be similar to those described for Iliamna.

AMERICAN OVERSIGHT

Igiugig

Construction and operations of the mine access roads and the north ferry terminal under Alternative 1 may disrupt access to a small portion of the overall harvest areas near Upper and Lower Talarik creeks, although they are low-use areas for Igiugig subsistence users. The south ferry terminal, south mine access road, and Kokhanok east ferry variant would be located in areas that a low to moderate number of Igiugig residents report as accessing for resources.

The ferry traffic would be noticeable to those using Iliamna Lake to access areas at the north east end of the lake, in the Sid Larson Bay and areas around the community of Kokhanok. These areas are all used by a low number of subsistence users in Iguigig. The impact would be of higher magnitude in the winter, when the ice-breaking ferry would be operating. However, there would be safe access on the eastern side of Kokhanok to access Sid Larson Bay without crossing the path of the ferry under the Kokhanok east ferry terminal variant.

Kokhanok

Construction and operations of the mine access roads, ferry terminals, and the east Kokhanok ferry terminal may impact Kokhanok residents' access to portions of the high overlapping harvest use areas in the immediate area surrounding the community, and the Gibraltar Lake and River areas. Portions of lower overlapping use areas near the Upper and Lower Talarik creeks where large land mammals are hunted would also be affected. Under the summer-only ferry variant, the volume of haul trucks on the southern access road would double in the summer, which could result in a greater impact in terms of access to resources in the use areas near the ferry and south access road. Summer ferry traffic would also double, increasing from one daily round-trip to two; however, that impact would be low intensity, as subsistence user boat traffic would only minimally be affected by the increase.

During the winter when the ferry would be breaking ice, ferry traffic would be noticeable to those using Iliamna Lake to access areas at the north east end of the lake, in the Sid Larson Bay and areas around the community of Kokhanok. Traditional access routes used by some Kokhanok residents would be affected, but there would be safe access on the eastern side of Kokhanok to access Sid Larson Bay without crossing the path of the ferry under the Kokhanok east ferry terminal variant.

Construction and operations of the Amakdedori port under Alternative Action 1 would affect access for residents of Kokhanok to low overlapping use areas for taking of marine invertebrates and seals in Kamishak Bay. Construction of the Amakdedori Port under Alternative 1 is not expected to impact access to resources for communities other than Kokhanok because resident of other communities do not harvest resources in that area.

4.9.2.3 Changes in Competition for Resources

The project would result in employment opportunities for non-local workers during construction and operations; however, such opportunities are unlikely to increase competition for subsistence resources from sport hunting and fishing in areas where project employees are working or housed. Employees would be prohibited from hunting, fishing, and gathering while onsite to minimize competition to local subsistence resources. Non-local mine site employees would be transported to and from the mine site by aircraft, so that non-local employees could continue to live outside the region and commute to project work sites. Similarly, access to and use of project roads and other facilities for non-resident sport hunting would be prohibited. Non-local workers would not likely contribute to an increase in recreational use, although some may occasionally stay in the area when off duty or visit for recreational trips to nearby destinations.

AMERICAN OVERSIGHT

There is potential for a small population increase in communities closest to the mine site (see Section 4.3, Needs and Welfare of the People—Socioeconomics), which could increase resource competition among local residents. It is possible that visibility of the area for mine workers would encourage more recreational and sport hunting; however, such activities would require travel back to the region by non-local workers and be subject to the management of the ADF&G. The largest impacts could occur in Iliamna, which may see a small increase in population related to businesses developed to support the project.

After closure, the potential for non-local project employees to increase competition for subsistence resources would decrease.

4.9.2.4 Changes in Sociocultural Dimensions of Subsistence

Project construction and operations would result in both beneficial and adverse effects on sociocultural dimensions of subsistence. Subsistence activities are both cash dependent and highly cash-efficient. Cash income is required to pay for equipment, supplies, and operating costs, but modest cash investments result in large subsistence harvests and well-being. Increased incomes from project employment for local employees would likely be partially or largely invested in subsistence activities, increasing the efficiency and reliability of subsistence equipment and providing financial resources for a greater level of subsistence activities. Project activities would increase employment opportunities for residents of the project area, particularly for those living in communities surrounding Iliamna Lake. The number of local people who would be hired during the construction phase is not known, but PLP intends to prioritize opportunities for residents of the project area or those with close ties to the area (PLP 2018-RFI 027). During the operations phase, an estimated 50 employees would come from communities connected to project sites by road and an additional 200 employees would come from surrounding communities (out of 850 total employees during operations) (PLP 2018-RFI 027).

The effect of income on subsistence success (i.e., subsistence production) is evident among households with unique demographic structures. In many communities, 30 percent of households produce 70 percent of the subsistence harvest. These “super households” are distinguished because they include multiple working-age males, tend to have high incomes, and often are involved in commercial fishing. These three factors support high-producing households to be able to combine subsistence activities with paid employment and to arrange considerable labor in flexible ways that maximize harvests of subsistence foods, which are then shared with other households in the community and region. In contrast, the low-producing households usually have lower incomes, and are led by a single female or non-Native head of household, are single-person households, or households composed of elders (Wolfe et al. 2010).

At the same time, subsistence activities are labor intensive and require large investments of time and effort in hunting, fishing, and processing subsistence foods. Many subsistence resources are available only at certain times of the year. To the extent that project related employment reduces the time available for these employees to participate in subsistence activities and to pass on skills and knowledge to the next generation, their harvest effectiveness may decline. Proposed shift-work schedules, with two weeks at the project site and two weeks off in the community would likely reduce, but not eliminate, the conflict between project employment and subsistence activities.

Increased employment of adults and changes in work schedules would impact the nature of time spent training young people to subsistence hunt and fish. This change would impact the amount and quality of traditional knowledge passed on to younger generations and could potentially result in an adverse effect to communities. Households and communities would have

AMERICAN OVERSIGHT

to adjust to new roles of subsistence labor, changes in sharing networks, and possible changes in harvest levels. Rotational work schedules could affect levels of subsistence in different ways, since some families could adapt positively and some would find this an adverse effect. Legal hunting seasons are short, and if work schedules conflicted with seasons, then the effect on subsistence harvests could be greater. A main hunter's absence from the community at important times of the season or year could have a greater impact. However, the effects could be reduced, but not eliminated, with planned periods of leave options that allow for continuation of traditional subsistence practices and schedules during subsistence harvest periods.

Out-migration of mine project employees from local communities has been identified as an adverse sociocultural effect on subsistence. At the Red Dog Mine, nearly 50 percent of the workforce from local communities eventually migrated to lower cost, higher amenity communities like Anchorage and Wasilla, because the mine operator provided no-cost transportation to the mine site for workers' shifts (Tetra Tech 2009). To the extent that high-harvesting households relocated away from the community, the reduction in subsistence foods available in the community would be disproportionately larger. While a large in-migration of population is not anticipated, Alternative 1 may lead to changing population patterns in the region (see Section 4.3, Needs and Welfare of the People). The population in some potentially affected communities has been declining due to out-migration. The project could reduce or eliminate the decline because of the increase in employment opportunities and indirect effects improving education and infrastructure. Therefore, the impacts on population and effects to sociocultural changes of subsistence are difficult to anticipate.

Local residents participate in subsistence activities to a high degree. The level of participation may be affected by changes in resource abundance and quality, season and bag limits, changes in physical access, changes in cultural perceptions of resources (e.g., fish and animals are seen as tainted/contaminated, or water as polluted), the physical presence of project facilities in an area that was previously undeveloped and comfort level pursuing subsistence activities in their vicinity, and the times and funds available for subsistence activities. Changes in harvest participation are a leading indicator of cultural changes; continued participation is important to the transfer of knowledge and skills across generations, to the formation of social relationships within and between communities, and to cultural continuity. To the Yup'ik and Dena'ina cultures in the project area, salmon provide a large proportion of their nutritional food resources and represent an essential part of the language, spirituality, and social relations. In particular, subsistence and customary practices are the foundation of culture, maintain the connection of people to their land and environment, and support healthy diet and nutrition (Boraas and Knott 2013).

To the extent that project activities would have adverse impacts on resource abundance, availability, quality, and access, corresponding adverse sociocultural impacts on affected communities would occur, related to community health/well-being and cultural identity. Under routine operating conditions, the communities affected would likely be limited to those closest to the project's infrastructure and transportation activities: Nondalton, Iliamna, Newhalen, Pedro Bay, Igiugig, and Kokhanok. However, there could still be perceived concerns regarding potential contamination and the safety of subsistence resources in communities downriver from the project area.

At closure, both time commitments for and cash income from project employment would cease. Households would have to adjust to reduced cash income to support the maintenance and operating costs of a subsistence lifestyle. Workers who moved out of local communities may choose not to return. The indirect effects of mine employment and income on subsistence practices would cease.

AMERICAN OVERSIGHT

4.9.3 Action Alternative 2—North Road and Ferry

Impacts from the changes in the sociocultural dimension of subsistence would be the same as Alternative 1 for all project components. Impacts from the changes in resource availability, access to subsistence resources, and competition for resources would be the same as Alternative 1 at the mine site. Along the transportation corridor and natural gas pipeline, impacts would be similar to Alternative 1, except for differences described below.

Changes in resource availability along the transportation corridor and the natural gas pipeline for Alternative 2 would be similar to Alternative 1, but would affect a different area for the access road, ferry, pipeline and port, and therefore affect communities to a different degree. Individual mortality and behavior disturbance to and displacement of subsistence resources would occur at approximately the same levels as described under Alternative 1. The primary difference is that there are fewer communities using the area in between Pile Bay and Williamsport for subsistence, and so the magnitude and geographic extent of the impact would be less than Alternative 1. Based on the frequency of areas of overlapping subsistence users, Nondalton, Newhalen, and Pedro Bay use the North Road alignment to the Eagle Bay ferry terminal to a lesser degree, and Iliamna has a higher frequency use. Pedro Bay has high frequency overlapping use of the area of the Pile Bay terminal and portions of access road from Pile Bay to Williamsport. All six project area communities use the eastern end of Iliamna Lake for seal hunting to some degree.

Along the ferry route there would be a higher magnitude impact to resource availability for seals, than Alternative 1 because the ferry would pass through more seal hunting areas under Alternative 2. There would be less impact to seal hunting under the summer-only ferry operations as they do not tend to congregate in this area of the lake in the summer months and the preferred time for hunting seals is in the winter (see Section 4.23, Wildlife Values).

Under Alternative 2, there would be an overland pipeline ROW from Pile Bay to the mine site. This could introduce some competition to subsistence users from recreational sport hunting and fishing, although because of the relatively low recreational use of the area, the magnitude would be expected to be small.

4.9.3.1 Changes in Access to Resources

Iliamna

The mine access road from Eagle Bay would be located in medium- to high-use areas accessed by residents of Iliamna and would be likely to impact access. There are overlapping use areas near the Newhalen River and further inland, and near the site of the ferry terminal at Eagle Bay. The ferry under Action Alternative 2 would traverse the eastern portions of Iliamna Lake that are accessed by residents with low to medium overlapping uses. The ice-breaking ferry would disrupt access to these areas, and similar to Alternative 1 safe winter travel routes would need to be developed with arrangements between PLP and affected communities. With the summer-only ferry variant, there would be little disruption to access in the winter on Iliamna Lake or the mine access roads, but the summer access to resources would have a higher level of disruption from an additional daily ferry trip and a doubling of truck traffic on the mine access roads.

The addition of a pipeline ROW would potentially create an overland route that could be used by Iliamna residents to access additional subsistence resources.

Diamond Point port construction and operations under Alternative 2 could affect Iliamna residents' access to harvests locations in Cook Inlet. However, these areas are reported as low-use areas for harvested resources near Iliamna Bay and north of Augustine Island.

AMERICAN OVERSIGHT

Newhalen

The mine access roads of Alternative 2 would be located in the vicinity of a medium to high overlapping use area near the Newhalen River and would be likely to impact access to resources in the areas inland north of the community. The ferry route would be south of the islands in Iliamna Lake that are accessed by residents, but would not pass close to the islands and would not likely disrupt access in the summer. In the winter, the ice-breaking ferry could disrupt access to all resource use areas on the northeast end of the lake. With the summer-only ferry variant, there would be little disruption to access in the winter on Iliamna Lake or the mine access roads, but summer access to resources would have a higher level of disruption from an additional daily ferry trip and a doubling of truck traffic on the mine access roads.

The addition of a pipeline ROW would potentially create an overland route that could be used by Newhalen residents to access additional subsistence resources.

Diamond Point port construction and operations under Alternative 2 would not be expected to affect Newhalen access to harvests locations, as they do not access resources in that location.

Pedro Bay

The mine access roads and use of the Williamsport-Pile Bay Road under Alternative 2 would likely impact access to resource harvest areas for Pedro Bay residents in high overlapping use areas near the community and inland from Iliamna Lake and in Pile Bay, and have similar impacts to access as described in Alternative 1. However, there is the existing Williamsport-Pile Bay road, and Pedro Bay has experience with the adverse and beneficial effects of a road on subsistence access. The ferry route would be south of the islands in Iliamna Lake that are used by residents of Pedro Bay, and so access to those islands and their resources would not be likely to be affected. As described for Iliamna, winter ferry operations would impact traditional access and create travel safety concerns that would need to be mitigated in consultation with PLP.

The addition of a pipeline ROW would potentially create an overland route that could be used by Pedro Bay residents to access additional subsistence resources.

Diamond Point port construction and operations under Alternative 2 could impede access to subsistence activities and fishing and marine invertebrate harvesting for Pedro Bay residents in Iliamna Bay and near Augustine Island as the port would be located in the vicinity of these use areas. However, there is existing vessel traffic to Williamsport during the summer months, and some vessel traffic associated with the quarry at Diamond Point.

This community is smaller than the other lake communities and does not go as far to harvest subsistence resources. Therefore, small amounts of disruption would have a greater intensity of impact to this community.

Nondalton

The mine access roads of Alternative 2 are likely to impact access to resource harvest areas for Nondalton residents as they would be located in the vicinity of medium overlapping use areas. Impacts would be similar to those described for Iliamna. The ferry route would be south of the islands in Iliamna Lake that are used by residents of Nondalton; therefore, access to those islands and their resources would not likely be affected. However, winter subsistence harvest of seals would be affected by ferry operations, similar to impacts discussed for Iliamna.

The addition of a pipeline ROW would potentially create an overland route that could be used by Nondalton residents to access additional subsistence resources.

AMERICAN OVERSIGHT

Diamond Point port construction and operations under Alternative 2 would not be expected to affect Nondalton access to harvests locations as they do not access resources in that location.

Iguigig

Neither the transportation corridor, ferry, nor Diamond Point port of Alternative 2 are anticipated to impact the access to resource harvest areas for Igiugig residents as fewer subsistence users search for and harvest resources in these areas.

Kokhanok

The mine access roads of Alternative 2 are less likely to impact access to resource harvest areas for Kokhanok residents as fewer subsistence users search and harvest in areas inland from the north side of Iliamna Lake and closer to the mine site.

The ferry route would be south of islands in Iliamna Lake that are accessed by residents for seal hunting, but would not pass close to the islands and would not likely disrupt access in the summer. In the winter, the ice-breaking ferry could disrupt access to seal hunting in winter which is the preferred time of year when this activity occurs. With the summer-only ferry variant, there would be no disruption to access in the winter on Iliamna Lake, but summer access to resources would be more noticeable from an additional daily ferry trip. This area sees a low level of use by Kokhanok residents and the magnitude of disruption from the ferry would be small.

Diamond Point port construction and operations under Alternative 2 would not be expected to affect Kokhanok residents' access to harvest locations, as they do not typically access resources in that location.

4.9.4 Action Alternative 3—North Road Only

Impacts from the changes in the sociocultural dimension of subsistence would be the same as Alternative 1 for all project components. Impacts from the changes in resource availability, access to subsistence resources, and competition for resources would be the same as Alternative 1 at the mine site. Along the transportation corridor and natural gas pipeline, impacts would be the same as Alternative 1, except that there would be no ferry operations and access would be provided entirely by road.

Changes in resource availability along the transportation corridor and the natural gas pipeline for Alternative 3 would be similar to Alternative 1, but occurs over a different geographic area. Individual mortality and behavioral disturbance to, and displacement of, subsistence resources would occur at approximately the same levels. The primary difference is that there are slightly fewer communities using the area between Pile Bay and Williamsport for subsistence (Iliamna, Newhalen, Nondalton, and Pedro Bay). However, there are a high number of overlapping use areas along the road corridor of Alternative 3 from Pedro Bay to the mine site for Iliamna and Pedro Bay, and so the magnitude of the impact to those communities would be a little higher than Alternative 1.

Under Alternative 3, there would be a road from Pile Bay to the mine site, it would be under controlled access, limiting potential competition to subsistence uses of resources from non-local recreational sport hunting and fishing. The magnitude of potential would be expected to be small.

Access to subsistence resource use areas would be the similar to Alternative 2 for residents of Iliamna, Newhalen, Pedro Bay, Nondalton, Iguigig, and Kokhanok. The primary difference is the road from Pile Bay to the mine site, which would affect access in ways similar to the discussion

AMERICAN OVERSIGHT

for Alternative 1. There would be no ferry operations, and therefore no impacts to winter seal hunting access on Iliamna Lake.

4.9.5 Summary of Key Issues

See Table 4.9-1 for a summary of key issues.

Table 4.9-1: Summary of Key Issues for Subsistence

Impact	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Impacts to availability of subsistence resources	Reduced availability of subsistence resources through habitat loss, disturbance and displacement of resources, fugitive dust deposits on resources, and increased costs and time for traveling to harvest areas.	Similar impacts to Alternative 1 would affect subsistence resources in the Alternative 2 project area.	Similar impacts to Alternative 1 would affect subsistence resources in the Alternative 3 project area.
Impacts in competition for resources	There would be some availability to access other areas for harvest of resources, which could increase competition in some areas by providing additional access for local residents.	The addition of the pipeline ROW may increase competition for resources in that area by providing additional access for local residents.	Similar to Alternative 1
Impacts to sociocultural dimensions of subsistence	Beneficial effects from new income to invest in subsistence activities. Challenges in balancing time required for employment and time for subsistence activities. Adverse effects from out-migration, particularly if high-harvesting households leave.	Same as Alternative 1	Same as Alternative 1
Impacts to access to subsistence resources	Snowmachine access could be disrupted in the winter by the ice-breaking ferry, and could also create a safety hazard. PLP would put measures in place to minimize impacts, such trail marking and crossings. The east Kokhanok ferry terminal variant would allow for access to Sid Larson Bay without crossing the ferry route. There would be no impact from ferry traffic during the winter under the summer-only ferry variant.	Impacts would be the same as for Alternative 1, except that the routes affected would be trails from Pedro Bay and the north end of the lake instead of the mid-lake region. There would be no impact during the winter under the summer-only ferry variant.	Impacts would be similar to Alternative 2, except the impacts from the road from Pile Bay to the mine site would be more similar to the road under Alternative 1.

AMERICAN OVERSIGHT

4.9.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) as described in Section 4.1, Introduction to Environmental Consequences, have the potential to contribute cumulatively to effects on subsistence resources and uses. These RFFAs may result in direct and indirect effects on subsistence resources and uses. The following RFFAs apply to the consideration of cumulative effects on subsistence resources and uses.

- Pebble Project build-out—develop 55 percent of delineated resources over a 78 year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun
- Johnson Tract*
- Copper Joe*
- Donlin Gold
- Diamond Point Rock Quarry
- ASAP
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Hydrocarbon Exploration*
- LPB Transportation Projects
- LPD Capital Improvement Projects
- USDA Rural Development Projects
- LBP Renewable Energy Projects
- Nushagak Intertie Project
- Subsistence Activity
- Tourism, Recreation, Hunting, Fishing
- Scientific Surveys and Research

**Indicates exploration activities only.*

Each of these RFFAs contribute to the increased potential for impacts on subsistence resources, as each involves some aspect of ground-disturbing activity that can lead to the disturbance and displacement of subsistence resources at those locations.

Actions that expand mineral development near the Pebble deposit and around Iliamna Lake contribute to landscape-level effects, where there is continuous introduction of additional impediments to the movement of people and animals; increased noise, vibration, and atmospheric pollution; and increased numbers of people to the area. Expansion would increase the geographic area affected by the project by combining project elements of Alternative 1 and 3, with potential combined impacts to resource availability, access to resources, competition, and sociocultural dimensions of subsistence. Expansion of the mine site would affect more fish habitat in the upper reached of the North and South Forks of the Koktuli Rivers, and Upper Talarik Creek. The Pebble Project build-out RFFA would contribute to the cumulative effects with additional infrastructure, habitat loss, and disturbance over a long period of time, up to an additional 98 years depending on the period of post-mining milling and closure activities.

These effects can affect the quality and cultural experience of subsistence activities, leading to adverse impacts on subsistence resources that are central to cultural belief systems and the way of life of local people. Effects such as habitat fragmentation, noise, and potential for increased access for recreational hunting and fishing disrupt subsistence cycles, which may result in direct impacts on resource gathering areas and harvest quantities. Local residents have observed that there has already been a loss to subsistence opportunities and the way of life due to planning and exploration activities that are associated with the Pebble Project from helicopter traffic and that there have been disruptions to local wildlife. Subsistence users in Nondalton noted that their community uses traditional trapping and hunting areas near Groundhog

AMERICAN OVERSIGHT

Mountain (Fall et al. 2006). Impacts to Nondalton from the Groundhog project (listed above) would be additive to impacts from the proposed Pebble Project and the Pebble expansion RFFA, likely causing them to travel further and expend more time to trap and hunt.

These types of effects are also applicable to an increase in resource development actions along the coast of Cook Inlet, which may impact those communities that use Amakdedori and Iniskin Bay areas for subsistence resources and access to sites that are important for harvest and cultural practices central to the healthy relationship of people to the land they inhabit. The cumulative impacts would be long-term to permanent, and geographically broad in scope (i.e., regional level).

AMERICAN OVERSIGHT

4.20 AIR QUALITY

This section addresses air quality impacts during the project. Direct and indirect air quality impacts from all phases of the project are evaluated using project emissions, and where applicable, air modeling results. Project emissions consist of criteria pollutants, hazardous air pollutants (HAPs), and greenhouse gases (GHG). The project's HAP emissions include acetaldehyde, benzene, formaldehyde, hexane, hydrochloric acid (HCl), toluene, lead compounds, mercury compounds, and arsenic compounds.

4.20.1 Methodology for the Analysis of Air Quality Impacts

Emissions in the project area are described as direct emissions. The Environmental Impact Statement (EIS) analysis area is the larger geographical area that would experience indirect impacts; those impacts are also described for each project component. Indirect emissions are not quantified in this EIS.

Emission sources are categorized three ways: fugitive, mobile, and stationary point sources:

- Fugitive emission sources are those that could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening (40 Code of Federal Regulations [CFR] 52.21[b][20]). Some examples of fugitive sources are fugitive dust from vehicles on unpaved roads, fugitive leaks from piping and connectors, blasting, or dust from material handling.
- Mobile sources are on-road and off-road vehicles, non-road engines, or portable sources such as trucks, light plants, heaters, portable generators, construction equipment, ships, and aircraft.
- Stationary point sources are those that pass through a stack, chimney, vent, or other functionally equivalent opening (40 CFR 52.21[b][20]). Examples of stationary sources associated with the project are enclosed material processing and handling activities (for which emissions pass through a stack or vent), power plant generators, and incinerators.

Expected air quality impacts are evaluated based on the results of dispersion modeling and emissions estimates. The impact methodology framework applied to assessing direct or indirect impacts on air quality is based on the following factors:

- Magnitude or intensity – Modeled project impacts are compared to Alaska ambient air quality standards (AAAQS) and prevention of significant deterioration (PSD) increments (Table 4.20-1), and/or regulatory standards. In addition, if regulatory standards are not met, an assessment of the effectiveness of the mitigation measures is conducted.
- Duration – The time span of project impacts is quantified. For example, an assessment is conducted to determine whether air quality would be either reduced infrequently but not beyond the project's construction phase, would be reduced only during the project's lifespan, or would continue to be reduced after project completion.
- Extent – An assessment of the spatial range of project impacts is conducted. For example, an assessment is conducted to determine whether the impacts would locally affect air quality in only discrete portions of the project area, or would occur outside of the project area.

AMERICAN OVERSIGHT

The type of area (attainment, maintenance, nonattainment, or Federal Class I area) affected by project impacts is also assessed. No project components would be in or near an area of nonattainment or maintenance, or an area with local regulations.

The PSD increments and AAAQS criteria used to evaluate project impacts based on the results of dispersion modeling are provided in Appendix K4.20. The comparison of impacts using PSD increments has been provided for informational purposes only, and does not represent a regulatory PSD increment consumption analysis. PSD increment consumption would be assessed as part of a formal increment consumption analysis during the permitting process, if required. Additionally, details of the air quality permit applicability assessment are provided in Appendix K4.20.

To estimate emissions for the air quality impact analyses for all project components, several avoidance and control measures were considered. Examples are listed below, and a more comprehensive list of measures is provided in Chapter 5, Mitigation:

- During the summer months, dust suppression techniques, such as watering, would be used to minimize the impacts of fugitive dust emissions from the unpaved roads.
- Following an idling policy, such as not allowing haul trucks to idle for more than a set amount of time if the vehicle or equipment is not in motion, would reduce fuel consumption, thereby reducing oxides of nitrogen (NO_X), carbon monoxide (CO), particulate matter (PM), volatile organic compounds (VOCs), sulfur dioxide (SO_2), and GHG emissions.
- The combustion turbines would be equipped with post-combustion emission controls (catalytic oxidation and selective catalytic reduction systems), which reduces NO_X, CO, and VOC emissions.
- For the mine site, the heat recovery steam generator (HRSG) steam would be used to drive a steam turbine attached to a generator to provide ancillary power to the facility, which would reduce the need for additional fuel use.
- The boilers would be equipped with low NO_X burners, which would reduce NO_X emissions.

Total potential criteria pollutant and hazardous pollutant emissions are calculated using vendor data, US Environmental Protection Agency (EPA) AP-42 emission facts, mass balances, EPA Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories, and New Source Performance Standards (NSPS). The methods for estimating GHG emissions for fuel combustion sources are applied in accordance with the guidance provided in Subpart C of the Mandatory Reporting of Greenhouse Gases Rule (40 CFR Part 98) for Tier 1 units, and EPA Current Methodologies in Preparing Mobile Source Port-Related Emission Inventories for marine vessel emissions. The carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O) emission estimates are calculated for all stationary and mobile equipment on an individual basis using Equation C-1 from 40 CFR 98.

4.20.2 No Action Alternative

Under the No Action alternative, the project would not be constructed, and would not have any new effects on air quality.

4.20.3 Alternative 1 – Applicant's Proposed Alternative

The results of the assessment of emissions and impacts of Alternative 1 are addressed for each project component by project phase (construction, operations, and decommissioning) in the following sections.

AMERICAN OVERSIGHT

4.20.3.1 Mine Site

For the mine site, the emissions from the construction, operations, and decommissioning phase are presented. Additionally, the potential mine site impacts are presented for mine construction activities and mine operations activities by completing a near-field and far-field impacts assessment.

Construction

Emissions during construction would be related to quarry crushing operation, concrete batch plant operation, incineration, and power generation.

The total emissions were calculated based on the worst-case construction year of the mine site. Emissions were calculated assuming that each emission unit would be operated continuously (8,760 hours per year) with the appropriate load factors, except for quarry crushing operations and for those emission units that would be subject to operating restrictions under an air quality permit. Quarry crushing operations emission calculations were based on operating 300 days per year. The potential emissions for restricted emission units were calculated assuming those emission units would be operated at the maximum load for the maximum allowed hours per year. The construction emission inventory for the mine site is provided in Table 4.20-1 for a representative year of construction activities.

Table 4.20-1: Mine Site Construction Emission Summary

Air Pollutant	Stationary Emission Units (tons/year)	Non-road Engines (tons/year)	Mobile Emission Units (tons/year)	Fugitive Emission Units (tons/year)	Total Emissions (tons/year)
NOx	110	24	2,050	9	2,193

Source: PLP 2018-RFI 007

The representative air quality impacts related to the construction of the mine site were assessed using a near-field model demonstrating compliance with modeled air quality standards and PSD Class II increment. Minimal and localized impacts would occur during construction of the mine site. Impacts would dissipate once the construction was complete. Details of the near-field impact assessment are presented in Appendix K4.20.

Operations

Emissions during mine site operations would be related to mining activities, ore processing activities, incineration, and power generation.

The mine site stationary emission unit inventory would include a combined-cycle combustion turbine power plant, internal combustion engines, boilers, fuel storage tanks, and a small incinerator. The mobile equipment inventory would include haul trucks, bulldozers, graders, shovels, light-duty vehicles, and loaders that would be used in the mining activities. Fugitive emissions would result from blasting, drilling, vehicle traffic on unpaved roads, and material handling. The fuel-burning equipment are sources of combustion-related air pollutant emissions. A summary of the emissions during operations at the mine site is presented in Table 4.20-2 for a representative operations year.

Table 4.20-2: Mine Site Operations Emission Summary

A near-field modeling assessment was prepared to address the likely air quality impacts related to the operation of the mine site. Compliance with modeled air quality standards and PSD Class II increments is demonstrated. Any air quality impacts that would occur would be minimal and localized occurring when the mine is operational.

A far-field impact assessment was prepared to assess representative air quality impacts related to the operation of the mine site and included an analysis of impacts to air quality–related values (AQRVs). AQRVs are a resource adversely affected by a change in air quality, such as visibility, deposition, and ozone. Far-field AQRV impacts from the mine site are not anticipated at any nearby Federal Class I area. Appendix K4.20 presents additional information regarding the near-field and far-field assessments.

Decommissioning

Closure and reclamation activities are described in Chapter 2, Alternatives. Support facilities would include operation of the camp and power generation. The reclamation emissions inventory would include internal combustion engines, a gas turbine, boilers, and an incinerator. The mobile equipment would include haul trucks, shovels, bulldozers, compactors, graders, and service and light-duty vehicles. Fugitive dust emissions would result from stockpile overburden handling, bulldozing, grading, vehicle traffic on unpaved roads, and wind erosion of road surfaces and active reclamation areas. The duration of the closure phase at the mine site is expected to be approximately 20 years. Table 4.20-3 presents a summary of the mine site decommissioning emissions for a representative decommissioning year.

AMERICAN OVERSIGHT

4.20.3.2 Transportation Corridor

For analysis of impacts to air quality, the transportation corridor includes all-season gravel roads, ferry terminals on Iliamna Lake, port, and spur roads, and the onshore pipeline segment at the port, because the pipeline and road would be constructed jointly. The transportation corridor would be operational throughout the life of the project.

AMERICAN OVERSIGHT

This section addresses the emissions from the construction and operations phases of the facilities in the transportation corridor. Because the road and onshore pipeline are constructed in the same right-of-way at the same time, the emissions from the construction of both the road and onshore pipeline are calculated together. It is anticipated that the construction and operations of the transportation corridor would have similar or lower near-field and far-field impacts as presented for the mine site.

Construction

During construction, the main emission sources would be heavy-duty non-road and mobile construction vehicles, as well as fugitive dust generated by vehicles on unpaved roads and wind erosion. Additional fugitive emissions would result from blasting, drilling, and material handling. Stationary emissions sources would include internal combustion engines and fuel storage tanks. The representative emissions were calculated based on the total construction duration of the transportation corridor and estimated equipment operation. The duration of construction for the road corridor and onshore pipeline facilities is expected to be approximately 1 year. Table 4.20-4 presents a summary of the construction emissions for the transportation corridor during the one year of construction. Further details of the transportation corridor emission inventory are provided in PLP 2018-RFI 007. Air quality impacts would be localized and minimal occurring while construction activities are on-going. Once construction is complete, the impacts would diminish.

Table 4.20-4: Transportation Corridor Construction Emission Summary

Source: PLP 2018-RFI 007

Operations

Emissions sources during operations would consist of internal combustion engines at the ferry terminals, fuel storage tanks, and other fuel burning engines such as ferry engines, light duty vehicles, truck/trailer vehicles, container-handing forklifts, graders, and aircraft. Additionally, fugitive dust emissions would result from vehicle traffic on unpaved roads. A summary of the operations emissions within the transportation corridor is presented in Table 4.20-5. Further details of the transportation corridor emission inventory are provided in PLP 2018-RFI 007. Air quality impacts would be localized and minimal occurring when the transportation corridor is in use.

Table 4.20-5: Transportation Corridor Operations Emission Summary

Air Pollutant	Stationary Emission Units (tons/year)	Mobile Emission Units (tons/year)	Fugitive Emission Units (tons/year)	Total Emissions (tons/year)

Decommissioning

The road system would be retained as long as required for the transport of bulk supplies needed for long-term post-closure water treatment and monitoring. As operations end, the Iliamna Lake ferry facilities would be removed, and all supplies would be transported across the lake using a summer barging operation. Impacts to air quality during closure activities are expected to be similar to those during the construction phase.

4.20.3.3 Amakdedori Port

This section presents the emissions from the construction and operations phases of the Amakdedori port and offshore pipeline portions in the Cook Inlet and Iliamna Lake. Additionally, the potential near-field impacts are presented for Amakdedori port operations. It is anticipated that the construction of the Amakdedori port would have similar near-field impacts as presented for the mine site.

Construction

The construction of the port and offshore pipeline uses similar equipment and methods. Therefore, the emissions are calculated together; however, the construction would not take place at the same time. The construction of the offshore pipeline would occur after the port construction. The construction emissions are calculated based on the estimated construction time, regardless of which activity takes place first.

The port site construction activity would include construction of port facilities to support later phases of construction and mine operations. Emissions from material mining and crushing operations required for fill material, principally for the earthen access causeway, are captured in the road construction emissions provided for the transportation corridor. Emissions associated with operation of the port facilities, including trucking or offshore pipeline construction, are assumed to be similar to emissions during mine operation, and are represented by the annual transportation emissions estimate for mine operations.

The construction activity of the port and offshore pipeline would include reciprocating internal combustion engines, an asphalt plant, boilers, fuel storage tanks, and a small incinerator. The mobile equipment inventory would include bulldozers, excavators, loaders, and cranes in the port construction; and tugs, long-reach excavators, and welders in the pipeline construction. The

AMERICAN OVERSIGHT

fuel-burning equipment would be sources of combustion-related air pollutant emissions. Fugitive emissions would result from site grade preparation and mobile equipment traffic. The construction of the port and offshore pipeline is expected to take approximately one year. Table 4.20-6 presents an emission summary for construction of the port and associated offshore pipeline. Air quality impacts would be localized and minimal occurring during construction activities. Once construction is complete, the impacts would diminish.

Table 4.20-6: Amakdedori Port and Offshore Pipeline Construction Emission Summary

Operations

Operations would consist of barge loading and unloading activities, lightering activities, power generation, heating, and incineration.

The Amakdedori port emission unit inventory would include reciprocating internal combustion engines, heaters, fuel storage tanks, and a small incinerator. Mobile equipment would include light-duty vehicles, skidsteers, forklifts, and container-handing forklifts. Marine vessels would include barges, tugs, and bulk carriers at the lightering locations. The concentrate containers would be emptied into the bulk carriers at the bulk carrier lightering point. A summary of the operations emission at the port is presented in Table 4.20-7 for representative year of operations activity.

Source: PLP 2018-RFI 007

Air quality impacts from port operations emissions have been demonstrated to be in compliance with modeled air quality standards and PSD Class II increments. If near-field impacts occur from the port, those impacts would be minimal and localized. The far-field impact assessment is based on an analysis of the port emissions that would affect the AQRVs in the nearby Federal Class I areas. As a result of this assessment, the AQRVs would not likely to be impacted at any of the Federal Class I areas. The details of the near-field and far-field impact assessment are found in Appendix K4.20.

Decommissioning

There would continue to be emissions and air quality impacts associated with the port until operations end, when physical site closure work would commence. At that time, the Amakdedori port facilities would be removed, except for those required to support shallow draft tug and barge access to the dock for the transfer of bulk supplies. Air impacts from port decommissioning are expected to be minimal occurring while the port is being decommissioned. Any remaining activities at the port would result in localized and negligible air quality impacts.

4.20.3.4 Natural Gas Pipeline Corridor

The pipeline corridor consists of onshore pipeline in the transportation corridor, offshore pipeline, and the Kenai compressor station. The construction air quality impacts of the onshore portion of the pipeline are addressed above under transportation corridor. The construction air quality impacts of the offshore portion of the pipeline are addressed above under Amakdedori port. This section addresses emissions and air quality impacts from the construction of the Kenai compressor station on the east landfall of the natural gas pipeline corridor, as well as the air quality impacts from operations and decommissioning of the entire pipeline corridor.

Additionally, potential near-field impacts are present for compressor station operations. It is anticipated that the construction of the compressor station would have lower near-field air quality impacts as presented for the mine site in Section 4.20.3.1 since the construction of the compressor station has less emissions than the construction of mine site making the mine site a conservative surrogate.

Pipeline Corridor Construction

During construction of the compressor station, activity would involve site grading and mobile equipment use for assembly of the compressor station from pre-constructed modules. The compressor station emissions inventory would include combustion engines and mobile equipment inventory, including bulldozers, loaders, excavators, cranes, and light-duty vehicles. The fuel-burning equipment would be sources of combustion-related air pollutant emissions. Fugitive dust emissions would result from site grade preparation and mobile equipment traffic. The emissions from the compressor station construction are presented in Table 4.20-8. Further details of the Compressor Station emission inventory are provided in PLP 2018-RFI 007. Air quality impacts would be localized and minimal occurring while construction activities are on-going. Once construction is complete, the impacts would diminish and become negligible.

AMERICAN OVERSIGHT

Table 4.20-8: Compressor Station Construction Emission Summary

Air Pollutant	Stationary Emission Units (tons/year)	Non-road Engines (tons/year)	Mobile Emission Units (tons/year)	Fugitive Emission Units (tons/year)	Total Emissions (tons/year)
NO_x	N/A	2.60	1.40	N/A	4.00
CO	N/A	6.40	5.60	N/A	12.00

PM = particulate matter

PM_{10} = particulate matter with an aerodynamic diameter less than or equal to 10 microns

$PM_{2.5}$ = particulate matter with an aerodynamic diameter less than or equal to 2.5 microns

SO_2 = sulfur dioxide

VOCs = volatile organic compounds

Source: PLP 2018-RFI 007

Pipeline Corridor Operations

During the operations of the pipeline corridor, the emissions and associated impacts from the onshore and offshore pipelines would be negligible. The Kenai compressor station, which would be the single compressor station for the natural gas pipeline, would have emissions and possible air impacts. For the operations phase, only the compressor station is assessed.

AMERICAN OVERSIGHT

The Kenai compressor station inventory would include natural-gas-fired simple-cycle combustion turbines driving the compressors. A summary of the operations emissions at the compressor station is presented in Table 4.20-9.

Table 4.20-9: Pebble Compressor Station Operations Emission Summary

Air Pollutant	Total Emissions (tons/year)
NO_x	69.30
CO	17.80
PM	1.40
PM_{10}	1.40
$PM_{2.5}$	1.40
VOC	0.50
SO_2	0.20
Pb	0.00
Total HAPs	0.22
CO_2	22,992 tonnes/year
CH_4	0.43 tonnes/year
N_2O	0.04 tonnes/year
CO_2e	23,015 tonnes/year

Source: PLP 2018-RFI 007

Air quality impacts from the compressor station have been demonstrated to be in compliance with modeled air quality standards and PSD Class II increments. If near-field impacts occur from the compressor station, those impacts would be minimal and localized. The far-field impact assessment is based on an analysis of the compressor station emissions that would affect the AQRVs in the nearby Federal Class I areas. As a result of this assessment, the AQRVs would not likely be impacted at any nearby Federal Class I areas. The details of the near-field and far-field impact assessment are provided in Appendix K4.20.

AMERICAN OVERSIGHT

Pipeline Corridor Decommissioning

The natural gas pipeline would be maintained until such time as it is no longer required to provide energy to the project site. The pipeline would be pigged and cleaned before being abandoned in place. Surface utilities associated with the pipeline would be removed and reclaimed. The air quality impacts from the decommissioning activities are expected to be short-term and negligible.

4.20.4 Alternative 2 – North Road and Ferry

The mine site under Alternative 2 would be similar to the mine site under Alternative 1 (Chapter 2, Alternatives). Under Alternative 2, the locations of the transportation corridor, natural gas pipeline corridor, and port would be different. However, it is anticipated that emissions and impacts from the construction, operations, and decommissioning of the project components from Alternative 2 would be similar to Alternative 1. The results of the assessment of emissions and impacts of Alternative 2 are addressed for each project component by project phase in the following sections.

4.20.4.1 Mine Site

Criteria pollutants, HAPs, and greenhouse gas (GHG) emissions from mine construction, operations, and decommissioning would be similar to those presented for Alternative 1, because the mine construction, operations, and decommissioning are the same as Alternative 1. Although modeling was not directly assessed for Alternative 2, representative near-field and far-field air quality impacts from mine construction, operations, and decommissioning would be the same as impacts predicted under Alternative 1.

4.20.4.2 Transportation Corridor

Although the total length of road and distance of the ferry route would be different under Alternative 2 versus Alternative 1, it is not anticipated that the total emissions presented for Alternative 1 would differ meaningfully from Alternative 2, and would not result in a change of the possible project impacts.

4.20.4.3 Diamond Point Port

Because construction and operations for a port at Diamond Point would be similar to Amakdedori port (Alternative 1), the criteria pollutant, HAPs, and GHG emissions from construction and operations would be consistent with those presented for Alternative 1. Maximum potential near-field effects from the operations at the port would be similar to impacts predicted under Alternative 1.

4.20.4.4 Natural Gas Pipeline Corridor

For the onshore and offshore pipeline, the emissions and impacts from the construction of the onshore and offshore pipeline would be similar to those presented in Alterative 1. Although a portion of the pipeline would not follow the road alignment, the differences in emissions based on construction changes would not be meaningfully different. The operations and decommissioning of the pipeline would be negligible, as discussed in Alternative 1.

Because the compressor station would be identical to Alternative 1, the criteria pollutant, HAPs, and GHG emissions from compressor station construction and operations would be same with those presented for Alternative 1. Maximum potential near-field effects from the compressor station operations would be the same as the impacts predicted under Alternative 1.

AMERICAN OVERSIGHT

4.20.5 Alternative 3 – North Road Only

Alternative 3 eliminates the need for ferry transportation across Iliamna Lake. The assessment of emissions and impacts of Alternative 3 are addressed for each project component by project phase in the following sections.

4.20.5.1 Mine Site

Criteria pollutants, HAPs, and GHG emissions from mine construction, operations, and decommissioning would be consistent with those presented for Alternative 1, because the mine construction, operation, and decommissioning are the same as Alternative 1. Although modeling was not directly assessed for Alternative 3, maximum potential near-field and far-field effects from mine construction, operations, and decommissioning would be the same as impacts predicted under Alternative 1.

4.20.5.2 Transportation Corridor

Alternative 3 does not include ferry transportation, because traffic and materials transport would only use roads. Relative to emissions calculated for the Alternative 1 transportation corridor construction, the increase in road construction would increase emissions, while the removal of ferry traffic and terminal construction would decrease emissions. Overall, the changes in the construction emission inventory are not anticipated to be meaningfully different from Alternative 1, and would not result in a change of the possible construction impacts. The operations and decommissioning emissions and air impacts are anticipated to be lower than Alternative 1, because the ferry terminals would not be operated and constructed.

4.20.5.3 Diamond Point Port

Because construction and operation of a port at Diamond Point would be similar to Amakdedori port (Alternative 1), the criteria pollutants, HAPs, and GHG emissions during construction and operation would be consistent with those presented for Alternative 1. Maximum potential near-field effects from the operations at the port would be similar to impacts predicted under Alternative 1.

4.20.5.4 Natural Gas Pipeline Corridor

For the onshore and offshore pipeline, the emissions and impacts from the construction of the onshore and offshore pipeline would be similar to those presented in Alterative 1. Although a portion of the pipeline would not follow the road alignment, the differences in emissions based on construction changes would not be meaningfully different. The operations and decommissioning of the pipeline would be negligible, as discussed in Alternative 1.

Because the compressor station would be identical to Alternative 1, the criteria pollutants, HAPs, and GHG emissions from compressor station during construction and operations would be the same as those for Alternative 1. Maximum potential near-field effects from the compressor station operations would be the same as the impacts predicted under Alternative 1.

4.20.6 Key Issues/Impacts Summary

Table 4.20-10 provides summary statements regarding key issues or impacts related to air quality for the project.

AMERICAN OVERSIGHT

Table 4.20-10: Summary of Key Issues for Air Quality Resources

Impact-Causing Project Component and Phase	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Construction	Direct, minimal, and localized, impacts to air quality would result from stationary, fugitive, and mobile sources. Impacts would dissipate once the construction was complete. Impacts due to air emissions would not exceed the modeled AAAQS and PSD Class II increments, and would meet regulatory standards during this phase.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Operations	Direct impacts to air quality would result from fugitive, stationary, and mobile sources. Impacts would occur through the duration of the operations phase. Impacts would comply with modeled AAAQS, and PSD Class II increments.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Decommissioning	Direct impacts to air quality would result from fugitive, stationary, and mobile sources. Impacts would dissipate after decommissioning was complete.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Transportation Corridor			
Construction	Direct, minimal, and localized, impacts to air quality would result from stationary, fugitive, and mobile sources. Impacts would dissipate once the construction was complete.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to or less than Alternative 1.
Operations	Direct impacts to air quality would result from fugitive, stationary, and mobile sources. Impacts would occur through the duration of the operations phase.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to or less than Alternative 1.

AMERICAN OVERSIGHT

Decommissioning	Direct impacts to air quality would be less than the mine site decommissioning phase.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to or less than Alternative 1.
Port Site			
Construction	Direct, minimal, and localized, impacts to air quality would result from stationary, fugitive, and mobile sources. Impacts would dissipate once the construction was complete.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Operations	Direct impacts to air quality would result from fugitive, stationary, and mobile sources. Impacts would occur through the duration of the operations phase. Impacts would comply with modeled AAAQS, and PSD Class II increments.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Decommissioning	Direct impacts to air quality would be less than the mine site decommissioning phase.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Natural Gas Pipeline			
Construction	Direct, minimal, and localized impacts to air quality would result from stationary, fugitive, and mobile sources. Impacts would dissipate once the construction was complete.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Operations	Direct impacts to air quality phase would result from fugitive, stationary, and mobile sources. Impacts would occur through the duration of the operations phase. Impacts would comply with modeled AAAQS, and PSD Class II increments.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.
Decommissioning	Direct impacts to air quality phase would be less than the mine site decommissioning phase.	The impacts are anticipated to be similar to Alternative 1.	The impacts are anticipated to be similar to Alternative 1.

4.20.7 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to impacts on air quality. Section 4.1

AMERICAN OVERSIGHT

details the past, present, and RFFAs that may impact air quality. The potential future actions are similar to the proposed project in how they impact air quality by emitting combustion-related air pollutant emissions from fuel-burning equipment; and fugitive emissions from blasting, drilling, vehicle traffic on unpaved roads, and material handling. The following RFFAs identified in Section 4.1 were carried forward in this analysis, based on their potential to impact air quality in the analysis area:

- Pebble Project buildout – develop 55 percent of the resource over the 78-year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*
- Donlin Gold

**Indicates exploration activities only.*

- Diamond Point Rock Quarry
- Alaska Stand Alone Pipeline Project
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure and Energy Projects
- Villages and Communities in/nearby the project area

All of project components would be located in remote areas of Alaska characterized as attainment/unclassified areas for air quality. Past and present actions are expected to continue, such as existing infrastructure operations, transportation modes, and energy and utility development and upgrades. RFFAs were identified in the EIS analysis area, but these would likely induce minimal cumulative changes to air quality. Relevant future actions for air quality impacts include mineral exploration and mining activities occurring in southwest Alaska; oil and gas exploration and development in Cook Inlet; surface, marine, and air transportation developments such as new roads, bridge rehabilitation, shipping and barging traffic, and port and airport improvement projects; and transmission upgrades, installations, and maintenance. The proposed Donlin Gold Mine would be situated roughly 175 miles northwest of the Pebble mine site, and the proposed Alaska LNG facility would be roughly 140 miles east of the Pebble mine site. Combined with the RFFAs mentioned above, these projects could result in some potential for effects on air quality. However, given the distance between the RFFAs and the project components, and that the RFFAs would be developed on different timelines, the potential for regional cumulative air quality effects would be minimal. Overall, the cumulative impacts to air quality from the project and the past, present, and future actions are expected to increase air emissions, including GHGs, in the region and the state.

AMERICAN OVERSIGHT

3.23 WILDLIFE VALUES

The following section provides a description of the birds, and the terrestrial and marine mammals, that are known and have a potential to occur in the project area. Wildlife currently listed as federally threatened or endangered are discussed separately in Section 3.25, Threatened and Endangered Species. This chapter is divided based on the species present in or near the various components of the three action alternatives. Project components that are similar across all alternatives (such as the mine site) are only discussed once, under Action Alternative 1 – Applicant's Proposed Alternative.

3.23.1 Action Alternative 1 – Applicant's Proposed Alternative

3.23.1.1 Mine Site

Birds

The bird species present in the proposed action include those that are protected under the Migratory Bird Treaty Act of 1918 (MBTA) (16 United States Code [U.S.C.] 703-712) and the Bald and Golden Eagle Protection Act (16 USC 668-668c). Additionally, multiple agencies, as well as non-profit organizations, have created Alaska-specific lists of bird species of conservation concern due to small or vulnerable population sizes in Alaska, restricted geographic ranges (including breeding and wintering), and decreased population trends, among other reasons. Bird species of conservation concern are species listed on at least one of the following three lists: the US Fish and Wildlife Service's (USFWS) Birds of Conservation Concern in Bird Conservation Regions (BCR) 2 (western Alaska) and BCR 4 (northwestern interior forest US portion only) (USFWS 2008); the Alaska Department of Fish and Game's (ADF&G) Wildlife Action Plan (listed as a species of greatest conservation need in southwest Alaska) (ADF&G 2015a), and Audubon Alaska's WatchList 2017-Red List of Declining Populations (Warnock 2017). Bird species of conservation concern do not receive the same level of protection as those listed under the federal Endangered Species Act (ESA), but are protected by the MBTA. Bird species of conservation concern are not specifically detailed herein, but are recognized as occurring in the mine analysis area. Lists of all bird species and their conservation status detected within the mine analysis area and transportation and natural gas pipeline corridors are located in the various Pebble Project Environmental Baseline Data Reports (ABR 2011a-e). Avian species present in the mine site are divided into groups that include raptors, waterbirds, landbirds, and shorebirds.

Historical bird surveys around the mine site include cliff-nesting raptor surveys (detailed in ABR 2011a), reconnaissance avian surveys of the mine site and surrounding areas including waterfowl surveys on the Kvichak and Naknek rivers (Smith 1991), and landbird and shorebird studies from the Iliamna Lake region (Williamson and Peyton 1962). These historical studies cannot be directly compared to the surveys conducted in the mine analysis area due to differences in survey methods, timing of surveys, habitat surveyed, geographical extent, etc. (ABR 2011a). Therefore, historical survey data are of limited use and generally not presented herein. More recently, an examination of the wildlife resources of the Nushagak River and Kvichak River watersheds conducted by Brna and Verbrugge (2013) reviewed the mammalian and avian resources in these watersheds. These data are included where appropriate.

Avian surveys for the mine site were conducted from 2004 through 2005 by ABR, Inc. The full details of the survey methods and results are located in the Pebble Project Environmental Baseline Document 2004 through 2008 Chapter 16 Wildlife and Habitat Bristol Bay Drainages

AMERICAN OVERSIGHT

(ABR 2011a). The methods and results are summarized herein for the specific project components, where applicable.

Habitat mapping and habitat-value assessments were conducted across the mine analysis area in 2004 and 2005 in an effort to better understand the biological conditions present and how they relate to avian abundance and distribution. Wildlife habitats in the mine analysis area were mapped to provide a baseline inventory of the availability of wildlife habitats for use by various wildlife species (ABR 2011a).

The mine analysis area was defined as an area 476 square kilometers, centered on the mine footprint. The area is primarily composed of alpine and unforested, upland habitats on glacial moraine deposits with three prominent river corridors in the area (North Fork Koktuli [NFK] River, South Fork Koktuli [SFK] River, and Upper Talarik Creek [UTC]). Field data on the vegetation, physiography, landforms, and surface forms were applied to assess the potential use of the mapped habitat by avian species as detailed in ABR 2011a. Habitat use for each species was qualitatively categorized into one of four value classes (high, moderate, low, or negligible value) based primarily on avian survey data specific to the mine analysis area, and habitat-use information from scientific literature (ABR 2011a). Twenty-five wildlife habitat types were mapped in the mine analysis area, with Upland Moist Dwarf Scrub and Alpine Moist Dwarf Scrub representing over 52 percent of the mine analysis area wildlife habitat types. The complete list of all avian habitat types, their plant-species composition, and their value as avian habitat are detailed in ABR 2011a. The avian habitat mapping is useful for understanding the locations where various avian species are likely to occur, and how impacts from the project are anticipated to affect the vegetation communities used by birds.

The following sections detail the specific survey methods and results for the three categories of birds (raptors, waterbirds, and landbirds and shorebirds) that breed, stage, winter, and migrate through the mine analysis area.

Raptors

Methods. Historical raptor survey data were reviewed to understand the level of field effort by previous studies; however, data are not representative because the ABR data from 2004 and 2005 are more recent and comprehensive. Aerial-based raptor studies were conducted from April to May 2004 and May to August 2005 to collect baseline data on the distribution, abundance, nesting status, and habitat use of large tree and cliff-dwelling birds of prey (and large corvids) which included: bald eagles (*Haliaeetus leucocephalus*), golden eagles (*Aquila chrysaetos*), gyrfalcon (*Falco rusticolus*), peregrine falcon (*Falco peregrinus*), rough-legged hawk (*Buteo lagopus*), northern goshawk (*Accipiter gentilis*), osprey (*Pandion haliaetus*), great horned owl (*Bubo virginianus*), and common raven (*Corvus corax*). Additional fall and winter bald eagle surveys were conducted in 2005 and 2006 to gather information on wintering bald eagles. The mine analysis area included all suitable cliff habitat and woodland tracts that could provide nesting platforms for large cliff and tree-nesting raptors. Detailed survey methods are discussed in ABR 2011a, and followed the Draft Environmental Baseline Studies, Proposed 2004 and 2005 study plans (NDM 2004, 2005).

Two helicopter aerial surveys were conducted in the mine analysis area in 2004 and 2005, with the first survey conducted prior to leaf-out of deciduous trees to identify tree-nesting species, such as northern goshawk and bald eagle. The second survey for each year was timed to coincide with peak nesting for cliff-nesting raptors, such as golden eagle, gyrfalcon, peregrine falcon, and rough-legged hawk. During 2005, additional aerial surveys were conducted during the nestling period to determine nest success and productivity. Wintering bald eagle surveys were conducted

AMERICAN OVERSIGHT

in February and November 2005 and November 2006 to determine bald eagle winter use of the mine analysis area.

Results. No raptor nests were found directly within the mine site footprint based on ABR surveys (ABR 2011a). The mine site footprint itself lacks cliffs, large trees, and other structures that could support nesting raptors. The habitat is primarily open rocky tundra surrounded by rolling hills. Habitat for most tree-nesting raptors is limited in the mine analysis area to trees along UTC and its tributaries, as well as the lower reaches of the Koktuli River. More extensive woodlands (spruce-dominated) occur in the area between Iliamna Lake, and between Upper and Lower Talarik creeks. Habitat for cliff nesting species is limited to isolated cliffs, and bluffs along riparian areas. This includes hills between the NFK and Upper SFK rivers, the eastern side of Koktuli Mountain, the eastern and southern slopes of Groundhog Mountain, and along UTC.

Of the 19 raptor species (12 day-active raptors and seven species of owl) that may occur in the mine analysis area and surrounding areas, 10 species were recorded during aerial surveys. A complete list of the detected raptor species, along with their breeding status, nest abundance, and nest productivity can be found in ABR 2011a, and is summarized herein. The most commonly detected nesting raptors were bald eagle (with the closest nest over 4 miles from the mine site footprint in the NFK), golden eagle, rough-legged hawk, and gyrfalcon (Figure 3.23-1). Not all of the nests detected were active or occupied at the time of survey, and the number of active raptor territories varied depending on prey availability. The nesting success (percentage of total nests that contained at least one live nestling at approximately 80 percent of the average age of first flight for the species during the productivity surveys) ranged from 67 percent for rough-legged hawk and golden eagle to 71 and 80 percent for bald eagle and gyrfalcon, respectively (ABR 2011a). Merlin (*Falco columbarius*), osprey, and great horned owls were detected nesting in the mine analysis area in low abundance and no peregrine falcon or northern goshawk nests were detected during surveys. Additionally, suitable nesting habitat existed for the northern harrier (*Circus hudsonius*), and short-eared owl (*Asio flammeus*); however, because both of these are ground-nesting species, it is difficult to find their nests via aerial surveys, and no nests of these species were detected. Additionally, these species exhibit variation in nest timing, nesting areas, and density in relation to prey species abundance. Therefore, while the mine site footprint lacks habitat suitable for tree- and cliff-nesting raptors, there is potential habitat for ground-nesting raptors, especially around wetland and marsh areas.

Bald eagle nests were found primarily along the lower NFK and SFK rivers, Upper and Lower Talarik creeks, along the Newhalen River, and generally were not in close proximity to the mine site (Figure 3.23-1). Cliff-nesting raptors such as golden eagles, gyrfalcons, and rough-legged hawks had nests located on cliffs much closer to the mine site along the NFK, SFK, and UTC drainages, including Groundhog Mountain and the mountains east of Frying Pan Lake (Figure 3.23-1). The closest nests of gyrfalcons and golden eagles to any component of the mine site were approximately 0.4 mile (near the bulk tailings storage cell south embankment sediment pond), and 0.8 mile away (near Frying Pan Slough water treatment plant discharge-south), respectively. Overall, two gyrfalcon nests were less than a mile from the mine site (south of the bulk tailings storage cell), and four golden eagle nests were observed in a large area between 0.8 mile to 2.5 miles from the mine site. Several rough-legged hawk nests were also in the vicinity and ranged from 1.7 to 2.5 miles from the mine site.

In summary, aerial raptor surveys in 2004 and 2005 documented nesting in the main river valleys and adjacent cliffs in the mine analysis area. Although no raptors were detected nesting directly in the mine site facilities (due to a lack of nesting structures, such as trees or cliffs), the habitat is suitable for foraging for a variety of raptor species that nest in the vicinity, including golden eagles, gyrfalcons, and rough-legged hawks.

AMERICAN OVERSIGHT

Waterbirds

The Iliamna Lake region serves as a migration route for many species of waterbirds (swans, geese, ducks, loons, shorebirds, and gulls) moving to and from the breeding grounds in western and northern Alaska (Platte and Butler 1995). The USFWS conducts aerial-based waterbird surveys annually each spring and summer as part of the North American Waterfowl Breeding Pair Survey (USFWS 2012a). In the late 1980s, the survey effort was expanded to include additional wetlands, to improve population estimates and map the distribution of several species. This expanded breeding pair survey area included the wetlands around the mine site (labeled the Bristol Bay lowlands; Platte and Butler 1995) and aerial surveys were conducted. A series of maps (USFWS 2012d) depicting the abundance and distribution of various waterbird species were created, and generally correlate to the distribution of waterbird species found during baseline surveys. Although these data are useful for understanding historical distributions of waterbird species around the mine site, the baseline data presented below are more recent, thorough, and include ground based surveys.

Important waterbird species that use the mine analysis area for breeding or staging include tundra swan (*Cygnus columbianus*), common loon (*Gavia immer*), harlequin duck (*Histrionicus histrionicus*), surf scoter (*Melanitta perspicillata*), black scoter (*Melanitta americana*), long-tailed duck (*Clangula hyemalis*), and a variety of dabbling and diving ducks (Williamson and Peyton 1962). Surveys were conducted in the mine analysis area from April to October 2004, in 2005, and in September 2006 using helicopters, fixed wing aircraft, and ground personnel to document the distribution, abundance, species composition, and habitat use of waterbird species during the breeding season (pre-nesting, nesting, molting, and brood-rearing), and during spring and fall migration. Waterbirds included species of geese, swans, ducks, loons, grebes, cormorants, cranes, shorebirds, gulls, terns, and jaegers. The complete details of the methods used for these various surveys are outlined in the Draft Environmental Baseline Studies, proposed 2004 and 2005 study plans (NDM 2004, 2005), and are summarized below.

Methods. The mine analysis area for waterbirds in 2004 and 2005 encompassed the mine site facilities plus a large buffer encompassing adjacent wetlands (Figure 3.23-2 and Figure 3.23-3). Field work was conducted from April to October 2004, April to October 2005, and September 2006. For waterbird spring and fall migration surveys, fixed-wing aircraft flew throughout suitable habitat in the mine analysis area every 7 to 10 days during spring and fall migration in 2004 and 2005. Waterfowl breeding population surveys were conducted with fixed-wing aircraft in June 2004 and May 2005. Swan nesting and productivity surveys were conducted in the mine analysis area in June 2005, May 2005, and September 2006 by aircraft. Harlequin duck pre-nesting and brood-rearing surveys were conducted by helicopter in the mine analysis area in May, July, and August 2004 and 2005. Species of loons were recorded incidentally as part of the spring and fall migration surveys and the waterbird brood-rearing surveys. A helicopter survey for nesting gulls was conducted in June 2005 in the mine analysis area. Ground surveys for brood-rearing waterbirds were conducted in July 2004 and 2005, and included a search of wetlands, ponds, and lakes in selected locations in the mine analysis area. Finally, surveys for flocks of molting waterbirds were conducted in the mine analysis area in July and August 2005. The complete details of the survey data, flight paths, data recorded, and timing of surveys are detailed in ABR 2011a.

Results. Thirty-seven species of waterbirds were observed, with 21 confirmed to breed in the mine analysis area due to the presence of a brood. A complete list of the waterbird species detected in the mine study area is not included here, but is detailed in ABR 2011a. Waterbirds used lakes and rivers throughout the mine analysis area for staging during spring and fall migration, with swans and dabbling ducks (*Anas species*) arriving late in April to early May. Many of these birds likely nested in the area. Diving duck species arrived in mid-to-late May, and staged

AMERICAN OVERSIGHT

on rivers and lakes. Some of these birds likely nested in the area, while small flocks (approximately 60 birds) were observed resting and feeding on lakes before continuing their northern migration. During fall migration, both dabbling and diving ducks were observed in the larger lakes in the mine analysis area in flocks of between 60 and 120 birds. Concentrations of birds in both spring and fall were noted in the northern half of the mine survey area from Frying Pan Lake, north to lakes in the NFK River basin. In the mine analysis area, UTC was the creek most heavily used by dabbling and diving ducks.

Nikabuna and Long lakes, and the outlets of UTC and Lower Talarik Creek are important migratory stopover locations for large flocks of waterfowl. In late April, hundreds of swans, greater white-fronted (*Anser albifrons*) and Canada geese (*Branta canadensis*), and dabbling and diving ducks staged on these lakes (Figure 3.23-2). Between August and mid-October, thousands of ducks (2,000 to 5,000 birds) staged around the Nikabuna and Long lakes, with hundreds of swans starting in early October (Figure 3.23-3). The outlets of UTC and Lower Talarik Creek at Iliamna Lake are important staging locations for swans, ducks, and gulls during spring and fall migration.

Tundra swans were common breeding birds in the mine analysis area in 2004 and 2005, with about half of the 14 nests (from 2004) and 15 nests (from 2005) found around the lakes in the NFK River drainage. Many swans returned to their same territories and nest sites in 2005 (ABR 2011a).

Harlequin ducks were common breeders in the UTC followed by the NFK and the SFK rivers. The highest numbers of broods counted by drainage were seven broods each on UTC and the NFK River, and three broods on the SFK River, totaling 71 young in 17 broods.

Common loons nested in the mine analysis area in 2004 and 2005 on Big Wiggly Lake and in 2004 on lakes east of UTC. One Pacific loon (*Gavia pacifica*) nest was found in the northern part of the NFK River drainage in 2005.

Small groups of nesting mew gulls (*Larus canus*) were found north of Frying Pan Lake (six nests) and in the NFK River drainage. A single Bonaparte's gull (*Chroicocephalus philadelphia*) brood was seen near Big Wiggly Lake in 2004.

Eighteen species of waterbird broods were recorded in the mine analysis area, with brood-rearing groups on 33 percent of the sampled lakes in 2004 (69 broods), and 26 percent in 2005 (168 broods). American wigeon, northern pintail, and scaup were the most common species seen on lakes, with red-breasted merganser (Mergus serrator), green-winged teal, and mallard broods more commonly seen on rivers. Most broods were found in lowland lakes in the central part of the NFK River drainage, in Frying Pan Lake, and in lakes in the floodplain of the lower SFK River drainage.

During the summer waterbird molting period, small flocks of ducks and numerous brood-rearing groups were observed in the mine analysis area. Flocks of 35 to 60 birds were observed on Big Wiggly Lake, Frying Pan Lake, and other large lakes adjacent to the NFK and SFK rivers. Species of scaup were the most commonly observed duck.

In summary, the mine analysis area encompasses a vast area of lowland lakes and rivers that support habitat for staging, migrating, and breeding waterbirds. The highest numbers of waterbirds pass through in late May on their northern migration, and in mid-August during fall migration. Nikabuna and Long lakes support large numbers of migrating waterbirds (primarily ducks). These lakes are approximately 20 kilometers north of the mine site facilities. The NFK River supported the greatest numbers of waterbird broods observed on ponds and lakes in the mine analysis area. The UTC supported the greatest number of waterfowl broods observed on rivers, and scaup species were the most numerous waterbirds observed during summer molt surveys.

AMERICAN OVERSIGHT

Landbirds and Shorebirds

Project baseline studies conducted in 2004 and 2005 are the most relevant source of data for landbirds and shorebirds in the mine analysis area. Various avifaunal studies have been conducted in the broader region around the mine analysis area, however; none of these studies were conducted directly in the mine site (ABR 2011a). The breeding landbird and shorebird survey mine site analysis area encompassed the mine site facilities plus a large surrounding buffer. Surveys for breeding landbirds and shorebirds were conducted in June 2004, and May and June 2005, to document the landbird and shorebird species present in the mine analysis area, their abundance, and the use of mapped habitats to provide data for the wildlife habitat mapping.

Landbirds were defined as passerines or songbirds (including species of ptarmigan, corvids, flycatchers, larks and pipits, swallows, kinglets, thrushes, warblers, sparrows and allies, and finches), and did not include any species of raptors, waterbirds, or waterfowl. Shorebirds consisted of species of plovers, sandpipers, and allies.

Methods. Surveys for breeding landbirds and shorebirds were conducted following the Draft Environmental Baseline Studies, proposed 2004 and 2005 study plans (NDM 2004, 2005). Surveys used variable circular-plot point count methods (Ralph et al. 1995; Buckland et al. 2001), which are designed primarily to detect singing male passerines defending their territories and to inventory breeding shorebirds. Prior to fieldwork, researchers used aerial photography to allocate point count locations (based on prominent photo signatures), with adequate spatial representation to sample the variety of habitats in the mine analysis area, and ensure point counts were at least 500 meters apart. Ten-minute point count surveys were conducted between 4:30 AM and 4:00 PM (but more were between 5:00 AM and 4:00 PM); point counts were accessed by helicopter and on foot. One biologist conducted each point count, and point counts were only conducted once at each location. Surveys in 2004 were conducted in June; those in 2005 were conducted at the end of May and throughout June to coincide with the peak breeding period for landbirds in southwestern Alaska. Point count locations were chosen to adequately determine the species and density of birds (using distance sampling methods), using specific habitat types (vegetation communities) that could be correlated to the wildlife habitat mapping.

Results. In 2004, 166 point count locations recorded 1,794 individual birds; in 2005, 227 point count locations recorded 2,636 birds. Including birds incidentally detected, 28 landbird species and 14 shorebird species were detected in 2004 and 2005, as detailed in ABR 2011a. Point count data were used to calculate a mean of 10.2 landbirds and 1.1 shorebirds per point count when both 2004 and 2005 data are combined. The following nine landbird species were the most abundant breeders in the mine analysis area: savannah sparrow (*Passerculus sandwichensis*), golden-crowned sparrow (*Zonotrichia atricapilla*), Wilson's warbler (*Cardellina pusilla*), orange-crowned warbler (*Vermivora celata*), common redpoll (*Acanthis flammea*), American tree sparrow (*Spizella arborea*), gray-cheeked thrush (*Catharus minimus*), fox sparrow (*Passerella iliaca*), and yellow warbler (*Setophaga petechia*). Of these species, the savannah sparrow, golden-crowned sparrow, and Wilson's warbler were the most common, constituting approximately 37 percent of the point count observations in both years. Species of larks, pipits, and swallows were less common; ptarmigan, flycatchers, corvids, and kinglets were rarely recorded.

AMERICAN OVERSIGHT

Figure 3.23-1: Raptor Nests around the Mine Site

AMERICAN OVERSIGHT

Figure 3.23-2: Staging Waterbird Locations during Spring 2005 around the Mine Site

AMERICAN OVERSIGHT

Figure 3.23-3: Staging Waterbird Locations during Fall 2005 around the Mine Site

AMERICAN OVERSIGHT

No shorebird species were considered common breeders. Six of the 14 species were the most common, and include greater yellowlegs (*Tringa melanoleuca*), Wilson's snipe (*Gallinago delicata*), least sandpiper (*Calidris minutilla*), black-bellied plover (*Pluvialis squatarola*), whimbrel (*Numenius phaeopus*), and American golden-plover (*Pluvialis dominica*).

Landbirds were recorded in 15 of the 19 wildlife-habitat types, and shorebirds were recorded in 12 wildlife-habitat types. The most productive breeding habitats in terms of bird abundance were Lowland Low and Tall Willow Scrub, Riverine Tall Alder or Willow Scrub, and Upland Moist Tall Willow Scrub. More than nine birds were observed per point count in these habitats. Most landbirds regularly used tall and low scrub habitats; most shorebirds were found in open habitats, including bogs, meadows, dwarf scrub types, and barren habitats.

Of the landbird and shorebird species that nested in the mine analysis area, gray-cheeked thrush and blackpoll warbler (*Setophaga striata*) prefer to breed in dense, tall-scrub habitats, including willows and alders (along riverine alder-willow thickets), with a thick understory of low shrubs. Breeding shorebirds such as surfbird (*Aphriza virgata*) and American golden-plover use high-elevation alpine habitats for nesting, including barren and dwarf-scrub-dominated types. The other shorebird species, such as whimbrel, Hudsonian godwit (*Limosa haemastica*), lesser yellowlegs (*Tringa flavipes*), and short-billed dowitcher (*Limnodromus griseus*), use open, wet, lowland and riverine habitats such as meadows scrub-bogs and marshes.

In summary, the majority of the mine site supports landbird species that are common in similar vegetation communities across Alaska. Shorebird species are not particularly numerous as breeding residents in the mine site.

Terrestrial Mammals

Historical terrestrial mammal surveys have been conducted in the area surrounding the mine site, including population and inventory studies by the ADF&G (ADF&G 1985; Butler 2006, 2007a, 2007b, 2008; Woolington 2006, 2007a, 2007b, and 2009). Smith (1991) conducted a broad reconnaissance survey to document the wildlife species present in the area around the mine site. Under an agreement with Cominco Alaska Exploration, ADF&G surveys focused on the area around the Pebble deposit in the early 1990s. Additional studies and analyses in recent years have been conducted as part of broad scale species inventories by the National Park Service and USFWS (Cook and MacDonald 2004a, 2004b; Brna, P.J, and L. A. Verbrugge 2013).

The mine site facilities are in the far eastern corner of Game Management Unit (GMU) 17B. Terrestrial mammal surveys for the mine site were conducted from 2004 through 2010 by ABR, Inc., for a variety of species. The full details of the survey methods and results are provided in the Pebble Project Environmental Baseline Document 2004 through 2008 Chapter 16 Wildlife and Habitat Bristol Bay Drainages (ABR 2011a). The methods and results are summarized herein for the specific project components.

To quantify the suitability of vegetation communities in the mine site as wildlife habitat, habitat mapping and habitat-value assessments were conducted across the mine analysis area in 2004 and 2005. Wildlife habitats were mapped in the mine analysis area to provide a baseline inventory of the availability of wildlife habitats for use by wildlife; specifically, for a selected set of mammal species (ABR 2011a). The mine analysis area for terrestrial mammals was defined as an area 476 square kilometers, centered on the mine footprint. The mine analysis area is primarily composed of alpine and unforested upland habitats on glacial moraine deposits, with three prominent river corridors in the area (NFK and SFK rivers and UTC). Field data on the vegetation, physiography, landforms, and surface forms were used to assess the use of the mapped habitat by 13 mammal species (see Section 16 in ABR 2011a). Habitat use for each species in each mapped habitat type was qualitatively categorized into one of four value classes (high, moderate,

AMERICAN OVERSIGHT

low, or negligible value), based primarily on wildlife survey data specific to the mine analysis area, and habitat-use information from scientific literature (ABR 2011a). Twenty-five wildlife habitat types were mapped in the mine analysis area, with Upland Moist Dwarf Scrub and Alpine Moist Dwarf Scrub representing over 52 percent of the mine analysis area wildlife habitat types. The complete list of all 25 wildlife habitat types, their plant-species composition, and their value as wildlife habitat is provided in Appendix 16.1C in ABR 2011a.

The following sections detail the specific survey methods and results for mammals that breed and migrate throughout the mine analysis area. Data from these surveys were applied to wildlife habitat mapping to understand the value of the wildlife habitat in the mine analysis area.

Large Mammals

Aerial strip-transect surveys were conducted from April to November 2004, March through December 2005, May through July and December 2006, June and July 2007, May 2009, and April 2010 to document the large mammal species present in the mine analysis area. A general bear (*Ursus species*) survey in 2009 and moose (*Alces alces*) survey in 2010 were designed to estimate the density of those species, while additional aerial surveys were intended to gather distribution, relative abundance, and general patterns of use of the analysis area. Specifically, ABR conducted the following surveys and analyses:

- Detailed analysis of ADF&G's radio telemetry data for the Mulchatna caribou (*Rangifer tarandus*) herd;
- Aerial strip-transect surveys in the mine analysis area during late winter, caribou calving, caribou post-calving, caribou rut/fall migration, and early winter;
- Aerial line-transect surveys to estimate the density of bears in the Iliamna Lake region;
- Aerial surveys of brown bears (*Ursus arctos*) along salmon-spawning streams and an examination of brown bear and gray wolf (*Canis lupus*) dens in and around the mine analysis area;
- Aerial quadrat surveys to estimate the moose population in the mine and transportation corridor analysis area; and
- Aerial survey of beaver (*Castor canadensis*) colonies throughout the mine analysis area.

Analysis of ADF&G's radio telemetry data for the Mulchatna caribou herd involved a detailed fixed-kernel analysis (a statistical method using spatial data for a defined area to estimate the relative density of use of that area by a species) of 29 years' worth of radio transmitter and satellite collar data. The data included 12,198 locations of radio-collared caribou representing a range of age and sex classes across the years. The fixed-kernel distributions for radio-collared caribou locations were analyzed using geographic information system software, with the output mapping represented by utilization-distribution contours of different-intensity colors (Rodgers et al. 2007). The high-density contour encompassed 50 percent of all collar locations, the moderate-density contour enclosed 75 percent of all collar locations, and the low-density contour enclosed 95 percent of all locations.

A series of aerial strip-transect surveys were flown to coincide with seasonal timing to detect late-winter moose and caribou distribution, spring bear locations, caribou and moose calving, caribou post-calving, bear locations along salmon streams, caribou rut, and early winter moose and caribou distribution. Surveys involved a fixed-wing aircraft at low altitude along established transects with two observers in the aircraft. The complete details of the methods for each survey type, including type of aircraft, count method, sampling method (e.g., quadrate or line/strip transects), and other pertinent details, are provided in ABR 2011a.

AMERICAN OVERSIGHT

Caribou

Caribou inhabit the Arctic and alpine tundra, as well as forested habitats throughout Alaska. At the time of Smith's reconnaissance survey in 1991 during early exploration of the area, the mine area was located within a calving and wintering area for the Mulchatna herd, and the valley where the deposit was located was in a known migration route. Between 1981 and 1988, the population of the Mulchatna caribou herd ranged from 20,000 to 60,000 caribou; from 1991 to 1993 the population expanded to 90,000 to 150,000 animals, and from 1994 and 1996 the population was 180,000 to 200,000 animals (Demma 2011). During this time, the Mulchatna caribou herd shifted their traditional calving grounds west and north. By 2008, that number decreased to around 30,000 animals (Woolington 2009); in 2012 and 2013, there were 22,809 and 18,308 caribou estimated, respectively (Barten 2015). The most recent survey data from July 2, 2014 yielded a population estimate of 26,275 caribou in the Mulchatna herd (Butler 2015). The downward trend in the Mulchatna caribou herd from historical high numbers in the 1990s is not fully understood. However, based on traditional knowledge of local elders in the region, one potential reason for the decline is that the population grew so large that the caribou herd had limited food, which led to an epidemic of hoof rot and the herd shifted their range north (Van Lanen 2018).

Analysis of telemetry data indicate that between 1993 and 2004, use of the mine area by the Mulchatna caribou herd occurred primarily during the post-calving aggregation period; and to a lesser extent, during the rut (Woolington 2003). Fixed-kernel analysis of the radio-collar data indicate that across 29 years' worth of data, the Mulchatna caribou herd has occurred in moderate to high-densities throughout the mine analysis area during spring; low-density during calving, high-density during summer and winter; and moderate density during autumn (Figure 3.23-4). Despite population declines, the herd continues to use a vast area primarily west of the mine analysis area. Although the mine analysis area does not appear to historically be a calving area, the area around the mine analysis area is used periodically, primarily in summer, by large groups of caribou. In summary, the area west and northwest of the mine site facilities (as compared to south or east) is used by the Mulchatna caribou herd to a greater degree (Figure 3.23-4).

Aerial transect surveys of the mine analysis area in 2004, 2006, and 2007 confirmed the Mulchatna caribou herd telemetry analysis in that the greatest numbers of caribou were found in the mine analysis area during the summer post-calving period (Figure 3.23-5). Incidental observations of caribou during other biological surveys for the project revealed small groups of caribou scattered throughout the mine analysis area in June 2004 and 2005. During post-calving surveys in July 2004, close to 10,000 caribou were observed in the mine analysis area moving southwest (ABR 2011a). Historical caribou trails are depicted on Figure 3.23-5 and illustrate that most of the caribou activity is located to the west of the mine site. Currently, the mine site does not appear to be used by the majority of the Mulchatna caribou herd for calving (Figure 3.23-6), but may occasionally be used by the herd during the post-calving summer period. Figure 3.23-6 depicts the density of calving areas from 1981 to 2010 based on radio-collar data.

Overall, the herd primarily occurs to the north and west of the mine site, with the mine site on the periphery of their annual range. Small groups of caribou that are likely associated with the Mulchatna caribou herd occur in the general vicinity of the mine site throughout the year based on surveys in 2004 and 2005, but not in large concentrations (ABR 2011a). Observations from locals in the eastern part of the Mulchatna caribou herd range indicate that habitat conditions are improving in formerly overgrazed areas and the population appears to be increasing (Van Lanen 2018).

Moose

AMERICAN OVERSIGHT

A moose population survey in April 2010 estimated 33 moose in the 1,178 square kilometer survey area, which corresponds to an estimated density of 0.03 moose per square kilometer (ABR 2011a). The mine site appeared to have a low density of moose; however, the population of moose may be higher in the fall and early winter, when moose use higher-elevation habitats. No moose were recorded directly in the mine site facilities footprint during the April 2010 survey, or during other surveys from 2004 through 2007. This is consistent with the habitat types and vegetation communities in the mine site, which are composed primarily of low-growing tundra plant species that are not the preferred habitat for moose. Moose were sighted in UTC and the drainages surrounding the mine site facilities footprint, which contain preferred forage and cover species.

Brown Bear

Brown bears are widespread and common in the Bristol Bay and Cook Inlet drainages, primarily because of large salmon runs that provide an abundant source of protein. Brown bears are relatively common tundra inhabitants in the mine analysis area (Figure 3.23-7)(ABR 2011a). Historical surveys by the ADF&G of the various GMUs around the mine site have yielded varying population estimates, but the focus of these surveys has been in areas not specifically related to the mine site. Therefore, those data are not included. Standardized surveys specifically for the mine site were conducted in 2009 by ABR and the ADF&G (Becker 2010). Aerial line-transect surveys flown in May 2009 used two similar analytical methods to determine the density of brown bears in the survey area surrounding the mine site, which included all of Iliamna Lake (which overlaps with the transportation and natural gas pipeline corridors). One analytical method (double-count method) resulted in a population density of 47.7 brown bears per 1,000 square kilometers (Becker 2010), and the second method (using the plane model) resulted in 58.3 brown bears per 1,000 square kilometers (ABR 2011a). Using the double-count method, the survey area contained approximately 412 brown bears. Per Becker (2010), the estimate of 47.7 brown bears per 1,000 square kilometers is a reasonable estimate given brown bear population estimates for other nearby areas. Surveys north of the Iliamna study area around Lake Clark National Park and Preserve in 1999 and 2000 (Becker 2003, Butler 2007) yielded estimates of 38.6 brown bears per 1,000 square kilometers and to the south in GMU 9C (in spring 2005 and 2006) had density estimates of 78.4 brown bears per 1,000 square kilometers (Olson and Putera 2007). Overall, brown bears were not common in the mine site footprint itself, but were distributed throughout the mine analysis area, primarily along streams and waterways.

Helicopter surveys of salmon-spawning streams around the mine site on August 18 and 19, 2004 recorded 16 brown bears located mainly 15 to 30 kilometers south and southeast of the mine site. Dense vegetation along streams limited visibility, and therefore the number of bears reported is likely under estimated. The survey area included the NFK and SFK rivers, and the mine analysis area south to Iliamna Lake and east to the Newhalen River (ABR 2011a). More recent surveys of bear use at select salmon-spawning streams from July to September 2012 utilized timelapse remote-sensor wildlife cameras positioned at one location in UTC (Figure 3.23-7). Overall, low bear activity was recorded (0.03 percent of useable photographs contained bears) with most activity in the late afternoon in July and August. No bears were recorded during September. Bears spent little time fishing at the location visible to the camera (ABR 2015a).

AMERICAN OVERSIGHT

Figure 3.23-7: Bear Observations, Den Locations, and Iliamna Lake Seal Haul-Outs around Iliamna Lake

AMERICAN OVERSIGHT

Surveys of bear dens and incidentally detected brown bear dens (during other biological surveys) from 2004 through 2006 indicated suitable denning habitat was common in the mine analysis area, and dens were generally found in low-elevation wooded sites and high-elevation scree slopes. Brown bear dens were not found in the mine site footprint.

Black Bear

Black bears (*Ursus americanus*) are uncommon in forested areas around the mine site, and tend to be more common on the eastern side of Iliamna Lake. Black bears were not observed in the mine analysis area during project wildlife surveys in 2004 through 2007 (Figure 3.23-7). During regional surveys in May 2009, which encompassed the mine analysis area and Iliamna Lake, black bears were found in more forested habitats (which are lacking in the mine analysis area) on the east side of Iliamna Lake. During the survey, which covered 1,004 20-kilometer long transects, only 18 black bear groups were observed. Given the intensive survey effort and scarcity of black bear sightings, abundance estimates were not developed. Black bears were almost absent from the study area in spring 2009 (Becker 2010).

Gray Wolf

Wolves are generalist species found and able to thrive in a wide variety of habitats, whose main prey items in the northern Bristol Bay region include moose, caribou, and beaver (Woolington 2006), and salmon seasonally, among other items. Several individual wolves were detected scattered across the mine site over multiple years, but no packs or groups of wolves were detected (ABR 2011a). Three wolf dens were found during bear den surveys and during other biological surveys (one in UTC, one at the base of Sharp Mountain, and one on the east side of the Newhalen River), but none appeared to be active (ABR 2011a).

Currently, the ADF&G has an intensive caribou management plan for the Mulchatna Caribou Herd involving wolf predation control (ADF&G 2014). The ADF&G actively removes wolves in a large portion of GMU 17B/C in the range of the Mulchatna Caribou Herd, west of Iliamna Lake, which does not overlap with the mine site.

Small Terrestrial Vertebrates

No project-specific surveys were conducted for small mammal species. Some species are managed by the ADF&G as "furbearers," which are trapped or hunted for hides, fur, or meat. Population information for these species is limited, and is provided by trapper questionnaires (Parr 2018). Table 3.23-1 lists species with their relative abundance, if known, based on trapper questionnaires for GMU 17B, where the mine site facilities are located, and for GMU 9, where the transportation and natural gas pipeline corridors exist (west of Cook Inlet)(Parr 2018).

Table 3.23-1: Furbearer Species Status

Common Name	Scientific Name	General Habitat	Mine Site (GMU 17B[1])	Transportation and Natural Gas Pipeline Corridors (west of Cook Inlet; GMU 9A/B[1])
Coyote	*Canis latrans*	Diverse	scarce	scarce
Red fox	*Vulpes vulpes*	Diverse	abundant	abundant
Arctic fox	*Vulpes lagopus*	Tundra/grassland	not present	scarce
Canadian lynx	*Lynx canadensis*	Forests and shrubs	scarce	common

AMERICAN OVERSIGHT

Table 3.23-1: Furbearer Species Status

Common Name	Scientific Name	General Habitat	Mine Site (GMU 17B[1])	Transportation and Natural Gas Pipeline Corridors (west of Cook Inlet; GMU 9A/B[1])
American marten	*Martes americana*	Conifer and mixed forests	abundant	scarce
American mink	*Mustela vison*	Mixed forests	common	common
Ermine	*Mustela erminea*	Diverse	common	common
River otter	*Lutra canadensis*	Riparian	abundant	common
Wolverine	*Gulo gulo*	Diverse	common	scarce

Muskrat	*Ondatra zibethicus*	Wetlands	common	common
Red squirrel	*Tamiasciurus hudsonicus*	Forests	common	abundant

[1]Source: Parr 2018

Of the fur-bearers listed above, only two coyotes were observed in the mine analysis area; however, red foxes were more common, and were observed on numerous occasions. Two groups of river otters were detected in the mine analysis area in 2005, and two wolverines were incidentally detected in the mine analysis area during avian surveys in 2004 and 2005. Aerial surveys for beaver colonies were conducted in October 2005, and recorded 113 active colonies in the mine analysis area. Active colonies were also found along UTC, and in both NFK and SFK rivers, as well as isolated tundra ponds. The locations of these species in relation to the mine site are shown on figures in ABR 2011a.

There are additional mammal species that are not considered "furbearers," and are known to occur in the mine analysis area. These include hoary marmot (*Marmota caligata*), arctic ground squirrel (*Spermophilus parryii*), snowshoe hare (*Lepus americanus*), tundra hare (*Lepus othus*), collared pika (*Ochotona collaris*), and various species of mice, lemmings, shrews, and voles. These species are generally common to abundant, depending on their population cycles.

Wood Frog

The wood frog is the most widely distributed amphibian in Alaska, ranging from the mainland of southeast Alaska north to the Brooks Range, and is the sole amphibian found north of Prince William Sound (ADF&G 2015b). Wood frogs breed virtually anywhere that has standing water for at least part of the summer, including ponds, bogs, marshes, temporary pools, tire tracks, or roadside ditches. However, specific studies have shown that the highest breeding activity is in waters from about 1 to 7 feet deep (ABR 2011a). The waterbodies must remain long enough for the tadpoles to mature and metamorphose. Another important habitat factor is vegetation nearby for hibernating (typically forest vegetation with enough dead leaves and duff covering the ground to form suitable hibernating sites).

The ADF&G has a wood frog monitoring program, with the goal of assessing the current status of wood frogs in Alaska (ADF&G 2018). Therefore, wood frog studies were conducted in 2007 by ABR to determine their occupancy and distribution in the mine site, as detailed below.

Occupancy surveys for wood frogs were conducted in the mine analysis area in 2007 to determine their distribution and rate of occupancy for waterbodies in the mine analysis area, and to describe the important habitat characteristics associated with breeding waterbodies. ABR conducted

AMERICAN OVERSIGHT

ground-based surveys in May 2007, in which 119 randomly selected waterbodies (out of 1,668 potential waterbodies) were sampled for wood frogs. Surveys were conducted by passive listening for vocalizing male wood frogs from these preselected waterbodies at locations spaced around each waterbody following standard amphibian-calling survey protocols, with slight modifications for time of day (USGS 2005). The sampling design involved a repeat survey for each waterbody (2 to 4 days apart) during peak breeding.

Wood frogs were detected at waterbodies throughout the mine analysis area, and the occupancy rate of wood frogs breeding in the mine analysis area was estimated at approximately 50 percent (ABR 2011a). In the mine site facilities, several waterbodies contained wood frogs. Deep waterbodies, greater than 1.5 meters deep, were 10 times more likely to be occupied by wood frogs than waterbodies less than 1.5 meters. Wood frogs seemed to prefer waterbodies with herbaceous, low shrub shoreline vegetation and aquatic vegetation.

3.23.1.2 Transportation Corridor and Natural Gas Pipeline Corridor

Terrestrial wildlife resources along the transportation and natural gas pipeline corridors from the mine site to Amakdedori port are described below. The portion of the natural gas pipeline corridor that occurs on the Kenai Peninsula would be trenched into the ground (via horizontal directional drilling), tie into an existing pipeline near Anchor Point, and connect to a compressor station built on private land.

The portion of the transportation and natural gas pipeline corridors from the mine site south to the north ferry terminal (mine access road) was previously surveyed as part of the mine analysis area. The methods used for biological surveys for this portion of the transportation and natural gas pipeline corridors are the same methods used for the mine analysis area, and are not repeated in the individual sections below. Only specific results that relate to the portion of the Iliamna spur road and mine access road are discussed.

Birds

In general, many of the same species that were documented in the mine analysis area also occur along the transportation and natural gas pipeline corridors. The main difference is that portions of the corridor on the north side of Iliamna Lake and south of the mine site tend to lack the high-elevation alpine tundra habitats that characterize the mine site, and the corridor includes a greater portion of lowland marsh, meadows, scrub, and boreal forest habitat types. This is reflected in a transition of avian species where obligate-tundra nesting species are less common, and species that prefer more scrub and forested habitat types are more common, as detailed in the following sections. However, the portion of the corridor from Kokhanok to Amakdedori port (south access road) is similar in habitat types and vegetation communities to the mine site.

Raptors

Raptor data for the transportation corridor and natural gas pipeline corridor along the mine access road and Iliamna spur road were collected by ABR in 2004 and 2005 (ABR 2011a). The methods are the same as those detailed above, for the mine analysis area, and are not repeated here. Raptor data along the mine access road are included in the mine site section, above, and shown on Figure 3.23-1. The main species documented along the mine access road include bald eagles along UTC, osprey, and cliff nesting raptors such as gyrfalcons and rough-legged hawks. Based on surveys in 2004 and 2005, bald eagles were the main raptor species nesting in trees along the Newhalen River. On the hills and bluffs to the west of the Newhalen River were several cliff-nesting species, including golden eagle, gyrfalcon, rough-legged hawk, and common ravens (Figure 3.23-1).

AMERICAN OVERSIGHT

Based on project-specific raptor surveys conducted in summer 2018 for areas south of Iliamna Lake, from the south ferry terminal to the Amakdedori port along the south access road, bald eagles were the most commonly detected nesting raptor species followed by golden eagles (Figure 3.23-8). Overall, there were few nests along the south access road due to a lack of large trees and limited cliff habitat. Several nests were located on the north and south sides of Gibraltar Lake with additional nests clustered along the coastal bluff around Cook Inlet. The closest golden eagle nest is approximately 0.2 miles north of the south access road near one of the proposed material sites. The nest was not active in 2018, but may be active in the future. Overall, most nests were located over 0.5 miles away from the south access road.

Waterbirds

No project-specific waterbird surveys have been conducted to date for areas south of Iliamna Lake. All waterbird data north of Iliamna Lake were collected in 2004 and 2005, and are described above. This section details waterbird distribution and abundance along the Newhalen River near the Iliamna spur road, based on surveys conducted by ABR in 2004 and 2005 (ABR 2011a). Timing of waterbird migration in spring and fall was similar to the mine analysis area, with similar species detected. During spring, the highest concentrations of swans, geese, and ducks were found in an area of the Newhalen River known as Three-mile Lake (Figure 3.23-2). During fall migration, concentrations of waterbirds occurred at many of the same locations as in spring (Figure 3.23-3). No groups of swans or geese were observed staging in the area during fall, only brood-rearing groups and adult swans as singles and pairs. Thousands of ducks and gulls were recorded during fall surveys, with duck abundance remaining high from mid-August to mid-October, and gull abundance peaking in mid-to late September. The northern part of Iliamna Lake (near creek outflows) also supports large concentrations of staging and migrating waterbirds. Waterfowl breeding density was estimated at 12.2 birds per square kilometer in 2004, and 6.8 birds per square kilometer in 2005.

Several tundra swan nests (four nests in 2004 and two in 2005) were observed around the Newhalen River, but primarily on the east side in the greater floodplain area of the river.

A few pairs of harlequin ducks were found along the Newhalen River during pre-nesting surveys, along with a few broods later in the season.

Several common loon broods were detected in lakes in the floodplain of the Newhalen River, with adult birds on several lakes in the vicinity. They were found on large, deep lakes from early May to late September in 2004 and 2005. No Pacific or red-throated loon (*Gavia stellata*) nests or broods were observed.

In summary, the transportation and natural gas pipeline corridors north of Iliamna Lake do not overlap any areas where large concentrations of waterbirds breed or stage. The Iliamna spur road crosses the Newhalen River several miles south of Three-mile Lake, where the majority of waterbirds are located. The northern part of Iliamna Lake (near creek outflows) also supports large concentrations of staging and migrating waterbirds. Waterfowl breeding density was estimated at 12.2 birds per square kilometer in 2004, and 6.8 birds per square kilometer in 2005.

[Note: 2018 field data for the south access road will be incorporated into the analysis of the Draft EIS.]

AMERICAN OVERSIGHT

Figure 3.23-8: Raptor Nests around the South Access Road and Amakdedori Port

AMERICAN OVERSIGHT

Landbirds and Shorebirds

Landbird and shorebird surveys were conducted in 2005 for the Alternative 2 transportation corridor, but a small portion of this corridor overlaps with the proposed corridor where the Iliamna spur road connects to the existing road heading south to the town of Iliamna. The point count survey methods for conducting landbird and shorebird surveys are detailed above. The analysis area for the transportation corridor in 2005 was 610 meters wide, and stretched from the mine site along the north side of Iliamna Lake to the Cook Inlet. Only the portion that overlaps with the Iliamna spur road is discussed here. In this section of the analysis area, 15 point counts (all located around the Newhalen River) were conducted in June 2005. Additional point counts were located on the east side of the Newhalen River near the base of Roadhouse Mountain, but these were considered to be outside of the proposed transportation and natural gas pipeline corridors. The wildlife habitats east of the mine site in the transportation and natural gas pipeline corridors include a large percentage of Upland and Lowland Spruce and Moist Mixed Forest. These wildlife habitats support a slightly different assemblage of bird species that are more dependent on forested habitats. Ten landbird species were considered the most abundant in the area, and include Wilson's warbler, orange-crowed warbler, Swainson's thrush (*Catharus ustulatus*), yellow-rumped warbler (*Setophaga coronata*), golden crowned sparrow, dark-eyed junco (*Junco hyemalis*), ruby-crowned kinglet (*Regulus calendula*), American robin (*Turdus migratorius*), varied thrush (*Ixoreus naevius*), and hermit thrush (*Catharus guttatus*); with Wilson's warbler, orange-crowned warbler, and Swainson's thrush being the most abundant. The two most frequently observed common breeding shorebirds were greater yellowlegs and Wilson's snipe. Upland and Lowland Moist Mixed Forest, Upland and Lowland Spruce Forest, and Riverine Moist Mixed Forest had the highest numbers of breeding landbird and shorebird species.

The vegetation around the south ferry terminal and around Kokhanok is similar to the vegetation along the Iliamna spur road, and includes scattered sections of forest interspersed with types of low and tall shrubs. Therefore, avian species are anticipated to be similar to birds found on the north side of Iliamna Lake. However, a large portion of the south access road south of Kokhanok consists of rocky terrain with low growing tundra vegetation interspersed with small ponds. This habitat is similar to the montane areas of Katmai National Park and Preserve; from 2004 to 2006 the National Park Service conducted an inventory and monitoring program to document bird species in montane regions of Katmai National Park and Preserve and Lake Clark National Park and Preserve (Ruthrauff et al. 2007). Both Katmai and the south access road are in the Alaska Peninsula ecoregion and their habitat similarities indicate that species are likely to be similar between the two locations. From late May to early June 2004 through 2006, biologists conducted avian counts at sample plots across both national parks. The most commonly detected species were golden-crowned sparrow, fox sparrow, and American pipit (*Anthus rubescens*). High elevation sites (those most similar to the south access road) were composed of a high percentage cover of dwarf shrub and bare ground habitat. This type of habitat supported species such as rock ptarmigan (*Lagopus muta*), American golden-plover, wandering tattler (*Tringa incana*), surfbird (*Aphriza virgata*), and snow bunting (*Plectrophenax nivalis*). Therefore, the south access road is anticipated to contain a similar list of bird species, several of which are species of conservation concern.

The natural gas pipeline corridor traverses lower Cook Inlet, which is an important nesting, wintering, molting, and migrating area for a variety of seabirds. The most recent seabird surveys were conducted by the Bureau of Ocean Energy Management from 2012 through 2016 to document the seasonality of seabird distribution in lower Cook Inlet (Renner et al. 2017). Surveys were conducted from a boat traveling established transects at different times of the year across lower Cook Inlet. Overall, the total marine bird densities were high in winter, spring, and summer and half as abundant during the fall. Densities were higher on the east side of Cook Inlet,

AMERICAN OVERSIGHT
EPA-0135-0003126

especially in the shallow waters close to shore. The most common species were white-winged scoter (*Melanitta deglandi*); common murre (*Uria aalge*), observed year-round; black-legged kittiwake (*Rissa tridactyla*) observed in summer; red-necked phalarope (*Phalaropus lobatus*), observed in spring); and sooty shearwater (*Ardenna grisea*), observed in summer and fall. White-winged scoter was the most abundant marine bird across all seasons, with the highest numbers during winter. High concentrations were located north of Augustine Island near Ursus Cove in Kamishak Bay (Renner et al. 2017).

Several of the species detected in the transportation corridor are considered conservation species for Alaska, and were also detected in the mine analysis area. A list of all species of conservation concern for Alaska that were detected in the transportation and natural gas pipeline corridors are included in the Pebble Project Environmental Baseline Data Reports (ABR 2011a-e). Species only detected in the transportation and natural gas pipeline corridors include black-backed woodpecker (*Picoides arcticus*), olive-sided flycatcher (*Contopus cooperi*), varied thrush, rusty blackbird (*Euphagus carolinus*), and solitary sandpiper (*Tringa solitaria*). These species are associated with coniferous-forested habitats, which are generally lacking in the mine analysis area. Black-backed woodpecker, olive-sided flycatcher, rusty blackbird, and solitary sandpiper were detected in very low densities in appropriate habitat for these species.

[Note: 2018 field data for the south access road will be incorporated into the analysis of the DEIS.]

Terrestrial Mammals

Baseline surveys conducted in the mine site analysis area considerably overlap the transportation and natural gas pipeline corridors' analysis areas, which were discussed previously above. The transportation and natural gas pipeline corridors, including the mine access road, Iliamna spur road, and the northern two-thirds of the south access road, are in GMU 9B. The southern third of the south access road is in GMU 9A. The portion of the natural gas pipeline corridor on the Kenai Peninsula is in GMU 15C. Since the natural gas pipeline would connect below ground to existing infrastructure on the Kenai Peninsula, a discussion of terrestrial mammals on the Kenai Peninsula is not included here. The methods used for biological surveys for this portion of the transportation and natural gas pipeline corridors are the same methods used for the mine analysis area, and are not repeated in the individual sections below. Only specific results that relate to the portion of the Iliamna spur road and mine access road are discussed.

The general vegetation types along the transportation and natural gas pipeline corridors consist of spruce forest and mixed-species forest. This change in vegetation from an open landscape in the mine site to a more closed, forest-dominated landscape in the corridor is reflected in the species type and abundance, as detailed in the following sections.

Large Mammals

The majority of the Mulchatna caribou herd does not typically range in the area of the transportation and natural gas pipeline corridors (Figure 3.23-6). They tend to occur farther north and west, and the 29 years' worth of telemetry data that were analyzed found few instances of caribou in the area covered by the transportation and natural gas pipeline corridors. The Northern Alaska Peninsula caribou herd occurs in GMUs 9E and 9C, with the northern extent of their current range approximately 70 miles south of the transportation and natural gas pipeline corridor around Naknek Lake (ADF&G 2015). The population of the Northern Alaska Peninsula caribou herd is approximately 2,700 individuals (ADF&G 2015) and it is possible that the herd may expand their range north in the future. While there are no designated herds that regularly use the transportation and natural gas pipeline corridor as part of their home range, there are isolated groups of caribou that use the area. Some of these groups may be associated with the Mulchatna caribou herd.

AMERICAN OVERSIGHT

According to the ADF&G, there are localized herds that inhabit parts of the transportation and natural gas pipeline corridors, such as a herd in the area south and east of Kokhanok, in the higher country around Kukaklek and Nonvianuk lakes, and east to the Kamishak Bay coast (ADF&G pers comm 2018). Surveys conducted during the summer of 2018 along the south access road documented a few individual caribou (usually one or two caribou, with one group of four individuals) between Iliamna Lake and the port, but no large groups were detected.

Brown bear density estimates from the bear population survey in May 2009 ranged from 47.7 to 58.3 brown bears per 1,000 square kilometers (Becker 2010). The area covered by the survey included the southern portion of GMU 9B, plus a small section of the eastern part of GMU 17B. All but one of the black bear sightings occurred east of Nondalton and north of Kokhanok. Therefore, black bears appear to be more closely tied to forested environments, with brown bears occurring in more open terrain and around salmon streams during periods of salmon spawning. Specific to the transportation and natural gas pipeline corridors, brown bears were concentrated around the northern portion of Katmai National Park and Preserve, south of Gibraltar Lake (Becker 2010).

Surveys conducted by the National Park Service in May 2003 using an aerial line-transect double-count technique estimated that in GMU 9A the brown bear density was 150 bears per 1,000 square kilometers with a standard error of +/- 28 bears, and for black bears the density was 85 +/- 20 bears per 1,000 square kilometers. This corresponds to a population of 703 +/- 134 brown bears and 413 +/- 62 black bears in GMU 9A (Olson and Putera 2007). No surveys were conducted in 2003 to determine a density estimate for GMU 9B. The aerial surveys by Becker (2010) included GMU 9B; therefore, in conjunction with the National Park Service survey in 2003 (Olson and Putera 2007) for GMU 9A, the entire transportation and natural gas pipeline corridors have had bear surveys conducted. Overall, brown bears were more common along the coast and around the southern part of Iliamna Lake, with black bears more common to the east of Iliamna Lake and areas adjacent to Lake Clark National Park and Preserve.

Surveys conducted in May 2018 documented a concentration of brown bear dens on both sides of the south access road and around Amakdedori port (Figure 3.23-7). Surveys documented bear dens throughout the length of the south access road, with the majority observed near Cook Inlet north of Amakdedori Creek. Additional dens were located around the outflow to Gibraltar Lake near the south shore of Iliamna Lake. Several of the dens were close to the south access road, with the closest one around 300 feet north of the road. Additional surveys for bears around salmon streams were conducted in mid-August 2018. Bears were primarily located near the south shore of Iliamna Lake, at the east end of Gibraltar Lake, and fishing in the river flowing into Bruin Bay, with a few individuals upstream in Amakdedori Creek.

The moose density was estimated at 0.05 moose per square kilometer, based on data from the April 2010 aerial survey (ABR 2011a). Moose were more heavily concentrated in river drainages, due to the presence of suitable forage. Per ADF&G area management biologist Dave Crowley, for GMUs 9 and 10, there are approximately 0.19 moose per square kilometer or less for most of the Alaska Peninsula due to limited habitat (Lill 2017). Generally, the habitat along the south mine access road is rocky substrate covered in low-growing tundra plant species. Therefore, moose densities are generally low along the south mine access road with moose limited to river valleys and drainages with appropriate forage and cover. Surveys in summer 2018 documented very low numbers of moose along the south access road, primarily in drainages on the south side of Iliamna Lake.

Multiple beaver colonies were detected on the western side of the Newhalen River, but were generally absent from the south access road.

AMERICAN OVERSIGHT

In summary, the transportation and natural gas pipeline corridors contain more suitable caribou and brown bear habitat compared to habitat for moose and black bears.

Small Terrestrial Vertebrates

Although no specific small mammal surveys were conducted for the project, Table 3.23-1 details the general abundance of furbearers in GMU 9A and 9B, based on the results of trapper questionnaires from 2013 (Parr 2018). Many of the same species have abundance similar to the mine site. Some of the main differences are that lynx are considered common, and American martins and wolverines are considered scarce in GMUs 9A and 9B. Additional non-furbearer small mammal species occur in the transportation and natural gas pipeline corridors, including species of hares, squirrels, mice, lemmings, voles, and others previously mentioned under the mine site.

Other mammal species were incidentally detected during surveys conducted by ABR, and included red fox and river otter around the mouth of the Newhalen River (ABR 2011a). During surveys conducted in summer 2018, both red fox and wolverine were detected.

Surveys for wood frogs were not conducted; however, the species is anticipated to occur throughout the region in freshwater ponds, lakes, streams, and adjacent wetland vegetation.

3.23.1.3 Amakdedori Port

Birds

Existing data for avian surveys conducted in lower Cook Inlet, along with vegetation community mapping and aerial imagery, were used to describe the avian community around the Amakdedori port. Surveys around Amakdedori port were conducted in 2018 by ABR and the results are still being summarized. Therefore, only preliminary results are provided, where possible.

Raptors

The area immediately adjacent to Amakdedori port does not support habitat for tree-nesting raptors due to a lack of large trees to support bald eagle nests. Coastal bluffs to the north and south of the port support nesting bald eagles. These nests are approximately 0.6 and 0.7 miles north and south of the port, respectively (Figure 3.23-8). Both nests successfully raised one young eagle in 2018.

Waterbirds

The terrestrial habitat around the Amakdedori port generally lacks large waterbodies where waterbirds may breed and stage. Habitat is composed primarily of upland vegetation communities that drain east toward Cook Inlet and do not form extensive wetland areas. The port location itself does not contain rocky outcrops, crags, or other features along the water's edge that may support nesting seabirds.

The marine portion of the Amakdedori port is in Kamishak Bay, a globally important bird area (IBA) located along the Pacific Flyway. Kamishak Bay was designated by the National Audubon Society as an IBA due to large numbers (i.e., over 9,000) of breeding glaucous-winged gulls (National Audubon Society 2013a; Smith et al. 2012). In Kamishak Bay, there are two colony IBAs: Amakdedulia Cove Colony and Contact Point Colony (Smith et al. 2012; National Audubon Society 2014). Amakdedulia Cove is just south of the proposed port location in Kamishak Bay and supports 1 percent of a sub-species of double-crested cormorant (*Phalacrocorax auritus*), small numbers of glaucous-winged gulls (*Larus glaucescens*), tufted puffins (*Fratercula cirrhata*), and large numbers (i.e., 105 birds per square kilometer) of seaducks (National Audubon Society

AMERICAN OVERSIGHT

2013b). North of the proposed port location is another IBA known as Contact Point, which forms the southeastern border of Bruin Bay. A large seabird nesting colony exists here and includes over 1,000 seabirds of several species, including red-faced cormorants (*Phalacrocorax urile*), pelagic cormorants (*Phalacrocorax pelagicus*), common murres (*Uria aalge*), pigeon guillemots (*Cepphus columba*), tufted puffins, and horned puffins (*Fratercula corniculata*). Large numbers (i.e., 54 birds per square kilometer) of seaducks raft in the nearby waters (National Audubon Society 2013c). Therefore, although the Amakdedori port footprint may not support large numbers of breeding waterbirds, it is flanked by two nearby IBAs, and is situated in a global IBA (Smith et al. 2017).

Additionally, Kamishak Bay is an important molting and wintering location for a variety of waterbirds, including the federally threatened Steller's eider (*Polysticta stelleri*)(discussed in detail in Section 3.25), and merganser and scoter species (Larned 2005). In Kamishak Bay, the area around the Douglas River Delta (a series of shoals, reefs, and islands at the mouth of the Douglas River), which are approximately 15 to 20 miles south of the port location, is the primary location where waterbirds congregate in the winter.

[Note: 2018 field data for the Amakdedori port is being synthesized and will be provided in a later EIS draft]

Landbirds and Shorebirds

The main landbird and shorebird species at the Amakdedori port is similar to species that breed in various shrub habitats in the mine site (listed above), including species of sparrows, warblers, and flycatchers. The main difference is the potential for wintering rock sandpipers (*Calidris ptilocnemis*) to use the mudflats at the Amakdedori port for foraging during the winter. Rock sandpipers that spend the winter along the shores of Cook Inlet are the northernmost wintering shorebird species in the Pacific Basin (Ruthrauff et al. 2013). They often gather in large flocks numbering in the thousands during the winter, and forage on a variety of bivalve species depending on shore ice accumulation. Although rock sandpipers generally winter in a few locations in upper Cook Inlet, during periods of extreme cold, they shift their distribution to more southerly locations in the inlet (Ruthrauff et al. 2013). The subspecies of rock sandpiper that typically winters in Cook Inlet is the sensitive *Calidris ptilocnemis ptilocnemis* (Ruthrauff et al. 2013). Data from the citizen science project, eBird, have documented rock sandpipers in Amakdedulia Cove and Kamishak Bay in September and early October, and early March and late April (eBird 2018). Numbers range from several individuals to several hundred birds, and there is likely great fluctuation in numbers throughout the fall, winter, and spring.

Additional avian species that use the area around the Amakdedori port likely include a variety of shorebird species that may rest, forage, stage, and then continue migration. One historical survey conducted across four seasons in 1976 documented roughly 20,000 shorebirds using the embayments along the west side of lower Cook Inlet, of which 80 percent occurred during spring (Erickson 1977 as cited in Gill and Tibbits 1999). Surveys conducted each spring between 1994 and 1996 documented 86,000 to 122,000 shorebirds using Tuxedni and Chinitna Bays (Bennett 1996). Therefore, the Cook Inlet provides important migratory and breeding habitat for a variety of shorebird species. Surveys conducted from February 1997 to February 1999 in upper Cook Inlet from Susitna Flats south to Tuxedni Bay (approximately 80 miles north of Amakdedori port) confirmed that the Cook Inlet is important migratory bird habitat (Gill and Tibbits 1999). Twenty-eight species of shorebirds were recorded using the area, with a rapid increase in numbers of birds during early May, followed by an abrupt departure in mid-to-late May. During this time, the total number of birds frequently exceeded 150,000 birds per day with western sandpiper (*Calidris mauri*) accounting for three-fourths of all birds recorded (Gill and Tibbits 1999). Approximately 20 to 47 percent of the Pacific Flyway population of western sandpipers used Cook Inlet

AMERICAN OVERSIGHT

embayments, especially southern Redoubt Bay (approximately 100 miles north of Amakdedori port). Cook Inlet also supported approximately 11 to 21 percent of the population of dunlin (*Calidris alpina*), which travel in the Pacific Flyway. The main areas along the west side of Cook Inlet that provided critical shorebird habitat included southern Redoubt Bay (an average of 32,000 birds per day during spring) and Susitna Flats (8,400 rock sandpipers per day during winter)(Gill and Tibbits 1999). Therefore, the intertidal habitats and coastline around Amakdedori port likely provide critical shorebird migration habitat and support winter habitat for rock sandpipers.

[Note: 2018 field data for the Amakdedori port is being synthesized and will be provided in a later EIS draft]

Terrestrial Mammals

The Amakdedori port would be located in GMU 9A, on the northern side of Amakdedori Creek. Primary vegetation communities are shrub-dominated, with small, isolated wetlands. Amakdedori Creek is an anadromous creek surrounded by shrubs; the creek supports brown bears, moose, and other wildlife. Information previously provided for the transportation and natural gas pipeline corridors encompasses the Amakdedori port; only new information specific to the port is provided below. The most recent surveys around Amakdedori port were conducted in summer 2018. These surveys included aerial surveys for a host of terrestrial mammals including searching for bear dens and conducting aerial surveys of bears at salmon-spawning streams and along the coast. These data are being compiled and only preliminary results are included here. These results are detailed above under the transportation and natural gas pipeline corridors, and generally not repeated here.

Large Mammals

Large mammal species around the port are similar to those in the mine site, including caribou, brown and black bear, and moose. While the primary range of the Mulchatna caribou herd does not extend to the Cook Inlet based on 29 years' worth of radio-telemetry data, there may still be groups of caribou that occasionally move through the area (Figure 3.23-6). In 2018, the ADF&G observed caribou at Chenik Lake, about 5.5 miles south of the proposed Amakdedori port site (ADF&G pers comm 2018). The current range of the Northern Alaska Peninsula herd is approximately 70 miles south of the Amakdedori port site around Naknek Lake (Demma 2011, ADF&G 2015). Additional scattered individual caribou were observed in 2018 between 3 and 5 miles west of Amakdedori port.

As detailed in Section 3.24, sockeye and pink salmon are abundant in Amakdedori Creek near the port. Amakdedori port would be north of the McNeil River State Game Refuge and Sanctuary, which is a world-famous brown bear viewing location. During bear surveys in May 2009 for the mine site, black bears were more commonly documented east of Iliamna Lake and in some areas near the Cook Inlet. Brown bears were also common on the southern side of Iliamna Lake near Gibraltar Lake. Surveys for bears around salmon-spawning streams in summer 2018 documented a few brown bears fishing upstream in Amakdedori Creek, approximately 1 to 1.5 miles west of the port (Figure 3.23-7).

Moose are anticipated to occasionally occur in low and or tall willow scrub habitat in uplands, lowland, and riverine settings around the port. However, no moose were detected around the proposed Amakdedori port site during surveys in summer 2018, likely due to the presence of brown bears in the area.

Two gray wolves were incidentally detected at the Amakdedori port site during summer 2018 surveys during aerial bear surveys at salmon streams.

AMERICAN OVERSIGHT

Small Terrestrial Vertebrates

The same small mammal species and furbearers listed in Table 3.23-1 would be anticipated to occur around the Amakdedori port, but in proportion to their respective habitats. Additionally, wood frogs would be expected to occur in freshwater ponds around Amakdedori port, although specific surveys have not been conducted at this location.

Marine Mammals

[Note: the marine mammal section will be updated with 2018 marine mammal baseline survey data for the Draft EIS.]

This section addresses non-ESA whales, porpoises, and seals that may occur in the Cook Inlet project area, which includes the Amakdedori port and the natural gas pipeline corridor project components.

The Marine Mammal Protection Act (MMPA)(16 U.S.C. 1361 et seq.) mandates management of marine mammal population stocks and was enacted in 1972 to prevent the decline of marine mammal species and populations. The MMPA specifically prohibits the "taking" of marine mammals in US waters and by US citizens on the high seas, and the importation of marine mammals and marine mammal products into the US. As defined under the MMPA, “take” means, “to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal.” The MMPA defines “harassment” as, “any act of pursuit, torment, or annoyance which (i) has the potential to injure a marine mammal or marine mammal stock in the wild [Level A harassment]; or (ii) has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering [Level B harassment].” The MMPA provides exceptions for subsistence uses by Alaska Natives and authorized (i.e., permitted) scientific research. Also allowed, through a permit application process, is the "incidental," but not intentional, taking of small numbers of marine mammals by US citizens who engage in a specified activity (other than commercial fishing).

Implementation of the MMPA is shared between the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NMFS) and the Department of the Interior's USFWS, with NMFS managing whales, dolphins, porpoise, seals and sea lions and the USFWS responsible for the sea otters. Additional information on ESA species potentially found in the project area can be found in Section 3.25, Threatened and Endangered Species.

Under Section 3 of the MMPA, the “…term ‘population stock’ or ‘stock’ means a group of marine mammals of the same species, or smaller taxa in a common spatial arrangement, that interbreed when mature” (16 U.S.C. § 1362 (11)). “Population stock” (usually referred to simply as “stock”) designations of many groups of marine mammals have changed over the past decade, in large part due to focused efforts to define the stocks coupled with the availability of relatively new tools from molecular genetics. In the cases of marine mammals for which separate stocks have been delineated, the description and evaluation of potential effects on those stocks is focused on those that may occur in the Cook Inlet project area. However, information on the biological species as a whole is included if it enhances the understanding of the relevant stock(s) or aids in evaluation of the significance of any potential effects on the stock that occurs in or near the program area.

Gray Whale

There are two recognized stocks of gray whales (*Eschrichtius robustus*): the Eastern North Pacific (ENP) and Western North Pacific (WNP). The ENP gray whale stock range includes the project area.

AMERICAN OVERSIGHT

The ENP stock has been reported feeding along the Pacific Coast during their annual northern summer migration in waters off of southeastern Alaska, British Columbia, Washington, Oregon, and California. Northward migration, primarily of individuals without calves, begins in February; some cow/calf pairs delay their departure from the calving area until well into April (Muto et al. 2017).

Generally, gray whales arrive in the Gulf of Alaska between March and June, and typically depart in November and December (Consiglieri et al. 1982). Most of the population follows the outer coast of the Kodiak Archipelago to the Kenai Peninsula in spring or the Alaska Peninsula in fall (Consiglieri et al. 1982). This annual migration takes them past the mouth of Cook Inlet to northern feeding grounds in the Bering and Chukchi seas. Although most gray whales migrate past Cook Inlet on their way north, small numbers have been reported near Kachemak Bay, roughly 80 miles from the proposed Cook Inlet project area (USDOI BOEM 2015). During NMFS aerial surveys in Cook Inlet, gray whales were observed in June in 1994, 2000, 2001, 2005, and 2009 on the western side in Kamishak Bay (Shelden et al. 2013) near the project area.

Minke Whale

Minke whales (*Balaenoptera acutorostrata*) are most abundant in the Gulf of Alaska during summer where they occupy localized feeding areas (Zerbini et al. 2006). Minke whales become scarce in the Gulf of Alaska in fall; most whales are thought to leave the region by October. The current estimate for minke whales between Kenai Fjords and the Aleutian Islands is 1,233 individuals (Zerbini et al. 2006).

During NMFS Cook Inlet-wide aerial surveys conducted from 1993 through 2004, minke whales were observed on three separate occasions (1998, 1999, and 2006) near Anchor Point, approximately 90 miles south of the project area (Shelden et al. 2013, 2015, 2017). A minke whale was also reported in the same general location in 2011 and 2013 (Owl Ridge 2014).

Killer Whale

The killer whales (*Orcinus orca*) inhabiting Cook Inlet are thought to be a mix of resident and transient individuals from two different stocks: the Alaska Resident Stock, and the Gulf of Alaska, Aleutian Islands, and Bering Sea Transient Stock (Muto et al. 2017). Both stocks have the potential to occur in the project area. The Alaska Resident Stock is estimated at 2,347 individuals, with a minimum population estimate of 2,084 (Muto et al. 2017). The Gulf of Alaska, Aleutian Islands, and Bering Sea Transient Stock is estimated at a minimum of 587 individuals (Muto et al. 2017).

Killer whales are occasionally observed in lower Cook Inlet, especially near Homer and Port Graham (Rugh et al. 2005), approximately 80 miles south of the project area. Killer whales are not expected to occur in the project area.

Dall's Porpoise

Dall's porpoises (*Phocoenoides dalli*) are present year-round throughout their entire range, including the Cook Inlet area and Kamishak Bay (Morejohn 1979). They are regularly observed throughout Cook Inlet (Nemeth et al. 2007), particularly during spring eulachon and summer salmon runs. They have been observed in lower Cook Inlet around Kachemak Bay (USDOI BOEM 2015a), approximately 80 miles east of the project area.

Dall's porpoises were observed on NMFS aerial surveys during June 1997 (Iniskin Bay, approximately 40 miles north of Amakdedori port), 1999 (Barren Island, approximately 70 miles

AMERICAN OVERSIGHT

east of Amakdedori port), and 2000 (Barren and Elizabeth islands, approximately 70 and 80 miles east of Amakdedori port, respectively, and Kamishak Bay) (Shelden et al. 2013).

Harbor Porpoise

In Alaskan waters, three stocks of harbor porpoises (*Phocoena phocoena*) are currently recognized: Gulf of Alaska, Southeast Alaska, and Bering Sea stocks (Muto et al. 2017). Only the Gulf of Alaska Stock has the potential to occur in Cook Inlet near the project area.

Harbor porpoises have been reported in lower Cook Inlet from Cape Douglas north to the West Foreland and offshore (Rugh et al. 2005a). They have been frequently observed during aerial surveys in Cook Inlet; most sightings are of single animals and are concentrated at Chinitna and Tuxedni bays (north of the project area) on the west side of lower Cook Inlet, and in the upper inlet (Shelden et al. 2014). The most recent population estimate for the Gulf of Alaska Stock is 31,046 individuals (Muto et al. 2017).

NMFS aerial surveys for belugas have documented harbor porpoise presence throughout Cook Inlet since 1993, except in 2002, 2003, 2006, and 2013. These surveys encompass the project area, and typically included Chinitna, Iniskin, and Iliamna bays and connecting coastline, all north of the project area.

Harbor Seal

Harbor seals (*Phoca vitulina*) are common in Alaskan waters, with statewide abundance estimates at 152,602 animals (Muto et al. 2017). There are 12 recognized stocks of harbor seals in Alaska. The Cook Inlet/Shelikof Strait harbor seal stock range extends from Unimak Islands along the coast north into upper Cook Inlet, and includes the project area. The current Cook Inlet/Shelikof Strait harbor seal stock population estimate is 27,386 individuals (Muto et al. 2017).

Harbor seals are found throughout the entire lower Cook Inlet coastline, hauling-out on beaches, islands, mudflats, and at the mouths of rivers, where they whelp and feed (Muto et al. 2017). Montgomery et al. (2007) recorded over 200 haul-out sites in lower Cook Inlet alone. Harbor seal haul-out areas occur in Kamishak Bay in close proximity to the project area, including the Amakdedori port.

A strong seasonal pattern of more coastal and restricted spatial use has been documented during the spring and summer for breeding, pupping, and molting, and more wide-ranging seal movements in and outside of Cook Inlet during the winter months (Boveng et al. 2012). Large-scale patterns indicate that a portion of harbor seals tagged in Cook Inlet move out of the area in the fall, and into habitats in Shelikof Strait, North of Kodiak Island, and coastal habitats of the Alaska Peninsula, considerably south of the project area. In the fall, harbor seals are concentrated in Kachemak Bay on the east side of Cook Inlet, Iniskin and Iliamna bays on the west side of Cook Inlet, and south through the Kamishak Bay to Cape Douglas (Boveng et al. 2012). A portion of the Cook Inlet seals move into the Gulf of Alaska and Shelikof Strait during the winter months (London et al. 2012). Seals move back into Cook Inlet as the breeding season approaches (London et al. 2012).

NMFS has conducted annual aerial surveys for beluga whales in Cook Inlet since 1993, which encompass the project; these surveys have also included incidental sightings of harbor seals every year from 1993 to 2016. Bennett (1996) counted a maximum of 90 harbor seals hauled-out along tidal channels in inner Chinitna Bay during aerial surveys conducted from 1994 to 1996.

Iliamna Lake Seal

AMERICAN OVERSIGHT

A discrete (Burns et al. 2013) population of approximately 400 harbor seals inhabit the freshwater environment of Iliamna Lake (Boveng et al. 2016). Iliamna Lake seals forage mainly on salmonids (salmon, trout, char, and grayling), but also forge heavily on lamprey, smelt, sculpin, whitefish, and stickleback (Hauser et al. 2008).

In spring, when the ice breaks up, seals begin to redistribute broadly in Iliamna Lake. When migrating salmon arrive in the summer and into autumn, seals may be found throughout the lake, but are especially common near and in spawning streams, including the lake's outflow, the Kvichak River, and along nearshore areas. Iliamna Lake seals are thought to overwinter in Iliamna Lake (Boveng et al. 2016). The peak date of births in Iliamna Lake was based on the peak percentage of pups found in aerial surveys of the lake during May through August of 2010 to 2013 (excluding 2012), compared to those in Navak Bay. The average peak pup-count dates were determined to be anywhere from July 12 to July 20 (Boveng et al. 2016).

A few seals are occasionally observed in small areas of open water in the southwestern portion of the lake during the ice-cover period, such as the head of the Kvichak River at Igiugig, roughly 40 miles from the proposed project barge route over Iliamna Lake near Kokhanok, but these are not regular occurrences (Burns et al. 2013). There are known and potential haul-out sites on islands found in the central portion of Iliamna Lake (Figure 3.23-7)(ABR 2011a).

3.23.2 Action Alternative 2 – North Road and Ferry

The components of Alternative 2 are described in Chapter 2. The mine site footprint is generally the same between Alternatives 1 and 2 with no expected difference in wildlife species presence and abundance; therefore, the affected environment is considered the same and not repeated here. Only aspects of Alternative 2 that differ substantially are discussed below. For Alternative 2, the port at Diamond Point is not discussed separately because it is part the transportation and natural gas pipeline corridors.

The most recent comprehensive biological surveys of the Alternative 2 area were conducted by ABR primarily between 2004 and 2006 with additional surveys conducted up until 2012. These surveys are detailed in the various chapters of the Environmental Baseline Document (ABR 2011a, 2011c, 2011d, 2013a, 2013b, 2015a-c) and are summarized briefly below. Details of the specific survey methods and results are referenced, and a summary of the results are provided. The area where biological surveys were conducted for the Environmental Baseline Document (referred to as the transportation corridor study area) stretches approximately from the Newhalen River east along the north shore of Iliamna Lake to Williamsport, and then along the western edge of Cook Inlet to Chinitna Bay. The transportation corridor study area included a swath of land between the northern edge of Iliamna Lake and the base of the nearby mountains (Roadhouse and Knutson Mountains) to the north of the lake. Specific to the project, the study area included the area around Eagle Bay, Pedro Bay, Pile Bay, Diamond Head, Williamsport, Cottonwood Bay, Iliamna Bay, and Iniskin Bay. Therefore, the entire terrestrial portion of Alternative 2 was surveyed apart from the portion of the natural gas pipeline corridor from Ursus Cove to Diamond Point. The only survey conducted in this section was an aerial raptor nesting platform survey in 2012, as detailed below.

3.23.2.1 Birds

Project-specific avian surveys conducted by ABR in 2004 and 2005 are the most comprehensive surveys that have been conducted for the region along the northern and eastern edge of Iliamna Lake from the mine site to Cook Inlet (ABR 2011a, c, d).

AMERICAN OVERSIGHT

Raptors

Raptor surveys were conducted in 2004 and 2005 for all large tree and cliff-nesting raptor species. Winter surveys for bald eagles were conducted in 2005 and 2006. Bald eagles were the most abundant nesting species (43 percent of all nests), followed by golden eagles (19 percent of nests), with low numbers of nesting common ravens, osprey, peregrine falcon, gyrfalcon, rough-legged hawk, great horned owl, and red-tailed hawk (ABR 2011a, 2011c)(Figure 3.23-9). The greatest densities of tree-nesting raptors were along the Newhalen and Iliamna rivers and along the shoreline of Iliamna Lake. Scattered bald eagle nests were also distributed on various islands in the eastern edge and along shoreline of Iliamna Lake. The greatest densities of cliff-nesting raptors were found in Canyon Creek and along the southern edge of the Alaska Range north of Iliamna Lake (Figure 3.23-9). Near Cook Inlet, most bald eagle nests were located in the trees along the coastline or in the lower reaches of rivers draining into Iliamna Lake and Cook Inlet. One peregrine falcon nest and several bald eagle nests were detected around Diamond Point and several golden eagle nests were located along the steep cliffs around Williamsport (Figure 3.23-9). The peregrine falcon nest at Diamond Point is located approximately 500 feet to the west/above the proposed road to Diamond Point. In September 2012, additional surveys were conducted by ABR for nesting raptors (ABR 2013a). One bald eagle nest is located directly in the area to be used as the Diamond Point barge dock cut and fill area (Figure 3.23-9). An additional bald eagle and one golden eagle nest were located in the valley between Ursus Cove and Cottonwood Bay, adjacent to the proposed natural gas pipeline corridor (ABR 2013a).

During surveys to determine if there were wintering congregations of bald eagles around Iliamna Lake, bald eagles were detected in February and November 2005, and November and December 2006, with a drastic decline in eagle by mid-winter suggesting that the area is not heavily used as a wintering area for bald eagles (ABR 2011a).

Waterbirds

The Iliamna Lake region of the Alaska Peninsula is an important migration route for many species of waterbirds moving to and from breeding areas in western and northern Alaska (Conant and Groves 2005). Waterbird surveys were conducted along the transportation and natural gas pipeline corridors by ABR in 2004 and 2005, with a 2006 survey for swans. Thirty-four species of swans, ducks, loons, cranes, and gulls were observed, with 14 of them recorded as breeding in the area. Waterbirds used lakes, rivers, and bays for staging during spring and fall migration. During spring migration, most swans, geese, and dabbling ducks arrived by late April to early May and staged along rivers and areas of open water on lakes and bays of Iliamna Lake (Figure 3.23-10). The highest concentrations were along the Newhalen River at Three-mile Lake, Goose Cove, and in Chekok Bay. Other locations where species staged included the floodplain of the Iliamna River and Eagle, Fox, and Pile bays. Diving ducks arrived in mid- to late May and staged in large flocks in Whistlewing Bay, Alexcy Lake, and on the Iliamna and Newhalen rivers (ABR 2011a).

During fall migration, waterbirds were congregated in many of the same locations as spring with additional concentrations of gulls and mergansers on Iliamna Lake at Knutson and Pile bays, and along the south shore of the lake (Figure 3.23-11). The highest numbers of birds were detected along the lower reaches of the Iliamna River and the southern shore of Iliamna Lake.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

Figure 3.23-10: Staging Waterbird Locations during Spring 2005 Along the Action Alternatives 2 and 3 Transportation Corridor

AMERICAN OVERSIGHT

Figure 3.23-11: Staging Waterbird Locations during Fall 2005 Along the Action Alternatives 2 and 3 Transportation Corridor

AMERICAN OVERSIGHT

Thousands of ducks and gulls were observed during fall surveys with high duck abundance during mid-August to mid-October (ABR 2011a). In contrast to the vast numbers of ducks and gulls, no groups of swans or geese were observed staging during the fall, only local groups that bred in the area were observed. Overall, there were low numbers of grebes, cormorants, cranes, and shorebirds during spring and fall migrations periods in 2004.

Tundra swans were documented breeding between Chekok Creek and the Newhalen River with more nests located in 2005 between UTC and the Newhalen River north of Iliamna Lake. Swans returned to the same territories on subsequent years and were on nests by early May. One pair of trumpeter swans (*Cygnus buccinator*) that bred locally was located near the Pile River, which is near the western edge of their breeding range.

Harlequin duck pairs were found along streams flowing into Iliamna Lake, with broods located on Stonehouse Lake, and on the Newhalen, Pile, and Iliamna Rivers.

Common loons were found on deep and large lakes between UTC and the Iliamna River with most broods locations near the Newhalen and Iliamna rivers. Both Pacific and red-throated loons were uncommon and no nests or broods were documented.

The marine waters of Iliamna, Cottonwood, and Iniskin bays are important year-round habitat for a variety of waterbird species. The rocky shoreline, adjacent cliffs, islands, and rock outcrops around these bays provide important breeding habitat. Some of the first intensive surveys of this area in 1976 detected the following species breeding around the mouths of Iliamna and Iniskin bays: common eider (*Somateria mollissima*), double-crested cormorant, pelagic cormorant, black oystercatcher (*Haematopus bachmani*), glaucous-winged gull, pigeon guillemot, horned puffin, and tufted puffin (Erickson 1977). The North Pacific Seabird Data Portal (an online database of seabird colony population numbers from various surveys) includes several seabird colonies in this area. These include South Head, White Gull Island, North Head, Knoll Head, Toadstools, Entrance Rock, Vert Island, Scott Island, Mushroom Islets, Iniskin Island, Twin Rocks, Pomeroy Island, and Oil Reef (USFWS 2018). Several of these islands (White Gull Island, Vert Island, Iniskin Island, and Pomeroy Island) had greater than 500 breeding birds in the late 1970s (Erickson 1977; ABR 2011a). In total, breeding birds recorded in 1976 and 1978 totaled 4,172 birds. ABR resurveyed many of these islands and the surrounding area and observed 1,264 and 1,585 breeding birds in 2004 and 2005, respectively. The main differences between surveys in the 1970's and ABR surveys were a drastic decrease in the number of breeding tufted puffins, and a smaller decrease in the number of most other species. The only species that increased in number between the 1970s and in the mid-2000s were red-faced cormorant and mew gull, both of which were not documented breeding in the 1970s (ABR 2011a). Overall, since the 1970s the number of breeding seabirds has declined drastically with the most recent surveys documenting 1,740 to 1,195 birds in 2011 and 2012, respectively. Numbers of nesting double-crested cormorants, common eiders, glaucous-winged gulls, pigeon guillemots, and tufted puffins all showed declines. Tufted puffin populations have declined by approximately 97 percent and double-crested cormorants by 88 percent. This may have been due to a collapse of the Pacific herring (*Clupea harengus*) fishery (ABR 2015c).

Surveys by ABR from summer 2004 to spring 2006 documented similar results from previous surveys, which indicated that the number of birds in Iliamna and Iniskin bays is substantial. In the mid-1970s the largest wintering concentration of seaducks in all of lower Cook Inlet occurred in Iniskin Bay; Iliamna and Iniskin bays contained a large concentration of summering scoters; and gulls, dabblers, and scaup all concentrated in Iniskin and Chinitna bays in the summer (Erickson 1977). Agler et al. (1995) documented large concentrations of birds on the western side of lower Cook Inlet in summer, and the number of wintering birds (primarily waterfowl) in Iliamna and Iniskin bays was the highest in western Cook Inlet.

AMERICAN OVERSIGHT

ABR surveys (2011c) recorded 69 species of birds within marine waters of Cook Inlet including Iliamna, Iniskin, and Chinitna bays. The greatest number of bird species and density occurred in spring (primarily due to large numbers of shorebirds). Large numbers of waterfowl migrate through the area in spring and fall and a substantial number of birds winter in the protected bays, especially seaducks. The highest densities of birds in spring and summer occur in nearshore waters and near the mouths of the bays, while the highest densities in winter occur in the offshore waters in the bays (ABR 2011c).

A supplemental reconnaissance-level waterbird survey was conducted in September 2012 between Iniskin and Bruin bays (ABR 2013b). This survey covered the area of the natural gas pipeline corridor between Ursus Cove and Cottonwood Bay. Several groups of waterbirds were located in the river delta at the end of Ursus Cove, but none were detected along the creek between Ursus Cove and Cottonwood Bay (ABR 2013b).

Landbirds and Shorebirds

Point count surveys were conducted throughout the transportation corridor study area in June 2005. The habitat types with the highest bird abundance (more than five birds per point count) included Riverine Moist Mixed Forest, Riverine Low Willow Scrub, Upland and Lowland Moist Mixed Forest, Upland and Lowland Spruce Forest, Upland Moist Tall Alder Scrub, and Upland Moist Low Willow Scrub. Forty-six species of landbirds (mainly passerines) and seven shorebird species were recorded. Warblers were the most abundant birds followed by thrushes, waxwings, sparrows and allies, finches, and kinglets. Lower numbers of flycatchers, woodpeckers, swallows, corvids, shrikes, chickadees, nuthatches, and sandpipers were recorded.

The 10 most common landbird species (in descending order of abundance) include Wilson's warbler, orange-crowned warbler, Swainson's thrush, yellow-rumped warbler, golden-crowned sparrow, dark-eyed junco, ruby-crowned kinglet, American robin, varied thrush, and hermit thrush. The two most common shorebird species, which comprised 92 percent of all shorebird detections, were greater yellowlegs and Wilson's snipe. Seven of the 53 landbird and shorebird species detected are considered conservation priority species in Alaska and include olive-sided flycatcher, gray-cheeked thrush, varied thrush, blackpoll warbler, rusty blackbird, American golden-plover, and solitary sandpiper.

The nearshore marine waters of Iliamna, Cottonwood, and Iniskin bays are important year-round habitat for a variety of shorebird species, primarily during spring migration. Surveys conducted from 2006 to 2012 documented a wide variety of species within Iliamna and Iniskin bays with the highest numbers of shorebirds moving through the area in early May on their northern spring migration. Surveys from summer 2004 through spring 2006 documented the numbers and species of shorebirds within Iliamna and Iniskin Bays. On May 3, 2005, over 5,000 shorebirds were recorded in Iliamna and Iniskin bays (ABR 2011c). During Spring 2006, the most common shorebirds were western sandpiper (5,682 birds) followed by unidentified sandpipers (17,322 birds), and dunlin (2,157 birds)(ABR 2011c). These birds fed on the mudflats at the back end of Iniskin Bay. Low numbers of rock sandpipers (generally less than 200 birds) also used the bays during fall, winter, and spring from late October through last April; however, they were most abundant in November when with a high of 406 were observed in early November 2006 (ABR 2015c). The largest flocks of rock sandpipers were found foraging on the soft-sediment substrates of inner Iliamna and Iniskin bays.

The only breeding shorebird species detected around Iliamna and Iniskin bays was the black oystercatcher. This species breeds in low numbers among the rocky edges around the bay and surrounding areas with seven nests recorded in 2011, and five nests in 2012 (ABR 2015c).

AMERICAN OVERSIGHT

Historical data from 1976 and 1978 documented 42 black oystercatchers in the area, and surveys in 2005 documented 41 birds, hence numbers had remained relatively constant (ABR 2011c).

3.23.2.2 Terrestrial Mammals

Large Mammals

Almost no caribou were observed during wildlife surveys in 2004 or 2005, the area is almost completely outside of the range of the Mulchatna caribou herd, and the steep coastal mountains that dominate the area are not preferred caribou habitat (ABR 2011a, ABR 2011d). A few caribou are located around the Newhalen River, and both radio and satellite-collared data indicate the species rarely occurs along the north shore of Iliamna Lake.

Moose were detected throughout the study area in low density, with the greatest local densities east of Roadhouse Mountain. The highest numbers of moose observations were at lower elevations along the Pile River and Chekok Creek. The estimated density of moose in the transportation corridor study area was 0.05 moose per square kilometer (ABR 2011a). Historical surveys in late March 1992 in the area between the Newhalen River and Williamsport found an estimated density of 0.07 moose per square kilometer, and 0.16 moose per square kilometer in the area between the mine site and Iniskin Bay (Boudreau et al., 1992).

The transportation corridor study area is in an area of transition between substantially higher coastal densities of brown bears and lower inland densities. Historical surveys have estimated 50 bears per 1,000 square kilometers in GMU 9B (excluding Lake Clark National Park and Preserve and Katmai National Park and Preserve lands)(Butler 2005). A more rigorous survey from May 1999 to 2000 estimated 38.6 brown bears per 1,000 square kilometers in GMU 9B North, including the area east of Iliamna Lake and Lake Clark National Park and Preserve (Becker 2003; Butler 2007). The line-transect bear survey in May 2009 (Becker 2010), which encompassed the transportation corridor study area (plus a large area around Iliamna Lake), resulted in two different brown bear estimates based on different models and ranged between 47.7 and 58.3 brown bears per 1,000 square kilometers.

Bear surveys around the eastern part of Iliamna Lake to Diamond Point and Iliamna and Iniskin bays between 2004 and 2007 documented high densities of brown bears particularly along the Iniskin River and the end of Iniskin Bay (ABR 2011c). Brown bears were also detected around Cottonwood and Iliamna bays, but in lower numbers. Large aggregations of brown bears were observed in the sedge meadows and mudflats at the heads of Iniskin and Chinitna bays during spring and summer each year, with highest numbers in June (ABR 2011c). Brown bears shifted to salmon-spawning streams later in July and August, which are primarily located in the eastern portion of the study area (ABR 2011a). Little evidence was found for bears digging clams, with only one observation of this behavior in May 2006. Brown bears were observed fishing for salmon in Iniskin River, and Portage Creek in Iniskin Bay. Overall, brown bears were concentrated foraging on vegetation early in the summer, and transitioned to salmon later in the summer and fall following the season salmon runs in the area.

From July through September 2012, ABR conducted a study of bear activity using timelapse cameras placed near the location where the transportation corridor and natural gas pipeline would cross UTC, to capture bear activity along the stream. Overall, little bear use was recorded on photographs, but bear activity peaked from late July to early August. The highest level of activity occurred late in the evening. Despite the abundance of salmon in UTC, it did not appear that the location where the camera was placed was important to foraging bears during daylight and twilight hours (ABR 2015a). Additional cameras were placed along seven anadromous streams along the north shore of Iliamna Lake from Roadhouse Mountain to the Pile River. Bear use reflected

AMERICAN OVERSIGHT

salmon run timing, with the highest activity from late July to early August. Small, shallow streams with high numbers of spawning salmon were the preferred foraging areas. The highest level of activity occurred during early morning and late evening, but bears spent limited time fishing in the portions of the river in the camera's viewshed according to the timelapse photography (ABR 2015a).

Black bears were more common in the area north and east of Iliamna Lake than any other locations around Iliamna Lake; their density estimate from 1999 to 2000 for GMU 9B North was 76.7 black bears per 1,000 square kilometers (with most bears in the northernmost portion of the subunit)(Becker 2003). Most black bears were observed in the eastern part of the survey area around the Iliamna River. Timelapse cameras placed along salmon-spawning streams in 2012 did not document any black bears.

Few wolves were detected during surveys along the north shore of Iliamna Lake to Diamond Point, but tracks of a pack of six individuals were noted during late fall 2004 along Chekok Creek (ABR 2011a). A lone wolf was incidentally detected along the Iliamna River. Therefore, the species is anticipated to occur in low numbers in the transportation and natural gas pipeline corridors.

Beavers were recorded west of the Newhalen River, along the Pile and Iliamna rivers, and west of Pile Bay north of Iliamna Lake.

Small Terrestrial Vertebrates

Small mammals were incidentally recorded during surveys in 2004 and 2005. Species detected included red fox, river otter, wolverine, and coyote (ABR 2011a). No particular spatial distribution for these species was noted, as most were incidental detections and dense vegetation made observations for less visible species more challenging.

Wood frog studies were not conducted for the transportation and natural gas pipeline corridors. The species is expected to occur in suitable habitat in ponds, lakes, streams, and other waterbodies along the north shore of Iliamna Lake to Cook Inlet.

3.23.2.3 Marine Mammals

Alternative 2 includes a more northern barge route across Iliamna Lake (Figure 3.23-7), which does not affect the species descriptions discussed in this section, except for harbor seals that occur year-round in Iliamna Lake. The species discussed in this section have broad distributions and are expected to occur in similar densities throughout the marine environment. A general description of marine mammals in the project area is discussed above. Where there are anticipated differences between species' distribution and habitat use or specific sightings during surveys identified during literature review across the preferred alternative and the other alternatives, further discussion is provided.

Gray Whale

During boat-based nearshore (Iliamna, Iniskin, and Chinitna bays) surveys, one gray whale was recorded off-transect in the summer of 2004, near the mouth of Iniskin Bay (ABR 2011d).

Minke Whale

Surveys conducted in Iliamna, Iniskin, and Chinitna bays did not record any sightings of minke whales (ABR 2015c). A single minke whale was recorded just inside the entrance of Iliamna Bay in 2006 (Houghton 2013, as cited in ABR 2015c).

AMERICAN OVERSIGHT

Killer Whale

A single killer whale was recorded near North Head, at the mouth of Iliamna Bay in 2009 (ABR 2015c). This is the only record of this species on all aerial and boat-based surveys combined (ABR 2015c).

Dall's Porpoise

During surveys of the northern portion of the analysis area between 2006 and 2012, ABR (2015c) observed one Dall's porpoise near North Head in 2009.

Harbor Porpoise

During helicopter-based surveys of the northern portion of the analysis area between 2006 and 2012, harbor porpoises were observed in Iniskin, Iliamna, and Chinitna bays, as well as offshore; but were most common near the mouths of Iliamna and Iniskin bays (ABR 2015c), all north of the project area. Harbor porpoises exhibited seasonality in abundance and inter-annual variation in abundance (ABR 2015c). There was a pronounced increase in the number and frequency of observations of harbor porpoise in the spring, specifically in late April and May. Harbor porpoises were recorded in every month except for January, June, and October, although in generally low numbers, and with a low frequency of observations (ABR 2015c).

Harbor Seal

Marine mammal surveys (Iliamna, Iniskin, and Chinitna bays) were conducted between 2004 and 2008 (ABR 2011d). Harbor seals were recorded during all seasons, and were the most abundant marine mammal encountered (ABR 2011d). During the boat-based surveys in Iliamna, Iniskin, and Chinitna bays, harbor seals occurred primarily in nearshore waters and were present primarily in the summer, with lower densities in the spring, and much lower densities in the winter and late winter (ABR 2011d). During offshore boat-based surveys, harbor seals were observed in the spring surveys in low densities, but higher in the summer, early winter, and late winter (ABR 2011d). In the spring, harbor seals occurred mostly in the nearshore waters, with only one recorded in the offshore area (ABR 2011d). The seals occurred throughout the entire bay systems, but were commonly hauled-out on the mudflats in upper Iniskin Bay. In the summer, harbor seals were primarily observed on the islands near the mouth of the bays, and secondarily on the mudflats in upper Iniskin Bay. In early winter, few seals were seen during the offshore surveys; those that were seen during the nearshore surveys were concentrated in the bays, and secondarily on the mudflats in upper Iniskin Bay (ABR 2011d). In the late winter, few seals were seen during the offshore surveys, and the few seals that were seen during the nearshore surveys were concentrated on the Iniskin Islands; few seals were seen in the bays, likely due to ice presence (ABR 2011d).

During fixed-wing surveys described above, the highest counts of harbor seals were during July and August. Most seals were recorded on the Iniskin Islands, but some seasonal variation occurred, especially with respect to the increased numbers hauled-out on Gull Island in Chinitna Bay (ABR 2011d).

Iliamna Lake Seal

Iliamna Lake seals are primarily found in the northeastern half of Iliamna Lake near Pedro Bay; however, depending on the time of year, stage of fish migrations, and state of ice cover on the lake, seals may be distributed throughout the lake (Burns et al. 2013).

AMERICAN OVERSIGHT

The highest use of haul-outs was in the Flat/Seal Island group (southwest of Pedro Bay) and the Thompson Island group (north of Kokhanok) (Figure 3.23-7)(ABR 2011a). Two haul-out locations identified during aerial surveys accounted for two-thirds of all the seals observed in Iliamna Lake (ABR 2011a).

In winter, the number of seals observed is relatively low as the vast majority of the lake surface freezes solid in winter, but is greatest in the northeastern parts of the lake (Burns et al. 2013). Small areas of water remain open, particularly in the northeastern portion of the lake, where harbor seals most commonly occur (Figure 3.23-7)(Boveng et al. 2016).

Pupping and nursing occur in June through August, taking place at haul-out sites in the northeastern half of the lake (Burns et al. 2013) near Pedro Bay.

3.23.3 Action Alternative 3 – North Road Only

There are no new geographic areas that are exclusive for Alternative 3 not previously covered under Alternatives 1 and 2. Since there will not be a ferry associated with this alternative, affected environment descriptions for Iliamna Lake do not apply to Alternative 3. The affected environment descriptions associated with all other components of this alternative is previously described by Alternatives 1 and 2 in the sections above.

3.23.4 Climate Change and Wildlife

Climate change trends are common to all alternatives.

Potential impacts from climate change on bird species are closely tied to changes in the physical and biological environment, including water resources (e.g., timing of spring thaw, freezing, ice/snow cover) and vegetation changes. Changes to vegetation from climate change are discussed in Section 3.26, Vegetation, and would directly impact avian communities. Changes in temperature, precipitation, their level of intensity, and timing all have the potential to impact avian species. Waterbird and shorebird species may experience an increase in habitat due to increased thawing. Warmer winters may permit an expansion of spruce bark beetles, which would attract various woodpecker species, but result in forest habitat loss. Some species, such as ptarmigan, which depend on adequate snow cover to survive winter, are likely to be adversely impacted. There is the potential for tropic mismatch where seasonally timed migration events and reproduction are not synchronized with vegetation and insect population fluctuations. Overall, some bird species may increase in abundance, while others may decline due a warming climate.

Climate change is anticipated to have a wide variety of impacts for various terrestrial species. An overall warming/drying trend would tend to convert some wetlands to uplands and tend to increase the cover of shrubs and trees in previously open areas. For terrestrial wildlife, a combination of more open water and more nearby upland or forested areas may benefit species like beavers, river otters, wood frogs, and others. An increase in fires due to drying may benefit caribou that use early successional habitat areas, but would be a detriment to species that rely on forested cover. Habitat important for moose would be affected, but effects are uncertain. Warming conditions may also lead to increases in infectious disease in wildlife (Bradley et al. 2005).

Climate change may cause shifts in plant phenology; species that cannot shift the timing of their reproductive cycle may be adversely impacted. This potential mismatch between a wildlife species and its food may vary depending on the degree to which they depend on dietary consumption and stored fat reserves (Gustine et al. 2017). A recent study in Alaska by Gustine et al. (2017) examined the long-term (i.e., from 1970 to 2013) changes in temperatures, and characteristics of the growing seasons in relation to forage quality for caribou during important life

AMERICAN OVERSIGHT

stages. Despite advanced thaw dates and increased growing season lengths, no decline in forage quality and no evidence for trophic mismatch was found during peak parturition or peak lactation. Another study in northern Canada examined the impacts of climate change on the seasonal distribution of two migratory caribou herds (Sharma et al 2009). The study found consequences of climate change may include alteration in habitat use, migration patterns, foraging behavior, and demography. Migratory caribou preferred regions with higher snowfall and lichen availability in fall and winter, and cooler areas in summer. Both herds of caribou avoided disturbed and recently burned areas.

Habitat changes in southwest Alaska have been documented by traditional ecological knowledge, which has resulted in improved moose forage with areas of taller and denser willows, dwarf birch, and alders (Lanen 2018). Traditional knowledge has documented ice breakup occurring earlier in the spring, freeze-up occurring later in the fall, lower than normal snowfall amounts, and other climatic changes. This has translated into earlier spring thaw, lakes opening up faster, expanding and taller-growing deciduous shrubs, and earlier leaf-out in spring (Lanen 2018). The result has been increased moose abundance, due to increasing range expansion of moose.

AMERICAN OVERSIGHT

4.23 WILDLIFE VALUES

The following section provides a description of the potential environmental consequences from the proposed project to non-federally listed birds, terrestrial wildlife, and marine mammals and their habitats. Impacts to federally listed wildlife species are discussed in Section 4.25, Threatened and Endangered Species. Direct and indirect impacts comprise:

- behavioral disturbance, including:
  - noise
  - presence of humans, vehicles, vessels, and aircraft
  - avoidance of nearby habitat
- injury and mortality, including:
  - collision with vehicles, vessels, and aircraft
  - exposure to contamination from pit lake or other project attractants
  - defense of life and property
- habitat changes, including:
  - vegetation removal (habitat loss)
  - fragmentation
  - spills (discussed in Section 4.21)
  - fugitive dust impacts (discussed in Section 4.26, Vegetation)
  - invasive species introduction or spread (discussed in Section 4.26, Vegetation)

The magnitude of impacts depends on the specific species' sensitivity to the disturbance or change, and the type of disturbance or change. The duration of potential impacts depends on the location and season in which the impact occurs. The extent of impact would vary depending on the location of the impact in relation to the species' range that may be impacted.

Potential impacts from a spill or leak (including natural gas, oil, diesel, and all other substances being transported to and from the mine site) are not discussed in this section, but are detailed in Section 4.27, Spill Risk.

Specific mitigation measures to minimize impacts are currently being developed. Impacts to wildlife species would be minimized or mitigated by development of a Wildlife Management Plan (WMP), which would detail management measures to minimize impacts to wildlife species. The WMP would describe the equipment, methodology, training, and assessment techniques that would be used to minimize the potential for wildlife interaction and minimize impacts to species from all aspects of the project.

4.23.1 No Action Alternative

Under this alternative the project would not be constructed and there would be no project-related impacts to wildlife species.

4.23.2 Action Alternative 1 – Applicant's Proposed Alternative

4.23.2.1 Birds

The project has the potential to directly and indirectly impact breeding, wintering, migrating, and staging bird populations through behavioral disturbance, injury and mortality, and habitat changes as detailed in the following sections. Impacts to raptors, waterbirds, landbirds, and shorebirds are

AMERICAN OVERSIGHT

anticipated to differ among individual species; however, impacts are discussed collectively herein for the majority of avian groups. Additionally, potential impacts at the mine site, transportation and natural gas pipeline corridors, and the Amakdedori port are discussed collectively under each project component.

Behavioral Disturbance

All project phases and components would result in elevated noise levels (above current ambient levels) from a variety of sources (e.g., blasting activities in the open pit, aircraft, vehicles, construction equipment, barges and other oceanic vessels, operations-related noise) and would occur in varying levels throughout the life of the mine. Noise levels would increase above present levels (detailed in Section 4.19, Noise) during all phases of the project because there are currently no recurrent anthropogenic noise sources in the mine site. Blasting would occur on a regular basis during construction as needed at several material sites to construct the access roads and other infrastructure, and during operations in the mine pit (as outlined in Chapter 2, Alternatives). Various studies have been conducted around the globe detailing impacts of noise on bird populations and a general conclusion is that some bird species are sensitive at least during the breeding season to noise levels and the distance of disturbance can vary from several feet to more than 2 miles (Kaseloo and Tyson 2004). Loud noises from short-term events (e.g., blasting) are known to startle nearby birds and may cause them to leave the area, and can also lead to nest abandonment. Bird use of otherwise suitable habitat may be reduced due to sensitivity to noise. The degree of disturbance would vary among individuals, species, and time of year. Noise can change the composition of avian communities in favor of more noise-tolerant species, thereby reducing nesting species richness (number of species), although not necessarily density. Predatory birds may avoid noise because it could mask their calls or make it more difficult to locate prey, thereby causing nests in noisier areas to be safer from predators (Francis et al. 2009). See Section 4.19, Noise, for detailed analysis of current and proposed noise levels.

Some birds may habituate to noise from continuous sources, such as equipment and facilities, and such noise alone may not result in substantive changes in normal activities. Because mining-related exploration activities have occurred in and around the mine site, some birds may already be habituated to human-related disturbances. Birds migrating through the area may avoid the project vicinity during noisy periods rather than stopping over during migration.

[Note: Additional information on noise will be included in Appendix K4.25].

Vehicle traffic along the access roads, vessel and aircraft traffic at the Amakdedori port, and barge traffic on Iliamna Lake may cause behavioral disturbance to birds in the surrounding areas. These types of traffic may have three classes of impacts: direct impact on offspring survival due to brood scattering; reduction in foraging behavior and an increase in energetically costly behavior; and a loss of suitable habitat (Kaiser and Fritzell 1984; Korschgen et al. 1985; Keller 1991; Mikola et al. 1994).

Disturbances of nesting birds may cause abandonment of the nest, disruption of the pair bond, reduction in clutch size, increased egg mortality, abandonment of the nesting area, and increased predation of the nest. Disturbances during brood-rearing may cause exhaustion of young and an increase in losses from predation (Korschgen and Dahlgren 1992). Disturbances during critical times of the nesting cycle may eventually cause birds to nest elsewhere or not to nest at all (Korschgen and Dahlgren 1992). One study has shown that human disturbance may compel waterfowl to change food habits, feed only at night, lose weight, or desert the feeding area. Waterfowl generally respond to both loud noises and rapid movements, such as boats powered by outboard motors or other threatening visible features (Korschgen and Dahlgren 1992).

AMERICAN OVERSIGHT

Some species are easily disturbed by the presence of humans, vehicle, and other activities around their nest sites, even if their nesting habitat has not been directly impacted. Several species of raptors (e.g., golden eagles [*Aqulia chrysaetos*]) are especially prone to disturbance around nest sites and may abandon them if disturbed early in the nesting season. Disturbance to golden eagle foraging and roosting areas can stress eagles, leading to reproductive failure or mortality (USFWS 2011).

Habituation of some bird species to disturbance may occur (Stolen 2003). Waterbird responses to vessel traffic may be dependent on species, biological cycle (e.g., breeding, migrating, stopover, and wintering), and/or vessel attributes (e.g., vessel type, size, and speed). When vessels are closer to occupied habitat, a flight response is likely to be greater, especially if the vessel is approaching rapidly. Waterbirds in Cook Inlet may be habituated to vessel traffic (especially around existing port locations); however, additional vessel traffic at the proposed Amakdedori port may cause disturbance as the area currently has no port development.

Behavioral disturbances to birds in Cook Inlet could occur while the pipeline is being installed in Cook Inlet, but the disturbance would be temporary during the installation period, and expected to return to current disturbance levels after installation. Pipeline installation is anticipated to occur during summer months, when breeding birds are nesting. There are no nearby seabird colonies that could be disturbed (e.g., by being flushed off the nest or avoiding foraging areas) during pipeline installation. Additionally, there is a high level of summer vessel traffic in Cook Inlet, and additional boats associated with pipeline installation are not anticipated to contribute in a measurable manner to avian disturbance due to increased vessel traffic.

Injury and Mortality

Avian vehicle collision mortality may occur throughout the mine site and along the transportation and natural gas pipeline corridors. Currently, there are no roads to the mine site, and the project would involve the construction of approximately 76 miles of road through habitat that supports nesting birds; this would create vegetation edge habitats on either side of the road. There is potential for vehicle collisions for birds flying across the new roads created by the project. Mortality rates for avian species may be expected to decline over time, due to a postulated "learning effect," whereby resident birds may acclimate to the presence of the road and develop behaviors to avoid collisions (e.g., flying higher when crossing the road to avoid vehicles) (Havlin 1987). However, this is not likely to apply to migratory birds passing through the area that are unfamiliar with the road. Birds have been shown to change flight initiation distances in response to vehicles according to road speed limit (a factor affecting mortality rates on roads) rather than particular car speed, suggesting that birds are able to associate road sections with overall speed limits as a way to assess collision risk (Legagneux and Ducatez 2013). Bird species that spend a considerable amount of time on the ground (e.g., species of grouse and ptarmigan) are more susceptible to vehicular collisions as opposed to species that are found higher up in the tree canopy (such as species of flycatcher, warblers, and sparrows). Some avian groups tend to fly low/close to the ground and may be more prone to vehicle strikes when flying between brushy areas that are bisected by a road.

Bird collisions with aircraft have been well documented and appear to be increasing (Dolbeer et al. 2013). Contributing factors are greater populations of large birds near some airports, more air traffic, and higher use of quieter aircraft (e.g., turbofan-powered). Waterfowl, gulls, and raptors were groups with the most numerous and most damaging strikes. Species with high numbers of strikes in Alaska (Dolbeer et al. 2013) include bald eagle (*Haliaeetus leucocephalus*), Canada goose (*Branta canadensis*), American golden-plover (*Pluvialis dominica*), bank swallow (*Riparia riparia*), and ducks (*Anas* species and others), which all occur in the project area.

AMERICAN OVERSIGHT

Air traffic over Cook Inlet around Amakdedori port may pose a collision risk to bird species (particularly waterbird species), as well as a safety hazard to the aircraft. The degree of risk would be related to number and timing of the flights with respect to avian habitats (such as over ponds, lakes, and Cook Inlet), time of year, weather conditions, and flight pathways. The number of birds potentially affected is expected to be small because the interaction opportunities would be relatively small; however, there would be increased potential during periods of inclement weather with reduced visibility and higher winds. Flight paths toward the east end of the proposed runway would be over the water upon final approach (as low as 300 feet for approximately 1 mile based on a 3 degree angle [Owl Ridge 2018]). This may result in waterbirds swimming, diving, scattering, or flying away, which could lead to avian injury and mortality.

Additionally, collisions may occur from vessel traffic on Iliamna Lake and Cook Inlet. Avian species that breed, stage, migrate, and winter on Iliamna Lake and at Amakdedori port would be at risk of collision with watercraft. However, in both locations, the watercraft would be traveling slowly, particularly as they reach the shore; therefore, birds are anticipated to be able to move to avoid collision. In some port areas, waterbirds have become accustomed to boats (particularly around the Homer harbor); therefore, waterbirds are anticipated to develop some level of habituation to vessel traffic at Amakdedori port.

The project would create new areas of standing water that may attract birds, including the various freshwater storage impoundments, the tailings pond, and the pit lake. Environmental contamination by contact with water in these locations is possible. The pit lake is anticipated to be deep, contain no shallow water habitats (due to the steep walls), and not support freshwater vegetation that is attractive to many species of waterfowl and shorebirds. Wildlife management around the pit lake will be addressed in the WMP. [Note: Analysis of risk to wildlife from pit lake water is pending].

Habitat Changes

Temporary and permanent habitat loss would occur as existing vegetation is removed and replaced with buildings, roads, runways, mine pit, and other project facilities and infrastructure. See Section 4.26, Vegetation, for information on direct and indirect impacts to vegetation, which would relate to loss of nesting, foraging, migrating, and staging habitat for species in various vegetation communities.

Habitat loss would directly impact bird species with home ranges in the disturbance area, as well as those migrating through the area. Loss of habitat during migration may affect bird populations beyond the project area, because migrating birds could be forced to use other areas to rest and forage. The effect on migrating birds would be smaller than the effect on breeding birds, because migrants would use the habitat briefly and would not depend on it to feed young. Waterbirds would be the primary migratory species around the mine site that would be impacted. As detailed in Section 3.23, Wildlife Values, there are several important staging areas to the north of the mine site where large numbers of waterbirds congregate. Large numbers of waterbirds stage during spring at Nikabuna Lakes, Long Lake, and along the Chultina River, over 11 miles north of the mine site. Development of the project is not anticipated to impact spring migratory waterbird habitat in these distant areas. However, in the fall, high numbers of waterbirds are located directly adjacent to the mine site. Waterbirds are anticipated to move to other nearby ponds and lakes not directly in or adjacent to the mine site.

The avian response to habitat fragmentation is species-specific. Some species avoid edge habitat for reasons such as less suitable microclimate or increased predation. Some avian species prefer early successional habitats; habitat availability for these species may increase as a result of fragmentation. Some avian species, particularly raptors, would lose foraging habitat (due to lower

AMERICAN OVERSIGHT

prey abundance) as the vegetation communities in the mine site are converted to urban/developed land cover types. This could cause raptor species to seek new foraging locations, thereby potentially placing them in competition with nearby occupied territories. This may lead to fewer individual raptor territories in and adjacent to the mine site, reduced number of young, and decreased raptor abundance in the area. Based on the most recent surveys (detailed in Section 3.23, Wildlife Values), one golden eagle nest was located within a 1-mile radius of the mine site. According to the Bald and Golden Eagle Protection Act (Eagle Act)(16 United States Code Sections 668-668c), activities that result in nest-site abandonment constitute take under the Eagle Act since they are cited in the definition of "disturb" (Pagel et al. 2010). Disturb also extends to impacts that decrease eagle productivity by substantially interfering with normal breeding, feeding, or sheltering behavior (USFWS 2007). Therefore, both the direct impact of loss of foraging habitat, and indirect impacts, may necessitate the application for an Eagle Take Permit (USFWS 2016).

4.23.2.2 Terrestrial Wildlife

Behavioral Disturbance

Terrestrial mammals may be affected by blasting and noise from heavy machinery used during construction and operations. See Section 4.19, Noise, for detailed analysis of noise impacts. Individuals may move away from the construction zones to avoid loud continuous sounds, periodic percussive sounds, and the presence of people and machinery that would disrupt their normal behaviors. Behavioral responses to disturbance can range from mild "alert" behavior to fleeing, depending on disturbance type, distance, species, season, or other variables. The size of the "avoidance zone" would depend on the type of disturbance, terrain/topography, vegetative cover, as well as species' behavior, but could result in indirect loss of habitat for each species. Some species, such as moose (*Alces alces*) may habituate (i.e., adapt) to human disturbance, while others, such as gray wolves (*Canis lupus*) and brown bears (*Ursus arctos*), generally do not, and will avoid areas or move as people approach. Some facility noise and operations disturbances may allow for habituation. For example, lower level, continuous noise disturbance at the water treatment plant, would have lower effects than louder erratic sources of activity, such as blasting, vehicles or aircraft. The size of the area avoided would vary by species and would fluctuate over time, but would be larger than construction area footprints. Avoidance of project activities could cause increased physical stress, habitat fragmentation, or abandonment, thereby reducing survival and reproductive success for certain species.

Behavioral avoidance may function as a barrier to movement for some species (particularly small species with reduced home ranges and dispersal distances) or for particular sex and age classes within species. Physical features of the mine and port facilities, access roads, ferry terminals, steep cutbanks, holding ponds, material yards, or retaining walls may prevent or limit animal movements through the area. For species with large home ranges, or species that travel seasonally between winter and summer ranges, such as caribou (*Rangifer tarandus*), moose, brown and black bears (*Ursus americanus*), and gray wolves, a barrier to movement could fragment and decrease the size of preferred habitat. Traffic on the access road during the operations phase would be subject to speed restrictions, but would be a long-term, intermittent source of disturbance.

Project activities may disturb terrestrial mammals throughout construction and operations, with the disturbance zone expanding as the mine is developed to its maximum size. During the closure phase, the mine site would be subject to periodic monitoring activities involving small numbers of workers and vehicles for relatively brief periods of time. The potential disturbance of animals from these activities would be minimal and periodic.

AMERICAN OVERSIGHT

In addition to inhibiting movement patterns, high levels of disturbance could have effects that range from physiological reactions to stress, potential for injury and mortality from exposure to predators (including interspecific species competition) and from sub-optimal habitats, injury and mortality for denning mammals and small mammals in sub-nivean (under snow) spaces during winter construction, and reduced survivability and/or reproductive success in unfamiliar territories. Some species are particularly sensitive at certain times of year (e.g., caribou calving in spring, bear and wolf denning in winter, and moose rutting in fall). Ground-based activities would be the primary concern for most species, but airplane and helicopter traffic could also adversely impact certain species, such as caribou, which are known to react strongly to low-flying aircraft by fleeing.

If animals abandon their familiar territories or alter their movement patterns, they may enter the territories of other animals that aggressively defend their area, with the potential for injury or mortality. They may also be more susceptible to predation through lack of experience with local cover and escape terrain. Disturbance may also lead to mortality due to young separation or abandonment, or if the animal is injured trying to flee.

The Amakdedori port would also be a source of long-term disturbance due to vessel traffic, loading and unloading activities, and the presence of workers and vehicles. The disturbance zone around the port site would likely be much smaller than the area around the mine site due to a lack of explosives, smaller vehicles, and less frequent human presence.

Caribou

Various studies have been conducted on caribou behavior associated with development such as roads, oil drilling, pipelines, and mines. In Alaska, several studies on caribou have been conducted on the North Slope around Prudhoe Bay to document impacts from roads, oil drilling operations, oil pipelines, and other infrastructure. One study (Shideler 1986) found that maternal caribou groups avoided the Trans Alaska Pipeline corridor (including the Dalton Highway) during every season except fall, while bull caribou did not appear to avoid the corridor. Maternal groups almost completely avoided the Prudhoe Bay oil field during summer. Shideler found that traffic levels averaging 15 vehicles per hour caused significant declines in crossing success of caribou during the mosquito season; traffic levels averaging six vehicles per hour have not impacted crossing success of a road or pipeline complex. Multiple factors affect the ability of caribou to successfully cross a road including time of year, effects of mosquitoes and other insect harassment, and group size. Therefore, while the project transportation corridor is primarily east of the main use area of the Mulchatna caribou herd, the summer-only ferry variant would double vehicle traffic during a time that coincides with post-calving use of the mine site.

A study in the Canadian Arctic estimated the zone of influence (i.e., area of reduced caribou occupancy based on a change in behavior, habitat selection, and distribution relative to disturbance) surrounding two open pit mines in a caribou herd's summer range (Boulanger et al. 2012). During operation of the mines, an 8.7-mile zone of influence based on aerial surveys and a 6.8-mile zone based on satellite-collar locations were detected. The study found that caribou were approximately four times more likely to choose habitats greater than 8.7-miles from the mine complex (Boulanger et al. 2012). Caribou responded to industrial development at greater distances, possibly related to fine dust deposition from mine activities in areas of open tundra habitats. Therefore, in addition to avoiding the mine site facilities, caribou may avoid a 6.8- to 8.7-mile radius buffer around the mine site.

The Mulchatna caribou herd currently does not typically range in the area of the transportation and natural gas pipeline corridors. Caribou move between calving grounds (May to June), insect relief areas (June to July), and seasonal foraging areas (fall and winter months); however, none of these movements are through the transportation and natural gas pipeline corridors. They tend

AMERICAN OVERSIGHT

to occur further west (toward the mine site); 29 years of telemetry data that were analyzed found rare instances of caribou in the area covered by the transportation and natural gas pipeline corridors. Therefore, they are not anticipated to occur in large numbers in this area of the project, and may only be encountered on rare occasions. Therefore, no behavioral disturbance impacts on the population (such as shifting migration routes or patterns) are expected to occur.

Moose

Moose seasonally migrate between higher elevations in the summer, and lower elevations in the winter; bull moose move extensively during the fall rut (in September and October) as they search for cows. These movements may be affected by activities at the mine site, which may cause abandonment of foraging and rutting areas and alteration of movement routes. However, moose densities are low in the mine site due to a lack of suitable habitat; therefore, moose impacts would be anticipated to be low.

Moose are known to occur more commonly in the transportation corridor (due to higher quality habitat), and may be adversely affected during construction and operations; and to a lesser extent, after closure, because the roadway would remain open but the traffic level would be reduced. Laurian et al. (2008) found that moose avoid roads by up to 1,640 feet, which can fragment their available habitat. Shanley and Pyare (2011) studied the effect of roads on moose distribution in Yakatat, Alaska, and found that even dispersed vehicular activity on rural road networks significantly affects moose distribution. This activity could also substantially affect the amount of available habitat by moose avoiding areas near roads, particularly if roads are near preferred habitat. In particular, male moose were negatively impacted at least 1,640 feet from rural roads; for female moose, the road-effect zone extended greater than 3,281 feet (Shanley and Pyare 2011). Therefore, the extent of road avoidance by moose would be anticipated to be approximately 0.6 miles on either side of the road. The level of avoidance would vary depending upon time of day and actual vehicular traffic, and is likely to increase under the summer-only ferry variant, where vehicle traffic would be doubled during the summer. Possible reasons for the road effect may be related to actual vehicle noise, as well as perceived risk from hunting (Stankowich 2008). Stankowich (2008) found that ungulates in rural landscapes with low-levels of disturbance are less likely to habituate, and therefore show stronger effects from disturbance.

Bear

Brown and black bears may experience a range of potential impacts from the project. This includes loss of habitat due to land conversion, increased mortality from vehicular collisions and defense of life and property, and behavioral changes based on avoidance of humans. Since brown bears are common around all components of the project (see Section 3.23, Wildlife Values for specific bear densities), and black bears only occur at a low density in the area, this impacts section will focus primarily on impacts to brown bears.

Brown bears have been shown to avoid roads regardless of traffic volume (McLellan and Shackleton 1988), and may avoid mine facilities. McLellan and Shackleton found that most bears used habitat within 328 feet of roads less than expected, resulting in an additional 8.7 percent habitat loss. They found that roads and adjacent areas were used more at night and avoided during the day. Additionally, yearlings and females with cubs used habitats near roads more than other bears, likely because roads were avoided by adult male bears. However, some brown bears at a coal mine in Alberta, Canada have appeared to adapt to disturbance from the mine (Cristescu et al. 2016). Based on the study, female brown bears with cubs appeared most adaptable to mining disturbance (their home ranges overlapped with areas of active mining), while male brown bears appeared to leave the area during active mining. This study concluded that active mining influenced the incidence of encounters between male bears and females with cubs, which may

AMERICAN OVERSIGHT

increase the likelihood of cubs' survival while active mining is taking place. Once mining stopped and the area was restored, male bears appeared to return to the area, and females indicated some flight response (Cristescu et al. 2016).

In Denali National Park between 1996 and 1997, a study was conducted that compared brown bear, caribou, and moose densities in proximity to the gravel road in the park with backcountry areas (Yost and Wright 2001). Overall, brown bear and caribou distributions indicated no pattern of traffic avoidance, while moose distribution suggested possible traffic avoidance (confounded by preferred forage located farther from the road).

Roads can also cause functional habitat loss if bears avoid them. While roads can cause habitat avoidance, alter movement patterns, and become ecological traps, many of the negative effects of roads are related to human use of roads, and not the roads themselves (Northrup et al. 2012). In a study in Alberta, Canada, Northrup et al. (2012) found that traffic patterns caused a clear behavioral shift in brown bears, with increased use of areas near roads and movement across roads during the night, when traffic was low. Typically, brown bears in areas of low human population are most active during the day with no daily pattern of road use (Boyce et al. 2010); Northup et al. (2012) found that vehicular activity shifted these patterns. Bears selected areas near roads traveled by fewer than 20 vehicles per day, and were more likely to cross these roads, avoiding roads receiving moderate traffic (i.e., 20 to 100 vehicles per day). They strongly avoided high-use roads (i.e., more than 100 vehicles per day) at all times. The traffic on the transportation corridor roads is expected to be approximately 35 round trips per 14-hour work day (one truck passing in either direction every 12 minutes) during operations, and therefore bears may avoid crossing the mine access road, especially during daytime hours. Under the summer-only ferry variant, the number of truck trips on the access roads would double during the summer to 78 round-trip truck trips per 14-hour work day, or one truck passing in either direction every 5 minutes. Therefore, under this alternative, brown bears are more likely to avoid the transportation corridor roads, especially during the summer when road volumes are expected to be highest.

In summary, bear movement patterns around the mine site and along the transportation corridor would be impacted by the project. Some age and gender groups of bears may avoid the mine site, specifically during operations (such as adult male bears), and others may be less affected or become habituated to mine site disturbance. Vehicular traffic along the transportation corridor (in particular the south mine access road) is anticipated to alter movement patterns as there are currently no roads in the majority of the transportation corridor. Some bears may avoid the transportation corridor or shift their movement patterns during periods of increased vehicular use. The WMP would detail specific parameters to prevent disturbance to bears.

Gray Wolf

Gray wolves travel widely in pursuit of prey, using a variety of habitat types; however, gray wolves strongly avoid roadways and other areas with high levels of human activity (USFWS 2000; Person 2001) and may have a large avoidance zone around the mine site and access roads. As detailed in Chapter 3.23, Wildlife Values, low numbers of wolves were incidentally detected, and no wolf dens were detected in the mine site. Wolf behavior in the transportation corridor may be affected; either by avoiding the roadways or using them for travel (especially during the winter when roads are plowed/maintained). Overall, impacts to gray wolves would be anticipated to be low, due to overall low numbers of wolves in the area and their general avoidance of humans.

Small Terrestrial Vertebrates

Some small mammals present at the mine site at the beginning of construction are anticipated to vacate the area due to human presence. Other species may be attracted to the mine site, due to

AMERICAN OVERSIGHT

newly created shelter. Some individual small mammals and wood frogs (*Lithobates sylvaticus*) may be more susceptible to predation during the process of mine site development. Any habitat avoidance during construction and operations would be additive to the direct habitat loss at the mine site.

Some small mammals and wood frogs are expected to avoid the transportation and natural gas pipeline corridors and Amakdedori port due to loss of habitat, and resulting edge impacts (e.g., increased predation along edge habitats and habitat changes).

Injury and Mortality

Species may experience injury and mortality from a variety of sources such as habitat avoidance and food/territory competition, vehicular collisions, lethal removal due to defense of life and property, and increased access to areas for hunting. The potential for an increase in access for hunting from the transportation corridor is discussed in detail in Section 4.5, Recreation, and Section 4.9, Subsistence. The WMP will outline measures to reduce impacts to wildlife species including proper trash disposal, containment of wildlife attractants, defining speed limits on roads, and prohibition of hunting among others.

The main source of injury and mortality directly related to the project is the potential for wildlife strikes along the transportation corridor. Overall injury and mortality is not anticipated to occur at the mine site and Amakdedori port, and therefore it is not discussed herein. Injury and mortality on project roads would be greatest during construction when the road is built through previously undeveloped habitats. In the transportation corridor, 76 miles of gravel road would be constructed between the Amakdedori port and the mine site (including mileage from spur roads to Iliamna and Kokhanok). During operations, daily truck traffic is anticipated at 35 roundtrip truck trips per day during all seasons and on both sides of Iliamna Lake. Therefore, in a 14-hour work day, a vehicle will pass along the road every 12 minutes (i.e., five vehicles every hour). Under the summer-only ferry variant, the number of round-trip truck trips would increase to 78, and therefore a truck would pass every 5 minutes. A low speed on the gravel transportation corridor roads will be maintained for dust suppression and safety. While the WMP will outline ways to reduce the potential for wildlife mortality along the road, varying weather and seasonal conditions would likely cause periods of increased mortality for some species (such as increased moose mortality during winter months, and reduced bear mortality during hibernation).

Caribou

Caribou distribution around project components is detailed in Section 3.23, Wildlife Values. Caribou would not be anticipated to occur in large numbers in the vicinity of the mine site during construction and operations, would be anticipated occur as scattered individuals around Amakdedori port, and anticipated to occur uncommonly in the transportation and natural gas pipeline corridors. Caribou are likely to move away from areas of human activity during operations, especially during blasting. As detailed in Boulanger et al. 2012, caribou are likely to avoid a large area of habitat around the mine site due to behavioral disturbance; therefore caribou are not anticipated to occur within range during any blasting. The primary potential for injury or mortality is through vehicle collision while crossing roads in the mine site. A low speed limit at the mine site and regular presence of equipment, vehicles, and humans, would likely cause caribou to avoid the area altogether, which would reduce the potential for injury or mortality. Additionally, the WMP will outline vehicle restrictions for when caribou are adjacent to roadways to prevent injury and mortality.

Moose

AMERICAN OVERSIGHT

Moose are known to occur in the project area, and are at risk of vehicular collisions during construction and operations; and to a lesser extent, after closure because the roadway will remain open to local traffic.

The mine site contains low densities of moose due to less suitable habitat, compared to the habitat of the transportation and natural gas pipeline corridors. Moose sometimes feed near roads (often depending on shoulder vegetation management), and rest or travel along cleared roads during heavy snow conditions. They frequently cross roads when vehicles are present, and are often startled, running from one side to the other. This may cause cows to be temporarily separated from their calves, and increases their risk of injury or mortality through vehicle collisions when the animals try to reunite. Although construction vehicles typically travel at slower speeds that would reduce the risk of collisions, the potential for injury and mortality exists during all three project phases, especially at night or during other periods of poor visibility, and in winter when animals may use access roads to escape deep snow. Since most vehicles and equipment will be traveling at low speeds in the mine site, moose density is low, and the open, low-growing vegetation permits greater visibility, the potential for moose to be struck in the mine site is low. However, the transportation and natural gas pipeline corridors contain higher quality moose habitat. The vegetation is taller and dense, and vehicles will likely be traveling at higher speeds. Therefore, there is a greater potential for moose injury or mortality while crossing the 76 miles of road in the transportation corridor. This risk would be greatest during winter months and periods of low visibility. The summer-only ferry variant is likely to decrease the potential for moose collision, even though truck traffic will double, due to improved visibility for truck drivers during summer.

Bear

Across the species' range, one factor causing reduction in brown bear populations has been the availability of human access into brown bear habitat by roads built for resource extraction (Boulanger and Stenhouse 2014). One study in Alberta, Canada by Boulanger and Stenhouse (2014) attempted to estimate the direct demographic impact of roads on survival rates, reproductive rates, and other demographic parameters for brown bears. They found that sex and age class survival was related to road density with sub-adult bears being most vulnerable to road-based mortality. Additionally, females with young of the year and/or yearling cubs had lower survival rates compared to females with 2 year olds or no cubs (Boulanger and Stenhouse 2014).

Bears are at risk of vehicular collisions during construction and operations; and to a lesser extent after closure, because the transportation corridor would remain open, but the traffic level would be reduced. The south mine access road would remain in place for Kokhanok residents to travel to Amakdedori port.

The south mine access road is located in an area with high brown bear densities and occurs between Katmai National Park and Preserve and Lake Clark National Park and Preserve. Brown bears are common in the area, especially along coastal plains in the early summer, and then along salmon-spawning streams later in the summer and fall. Thus, bears are moving around in relation to available food resources. Bears would likely cross the south mine access road as part of their regular movement patterns, and would experience increased traffic with the summer-only ferry variant. As detailed above under "Behavioral Disturbance," brown bears in particular would likely avoid the transportation corridor during periods of high vehicular traffic. The number of bears that may potentially be injured or killed in the transportation corridor across the life of the project may demonstrate an initial increase, until bears become accustomed to the road. Overall, the impact from vehicle collisions would be anticipated to be low.

There is a potential for bear mortality due to defense of life and property. Bears that become habituated and frequent the mine site, ferry terminal vicinity, Amakdedori port, or other project

AMERICAN OVERSIGHT

locations, may become a safety risk. Implementation of a WMP is anticipated to minimize the potential for conflict between wildlife and humans. Additionally, the project will have a no hunting policy for non-local employees.

Gray Wolf

Similar to other large mammal species discussed above, the greatest risk to gray wolves from the project would be the potential for vehicular collisions. However, given the low abundance of wolves in the area, regulated speed limits on the access roads, and guidance provided in the WMP, the potential for injury and mortality to gray wolves would be anticipated to be low.

Small Terrestrial Vertebrates

Small mammal species have the potential for injury and mortality from a variety of sources, and impacts are often species-specific. Blasting and removal of rock and vegetation during construction and operations of the mine (including clearing and grubbing) may cause injury and mortality especially to small mammal and wood frogs that have limited abilities to move away or avoid heavy machinery. Some species may experience injury and mortality due to collisions with project vehicles, especially along the transportation and natural gas pipeline corridors. The number and frequency of vehicles on the mine access road would be high, especially while mine equipment and construction materials are delivered to the Amakdedori port and transported on the road. Given speed restrictions and the noise of heavy equipment moving along the road, the risk of injury or mortality due to collisions with some wildlife on the road may be reduced. The risk of injury and mortality from collisions with vehicles would be higher during limited visibility such as during the winter, twilight hours, and during inclement weather. When roads are icy, increased slowing and stopping distances, coupled with decreased visibility, may lead to increased mortality. Additionally, small mammals may experience increased predation from predatory species using the newly created edge habitat.

Habitat Changes

There would be permanent and long-term removal of vegetation in the mine site during construction and operations of the mine, which currently provides habitat for a variety of wildlife species. Project component acreages are provided in Chapter 2, Table 2-11 and highlighted in this section. Terrestrial wildlife species that use the mine site will experience a loss of 8,129 acres of breeding, foraging, summering, wintering, and dispersing habitat during construction and operations. Some of the large mammal species such as caribou, moose, bears, and gray wolves occupy the habitat in the mine site at varying densities and at different times of the year. A large portion of this habitat would be revegetated once the project is completed, and the species are anticipated to return over time as the vegetation and habitat mature to conditions suitable for each species. The open pit lake, at approximately 608 acres, and other project components that are not reclaimed and restored, would result in a permanent loss of habitat for all terrestrial species.

The Amakdedori port facilities would result in a loss of 14 acres of vegetation that support a variety of wildlife species. The port facilities would be removed during closure, except for those required to support shallow draft tug and barge access to the dock for the transfer of bulk supplies. Disturbed areas would be recontoured, graded, ripped, and scarified. Topsoil and growth media would be placed as needed, and surfaces would be seeded for revegetation.

Construction of the transportation and natural gas pipeline corridors would include the removal and conversion of 1,157 acres of vegetation to gravel roads, ferry terminals, and material sites. This habitat removal would be additive to that at the mine site and Amakdedori port; post-closure the roads would remain in place.

AMERICAN OVERSIGHT

Changes in vegetation communities are discussed in Section 4.26, Vegetation. These changes would affect the availability and quality of habitat for terrestrial wildlife in the immediate project area, during both construction and operations, and potentially post-closure. Although affected habitat would not be directly lost (apart from habitat converted to open water, such as the pit lake), it may be become less suitable, and may cause displacement of individuals to more suitable habitat.

Caribou

As described previously in Chapter 3.23, the mine site is in the historical range of the Mulchatna caribou herd. While the mine site does not appear to be currently used by the herd for calving, the habitat in the mine site may be used by the herd during the post-calving summer period. Traditional ecological knowledge of the Mulchatna caribou herd identified areas of caribou concentration, which has shifted over time from the eastern portion of the range (1960-1979) to the west during the 1990s (Lanen 2018). During the mid-1990s when the Mulchatna herd had reached its peak population, the herd expanded its range north and west. At the same time, the herd shifted away from the project area. The Mulchatna caribou herd may shift back toward its traditional calving areas at some point in the future, which are closer to the mine site. Therefore, construction and operations of the mine site would represent a loss of 8,129 acres of post-calving summer habitat. In addition to direct removal of habitat, per Boulanger et al. 2012, caribou avoided area radius of 6.8 to 8.7 miles around an active mine in Alberta, Canada. This area of avoidance is considered habitat that may not be used due to behavioral disturbance. With a conservative approach, an 8.7-mile buffer around the mine site corresponds to a total avoidance area of approximately 291,313 acres.

Loss of habitat from development of Amakdedori port and the transportation and natural gas pipeline corridors represent habitat that is not currently used extensively by caribou.

Moose

As detailed in Section 3.23, moose density is low in the project area (i.e., 0.01 moose per square mile)(ABR 2011a). Moose density in the transportation and natural gas pipeline corridors is slightly higher at an estimated 0.02 moose per square mile (for areas around Iliamna Lake). Given the low density of moose throughout the project area, the combined acreage of direct habitat removal from all project components (9,300 acres) would have a low impact on moose.

Bear

The loss of approximately 9,300 acres of habitat from construction and operations of the project (including the mine site, Amakdedori port, ferry terminals, and transportation and natural gas pipeline corridors) would likely displace a few individual brown bears that use the habitat for foraging as part of their home range. These individual bears would be anticipated to use the surrounding habitat, although they may encounter increased competition with other bears. Brown bears are not evenly distributed throughout the landscape and are concentrated around resources such as high quality vegetation sources (sedges, grasses, berry sources) and salmon-spawning streams. Density estimates from a bear population survey in May 2009 ranged from 47.7 to 58.3 brown bears per 386 square miles (Becker 2010). Given the brown bear density estimate and the acreage of habitat that would be removed by the project, habitat would be lost for a few brown bears. This estimate is based entirely on direct habitat removal, and additional brown bears would likely avoid areas around the project. A large portion of the project would be restored following closure of the mine; therefore, the actual amount of long term habitat loss would be less.

AMERICAN OVERSIGHT

Brown bears congregate along salmon-spawning streams seasonally and may avoid locations or alter foraging patterns where the transportation corridor crosses the stream. The indirect loss of this habitat may force bears into adjacent suitable habitat, potentially causing competition with other bears, which may result in injury or mortality to displaced bears. However, time-lapse wildlife cameras at the location where the transportation corridor crosses Upper Talarik Creek revealed that brown bears spent little time fishing at that specific location (ABR 2015a).

The project area is generally considered low-quality habitat for black bears, and the loss of habitat would be anticipated to have little effect on the species.

Gray Wolf

Several individual gray wolves were detected dispersed across the project area over multiple years, but no packs of wolves or dens were detected in the mine site (ABR 2011a). This is likely correlated to the low numbers of caribou and moose in the project area. Therefore, the loss of habitat from the project is expected to have minimal impact on gray wolves in the area, which are likely to continue to forage in the surrounding habitat.

Small Terrestrial Vertebrates

As detailed in Chapter 3.23, Wildlife Values, multiple smaller mammalian species such as coyotes (*Canis latrans*), red foxes (*Vulpes vulpes*), river otters (*Lontra canadensis*), wolverines (*Gulo gulo*), beavers (*Castor canadensis*), and others were found throughout the project area. There are additional mammal species that are not considered "furbearers," and are known to occur in the project area. This includes hoary marmot (*Marmota caligata*), arctic ground squirrel (*Spermophilus parryii*), snowshoe hare (*Lepus americanus*), tundra hare (*Lepus othus*), collared pika (*Ochotona collaris*), and various species of mice, lemmings, shrews, voles, and wood frogs. These species would experience a direct loss of habitat during construction and operations of the mine. Some of the habitat would be restored and likely repopulated by these species, but the pit lake would remain a permanent loss of habitat.

4.23.2.3 Marine Mammals

Potential impacts specific to construction, operations, and reclamation activities of the mine site, transportation corridor across Iliamna Lake, Amakdedori port, and the natural gas pipeline corridor across Cook Inlet are described in the following sections. The project has the potential to directly and indirectly impact marine mammal populations through behavioral disturbance and habitat changes, as detailed in the following sections. Injury and mortality of marine mammals would not be anticipated to be significant factors as a result of any of the components of the proposed project.

Impacts as a result of the construction and operations of the proposed mine site would not be expected for marine mammals. Project sources of noise, which may disturb the behavior of marine mammals in project component areas include vessels used during installation of the natural gas pipeline across Iliamna Lake and Cook Inlet from Kamishak Bay to Nikiski and associated vessel traffic; pile driving and other construction noise associated with the construction of the Amakdedori port, ice breaking to conduct barging operations across Iliamna Lake, and aircraft used during construction and operations.

Project components most likely to impact marine mammals are the marine and freshwater portions of the transportation corridor, which would involve near and offshore vessel activity across Iliamna Lake and Cook Inlet, and the construction of the Amakdedori port. In this section, species-specific potential impacts are discussed by project component, if information is available. Potential impacts from oil or another substance spill are discussed in Section 4.27, Spill Risk.

AMERICAN OVERSIGHT

Noise sources described in Section 3.23, Wildlife Values, for non-listed marine mammals are the same for listed marine mammals. Potential environmental consequences to threatened and endangered species are discussed in Section 4.25, Threatened and Endangered Species. Where available, species-specific information is discussed regarding potential impacts from published literature, otherwise potential impacts to all marine mammals are discussed.

Behavioral Disturbance

Underwater and Airborne Noise

The effects of underwater and airborne sound from industrial activities on marine mammals might include one or more of the following: tolerance, masking of natural sounds, behavioral disturbance, temporary or permanent hearing impairment, or non-auditory physical effects (Richardson et al. 1995). See Section 4.19, Noise, for detailed analysis of noise impacts.

Anticipated sources of noise include vessels used during installation of the natural gas pipeline in Iliamna Lake and Cook Inlet; anchor handling operations associated with natural gas pipeline construction, construction noise associated with the Amakdedori port and ferry terminals on Iliamna Lake; vessels used in the transportation corridor across Iliamna Lake, which includes the need to break ice during mining operations; and aircraft during construction and operations. A variant includes operating the ferry for 6 months during summer. The east Kokhanok ferry terminal variant includes moving the ferry terminal to the east of Kokhanok, which may bring ferry operations closer to areas where the harbor seals that inhabit Iliamna Lake are more regularly observed. The pile-supported dock variant under Alternative 1 includes pile driving a dock structure instead of using a solid fill dock.

Vessel and aircraft noise generally does not exceed thresholds that may result in injury, but pile-driving noise may exceed injury thresholds. A detailed discussion on project noise is presented in Appendix K4.25; there are no seal haul-out sites in range to exceed airborne thresholds.

The magnitude of the impact from underwater noise from construction, operations, and reclamation activities of the mine site, transportation corridor, Amakdedori port, and the natural gas pipeline corridor across Cook Inlet and Iliamna Lake on non-threatened and endangered marine mammals would be expected to be minimal with the anticipated implementation of industry-standard mitigation measures required through required Marine Mammal Protection Action (MMPA) permitting. The extent to which project noise would be audible depends on source levels, frequency, ambient noise levels, the propagation characteristics of the environment, and sensitivity of the receptor (Richardson et al. 1995).

However, project activity noise would be expected to be localized, and only affect the area in the immediate vicinity of project activities. Noise from ice-breaking operations in Iliamna Lake could displace harbor seals from overwintering sites. During periods when Iliamna Lake is covered in ice, seals may access dry platforms for hauling-out, and air spaces for breathing by exploiting air pockets that develop along shorelines when the water levels drop (Burns et al. 2016). In winter months when ice breaking would occur, seals have historically been located on the eastern portion of the lake, east of an imaginary line between Kokhanok and Newhalen, where small areas of water can remain open (Burns et al. 2016). Should the summer-only ferry operations variant be implemented, ice breaking will not occur and therefore would have no effect on overwintering seals in Iliamna Lake. The pile-supported dock variant would produce more noise into the water than constructing a solid fill dock. The duration of time that marine mammals may be exposed to underwater sound would be short-term and temporary during pipeline installation, dredging, and construction activities, and from vessel traffic during mine operations. Exposure is only expected when seasonal distribution and habitat selection overlap in time and space with in-water project

AMERICAN OVERSIGHT

activities. Further MMPA permitting will define likely impacts from noise on marine mammal species.

Physical Presence (Vessel and Aircraft)

Impacts from physical presence can occur either from increased vessel traffic or newly erected human-made structures. Sources of physical presence include vessels used during installation of the natural gas pipeline in Iliamna Lake and across Cook Inlet from Kamishak Bay to Nikiski; in-water construction associated with the development of Amakdedori port and the ferry terminals; vessels used throughout the transportation corridor (across Iliamna Lake and Cook Inlet); and aircraft and vessels during construction and operations.

The physical presence of low-flying aircraft can disturb marine mammals, particularly individuals resting on the sea surface (reviewed in BOEM 2012). Observations made from low-altitude aerial surveys report that the behavioral responses of marine mammals are highly variable, ranging from no observable reaction to diving or rapid changes in swimming speed or direction (Smultea et al. 2008). Helicopter traffic may result in temporary behavioral responses.

Reactions of marine mammals to vessels often include changes in general activity (from resting or feeding to active avoidance), changes in surfacing-respiration-dive cycles, and changes in speed and direction of movement (NMFS 2013). Because there is existing oil and gas infrastructure in Cook Inlet, as well as numerous shipping routes and large amounts of vessel traffic, it is unlikely that the addition of physical presence as part of this project would change marine mammals' behavioral patterns.

Minke whales have been observed to avoid boats when approached, and approach boats when they are stationary (Richardson et al. 1995). Minke whales are thought to react similarly to baleen whales, namely the humpback and fin whales, discussed in Section 4.25, Threatened and Endangered Species. Harbor porpoises often rest at the surface, and their reaction to boats can be strong within 1,300 feet (Polachek and Thorpe 1990) out to 10.9 miles (Palka 1993). Harbor porpoises have often been seen changing direction in the presence of vessel traffic (Richardson et al. 1995). Avoidance has been documented up to 1 mile away from an approaching vessel, but the avoidance response is strengthened in closer proximity to vessels (Palka 1993). Collisions with vessels associated with the project would not be expected to occur, and are not known to have occurred in lower Cook Inlet to date.

The distances at which harbor seals were disturbed and the level of disturbance (e.g., detection, alarm, and harassment) varied by region, type of vessel, and vessel speed. The presence and movements of ships in the vicinity of seals can cause disturbance to harbor seals' normal behaviors (Jansen et al. 2010), and could potentially cause seals to abandon their preferred breeding habitats in areas with high traffic (Reeves 1998). Depending on circumstance, seals may not respond at all to vessel traffic, or may respond by deflection from the noise source, avoidance behavior, short-term vigilance behavior, or short-term masking behavior (NMFS 2015). Harbor seals hauled-out on mudflats have been documented returning to the water in response to nearing boat traffic (Richardson et al. 1995). Vessels that approach haul-outs slowly may also elicit alert reactions without flushing from the haul-out; small boats with slow, constant speed elicit the least noticeable reactions (Richardson et al. 1995). However, in Alaska specifically, harbor seals are documented to tolerate fishing vessels with no discernable reactions, and habituation is common (Johnson et al. 1989). Overall, vessel noise does not seem to strongly affect pinnipeds that are in the water (Richardson et al. 1995).

Impacts from physical presence of vessels or construction equipment on marine mammals are expected at some level of intensity. Cook Inlet has historical and current high use from fishing- and tourism-related vessel traffic, and the incremental addition of vessels associated with the

AMERICAN OVERSIGHT

project would be unlikely to result in increased impacts to marine mammals. The construction of the natural gas pipeline and later operations of the proposed ferry across Iliamna Lake may initially cause some disturbance of harbor seals occurring in the immediate area; however, harbor seals are known for vessel tolerance (Richardson et al. 1995). Thus, whereas impacts are expected at some level of intensity to harbor seals inhabiting Iliamna Lake, they are not expected to have a detrimental effect on the species. Also, as discussed under "Underwater and Airborne Noise," above, harbor seals inhabiting Iliamna Lake are most commonly observed on the eastern side of the lake, east of an imaginary line between Kokhanok and Newhalen, and therefore east of the natural gas pipeline and transportation corridor. If the Kokhanok east ferry terminal variant is chosen, the ferry terminal would be moved to the east of Kokhanok and closer to areas where harbor seals that inhabit Iliamna Lake are more regularly observed. The extent that physical presence would occur is expected to be local, and only affect the area in the immediate vicinity of the project activity. The duration that marine mammals may be exposed to vessel presence would be temporary during pipeline installation and construction activities, but would result in permanent increase in physical presence from the operations of the ferry across Iliamna Lake. However, vessels associated with activities would have a transitory presence in any specific location with a likely limited effect on marine mammals, because marine mammals typically avoid known high-vessel areas.

Impacts from the physical presence of aircraft on marine mammals would be expected at some level of intensity. The project area has a high volume of small aircraft, and the incremental addition of aircraft is unlikely to be detected by marine mammals. The duration that marine mammals may be exposed to aircraft presence is temporary, because aircraft support is expected to be intermittent and of short duration. Based on the short duration of potential exposure to aircraft-related noise and visual disturbance at any given location when the aircraft passes over, it is expected that effects on marine mammals would be limited to brief behavioral responses. The potential of impacts is unlikely, because aircraft presence is expected to occur infrequently. Any potential impacts on marine mammal behavior would be localized in the project area, and would not result in population-level effects. If any responses of marine mammals associated with aircraft were to occur, they would likely be of short duration.

Injury and Mortality

Vessel Collision

Marine mammal species are vulnerable to collisions with moving vessels (Pace 2011). There would be increased vessel traffic through Cook Inlet from Kamishak Bay to Nikiski as well as through Iliamna Lake as a result of the proposed project components, and therefore a greater possibility of vessel strikes of marine mammals. Between 1999 and 2003, the California Stranding Network reported only one ship strike of a gray whale in Alaska (Allen and Angliss 2012). No collisions of gray whales with vessels have been reported in Cook Inlet. The majority of the gray population migrates outside of the project area, and those individuals that do occur in lower Cook Inlet would be expected to avoid vessels. There have been three reports of whale-vessel collisions in Alaska waters between 1978 and 2011 (Neilson et al. 2012), but none have been reported in lower Cook Inlet. In rare instances, killer whales have been injured or killed by collisions with passing ships and powerboats, primarily from being struck by the propeller blades (Carretta et al. 2004).

Impacts to marine mammals as a result of injury or mortality from vessel collision would not be expected; therefore, the extent and duration that injury or mortality would occur is not included in this analysis.

AMERICAN OVERSIGHT

Habitat Changes

Habitat alteration, turbidity, and discharge from routine activities may impact prey species. Turbidity may affect the prey species distribution and diversity, as well as the ability of marine mammals to locate prey in the immediate area of the project activity. The effects of habitat alteration would not be expected to impact gray or minke whales, because gray whales are not expected to feed in the project area, and minke whales are not found in great concentrations. Impacts to killer whales from habitat alteration include the reduction of prey availability, but the area affected over time is too limited to have adverse effects to populations of fish and shellfish in the project area. Habitat alteration would be limited over time, and would not have adverse effects to populations of fish and shellfish prey of Dall's or harbor porpoises.

Development of onshore support facilities might displace a small number of harbor seals near the Amakdedori port and the south ferry terminal site (in Iliamna Lake and Kamishak Bay), as well as the proposed variant to the transportation corridor, which involves construction of the ferry terminal to the east of Kokhanok, but would not have measurable effect on local populations. Localized, temporary habitat alteration should not affect harbor seals, because the animals are highly mobile and feed near river mouths. Harbor seals have not been documented feeding at the mouth of Amakdedori Creek.

Impacts from habitat alteration as a result of construction activities on marine mammals are expected at some level of intensity. Impacts to marine mammals from habitat alteration as a result of mining or reclamation operations at the mine site would not be expected. These effects should be consistent with, or less than, what is currently occurring throughout Cook Inlet. The extent that habitat alteration would occur is expected to be local, and only affect the immediate area around the south ferry terminal and Amakdedori port during construction. Potential effects from seafloor disturbance are likely to limit the foraging quality of the disturbed area during construction. Direct habitat loss would result from the construction of the south ferry terminal in Iliamna Lake and Amakdedori port in Kamishak Bay under Alternative 1 and the pile-supported dock variant. The duration that marine mammals may be exposed to habitat alteration from construction would be temporary, because habitat alteration activities would be of short duration, and possibly for a few years afterward in some locations. The duration that marine mammals may be exposed to habitat loss from development of Amakdedori port and the south ferry terminal would be permanent. The amount of habitat affected in the project area would be small compared to that available to marine mammal species for foraging.

4.23.3 Action Alternative 2 – North Road and Ferry

Impacts to wildlife from the mine site are discussed previously under Action Alternative 1 and not reiterated here. Under this alternative, the mine site footprint would be approximately 115 acres larger than Action Alternative 1. From a wildlife perspective, the primary difference with Action Alternative 2 is the geographical shift of the transportation and natural gas pipeline corridors to the north above Iliamna Lake, and the Diamond Point port. Impacts that may occur to wildlife species along Action Alternative 2 transportation and natural gas pipeline corridors are discussed below.

4.23.3.1 Birds

Impacts to birds that occur along the transportation and natural gas pipeline corridor would be similar to Alternative 1, but located along the northern shore of Iliamna Lake. These include a loss of foraging and nesting habitat as a result of construction, increased potential for injury and mortality along the road, behavioral disturbance due to increased noise and other edge effects associated with a road. The main difference is that the Diamond Point port is located in an area

AMERICAN OVERSIGHT

that provides important migratory bird stop-over habitat (especially for shorebirds), important summering and wintering habitat for a variety of waterbirds, and an important nesting area for several species of seabirds.

Behavioral Disturbance

As discussed in Section 3.23, Wildlife Values, there are several golden eagle nests located along the Williamsport-Pile Bay Road, one peregrine falcon nest at Diamond Point, a bald eagle nest located in the Diamond Point barge dock cut and fill area, and bald and golden eagle nests in the valley between Ursus Cove and Cottonwood Bay. Construction of the transportation corridor to Diamond Point, and construction of the port will likely cause disturbance through increased noise (particularly if blasting is needed to construct the road) and increased human presence. The greatest source of disturbance would occur during road construction since there is currently no road to Diamond Point. Disturbance to any golden eagle or bald eagle nest would likely involve coordination with the US Fish and Wildlife Service, and possibly an Eagle Take Permit (USFWS 2016).

Additional impacts to avian species may occur through noise and physical presence of vessels near the mouths of Iliamna and Iniskin bays, where multiple seabird species (e.g., gulls, cormorants, and puffins) nest on adjacent cliffs, rock outcrops, and small islands. The increase in vessel traffic would likely cause disturbance to birds molting, wintering, feeding, resting, and migrating through Iliamna and Iniskin bays. In particular, the protected Iliamna and Iniskin bays provide sheltered feeding and wintering habitat for a variety of waterbirds (especially scoter species). Vessel traffic would likely cause species to swim away, fly, dive, or otherwise avoid approaching vessels. Since vessel speeds would be low in the bays, birds would likely avoid approaching vessels and the impact would be anticipated to be low.

Injury and Mortality

There would be potential for avian mortality along the transportation corridor while flying between patches of habitat bisected by the road. Since the transportation corridor along the northern shore of Iliamna Lake includes large portions of forested habitats, the avian species that may be impacted include warblers, thrushes, waxwings, sparrows, finches, kinglets, flycatchers, woodpeckers, and others that use those types of habitats. There may be increased predation from predatory species along the road due to increased visibility and clear flight path along the road edge.

There is increased potential for bird collisions during inclement weather in Iliamna and Iniskin bays, especially if lights are used on the lightering vessels. As detailed in Section 4.25, Threatened and Endangered Species, some waterbird species such as eiders have a potential to collide with stationary objects, especially if illuminated by lights at night during inclement weather. Therefore, there would be potential for vessels moored at the lightering location to pose a collision hazard to birds in Iniskin Bay. The lightering location is near the mouth of Iniskin Bay, and the local topography creates narrow passage at the mouth where there would be increased potential for avian collisions.

Habitat Changes

Loss of habitat from construction of the transportation and natural gas pipeline corridors would occur primarily in forested habitat types to the north of Iliamna Lake. There is suitable habitat adjacent to the transportation corridor that species may disperse to; however, loss of some individual territories may occur. Overall impacts from habitat changes are anticipated to be

AMERICAN OVERSIGHT

minimal due to the relatively narrow nature of the transportation corridor and presence of nearby suitable habitat.

4.23.3.2 Terrestrial Wildlife

Impacts to terrestrial wildlife from the mine site under Action Alternative 1 would be similar and not repeated here. The primary difference would be the impact to wildlife from the transportation and natural gas pipeline corridors along the northern part of Iliamna Lake. This area is forested compared to the mine site, and therefore has a lower abundance and distribution of caribou, and a higher population of moose and black bears. Overall, the abundance of caribou from Newhalen east to Cook Inlet along the transportation and natural gas pipeline corridors would be low (due to a lack of suitable caribou habitat); therefore, impacts to caribou are not expected from the transportation and natural gas pipeline corridors of Action Alternative 2 and not discussed herein. Impacts to moose, brown and black bears, gray wolves, and other terrestrial wildlife are primarily related to increased noise, vehicular traffic, increased human interaction, and loss of habitat (both directly through vegetation removal, and avoidance of areas near the transportation and natural gas pipeline corridors). Therefore, these species are discussed collectively. Additionally, potential impacts to terrestrial wildlife from the port at Diamond Point would be expected, since the habitat is primarily rocky coastline that is not suitable habitat for most terrestrial wildlife species.

Impacts to small mammal species and wood frogs would be similar to those detailed under Action Alternative 1 and are not repeated here. Impacts would be primarily related to loss of habitat, increased potential for injury and mortality along the access road, and increased edge effects. These impacts would be anticipated to be localized around the access road, impact species with home ranges that overlap the road, and impact dispersing individuals (e.g., juveniles seeking new territories, or males in search of mates).

Behavioral Disturbance

Wildlife would be anticipated to avoid the transportation and natural gas pipeline corridors as a result of vehicular traffic in an area that currently has no established roads (apart from the existing Williamsport-Pile Bay Road). Moose have been known to avoid roads by up to 1,000 feet, and bears would be anticipated to alter feeding patterns in salmon-spawning streams adjacent to the transportation and natural gas pipeline corridors. Traffic volumes, at 35 round-trip truck trips per day (one vehicle every 12 minutes) would be anticipated to temporarily disturb wildlife while vehicles are passing. The summer-only ferry variant would double traffic during the 6 months that the ferry is in operation, and therefore a vehicle would travel the road approximately every 5 minutes, which would result in greater avoidance of the road. The summer-only ferry variant would have lower impacts on moose because fewer moose might be struck on the road during winter (due to lower traffic volumes), but the increased traffic may cause road avoidance in bears.

Injury and Mortality

Since the transportation and natural gas pipeline corridors roughly parallel to the north shore of Iliamna Lake, wildlife that follow the various creek and stream drainages the flow towards Iliamna Lake would intersect the access road. While fish passage structures would permit some wildlife to pass underneath the road along anadromous streams, other wildlife may cross the road while moving to and from Iliamna Lake. The elevated road prism, regulated speed limit, and WMP are designed to minimize wildlife injury and mortality. Increased moose densities along several of the creek and river drainages that flow into Iliamna Lake, along with increased black bear density, may result in increased wildlife injury and mortality compared to Action Alternative 1.

AMERICAN OVERSIGHT

Habitat Changes

Construction and operations of the transportation and natural gas pipeline corridors will result in loss of wildlife habitat detailed in Chapter 2, Table 2-11. Habitat removal may result in edge effects, such as wildlife traveling along the road in winter (especially if the road is plowed), dust accumulation of surrounding vegetation, changes in plant phenology due to earlier spring melt in vegetation along the road prism, and other vegetation changes that directly affect foraging habitat for several mammal species.

4.23.3.3 Marine Mammals

A discussion of the affected environment for marine mammals is presented in Section 3.23, Wildlife Values. Marine mammals would generally be expected to occur in the same densities throughout the marine environment analyzed and all impacts would be anticipated to be the same for the proposed alternatives. The exception would be the temporary modification of habitat resulting from an increase in turbidity and water quality during construction activities. Increased turbidity may potentially have impacts on marine mammal prey. The transportation corridor crossing Iliamna Lake would be longer under Action Alternative 2, potentially increasing interaction with harbor seals that inhabit Iliamna Lake. Likewise, the location of the north and south ferry terminal locations presented in Action Alternative 2 would be closer to areas where harbor seals are more commonly observed in Iliamna Lake (see Section 3.23, Wildlife Values, Figure 3.23-7). The transportation corridor component of Action Alternative 2 includes the summer-only ferry operations variant, which would limit ferry use to 6 months in the summer, resulting in less likelihood for impacts to harbor seals that overwinter in Iliamna Lake. The natural gas pipeline route presented in Action Alternative 2 would be shorter and impact fewer acres than that proposed for Action Alternative 1. Therefore, impacts to marine mammals would be anticipated to be low.

4.23.4 Action Alternative 3 – North Road Only

Direct and indirect impacts to wildlife species from Action Alternative 3 are similar to Action Alternatives 1 and 2, except there would be no ferry in Iliamna Lake, and the length of the road associated with the transportation corridor would be 82 miles. This all-road option for the transportation corridor would increase the amount of permanent habitat loss (1,085 acres of habitat loss) and increase the potential for vehicular collisions.

Anticipated wildlife impacts from Action Alternative 3 variants include habitat loss from the concentrate pipeline pump house (1 acre located in the mine site), booster station (0.7 acre), and a slight increase in the transportation and natural gas pipeline corridors' width by 3-feet to accommodate the concentrate pipeline and return water pipeline. Under the concentrate pipeline variant, the number of round-trip truck trips would be greatly reduced, with a potential reduction in wildlife injury and mortality along the transportation corridor.

Action Alternative 3 would have no ferry in Iliamna Lake; therefore, there would be no impacts to Iliamna lakes seals from the project. All other impacts to marine mammals would be anticipated to be the same as Action Alternative 2.

4.23.5 Summary of Impacts

The project is anticipated to have a wide variety of potential impacts to terrestrial wildlife, birds, and marine mammals. Table 4.23-1 summarizes the key issues for wildlife resources from Alternatives 1, 2, 3, and their variants.

AMERICAN OVERSIGHT

Table 4.23-1: Summary of Key Issues for Wildlife Resources

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Behavioral changes	Avoidance of the mine site by the majority of terrestrial wildlife and bird species, especially during construction and operations. N/A for marine mammal species	Same as Alternative 1	Same as Alternative 1
Injury and mortality	During construction, and less so during operations, some terrestrial wildlife and bird species unable to move out of harm's way may be crushed during initial site clearing. Potential for bears to be killed in defense of life and property. N/A for marine mammal species	Same as Alternative 1	Same as Alternative 1
Habitat changes	Loss of 8,129 acres of habitat and 8,167 acres with the summer only ferry operations variant. Additional terrestrial wildlife avoidance of surrounding habitat. Potential water quality degradation due to turbidity from runoff.	Loss of 8,248 acres of habitat and 8,286 acres with the summer-only ferry operations variant. Additional terrestrial wildlife avoidance of surrounding habitat. Potential water quality degradation due to turbidity from runoff.	Loss of 8,130 acres of habitat. Potential water quality degradation due to turbidity from runoff.
Transportation Corridor			
Behavioral changes	Terrestrial wildlife avoidance due to increased noise, vehicle, and human presence. Underwater noise may exceed injury thresholds as defined by regulatory agencies. Physical presence of vessels over 18 miles of travel and aircraft may displace harbor seals that inhabit Iliamna Lake.	Same as Alternative 1. Physical presence of vessels over 29 miles of travel and aircraft may displace harbor seals that inhabit Iliamna Lake.	Same as Alternative 1.
Injury and mortality	Potential for terrestrial wildlife collisions with vehicles across 76 miles of road. Summer-only ferry operations variant may increase collisions	Potential for terrestrial wildlife collisions with vehicles across 54 miles of road. Summer-only ferry operations variant may increase collisions	Potential terrestrial wildlife collisions with vehicles across 82 miles of road.

	preferred alternative and an additional 27 acres under the summer-only ferry operations variant. Loss of 10.5 acres of benthic marine foraging habitat with an earthen causeway port and 0.07 acre of marine habitat loss with a pile supported dock.	benthic marine foraging habitat with an earthen causeway port and 57.2 acres of marine habitat loss with a pile supported dock.	benthic marine foraging habitat.
Natural Gas Pipeline			
Behavioral changes	Underwater noise may exceed injury thresholds as defined by regulatory agencies. Physical presence of vessels and aircraft may displace marine species.	Same as Alternative 1.	Same as Alternative 1.
Injury and mortality	Potential for bird species to collide with vessels during construction.	Same as Alternative 1.	Same as Alternative 1.
Habitat changes	446 acres of disturbed habitat from pipe lay activities.	Acreage of disturbed habitat has not been determined from pipe lay activities.	Similar to Alternative 2.

Note: Acres and miles derived from Table 2-11.

4.23.6 Cumulative Effects

4.23.6.1 Terrestrial Wildlife and Birds

Past, present, and reasonably foreseeable future actions (RFFAs) in the cumulative impact study area have the potential to contribute cumulatively to impacts on terrestrial mammals. This includes species with large home range sizes such as caribou, moose, bears, and wolves, in addition to smaller-bodied species with more restricted home range sizes. The potential future actions are similar to the proposed project in how they could impact terrestrial wildlife through habitat loss and alteration, disturbance from construction and operations activities, collisions with vehicles, altered predator-prey relationships, and increased/altered subsistence and recreational hunting, among others.

The following RFFAs identified in Section 4.1 were carried forward in this analysis based on their potential to impact terrestrial wildlife in the analysis area:

- Pebble Project buildout- develop 55 percent of the resource over 78-year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*
- Donlin Gold

AMERICAN OVERSIGHT

- Diamond Point Rock Quarry
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure and Energy Projects

**Indicates exploration activities only.*

The most important potential future actions included in this analysis are those that contribute to the cumulative loss of habitat for terrestrial wildlife, such as avoidance of areas that are noisy or have increased human presence. Habitat loss for raptors, waterbirds, landbirds, and shorebirds would contribute to the global decline of many avian species. Loss of habitat or habitat fragmentation for wide-ranging species, such as caribou, may occur through the creation and expansion of new roads into calving areas and other critical life stage areas. New active mining projects in the range of the Mulchatna caribou herd may cause the herd to shift locations at critical times or seek out new foraging areas, thus reducing overall fitness. New roads, gas lines, and other infrastructure features may cause habitat fragmentation or avoidance of insect-relief habitat. Moose may be more prone to vehicular collisions while crossing new roads and may avoid areas of high quality forage habitat in close proximity to roads. Additional development may alter predator-prey relationships through increased levels of certain predators, such as red foxes. Bear species may have altered foraging locations and have increased mortality through the killing of bears for defense of life and property.

4.23.6.2 Marine Mammals

The following past, present, and reasonably foreseeable future actions were carried forward in this analysis based on their potential to impact marine mammals in Cook Inlet:

- Johnson Tract
- Diamond Point Rock Quarry
- Alaska Stand Along Pipeline Project / Alaska LNG (one or the other, project would be developed based on funding)
- Drift River Oil Pipeline Transportation Project
- Cook Inlet Oil and Gas Lease Sales
- Lake and Peninsula Borough and other regional Renewable Energy Initiatives
- Commercial, Sport and Subsistence Fishing
- Subsistence Activities
- Scientific Surveys and Research

Potential types of effects on marine mammals from the above include:

- Air and marine noise
- Behavioral disturbance of marine wildlife
- Marine mammal displacement from habitat alteration
- Resource consumption
- Bottom sediment disturbance

The important potential future actions included in this analysis are based on the spatial and temporal overlap of activities on marine mammals. Some potential future actions will increase exposure to marine mammals (e.g., underwater noise, vessel traffic). The expected potential incremental cumulative effects from project impacts are not expected to result in population level impacts for non-TES species of marine mammals utilizing the project area in Cook Inlet.

AMERICAN OVERSIGHT

Potential incremental cumulative effects from vessel traffic from the project would be expected. Those individuals or groups of marine mammals that could be disturbed by the project may experience high vessel activity during summer from recreation, commercial fisheries, barging, and other forms of commercial and scientific vessel traffic. Because of this frequent vessel activity in Cook Inlet, some marine mammals in the area may be at least partially habituated to vessel presence and noise, and impacts from vessel traffic from the project is expected to add negligible effects to marine mammals relative to the overall risks from vessel traffic in this area.

Noise, behavioral disturbance from physical presence, and vessel and helicopter traffic associated with routine operations could affect marine mammals. Noise generated during construction and operations may temporarily disturb some marine mammals, causing them to leave or avoid the area. Such effects would likely be short-term and would not be expected to result in population-level effects. While collisions with vessels may injure or kill some individuals, collisions are thought to be unlikely because of the low level of traffic expected from the proposed project.

Cumulative effects of past, present, and reasonably foreseeable future actions on marine mammals would be expected, except for large spill events, in which case the impacts may be measurable. The greatest potential adverse effect from the project to cumulative effects on marine mammals would be a result of increased exposure to oil from a large spill. Other potential adverse effects include those from increased noise levels and increased vessel strikes. There would be potential cumulative effects from noise for non-threatened and endangered marine mammals but not a population level effect. This is due to the existing large acoustic footprint in this area from marine traffic and other construction activities with no known population-level effects, as well as due to the expected monitoring and mitigation methods likely to be required from regulatory agencies to reduce the effects from noise and vessel traffic. Those individuals or groups of marine mammals that could be disturbed by the project experience vessel activity during summer from recreation, commercial fisheries, barging, and other forms of commercial and scientific vessel traffic. Because of the frequent vessel activity in Cook Inlet, some marine mammals in the area are thought to be at least partially habituated to vessel presence and noise, and impacts of vessel traffic from the project would be expected to add little contributions to marine mammal impacts relative to the overall risk from vessel traffic in the region.

3.21 FOOD AND FIBER PRODUCTION

The Farmland Protection Policy Act of 1994 was enacted to reduce the amount of highly productive farmland being converted to non-agricultural uses as a result of various federal programs. The United States Army Corps of Engineers is required to assess the potential impacts on farmland during the National Environmental Policy Act review process. Prime farmland is available land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops. Unique farmland is land other than prime farmland that is used for the production of specific high value food and fiber crops. While there may be some small outdoor or indoor garden projects in individual communities, there are no designated prime or unique farmlands in the project area.

In most of the United States, agriculture provides food, natural fibers, biofuels, and other products to American consumers. In southwest Alaska, however, subsistence is the most important source of non-imported food and raw materials; discussed in Section 3.9, Subsistence.

AMERICAN OVERSIGHT

TABLE OF CONTENTS

3.21 FOOD AND FIBER PRODUCTION 3.21-1

AMERICAN OVERSIGHT

4.21 FOOD AND FIBER PRODUCTION

While there may be some small outdoor or indoor garden projects in individual communities, there are no designated prime or unique farmlands in the project area. Therefore, there would be no impact to farmlands from the proposed project or any of the alternatives discussed in this Environmental Impact Statement (EIS).

In the project area, subsistence activities (e.g., hunting, fishing, and gathering) are the primary sources of food and fiber production; discussed in Section 4.9, Subsistence.

4.21.1 Cumulative Effects

There would be no contribution of cumulative impacts to farmlands from the proposed project or any of the reasonably foreseeable future actions discussed in this EIS due to the absence of designated prime or unique farmlands in the project area.

Good Morning:

Upon review of the files which were sent out, we have found that we had not yet provided Chapter 5 and Chapter 6.

Please find attached 2 Word files, the review drafts of Chapter 5, Mitigation, and Chapter 6, Consultation and Coordination.

v/r,

Katie McCafferty

AMERICAN OVERSIGHT

5.0 MITIGATION

5.1 INTRODUCTION

This section defines terminology, describes the process of identifying mitigation during the National Environmental Policy Act (NEPA) and the US Army Corps of Engineers' (USACE) Clean Water Act (CWA) Section 404 permitting processes, and identifies mitigation measures intended to avoid or minimize project impacts.

5.1.1 Overview of Mitigation

NEPA requires federal agencies to consider appropriate mitigation measures to avoid or minimize specific impacts. Consideration of project mitigation is a continuous process through completion of the Environmental Impact Statement (EIS) and Record of Decision (ROD). This includes efforts made as part of the project design or standard procedures; Best Management Practices (BMPs), industry standards, or standard permit requirements; and assessment of measures recommended for consideration during the NEPA process.

Additionally, the USACE, pursuant to Section 404 of the CWA, has very specific requirements for mitigation, including a sequence of: 1) impact avoidance, 2) minimization, and 3) compensatory mitigation for unavoidable impacts under their jurisdiction. Mitigation measures are also developed through other processes, such as consultation under Section 106 of the National Historic Preservation Act (NHPA), permit authorization by other federal and state agencies, and monitoring and adaptive management associated with specific permit requirements.

5.1.2 Definitions and Process

A general description of the key terms used in this chapter is provided in Table 5-1. Where mitigation measures are analyzed as part of the Proposed Action, their effectiveness in avoiding or reducing potential impacts has been taken into consideration in assessing potential environmental consequences.

Table 5-1: Common Mitigation Terms

Term Used in This EIS	Description
Applicant's Proposed Mitigation	Impact-reducing actions or designs that an applicant has committed to as part of their Proposed Action. Commonly referred to as avoidance and minimization.
Best Management Practices and industry standards	BMPs and industry standards are predictable actions necessary to comply with regulations and standard permit requirements that are designed to reduce impacts to the environment. These are typically reflected in the applicant's design and are analyzed as part of the Proposed Action. For example, the Construction General Stormwater Permit for Storm Water Discharges for Large and Small Construction Activities (2016 CGP, AKR100000) will require a Storm Water Pollution Prevention Plan (SWPPP).
Agency Considered Mitigation	Measures agencies consider that would further reduce impacts. These are not considered part of the Proposed Action. Special conditions are added to Department of the Army permits when such conditions are necessary to satisfy legal requirements or to otherwise satisfy the public interest requirement. Permit conditions will be directly related to the impacts of the proposal, appropriate to the scope and degree of those impacts, and reasonably enforceable.

AMERICAN OVERSIGHT

Table 5-1: Common Mitigation Terms

Term Used in This EIS	Description
Compensating for Unavoidable Impacts	Compensating for an impact by replacing or providing substitute resources or environments is one way an agency can use mitigation to reduce environmental impacts associated with proposed projects (CEQ 2010). Compensatory mitigation is a requirement under the CWA for impacts to Waters of the US (WOUS) that cannot be avoided or minimized. Compensatory mitigation requirements are identified in RODs based on the Final EIS.
Monitoring and Adaptive Management	Through monitoring, appropriate data are collected to assess predicted project impacts and the effectiveness of mitigation after initial and ongoing implementation. Mitigation that is not proving effective can be adapted. Adaptive management is often defined as "a structured, iterative process of robust decision making in the face of uncertainty, with an aim to reducing uncertainty over time via system monitoring." Mitigation monitoring can incorporate elements of adaptive management if monitoring results indicate a basis for changes to a mitigation program.

5.1.3 NEPA Guidance

NEPA requires federal agencies to describe potential impacts to resources potentially affected by the Proposed Action and alternatives to the Proposed Action. Alternatives may be designed to avoid or minimize potential impacts that may be caused by the Proposed Action. Because one of the purposes of NEPA is to promote efforts that will prevent or minimize damage to the environment (42 US Code Section 4321), mitigation and monitoring are important tools used to avoid, minimize, or compensate for potential adverse impacts. Early consideration of measures to avoid and reduce impacts is often integral to project design, and the effort to avoid, reduce, or offset impacts is a key component of the alternatives development and decision-making process. Many federal agencies, laws, and regulations have specific guidance regarding required efforts to reduce impacts to resources, and the Council on Environmental Quality (CEQ) requires mitigation to be considered during the NEPA process. According to the CEQ (1981):

> *Mitigation measures discussed in an EIS must cover the range of impacts of the proposal. […]. Mitigation measures must be considered even for impacts that by themselves would not be considered "significant." Once the proposal itself is considered as a whole to have significant effects, all of its specific effects on the environment (whether or not "significant") must be considered, and mitigation measures must be developed where it is feasible to do so.*
>
> *All relevant, reasonable mitigation measures that could improve the project are to be identified; even if they are outside the jurisdiction of the lead agency or cooperating agency, and thus would not be committed as part of the RODs of these agencies.*
>
> *The ROD must state whether all practicable measures have been adopted, and if not, why not.*
>
> *However, to ensure that environmental effects of a proposed action are fairly assessed, the probability of mitigation measures being implemented must also be discussed. Thus, the EIS and ROD should indicate the likelihood that such measures will be adopted or enforced by the responsible agencies.*

AMERICAN OVERSIGHT

> *Lead agencies "shall include appropriate conditions [including mitigation measures, monitoring, and enforcement programs] in grants, permits, or other approvals" and shall "condition funding of actions on mitigation." Any such measures that are adopted must be explained in the ROD.*

CEQ regulations describe several ways an agency can use mitigation to reduce environmental impacts associated with proposed projects (CEQ 2010). These include:

- Avoiding an impact by not taking a certain action or parts of an action.
- Minimizing an impact by limiting the degree or magnitude of the action and its implementation.
- Rectifying an impact by repairing, rehabilitating, or restoring the affected environment.
- Reducing or eliminating an impact over time, through preservation and maintenance operations during the life of the action.
- Compensating for an impact by replacing or providing substitute resources or environments.

On January 14, 2011, the CEQ issued a memorandum to federal departments and agencies containing guidance on establishing, implementing, and monitoring mitigation commitments identified and analyzed in Environmental Assessments and EISs, and adopted in the final decision documents. The Pebble Project EIS complies with federal guidance by considering mitigation during alternatives development and by disclosing mitigation as components incorporated into the Proposed Action as efforts to avoid and minimize potential impacts.

5.2 AVOIDANCE AND MINIMIZATION MEASURES UNDER NEPA

5.2.1 Best Management Practices, Industry Standards, and Standard Permit Requirements

Numerous state, federal, and local government permits and approvals are required before development and operation of a mining project in Alaska can begin. Appendix E describes the relevant permits and regulatory requirements for the Pebble Project. These permitting processes and regulatory requirements are established to ensure that projects are designed, operated, and reclaimed in a manner consistent with applicable laws and regulations.

5.2.1.1 Permitting for Large Mine Projects in Alaska

In order to coordinate state agency permitting and integrate federal and local permitting for large mining projects, the State of Alaska has developed a Large Mine Permitting Team (LMPT) process. The LMPT is an interagency group of regulatory experts that works cooperatively with large mine applicants and operators, federal resource agencies, and the Alaska public to ensure that projects are designed, operated, and reclaimed in a manner consistent with state laws and regulations. The goal of the LMPT process is to coordinate the sequencing and intergovernmental review of the numerous permits required of a large, complex hardrock mine. The following is a summary of the general process the State follows (ADNR 2017b):

Pre-Application. One of the first tasks for the LMPT is to work with the potential applicant to ensure the pending permitting process and regulatory requirements are understood, that appropriate baseline environmental data are collected, to define application information requirements, and develop a realistic schedule.

AMERICAN OVERSIGHT

Permit Application. The applicant submits an application package, typically consisting of the Plan of Operations, Reclamation Plan, Waste Management Plan, reclamation and closure cost estimates, associated monitoring and management plans, and baseline study reports. The LMPT reviews the package to make sure all the necessary information for a complete review is included.

Review and Analysis. The LMPT collaboratively reviews the proposed plans and supporting documents to inform their respective agencies' permitting decisions and to ensure the project design complies with all applicable state laws and regulations.

Issues Resolution. The team works with the applicant to resolve issues, usually resulting in modifications to the project design, operations, and monitoring plans.

Public Notice and Permit Issuance. Draft Plan of Operations Approval, Reclamation Plan Approval, Integrated Waste Management Permit, and financial assurance costs are publicly noticed together with final proposed plans and supporting documents from the applicant. Public comments are reviewed by the LMPT and incorporated, as appropriate, into final agency approvals, which are then publicly posted on the Alaska Department of Natural Resources' (ADNR) Large Mine Project website.

Post Permit Issuance. Once the permits are issued and construction and operations begin, the LMPT is active in permit maintenance, site inspections, and compliance monitoring.

Reclamation and Final Closure. The LMPT ensures that reclamation and closure objectives are met, including long-term environmental management, and that financial assurances are in place to ensure an orderly and stable closure.

5.2.1.2 Best Management Practices

Pebble Limited Partnership (PLP) would follow BMPs and industry standards required to comply with regulations and standard permit requirements that are designed to reduce impacts to the environment. A list of standard BMPs, permit requirements, and/or industry standards that would likely be required for the Pebble Project is provided below. This is not intended to be a complete list; rather, it reflects the most predictable actions for this type of project that would be necessary to comply with regulations and standard permit requirements designed to reduce impacts to the environment. Many of these are also captured in PLP's proposed mitigation measures discussed in the following section. USACE took these standard BMPs, permit requirements, and industry standards into consideration when assessing the impacts of the project.

- Using secondary containment for the storage of all fuel and hazardous chemicals during all phases of the proposed project to prevent potential releases from fuel handling, tank failures, or contaminated stormwater from reaching the aquatic environment.
- Designing and installing culverts and bridges on transportation routes to optimize fish passage.
- Implementation of Storm Water Pollution Prevention Plans (SWPPPs), Erosion and Sediment Control Plans (ESCPs), and use of industry standard BMPs for sediment and erosion control.
- Development and maintenance of Oil Discharge Prevention and Contingency Plan (ODPCPs), Spill Prevention, Control and Countermeasure (SPCC) Plans, and Facility Response Plans (FRPs).

AMERICAN OVERSIGHT

- Use of BMPs, such as revegetation planning, watering, and use of dust suppressants to control fugitive dust.
- Preparation and implementation of a Reclamation and Closure Plan (RCP).
- Compliance with ADNR Dam Safety requirements through certificates of approval to construct and operate dams to include preparation of Emergency Action Plans and completion of a Failure Modes Effects Analysis (FMEA).
- Appropriate bonding/financial assurance required by ADNR and ADEC.
- Compliance with ADNR Temporary Water Use Authorization conditions for water withdrawal, such as screening requirements to avoid fish entrainment or injury, establishing water withdrawal rates and volumes, and as appropriate timing of water withdrawal to avoid fish migration, spawning, and incubating eggs.
- Monitoring of water withdrawals to ensure permitted limits are not exceeded.
- Verification that project vessels are equipped with proper emergency towing equipment in accordance with 18 AAC 75.027(f).
- Application of industry-standard BMPs relating to invasive species prevention and management.
- Development of a Cultural Resources Management Plan (CRMP) as part of the Section 106 process.
- Verifying pipeline integrity with visual and other non-destructive inspections of welds, hydrostatic testing, use of in-line inspection tools, and aerial inspections.

5.2.2 Mitigation Measures, Best Management Practices, and Environmental Protections Incorporated into the Project

The EIS serves in part to inform the public and review agencies of mitigation measures, project elements, or other environmental protections that are included to reduce or avoid impacts. The USACE views these elements as part of the project, and considers PLP's proposed mitigation measures as inherent to the Proposed Action as well as applicable components of the other alternatives' descriptions. These measures, including any potential impacts associated with these measures, were considered when assessing the impacts of the project on the resources as described in Chapter 4, Environmental Consequences.

Table 5-2 lists the mitigation measures, project elements, and environmental projections, including BMPs that PLP is proposing to implement to avoid and minimize impacts. A description of PLP's Proposed Action (Alternative 1 – Applicant's Proposed Alternative) can be found in Chapter 2, Alternatives. Engineering design and construction, operations, or closure phase procedures are often preliminary at the time that an EIS is prepared; typically final engineering designs and construction and operations plans are finalized during the successive State permitting phase. Similar measures would be employed for the other action alternatives (Alternatives 2 and 3), as applicable.

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
Where feasible, mine facilities would be reclaimed in such a manner as to create new wetland areas and ponds.	General	Closure	Wetlands/Special Aquatic Sites
Overburden removed during construction would be stockpiled for use in reclamation.	General	Closure	Soils; Vegetation
Cultural resource experts would be retained during construction activities to respond to any potential cultural sites identified during construction.	General	Construction	Cultural Resources
Access agreements with Alaska Native Claims Settlement Act (ANCSA) Village Corporations would include bidding and employment preferences, revenue sharing, and other benefits to enhance local employment and revenue generation.	General	Construction/Operations	Needs and Welfare of the People—Socioeconomics; Environmental Justice
A Reclamation and Closure Plan (RCP) would be developed during feasibility design work to support State permitting. The RCP and associated bonding would be in place prior to construction commencement, would be updated on a regular basis, and regular site compliance audits would be conducted as required by State regulations. The project would fully bond for reclamation and closure before commencing construction and the bonding amounts would be updated to address any changes required on a regular basis. The RCP would document the plan for long term closure of the site in a stable condition in compliance with all applicable closure criteria and regulations and would serve as the basis for the development of the closure cost estimate and associated bonding.	General	Construction/Operations/ Closure	Land Ownership, Management and Use; Health and Safety; Water and Sediment Quality
The project would establish a local advisory committee to facilitate communications and address concerns during construction and operations.	General	Construction/Operations/ Closure	Transportation and Navigation; Subsistence
The project would provide for controlled use of the road corridor and ferry for local residents, improving the supply of goods and reducing the cost of importing goods.	General	Construction/Operations/ Closure	Transportation and Navigation; Needs and Welfare of the People—Socioeconomics
The project would implement workforce development programs and training to prepare local residents for employment at the project.	General	Construction/Operations/ Closure	Needs and Welfare of the People—Socioeconomics; Environmental Justice

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
The project would have a no hunting, fishing, or gathering policy for non-local employees to minimize competition for local resources.	General	Construction/Operations/ Closure	Subsistence; Commercial and Recreational Fisheries
A Fugitive Dust Control Plan (FDCP) would be developed for the project and the project would use Best Available Control Technology (BACT) and Best Management Practices (BMPs) for fugitive dust management. The FDCP would describe the equipment, methodology, training, and performance assessment techniques that would be utilized for controlling fugitive dust from site activities and wind erosion. The FDCP would be developed during feasibility design work to support State permitting and would be in place prior to construction commencement.	General	Construction/Operations/ Closure	Air Quality
A Wildlife Management Plan(s) (WMP) would be developed for the project prior to commencement of construction, and the project would use BMPs for wildlife management. The WMP would describe the equipment, methodology, training, and assessment techniques that would be used to minimize the potential for wildlife interaction with project activities and to minimize impacts to wildlife in the project area.	General	Construction/Operations/ Closure	Wildlife Values
The project would utilize BMPs for prevention, control, and management of invasive species. An invasive species management strategy would describe the equipment, methodology, training, and assessment techniques that would be utilized to avoid the importation of invasive species into the project area due to project activities during construction, operations, and closure.	General	Construction/Operations/ Closure	Vegetation; Wetlands/Special Aquatic Sites; Fish Values; Wildlife Values
An Aquatic Resources Monitoring Plan(s) (ARMP) would be developed for the project. The ARMP would be developed in consultation with ADF&G and ADNR as part of the plans of operation during State permitting and would be in place prior to construction commencement. The ARMP would describe the equipment, methodology, training, and assessment techniques that would be utilized to monitor the aquatic environment for any changes resulting from project activities and to allow for an adaptive management approach to address impacts identified.	General	Construction/Operations/ Closure	Wetlands/Special Aquatic Sites; Fish Values; Water and Sediment Quality

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
The project would propose fish habitat mitigation measures to enhance or create new habitat outside of the immediate project footprint.	General	Construction/Operations/ Closure	Wetlands/Special Aquatic Sites; Fish Values
A Cultural Resources Management Plan (CRMP) would be developed for the project. The CRMP would describe the equipment, methodology, training, and assessment techniques that would be utilized to manage cultural resources on State and private lands impacted by the project. The plan would describe the process for managing effects to these resources and ensure that agreed upon protocols and procedures are established and followed if any unanticipated cultural resources or human remains are discovered. The CRMP would be developed as part of the Section 106 consultation process and would be in place prior to the Record of Decision (ROD).	General	Construction/Operations/ Closure	Cultural Resources
A Project Communications Plan (PCP) would be developed for the project prior to construction commencement. The PCP would establish the methodology and infrastructure that would be utilized to keep local residents, guides, and other users informed about upcoming and ongoing activity.	General	Construction/Operations/ Closure	Recreation; Subsistence; Transportation and Navigation; Recreational and Commercial Fisheries
Drug and Alcohol Abuse Prevention, Cultural Sensitivity, Safety, and other workplace programs would be developed for all employees. The programs would be designed to provide employees with the training and resources needed to allow for a safe, healthy, and conflict-free workplace. These programs would be implemented for all project staff and contractors prior to construction commencement.	General	Construction/Operations/ Closure	Needs and Welfare of the People—Socioeconomics
The project would develop a Storm Water Pollution Prevention Plan (SWPPP) and follow BMPs for storm water management. The SWPPP would describe the BMPs (equipment, methodology, training, and assessment techniques) that would be used for the management of stormwater on the project, in compliance with State and federal requirements, to minimize the transfer of sediment and other pollutants in stormwater associated with project activities. The SWPPP would be developed during detailed design and would be in place prior to construction commencement.	General	Construction/Operations/ Closure	Water and Sediment Quality

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
The project would develop an Erosion and Sedimentation Control Plan (ESCP) and follow BMPs for erosion and sediment control. The ESCP would describe the BMPs (equipment, methodology, training, and assessment techniques) that would be used to minimize erosion and sedimentation associated with project activities. The ESCP would be developed during detailed design and would be in place prior to construction commencement.	General	Construction/Operations/ Closure	Soils; Water and Sediment Quality
The project would use BACT for all air emissions sources.	General	Construction/Operations/ Closure	Air Quality
Secondary containment would be used for all fuel and hazardous chemical storage and the project would utilize BMPs for handling of fuel and hazardous materials.	General	Operations	Health and Safety; Spill Risk
The project would contract with a Spill Response Organization (e.g., Alaska Chadux Corporation) to provide on-call response services and would also stockpile spill response equipment at all appropriate locations.	General	Construction/Operations/ Closure	Spill Risk
The project would offer to negotiate a Payment in Lieu of Taxes (PILT) to the Lake and Peninsula Borough as an alternative to the borough severance tax, to allow for predictability in annual revenues.	General	Operations	Land Ownership, Management, and Use
A shift schedule would be established to enable local employees to maximize opportunities to remain active in subsistence harvest activities.	General	Operations	Subsistence
Use of natural gas and a combined cycle power plant to generate power reduces air impacts and removes the need to transport large amounts of diesel fuel.	General	Operations/Closure	Air Quality; Transportation and Navigation
The natural gas pipeline design has been oversized to allow for regional access to gas which could reduce regional power costs and fuel shipments.	General	Operations/Closure	Needs and Welfare of the People—Socioeconomics
Blasting during construction would be done following the guidelines established in the 2013 ADF&G Technical Report (No. 13-03) Alaska Blasting Standard for the Proper Protection of Fish.	General	Construction	Fish Values

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
Dry closure of the bulk tailings storage facility (TSF) reduces both the likelihood and consequence of potential TSF failure post closure	Mine Site	Closure	Spill Risk; Water and Sediment Quality
At closure, the pit lake would be maintained at a level that promotes hydraulic containment of pit water during closure, protecting site groundwater.	Mine Site	Closure	Surface Water Hydrology; Hydrogeology
The pit lake would be maintained at a level that provides for additional storage capacity to allow for treatment downtime due to water treatment plant maintenance or other problems without over-topping.	Mine Site	Closure	Surface Water Hydrology; Water and Sediment Quality
TSF and mine facility locations were selected to minimize impacts to spawning habitat in the middle reaches of the South Fork Koktuli and Upper Talarik Creek (UTC) watersheds.	Mine Site	Construction/Operations/ Closure	Fish Values
The layout was designed to consolidate the majority of the site infrastructure in a single drainage, the North Fork Koktuli, and avoid the placement of waste rock, tailings and primary mine infrastructure in the UTC drainage.	Mine Site	Construction/Operations/ Closure	Surface Water Hydrology
The project would use only non-pit quarried rock, or non acid-generating (NAG) pit waste that is confirmed not to be neutral metal leaching, in site construction.	Mine Site	Construction/Operations/ Closure	Water and Sediment Quality
The project design uses flattened TSF slopes to improve factor of safety beyond industry norms.	Mine Site	Construction/Operations/ Closure	Geohazards
BMPs and design guidelines would incorporate avian protection for all powerlines.	Mine Site	Construction/Operations/ Closure	Wildlife Values
Construction laydown areas would be reused as material stockpiles or other storage facilities to minimize project footprint.	Mine Site	Construction/Operations/ Closure	Vegetation; Wetlands/Special Aquatic Sites
Two separate operations water treatment plants are proposed to avoid co-mingling mine water and contact water and optimize treated water quality.	Mine Site	Operations/Closure	Water and Sediment Quality
Immediate treatment and release of excess water to mitigate flow impacts to fish habitat.	Mine Site	Operations	Fish Values

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
The project would use pit blasting techniques that minimize the amount of explosives per delay, thereby reducing the overall vibration associated with the blast.	Mine Site	Operations	Noise
Only mining near surface portion of deposit, reduces strip ratio and eliminates the need for a permanent waste rock storage facility.	Mine Site	Operations/Closure	Vegetation; Wetlands/Special Aquatic Sites
Storage of all potentially acid -generating (PAG) and/or metal neutral metal leaching waste rock in the pyritic TSF and placement of that waste rock back into the pit at closure improves post closure water quality.	Mine Site	Operations/Closure	Water and Sediment Quality
Segregation of bulk and pyritic tails and placement of pyritic tails back into the pit at closure improves post-closure water quality and removes any potential for post-closure failure of the pyritic TSF.	Mine Site	Operations/Closure	Water and Sediment Quality
The pyritic TSF will be a fully lined facility to minimize water quality impacts and facilitate closure.	Mine Site	Operations/Closure	Water and Sediment Quality
Bulk TSF designed as a flow through facility, reducing pore pressures and allowing for improved tailings consolidation, reducing the impacts of a potential TSF failure.	Mine Site	Operations/Closure	Geohazards
A water balance that does not store excess water in the bulk TSF reduces the potential for TSF failure or spills.	Mine Site	Operations/Closure	Spill Risk
Three separate discharge points for treated water and strategic timing of water release to minimize impacts, or avoid, impacts to fish habitat.	Mine Site	Operations/Closure	Fish Values; Water and Sediment Quality
No secondary gold recovery plant, eliminating the need to use cyanide on the project.	Mine Site /Transportation Corridor	Operations	Health and Safety
The design of the lake ferry (relative to using standard tug/barge) significantly reduces the risk of grounding or sinking, thereby reducing the risk of any kind of spill.	Transportation Corridor	Operations	Spill Risk
Use of diesel electric propulsion for the ferry reduces noise impacts and air emissions.	Transportation Corridor	Operations	Noise

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
The project would work with communities (and supply funding) to provide for the marking and maintenance of snowmachine trails between communities across Iliamna Lake when lake ice is thick enough to support such traffic.	Transportation Corridor	Operations	Transportation and Navigation
Fuel delivery barges would be double hulled to reduce spill risk.	Transportation Corridor/Port	Construction/Operations/ Closure	Spill Risk
Tug and barge speeds in sea otter critical habitat would be controlled to minimize the potential for impacts with sea otters.	Transportation Corridor/Port	Construction/Operations/ Closure	Threatened and Endangered Species
Lightering concentrate at Amakdedori port eliminates the need for dredging a deep water channel.	Port	Construction	Water and Sediment Quality
The road includes crossing rivers at a right angle where feasible to minimize impacts in the riparian areas.	Transportation Corridor	Construction	Vegetation; Wetlands/Special Aquatic Sties
Culverts and bridges would be designed to optimize fish passage and the project would use BMPs for design, construction, and maintenance.	Transportation Corridor	Construction	Fish Values
Material sites would be sampled for acid rock drainage (ARD) and metal leaching potential prior to development during detailed design. Material sites that have the potential for ARD or metal leaching would not be utilized.	Transportation Corridor	Construction	Water and Sediment Quality
Use of a ferry to cross Iliamna Lake reduces the road length and associated wetlands impacts and other impacts.	Transportation Corridor	Construction/Operations/ Closure	Vegetation; Wetlands/Special Aquatic Sties
Road connections to communities enhance opportunities for local employment while residing at home.	Transportation Corridor	Construction/Operations/ Closure	Needs and Welfare of the People—Socioeconomics; Environmental Justice
Road connections to communities enables the use of existing airport facilities, eliminating the need to construct and operate parallel facilities.	Transportation Corridor	Construction/Operations/ Closure	Transportation and Navigation

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
Road and ferry terminals are sited to avoid private (non-Alaska Native Claims Settlement Act) lands, environmentally sensitive areas, archaeological resources, and areas of known high subsistence use.	Transportation Corridor	Construction/Operations/ Closure	Cultural Resources; Subsistence; Land Ownership, Management, and Use
Use of closed containers to transport concentrate reduces spill potential while trucking, barging, loading, and on the ferry and eliminates potential for concentrate dust.	Transportation Corridor	Operations	Spill Risk; Air Quality
All reagents would be shipped in their original, approved for shipping, containers. These original containers would be placed inside steel shipping containers at the factory or consolidation terminal and shipped to the mine site prior to unloading from the steel shipping containers.	Transportation Corridor	Construction/Operations/ Closure	Spill Risk; Transportation and Navigation
The use of fuel isotainers to transport diesel fill reduces spill potential while trucking and on the ferry.	Transportation Corridor	Operations	Spill Risk; Transportation and Navigation
Co-location of the road and natural gas pipeline alignment reduces wetlands and other impacts and removes the need for a separate corridor.	Transportation Corridor/Natural Gas Pipeline Corridor	Construction/Operations	Vegetation; Wetlands/Special Aquatic Sties
All road/pipeline material sites would be tested for ARD and metal leaching prior to excavation and use.	Transportation Corridor/Natural Gas Pipeline Corridor	Construction	Water and Sediment Quality
The road/pipeline alignment and material sites were designed to minimize impacts to wetlands.	Transportation Corridor/Natural Gas Pipeline Corridor	Construction/Operations	Wetlands/Special Aquatic Sties
Gas pipeline would be attached to bridge crossings, removing the need for horizontal directional drilling (HDD) under major river crossings, removing the potential for frac-out.	Natural Gas Pipeline Corridor	Construction	Surface Water Hydrology; Fish Values; Water and Sediment Quality
Detailed HDD plans would be developed during detailed design for all HDDs that are required and would be in place prior to construction commencement. The HDD plans would ensure that all HDD work is done in compliance with applicable regulations and would outline measures to be undertaken to avoid the potential for a frac-out and measures to respond to a frac-out should one occur.	Natural Gas Pipeline Corridor	Construction	Water and Sediment Quality

AMERICAN OVERSIGHT

Table 5-2: Applicant's Proposed Mitigation Incorporated into the Project

Description	Project Component(s)	Project Phase(s)	Primary Resource(s) Affected
Water used for hydrostatic testing of the pipeline would be obtained from and discharged back to sources local to the section of pipeline being tested, thereby minimizing the potential for mobilization of invasive species.	Natural Gas Pipeline Corridor	Construction	Water and Sediment Quality; Vegetation; Wetlands/Special Aquatic Sties
The pipeline would use HDD to access deep water from the compressor station area to avoid shoreline impacts from trenching on the Kenai Peninsula.	Natural Gas Pipeline Corridor	Construction	Soils; Geohazards

AMERICAN OVERSIGHT

5.2.3 Additional Mitigation Identified for Consideration in Permit Decisions

The mitigation and monitoring discussed in this section is used to inform agencies with individual permit reviews and authorizations as an outcome of the NEPA process. Mitigation and monitoring measures identified or recommended during the NEPA process have been compiled and will be considered by the USACE and cooperating agencies as part of their permit decisions to further minimize project impacts. However, it is important to note that measures identified during the NEPA process may not be required by the federal agencies in their RODs. For example, CEQ guidance uses terms such as "reasonable, practicable, and appropriate" when considering potential mitigation and permit conditions. In addition, there may be potential mitigation measures identified through the public process that are not within the federal agencies' authority to require as a condition to a permit. It is also possible that some of the individual mitigation measures listed in this section may be adopted by PLP and incorporated into project plans prior to completion of environmental review. Furthermore, the USACE may continue to refine mitigation subsequent to completion of the EIS and issuance of their ROD during the permit application review process, and other permitting agencies may do likewise. Additional mitigation identified during that process may include project modifications that are in part considered feasible from a cost and constructability perspective. The ROD would identify those mitigation measures that the agency has committed itself to adopt and explain why any other practicable mitigation measures have not been adopted.

It should also be recognized that many of the permits required for approval of the Pebble Project are under the jurisdiction of the State of Alaska. Specific agencies may have clear compliance standards and requirements for monitoring of environmental conditions; future risks associated with unexpected conditions may also be addressed in specific permitting authorizations. Potential mitigation and monitoring measures put forward for consideration in the EIS are not intended to dictate conditions of State permit approval, but to identify potential measures for consideration as applicable. In assessing whether or not to adopt a mitigation measure in a project permit, agencies may further take into account whether they have adequate resources to enforce mitigation or a source of funding to do so, and measurable metrics in the mitigation measure to assess compliance and performance.

Appendix M includes a list of specific measures suggested during the scoping process. This list will be updated after public review of the Draft EIS for a comprehensive list of all measures identified during the NEPA process. All measures will be assessed based on the following criteria, with the goal of disclosing the likelihood that the measure would be adopted by responsible agencies as part of their permit decisions following completion of the NEPA process.

1. Effectiveness: assessment of the measures effectiveness in reducing the project-related impact.
2. Jurisdiction/Enforcement: assessment of potential agency jurisdiction/authority to require the measure and if the measure is reasonably enforceable by the agency with potential jurisdiction.
3. Reasonable/Practicable: assessment of the measures ability to achieve the basic project goal and if it is capable of being done after taking into consideration cost, existing technology, and logistics.

See Appendix M for a preliminary assessment of all measures identified during the EIS process. Measures assessed as likely to be implemented are presented in Table 5-3.

AMERICAN OVERSIGHT

Table 5-3: Mitigation and Monitoring Measures Assessed as Likely to be Implemented

Proposed Measure	Resource(s)	Potential Jurisdiction
Use palliatives to reduce airborne dust.	Air quality; Water and Sediment Quality; Fish Values; Soils; Health and Safety	ADEC
Measure hydrocarbon concentrations and related compounds in surface and groundwater during the periodic water quality monitoring events.	Water and Sediment Quality	ADEC
Consider mitigation banks and in-lieu fee programs as forms of compensatory mitigation.	WOUS, including Wetlands	USACE
Treat bilge water to remove more than oil before discharging to protect Iliamna Lake's ecology.	Water and Sediment Quality	ADEC

5.3 AVOIDANCE, MINIMIZATION, AND COMPENSATORY MITIGATION UNDER THE CLEAN WATER ACT

Compensatory mitigation can be a critical tool to help the federal government meet the longstanding national goal of "no net loss" of wetland acreage, function, and value. For projects authorized under Section 404, compensatory mitigation is not considered until all appropriate and practicable steps have been taken to first avoid and then minimize adverse impacts to the aquatic ecosystem pursuant to 40 CFR Part 230 (e.g., the CWA Section 404(b)(1) Guidelines).

Regulatory standards and criteria for the use of compensatory mitigation to offset unavoidable impacts to Waters of the US (WOUS), including wetlands, authorized under the CWA, were established on April 10, 2008 under 33 CFR Part 332 (USACE) and 40 CFR Part 230 (US Environmental Protection Agency [EPA]). Compensatory mitigation for unavoidable impacts may be required to ensure that activities requiring a permit comply with Section 404(b)(1) Guidelines. Compensatory mitigation is the restoration (reestablishment or rehabilitation), establishment (creation), enhancement, and/or in certain circumstances preservation of aquatic resources to offset unavoidable adverse impacts. Compensatory mitigation requirements must be commensurate with the amount and type of impact that is associated with a particular Section 404 permit and may be achieved by purchasing credits through mitigation banks or in-lieu fee programs, by permittee-responsible mitigation, or by a combination of the three.

USACE and EPA signed a Memorandum of Agreement (MOA) in June 2018 concerning mitigation sequence for wetlands in Alaska under Section 404 of the CWA (US Department of the Army and EPA 2018). In this MOA, the agencies recognize that specific to the State of Alaska:

- Avoiding wetlands may not be practicable where there is a high proportion of land in a watershed or region which is jurisdictional wetlands.
- Restoring, enhancing, or establishing wetlands for compensatory mitigation may not be practicable due to limited availability of sites and/or technical or logistical limitations.
- Compensatory mitigation options over a large watershed scale may be appropriate given that compensation options are frequently limited at a smaller scale.
- Where a proportion of land is under public ownership, compensatory mitigation opportunities may be available on public land.

AMERICAN OVERSIGHT

- Out-of-kind compensatory mitigation may be appropriate when it better serves the aquatic resource needs of the watershed.
- Applying a less rigorous permit review for small project with minor environmental impacts is consistent with the Section 404 program regulations.

The MOA further specifies that although the USACE considers compensatory mitigation options in the order of: (1) purchase of credits from an approved mitigation bank; (2) purchase of credits from an approved in-lieu fee program; and (3) completion of a permittee-responsible mitigation project, in many parts of Alaska, the first two options may not be available or may not provide the appropriate number of resource type of credits to offset the proposed project impacts. In this case, some form of permittee-responsible mitigation is the only option and permittee-responsible mitigation developed using a watershed approach is preferred.

PLP is developing a Compensatory Mitigation Plan (CMP) in coordination with federal, state, and local governments, and landowners (Appendix M). The CMP will describe how PLP would compensate for the unavoidable losses of WOUS including wetlands, streams, ponds, and creeks in the project area. PLP will be required to evaluate a full suite of available and practicable permittee-responsible mitigation options to comply with the provisions of the 2008 Mitigation Rule and the 2018 MOA. [Note: This will be updated when the draft CMP is available].

Mitigation will be considered throughout the NEPA and permitting processes. The USACE has completed a draft 404(b)(1) evaluation for compliance with the CWA prior to issuance of the ROD (Appendix F). Specific mitigation conditions would be determined following completion of the environmental review and will be included in the ROD for any permit that may be issued. [Note: This section will be updated for the Draft EIS after the draft 404(b)(1) analysis is complete].

5.3.1 Applicant's Proposed Avoidance and Minimization

Note to USACE: We believe these are captured in Table 5-2. Will there be separate avoidance and minimization measures in the CMP?

5.3.2 Applicant's Proposed Compensatory Mitigation

Note: This section will be updated when the draft CMP is available.

6.0 CONSULTATION AND COORDINATION

This section summarizes the consultation and coordination with agencies, as well as the public involvement opportunities for the Environmental Impact Statement (EIS), through preparation of the Draft EIS.

6.1 AGENCY COORDINATION

The U.S. Army Corps of Engineers (USACE) is the lead federal agency for this EIS. Six federal agencies, the State of Alaska, Lake and Peninsula Borough, and two tribes are serving as cooperating agencies for this EIS, listed below. These cooperating agencies are involved in informing the EIS process based on their expertise, to ensure that this EIS provides a full and fair disclosure of the probable impacts of the proposed project and provides a sound basis for agency permit decisions. The cooperating agencies also informed the alternatives selection process to determine which alternatives would be carried through for analysis (see Chapter 2, Alternatives).

- Advisory Council on Historic Preservation
- Bureau of Safety and Environmental Enforcement
- Curyung Tribal Council
- Lake and Peninsula Borough
- Nondalton Tribal Council
- National Park Service
- Pipeline and Hazardous Materials Safety Administration
- State of Alaska
- U.S. Coast Guard
- U.S Fish and Wildlife Service

6.1.1 Biological Assessments

Additional agency consultation is required if there may be impacts to a resource under the jurisdiction of an agency outside of the lead agency. The Pebble Project has the potential to impact threatened or endangered species protected under the Endangered Species Act (ESA), and therefore requires consultation with the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NFMS). The USACE requested initiation of informal consultation to the USFWS and NMFS on [Date to be added once informal consultation is initiated]. Four species under ESA jurisdiction of USFWS are evaluated in a Biological Assessment (BA) regarding the impacts of project activities to each of the listed species (this Draft BA is included as Appendix G). Two species under the ESA jurisdiction of NMFS are evaluated in a BA regarding the impacts of project activities to each of the listed species (this Draft BA is included as Appendix H).

6.1.2 Essential Fish Habitat Assessment

Additional agency consultation is required if there may be impacts that potentially affect Essential Fish Habitat (EFH) for the species regulated under a federal Fishery Management Plan (FMP). Under the Magnuson-Stevens Fishery Conservation and Management Act, each FMP must describe and identify EFH for the fishery; minimize, to the extent practicable, the adverse effects of fishing on EFH; and identify other actions to encourage the conservation and enhancement of EFH. Federal agencies must consult with NMFS regarding any action they authorize, fund, or undertake that may adversely affect EFH, and NMFS must provide conservation recommendations to federal and state agencies regarding any action that would adversely affect EFH. The USACE requested initiation of informal consultation to the NFMS on

AMERICAN OVERSIGHT

[Date to be added once informal consultation is initiated]. The Pebble Project has the possibility to affect EFH for five species of Pacific salmon that could occur within the project area, including Chinook, sockeye, coho, chum, and pink salmon. A Draft EFH Assessment is included as Appendix I.

6.2 TRIBAL CONSULTATION AND GOVERNMENT-TO-GOVERNMENT CONSULTATION

Federal agencies are charged with engaging in regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications, pursuant to Executive Order 13175 on Consultation and Coordination with Indian Tribal Governments (November 6, 2000). The USACE Tribal Consultation Policy (2013) states that, "Commands will ensure that all Tribes with an interest in a particular activity that has the potential to significantly affect protected tribal resources, tribal rights (including treaty rights) and Indian lands are contacted and their comments taken into consideration." As the lead federal agency for the development of the Pebble Project EIS, the USACE is responsible for government-to-government consultation and coordination with federally recognized tribes that may be impacted by the proposed project.

The government-to-government consultation process for the Pebble Project EIS is designed to provide federally recognized tribes in Alaska that may potentially be impacted by the proposed project with opportunities for meaningful participation in the federal permitting process. Tribes and other Alaska Native stakeholders will have several opportunities throughout the environmental review process to participate and provide input. The USACE developed a list of 35 federally recognized tribes that could be potentially impacted by the proposed project. USACE notified and invited these tribes into government-to-government consultation early in the process. The consultation process was coordinated with the NEPA scoping effort to the extent possible. Information learned through tribal consultation will inform the EIS, as appropriate.

An initial letter was sent to the tribes on the USACE's list, including basic project information, how tribes may participate in the development of the EIS, and an invitation for formal government-to-government consultation. A tribe that does not request formal consultation may participate in informal consultation throughout the project review. Informal consultation consisted of the two-way sharing of information through mailings, teleconferences, and regional meetings with tribes during the NEPA process, held separately from the public meetings.

[Additional information to be added from USACE].

During consultations, the USACE took the opportunity to discuss Traditional Ecological Knowledge (TEK) and solicit information on subsistence, archaeological sites, and traditional cultural properties, and additionally to obtain special expertise regarding any environmental, social, and/or economic impacts. See Section 3.1, Introduction to Affected Environment, and Appendix K3.1 for more information on how TEK was collected and incorporated into the EIS.

6.2.1 National Historic Preservation Act, Section 106

In August 2018, the USACE initiated the process for the National Historic Preservation Act Section 106 Programmatic Agreement (PA), with an invitation to consult. The invitations were sent to the 35 federally recognized tribes, several village and regional Alaska Native corporations, and other interested organizations and individuals. An initial meeting was held with consulting parties on [Date to be added after the initial meeting is held]. After collecting input from the consulting parties, a draft PA was circulated [Date to be added after the draft PA is

AMERICAN OVERSIGHT

circulated] for consulting party review and comment. More information on the PA process can be found in Section 3.7, Cultural Resources. The PA is included in Appendix L.

6.3 SCOPING AND PUBLIC OUTREACH

Scoping is conducted to assist in determining the breadth of analysis, significant issues, and alternatives to be analyzed in depth in the Draft EIS. NEPA requires "scoping," which is described in 40 Code of Federal Regulations 1501.7 as, "an early and open process for determining the scope of issues to be addressed and for identifying the significant issues related to a proposed action, the process shall be termed scoping…" The scoping process provides an opportunity for people potentially affected by the project to express their views and concerns, and to contribute to the completeness of the EIS. The scoping period began on April 1, 2018 and continued through June 29, 2018.

The scoping effort for the Pebble Project EIS began with a press release issued by the USACE, and included mailing a scoping package to the 35 identified tribes, a newsletter mailed to every post office box in potentially affected communities, development of the project website, and nine public scoping meetings, detailed in Table 6-1.

Table 6-1: Scoping Meetings

Date	Community	Location and Time
April 9, 2018	Naknek	Naknek School, 3:30-7:30 PM
April 10, 2018	Kokhanok	Community Hall, 3:30-7:30 PM
April 11, 2018	Homer	Homer High School, 5:00-9:00 PM
April 12, 2018	Newhalen	Newhalen School, 3:30-7:30 PM
April 13, 2018	New Stuyahok	Community Building, 1:00-4:30 PM
April 16, 2018	Nondalton	Tribal Center, 3:30-7:30 PM
April 17, 2018	Dillingham	Middle School, 5:00-9:00 PM
April 18, 2018	Igiugig	Community Building, 3:30-7:30 PM
April 19, 2018	Anchorage	Dena'ina Center, 11:00 AM-9:00 PM

The complete scoping effort for the Pebble Project EIS is described in Appendix A.

Participation in the scoping process was widespread, with many hours of questions and testimony, along with comments submitted via the project website, email, and mail to the USACE. Public comments during scoping meetings were recorded as transcripts and used to identify specific comments for documentation in the scoping process. A summary of issues received during scoping is provided in Appendix A.

6.4 ONGOING COORDINATION EFFORTS

Coordination with cooperating agencies will continue to occur following the release of the Draft EIS. Agency expertise will remain important for informing the analysis and addressing critical comments from the public to develop the Final EIS. Consultation with the USFWS and NMFS will continue for ESA and EFH assessments.

Tribal consultation is an ongoing effort by the USACE to connect with leaders to share information, express concerns, and answer questions. Outreach and coordination for the PA will continue, with the Final PA being released around the same time as the Final EIS.

AMERICAN OVERSIGHT

Scoping was the first opportunity for public involvement under the NEPA process. A Notice of Availability of this Draft EIS was published in the Federal Register informing stakeholders and other members of the public that the Draft EIS is available for comment for 90 days. The Draft EIS comment period will include public meetings in the same communities where scoping meetings were held. A second newsletter announced the release of the draft; providing information for attending meetings and instructions on commenting.

The project website will continue to be updated throughout the EIS process.

AMERICAN OVERSIGHT

3.19 NOISE

Noise is typically characterized as unwanted sound. Because ambient sound is generally not considered a problem, they are not typically classified as noise. The ambient sound level is a composite of sound from all sources, including the natural background and anthropogenic sources—it is, by way of example, the total sound received by the microphone of a sound level meter. Ambient sound levels are often the starting point for analyzing noise impacts, since such environmental noise analysis typically compares Project-attributed noise to either ambient or natural background sound based on applicable adverse effect or impact assessment criteria.

The effects of noise on people can include general annoyance, interference with speech communication, sleep disturbance, and, in the extreme, hearing impairment.

At any location, both the magnitude and frequency of environmental noise may vary considerably over the course of each day and throughout the week and year. This variation is caused not only by various noise source activities, but also by changing weather conditions, the effects of seasonal vegetative ground cover, and the presence of ice or flowing water from nearby creeks and rivers.

Table 3.19-1 provides examples of outdoor noise levels used in this section to provide context for describing existing conditions in the project area. Table 3.19-2 provides examples of indoor noise levels that could be experienced by current residents of communities near the project area. These levels are measured in terms of "A-weighted" decibels (dBA), which are used to quantify sound and its effect on people (EPA 1978), and emphasize frequencies that humans hear best. In addition, noise levels in Table 3.19-1 represent day-night sound levels (L_{dn}), an energy-averaged value over a 24-hour period that reflects increased sensitivity to noise when people are usually sleeping. Additional information on applicable noise and vibration concepts and methodologies used in characterizing noise of the affected environment is provided by AECOM (2018b).

Table 3.19-1: Examples of Noise Levels

Outdoor	Noise Levels (dBA, L_{dn})	Indoor
Jet Fly-over at 1,000 feet	100	Rock band
Gas lawn mower at 3 feet	90	Blender at 3 feet
Next to Busy Highway	87.5	
0.75 Mile from Touchdown at Major Airport	86.0	Garbage disposal at 3 feet
Noisy urban area during the day	70	Vacuum cleaner at 10 feet
Wooded Suburban Residential	51.0	Refrigerator at 3 feet
Rural Residential	39.0	
Wilderness Ambient	35.0	Library

Notes:

dBA = A-weighted decibel

L_{dn} = Day-night sound level, expressed in dBA

Source: EPA 1978, Caltrans 2009

Existing noise levels in the areas of each project component are discussed below as compared to the typical levels shown in Table 3.19-1. A radius of 10 miles from the mine site is used as a reference distance for potential noise impact in this EIS because it is considered to be a distance

AMERICAN OVERSIGHT

beyond which the noise effects are expected to be negligible. For the project alternative port site, transportation routes, and natural gas pipeline corridors, a reference distance of 0.5 mile from the project feature or alignment was selected (FERC 2017) to help locate and identify potential noise-sensitive receptor (NSR) property parcels discussed in each of the subsequent subsections organized by alternative.

3.19.1 Action Alternative 1 – Applicant's Proposed Alternative

3.19.1.1 Mine Site

Existing Sound

The mine site would be in a remote region of Alaska, characterized as having no development. No actual baseline noise data were collected in the vicinity of the mine site. However, data on ambient noise levels for generic land use types are available (Table 3.19-1). The values in Table 3.19-1 can be used to estimate the baseline ambient sound level for corresponding land use types in the EIS analysis area. Due to its remoteness and lack of development, the existing land use in the vicinity of the mine site corresponds to the "wilderness ambient" classification in Table 3.19-1. Therefore, the baseline ambient sound level for the mine site would be 35 L_{dn} (Table 3.19-3).

Table 3.19-2: Baseline Outdoor Noise Levels at Mine Site

Pebble Project Component	Baseline Outdoor Ambient Sound Level (dBA)	Basis
Component includes all facilities in the mine site including: open pit, mill and ore processing, water treatment plants, water management ponds, bulk and pyritic tailings storage facilities, power plant, utilities, services and infrastructure, mine maintenance and safety controls	35 L_{dn}	Typical L_{dn} for Wilderness (EPA 1978), L_{dn} for Outdoor Locations

Notes:

dBA = A-weighted decibel

L_{dn} = day-night sound level, expressed as dBA

Source: EPA 1978

For purposes of comparison, National Park Service (NPS) staff measured outdoor sound levels at a variety of geographically and biologically representative regions of Denali National Park based on a percentile-exceeded sound level, L_{50} (NPS 2009b). This value reflects the time-varying character of environmental noise and represents the noise level exceeded during 50 percent of the measured time interval, which is also the statistical median during the measurement interval. Levels will be above and below this value exactly one-half of the measurement time. NPS (2009b) found that measured L_{50} for a set of five monitored areas ranged from 23.1 dBA to 41.4 dBA, depending on acoustical contributors such as proximity of flowing water and frequency of aircraft overflights. Assuming these monitored wilderness-type locations have geographic and biologic (e.g., vegetative ground cover and terrain) similarity to the mine site, if 32 dBA were to represent an arithmetic average of these L_{50} values, and if L_{50} were to be considered essentially equivalent to L_{eq} in these cases (L_{eq} is an energy-averaged value over a specific time period), then the corresponding calculated L_{dn} would be 38 dBA and thus comparable (i.e., within 3 dBA) to the presented L_{dn} value for the mine site in Table 3.19-3.

AMERICAN OVERSIGHT

Sensitive Receptors

There are no apparent existing NSR or properties known to have any "residential" classification within approximately 10 miles of the mine site.

3.19.1.2 Transportation Corridor

Existing Sound

For the purpose of describing existing noise levels, facilities in the transportation corridor are grouped and summarized according to location and use, as follows:

- **Mine Access Road** – As with the mine site, most of the mine access road would be in a remote area with no development. No actual ambient sound data were collected in the vicinity of the mine access road. The existing land use in the vicinity of the mine access road (including its southern terminus on the northern shoreline of Iliamna Lake) corresponds with the "wilderness ambient" classification in Table 3.19-1 and thus has a baseline noise level of 35 dBA L_{dn}.
- **Iliamna Spur Road** – As with the mine access road, the spur road would in a remote area with very little development. Aside from its southern terminus near Iliamna Airport, no actual ambient sound data were collected in the near vicinity of the spur road; existing sound levels appear to correspond with the "wilderness" classification in Table 3.19-1 and thus have a baseline noise level of 35 dBA L_{dn}. Within one mile of the vicinity of the southern terminus, where the spur road intersects with the existing Portage Road, existing outdoor noise levels were measured at position "M2" as reported in Michael Minor & Associates (MMA 2010) (Table 3.19-4). From measured L_{eq} data collected during daytime, evening[1], and nighttime periods at M2, and additional baseline field survey positions representing a variety of land uses (residential areas, a school, and a medical clinic), baseline L_{dn} values were calculated for the communities of Iliamna and Newhalen (shown in Table 3.19-4).

Table 3.19-3: Calculated Baseline Day-Night Sound Levels at Representative Iliamna and Newhalen Community Land Uses

Measurement Location (and Summary Description)[1]	Summer Season L_{dn} (dBA)	Winter Season L_{dn} (dBA)
M2 – Central Newhalen River Road (north of Iliamna Airport at the northernmost occupied residence on the Newhalen River Road)	53	47
M3 – Iliamna Airport (near Iliamna Air Taxi terminal)	54	61
M4 – Post Office and Community Medical Clinic (intersection of Iliamna Road and Newhalen Road)	51	52
M5 – North Newhalen (residential area just off Newhalen Road)	47	42

[1] The day-night level (L_{dn}) calculation considers 15 daytime hours (7 AM to 10 PM) and 9 nighttime hours (10 PM to 7 AM), the latter of which are penalized by +10 dB. Because the MMA (2010) report presents day and evening measured levels separately, this means the 3 evening (7 PM to 10 PM) hours in the L_{dn} calculated were potentially different from the daytime (7 AM to 7 PM) hours, but not penalized with the +10 dB for the nighttime hours.

If this were a community noise equivalent level (CNEL) value (weighted average of noise level over time) being calculated, these 3 evening hours (7 PM to 10 PM) would be penalized by +5 dB.

AMERICAN OVERSIGHT

Table 3.19-3: Calculated Baseline Day-Night Sound Levels at Representative Iliamna and Newhalen Community Land Uses

Measurement Location (and Summary Description)[1]	Summer Season L_{dn} (dBA)	Winter Season L_{dn} (dBA)
M6 – Newhalen School (in front of the school near Newhalen Road)	56	63
M7 – Roadhouse Bed and Breakfast (and single-family residence on Iliamna Road)	47	42
M8 – Iliamna General Store and Vicinity (on Iliamna Village Spur close to several residential buildings)	54	59
M9 – Iliamna Lake (near the docks at Slop Bucket Road and Iliamna Village Spur close to floatplane moorage)	59	47

Notes:

dBA = A-weighted decibel

L_{dn} = day-night sound level, expressed as dBA

Source: MMA 2010

- **Kokhanok Airport Spur Road** – Most of this spur road route is undeveloped and appears to be considered compatible with the "wilderness" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}. Baseline noise level measurements were not conducted in this vicinity. At the northern terminus of the spur road are an airstrip and the community of Kokhanok, a census-designated place with a population of 140 residents, which could be considered "wilderness ambient," per Table 3.19-1. Not counting noise from occasional aircraft taking off and landing from the existing airstrip (an active public airport with Federal Aviation Administration [FAA] identifier "9K2"), the indicated level of 35 dBA L_{dn} would be conservative when compared with an Federal Transit Administration (FTA) based estimate of 31 dBA L_{dn}, which used population density as an input (8.2 people per square mile, based on US Census Bureau [USCB] [2018c] data).
- **North Ferry Terminal** – The vicinity of this Iliamna Lake coastal area is undeveloped and considered compatible with the "wilderness ambient" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}, except for temporary increases in noise level due to wind and lake wave activity. Baseline noise level measurements were not conducted in this vicinity. Because the ferry terminal and natural gas pipeline corridor would be within a mile of the Upper Talarik Creek outlet into Iliamna Lake, the area is exposed to seasonal transportation noise sources such as small boat traffic for sport fishing during the summer, and possibly snowmachines during winter. No such motorized boats or vehicles would be expected during the shoulder seasons of lake freeze-up and break-up.
- **South Ferry Terminal** – The vicinity of this Iliamna Lake coastal area is undeveloped and would be considered compatible with the "wilderness ambient" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}, except for temporary increases in noise level due to winds and lake wave activity. Baseline noise level measurements were not conducted in this vicinity. Because the ferry terminal and natural gas pipeline corridor would be within 2 miles of the Gibraltar River outlet into Iliamna Lake, the area is exposed to seasonal transportation noise sources such as small boat traffic for sport fishing during the summer, and possibly snowmachines

AMERICAN OVERSIGHT

during winter. No such motorized boats or vehicles would be expected during the shoulder seasons of lake freeze-up and break-up.

  - **Kokhanok East Ferry Terminal Variant** – The south ferry terminal site would be on the southern shore of Iliamna Lake, east of the terminal site described in Alternative 1 (Chapter 2). The aforementioned seasonal transportation noise sources near the mouth of the Gibraltar River would not be expected, but the outdoor ambient sound level would be expected to have the same baseline noise level of 35 dBA L_{dn} with temporary increases due to winds and lake wave activity.

- **South Access Road** – This road would traverse between Iliamna Lake and Cook Inlet. No actual ambient sound data was collected in this undeveloped area. The expected baseline outdoor ambient sound level corresponds with the "wilderness ambient" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}.

Sensitive Receptors

- **Iliamna Spur Road** – Within 0.5 miles from the intersection of the spur road route with Portage Road, there are three possible NSRs with undetermined parcel types, which are apparently "Native allotments" with regard to ownership.
- **North Ferry Terminal** – Within 0.5 miles from the natural gas pipeline route (and the parallel road route) at the terminal location, there are two possible NSRs with undetermined parcel types, which are apparently "Native allotments" with regard to ownership.
- **South Ferry Terminal** – Within 0.5 miles from the natural gas pipeline route (and the parallel road route) at the terminal location, there are no identified possible NSRs.
- **South Access Road** – Within 0.5 miles from the natural gas pipeline route (and the parallel road route along this route), there are four possible NSRs with undetermined parcel types, which are apparently "Native allotments" with regard to ownership. All are within 6 miles of the south terminal ferry location, and within 4 miles of the village of Kokhonak.

3.19.1.3 Amakdedori Port

Existing Sound

The area in the vicinity of the Amakdedori port site that serves as both the western Cook Inlet landfall (see Section 3.19.1.4) and the southern terminus of the transportation corridor (see Section 3.19.1.3) is currently undeveloped, and thus is generally expected to have outdoor ambient sound levels consistent with the "wilderness ambient" classification in Table 3.19-1 and a baseline noise level of 35 dBA L_{dn}. Depending on proximity to the Cook Inlet shoreline along with the magnitude and direction of winds and wave activity, localized sound levels may be higher. Baseline noise levels were not measured at the Amakdedori port site.

Sensitive Receptors

Within 0.5 mile from the port site, there are three large properties that may be NSRs (depending on existing land use and/or occupancy) with parcel types and ownership as follows: two Bureau of Land Management properties, with one indicated as "residential vacant," and the other as "institutional vacant;" and one Alaska Department of Natural Resources property, classified as "residential vacant."

AMERICAN OVERSIGHT

3.19.1.4 Natural Gas Pipeline Corridor

Existing Sound

For the purpose of describing existing noise levels, features along the natural gas pipeline corridor are grouped and summarized according to location as follows:

- **Mine Site to Amakdedori Port** – This section of the pipeline corridor parallels the mine access road, ferry terminals, south access road, and Amakdedori port site described previously. It shares the same area and existing outdoor ambient sound environment with these project components, and thus is considered compatible with the "wilderness" classification in Table 3.19-1, with a baseline noise level of 35 dBA L_{dn}.
- **Anchor Point** – This census-designated community of 1,930 residents is near the compressor station site at the eastern Cook Inlet landfall of the natural gas pipeline. Baseline noise level measurements were not conducted in this vicinity. Using an FTA-based estimation method that uses population density (21.2 people per square mile, based on US Census data [USCB 2018a]) as input, the baseline outdoor ambient sound level could be calculated as 35 dBA L_{dn}, a value comparable to the "wilderness ambient" designation per Table 3.19-1; however, the Sterling Highway (Alaska Route 1), a major two-lane roadway that parallels the coastline with minimum posted speed limits of 50 miles per hour, would be expected to raise outdoor ambient noise levels to a minimum of 50 dBA L_{dn} per FTA guidance.

Sensitive Receptors

- **Mine Site to Amakdedori Port** – This section of the pipeline corridor parallels the mine access road, ferry terminals, south access road, and Amakdedori port site, and would have the same sensitive receptors described previously.
- **Anchor Point** – A total of 43 possible NSRs were identified within 0.5 mile of the compressor station, located approximately 0.25 mile southeast of the Sterling Highway near its intersection with Bourbon Avenue, where the proposed pipeline makes landfall from Cook Inlet. These 43 potential NSRs are indicated to be "residential" with respect to current land use. There are also the following property parcels in this 0.5-mile distance range from the boundary of the planned compressor station:
  - 33 privately owned "vacant"
  - 3 state-owned "vacant"
  - 1 Native-owned "vacant"
  - 9 privately owned with "accessory building"
  - 5 privately owned "commercial".

The methodology and data sources used to identify the possible NSRs and compile these other properties are described by AECOM (2018b).

3.19.2 Action Alternative 2 – North Road and Ferry

3.19.2.1 Mine Site

Existing sound and potential NSRs near the mine site would be the same as described for Alternative 1.

AMERICAN OVERSIGHT

3.19.2.2 Transportation Corridor

Existing Sound

For the purpose of describing existing noise levels, facilities in the transportation corridor are grouped and summarized according to location and use, as follows:

- **Mine Access Road** – As with the mine site, the majority of the mine access road would be in a remote area with no development. No actual ambient sound data were collected in the vicinity of the mine access road. The existing land use in the vicinity of the mine access road (including its southern terminus on the northern shoreline of Iliamna Lake, near Eagle Bay) appears to correspond with the "wilderness ambient" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}.
- **Eagle Bay Ferry and Pile Bay Ferry Terminals** – The vicinities of these Iliamna Lake coastal areas are generally undeveloped and would be considered compatible with the "wilderness ambient" classification in Table 3.19-1, and thus have a baseline noise level of 35 dBA L_{dn}, aside from temporary increases in noise level due to winds and lake wave activity. Baseline noise level measurements were not conducted in these vicinities.
- **Port Access Road** – This road would connect the Pile Bay ferry terminal site to the Diamond Point port site, bypassing all but 5 miles of the existing Williamsport-Pile Bay road. The existing road is primarily used by large tractor-trailer rigs in the summer season to haul boats and other bulky freight between Iliamna Lake and the Cook Inlet. No actual ambient sound data was collected in this area, which has little development. Given this existing land use condition, the expected baseline outdoor ambient sound level would appear to correspond with the "wilderness ambient" classification in Table 3.19-1, and thus has a baseline noise level of 35 dBA L_{dn}. The infrequent truck traffic on the existing Williamsport-Pile Bay road would temporarily raise the outdoor ambient sound level near the route.

Sensitive Receptors

- **Mine Access Road** – A portion of a Native patent property parcel (AKAA 007124) intersects the 0.5-mile distance from the proposed road alignment, and may be considered noise-sensitive if a structure (e.g., seasonal shelter or residence) is occupied.
- **Eagle Bay Ferry and Pile Bay Ferry Terminals** – There are no potential NSR parcels identified within 0.5 miles of the Eagle Bay ferry terminal site. The Pile Bay ferry terminal site appears to be within 0.5 miles of six Native patent parcels (AKAA 032735, AKAA 006025A, AKAA 033441, AKAA 063898B, AKAA 005720, and AKAA 003103). The potential for NSRs would depend on whether the seasonal shelters or residences on these properties are occupied.
- **Port Access Road** – This road alignment, which includes a portion of the existing Williamsport-Pile Bay Road, is within 0.5-mile distance of the following identified Native patent property parcels: AKAA 004592A, AKAA 051014, AKAA 008064B, AKAA 007125A, AKAA 001032B, AKAA 062887B, AKAA 006025B, AKAA 063898B, AKAA 005720, AKAA 003103, AKAA 032735, AKAA 006025A, and AKAA 033441. The potential for NSRs would depend on whether the seasonal shelters or residences on these properties are occupied. There is also property parcel 23116002, which is identified as "residential vacant," and thus a possible NSR.

AMERICAN OVERSIGHT

3.19.2.3 Diamond Point Port

Existing Sound

Based on recent project site vicinity visit observations (AECOM 2018h), the area in the vicinity of the Diamond Point port site that would serve as both the western end of the natural gas pipeline (see Natural Gas Pipeline Corridor, below) crossing the Cook Inlet, and the eastern terminus of the transportation corridor (see Transportation Corridor, above), is undergoing apparent development activity due to a nearby gravel and rock quarry. According to Special Condition #6 on the USACE permit (POA-2008-523) associated with this work (USACE 2012), such activities would only be permitted to occur from May 1 to October 31 each year. Depending on the progress of tideland fill and the corresponding pace of gravel and granite quarry production, noise-producing activities could include dredging, pile-driving, rock blasting, distribution of materials, and the operation of heavy equipment and trucks, consistent with the description in POA-2008-523. One or more of these noise-producing sources would temporarily elevate outdoor ambient sound levels to a degree that would depend largely on the distance between the listener and the source of the noise-producing activity or event.

Outside of this permitted site development activity, from October 31 to May 1, little or no noise-producing activities would be expected at the Diamond Point port site. This suggests that outdoor ambient sound levels would reflect naturally occurring acoustical contributors and be more consistent with the "wilderness ambient" classification in Table 3.19-1 and a baseline noise level of 35 dBA L_{dn}. Depending on proximity to the Cook Inlet shoreline and the magnitude of winds and wave activity, localized sound levels may be higher. Baseline noise levels were not measured at this project area.

Sensitive Receptors

Within 0.5 mile of the port site, there are three large properties that may be NSRs (depending on existing land use and/or occupancy) with parcel types and ownership as follows: three Native patent parcels (AKAA 006342, AKAA 004225B, and AKAA 004592A). According to online aerial imagery sources available through Google Earth, there are no apparent existing structures on these properties at the time of this writing.

3.19.2.4 Natural Gas Pipeline Corridor

Existing Sound

For the purpose of describing existing noise levels, features along the natural gas pipeline corridor are grouped and summarized according to location as follows:

- **Mine Site to Diamond Point Port** – This overland section of the pipeline corridor would parallel the north route mine access road (see description of Alternative 2, Chapter 2). Existing outdoor ambient sound environment along this corridor is considered compatible with the "wilderness" classification in Table 3.19-1, and thus have a baseline noise level of 35 dBA L_{dn}.
- **Ursus Cove to Diamond Point Port** – This section of the pipeline would be buried from Ursus Cove to Cottonwood Cove, on the seafloor across the cove, and connect to the onshore portion at the Diamond Point port site. The overland area represented by this pipeline section is undeveloped; it would be compatible with the "wilderness" classification in Table 3.19-1 and have a baseline noise level of 35 dBA L_{dn}.
- **Anchor Point** – This is the same natural gas pipeline eastern terminus on the Kenai Peninsula as described for Alternative 1.

AMERICAN OVERSIGHT

Sensitive Receptors

- **Mine Site to Diamond Point Port** – This section of the pipeline corridor parallels the north route mine access road described for Alternative 2, Chapter 2, and would have the same potential NSRs.
- **Anchor Point** – This is the same natural gas pipeline eastern terminus on the Kenai Peninsula as described for Alternative 1.

3.19.3 Action Alternative 3 – North Road only

3.19.3.1 Mine Site

Existing sound and potential NSRs near the mine site would be the same as what is described for Alternative 1.

3.19.3.2 Diamond Point Port

Existing sound and potential NSRs near the mine site would be the same as described for Alternative 1.

3.19.3.3 Transportation Corridor

Existing Sound

For the purpose of describing existing noise levels, facilities in the transportation corridor are grouped and summarized according to location and use, as follows:

- **Mine Access Road** – As with the mine site, most of the mine access road is remote with no development. Along the undeveloped portion of the overland transportation route, the "wilderness ambient" classification in Table 3.19-1 would be expected, and thus have a corresponding baseline noise level of 35 dBA L_{dn}. Pedro Bay is a village along the proposed route, where existing outdoor noise levels were measured at positions M10, M11, and M12 (Michael Minor and Associates [MMA 2010). From measured L_{eq} data collected during daytime, evening, and nighttime periods at these three positions, calculated baseline L_{dn} values for the Pedro Bay community are shown in Table 3.19-5.

Table 3.19-4: Calculated Baseline Day-Night Sound Levels at Representative Pedro Bay Community Land Uses

Measurement Location (and Summary Description)	Summer Season L_{dn} (dBA)	Winter Season L_{dn} (dBA)
M10 – Pedro Bay on Iliamna Lake (along the lake shore next to several cabins used for fishing trips and where several floatplanes were moored)	48	42
M11 – Pedro Bay Tribal Center (behind Tribal Center, up the hill)	48	40
M12 – Pedro Bay School (on school grounds near the main school entrance, additional readings taken behind school at power plant)	44	44

Notes:

dBA = A-weighted decibel

L_{dn} = day-night sound level, expressed as dBA

Source: MMA 2010

AMERICAN OVERSIGHT

Sensitive Receptors

- **Mine Access Road** – This road alignment, which includes a portion of the existing Williamsport-Pile Bay road, is within a 0.5-mile distance of the following identified Native patent property parcels: AKAA 004592A, AKAA 051014, AKAA 008064B, AKAA 007125A, AKAA 006055, AKAA 003102, AKAA 008064C, AKAA 050508, AKAA 006734A, AKAA 008060, AKA 062761, AKAA 006081, AKAA 007913, AKA 061262A, AKAA 006722, AKAA 001032A, AKA 057267, AKA 053553, AKA 062076, AKA 063273, AKA 063274A, AKAA 007150A, AKAA 008064A, AKAA 007844, AKAA 007724, and AKAA 007721. The potential for NSRs would depend on whether the existing seasonal shelters or residences on these properties were occupied. The parcels in the immediate vicinity of the Pedro Bay community, where the aforementioned sound level measurements were conducted by MMA in 2010, include AKA 057267, AKAA 006722, AKAA 001032A, and AKA 061262A. Near the eastern terminus of the road route, approximately 3 miles north of the Diamond Point port site, there is a property parcel (23116002) identified as "residential vacant," thus a possible NSR.

3.19.3.4 Natural Gas Pipeline Corridor

Existing Sound

For the purpose of describing existing noise levels, features along the natural gas pipeline corridor are grouped and summarized according to location as follows:

- **Mine Access Road** – This section of the pipeline would parallel the mine access road and Diamond Point port site as described for Alternative 2. It shares the same area and existing outdoor ambient sound environment with these project components, which are considered compatible with the "wilderness" classification in Table 3.19-1 (and thus have a baseline noise level of 35 dBA L_{dn}), or would be expected to have higher L_{dn} values in the vicinity of the Pedro Bay village per Table 3.19-5.
- **Ursus Cove to Diamond Point Port** – Existing sound would be the same as described for Alternative 2.
- **Anchor Point** – This is the same natural gas pipeline corridor east Cook Inlet landfall as described or Alternative 1.

Sensitive Receptors

- **Mine Site to Diamond Point Port** – This section of the pipeline parallels the aforementioned mine access road and Diamond Point port as described for Alternative 2and would have the same potential NSRs.
- **Anchor Point** – This is the same natural gas pipeline eastern terminus on the Kenai Peninsula as described for Alternative 1.

AMERICAN OVERSIGHT

4.19 NOISE

This section addresses primarily direct effects on human receptors during all three project phases. Potential noise impacts resulting from the project on resources, such as wildlife or threatened and endangered species, are described in Section 4.23, Wildlife Values, and Section 4.25, Threatened and Endangered Species.

4.19.1 Noise Impacts Analysis Methodology

The methodology framework applied to assessing direct noise-related impacts considers the intensity of project-attributed sound (or the resulting increase in outdoor ambient sound level over existing [pre-project] conditions), the geographic extent of noise transmission, and the duration over which that project-caused noise is expected to occur.

The quantitative and qualitative descriptions in this section use US Environmental Protection Agency (EPA) noise concepts and guidelines (EPA 1978) to assess the degree of noise impacts at the nearest noise-sensitive receptor (NSR) for each phase, and for each component of the project.

To quantitatively assess potential noise impacts at NSR locations, this analysis considers the aggregate of project-attributed noise sources of interest, on average, emitting from a common point (or in some cases, such as for transportation routes, a line segment) and applies the following sound attenuation factors:

- Geometric divergence – for point-source sound propagation, this yields 6 A-weighted decibels (dBA) of noise reduction per doubling of distance (DD) traveled by the sound, or 3 dBA per DD for a line source
- Atmospheric absorption – although frequency-dependent, the rate of sound attenuation due to sound energy absorbed by the air can typically be expressed as 1 dBA per 1,000 feet traveled
- Ground absorption – given acoustically absorptive ground surfaces near the source of noise emission and the receiver, up to 5 dBA can be realized.

Although natural terrain may offer expanses of forests and ridgelines that might occlude the direct sound paths between project noise source(s) and the noise-sensitive area (NSA) of interest, these additional attenuation factors are, unless otherwise noted, conservatively not incorporated into these analyses.

Reference sound levels of equipment, vehicles, and activities associated with the project are provided in AECOM 2018c. AECOM 2018c also includes acoustical terminology and concepts used during analysis and discussed in this section.

4.19.2 No Action Alternative

Under the No Action Alternative, the project would not be undertaken, and the required permits would not be issued. Consequently, there would be no noise or vibration impacts on any sensitive receptors from the implementation of the No Action Alternative.

4.19.3 Alternative 1 – Applicant's Proposed Alternative

4.19.3.1 Mine Site

The following factors used in the noise impact analyses are common to all project phases for the mine site component:

AMERICAN OVERSIGHT

- There is no known residential land use or other type of NSR within 10 miles of the mine site. However, subsistence hunters and recreationists may be temporarily present in any of these Alaska Department of Fish & Game (ADF&G) Management Areas that adjoin or are near the mine site: Mulchatna River, Lake Clark, and Iliamna Lake.
- The existing ambient noise level at the mine site and its adjoining vicinity is estimated to be comparable to "wilderness ambient" per Table 3.19-1, and therefore is 35 dBA day-night average sound levels (L_{dn}).

Although there are caribou, moose, bear, and other wildlife in the Bristol Bay Area Plan Management Unit Region 9 area that surrounds the mine site, there are no unique resources or resources protected by legislation with respect to noise. Impacts from noise on wildlife are addressed in Section 4.23, Wildlife Values.

Noise Sources

Construction

Construction of the mine site would occur over a 4-year period. Construction activities in the mine site would include initial pioneering and development of the pit to be mined; and the construction of mining facilities, milling facilities, tailings storage facilities, overburden storage facilities, roads, and support infrastructure. These activities would require use of heavy equipment such as wheel loaders, dozers, drills, and haul trucks.

Construction noise levels are rarely steady; instead, they fluctuate and are intermittent, depending on the number and type of equipment in use at any given time. There would be times when no large equipment is operating, and noise would be at or near existing ambient levels. In addition, construction-related sound levels experienced by a sensitive receptor in the vicinity of construction activity would be a function of distance and the presence and extent of vegetation and intervening topography between the noise source and the sensitive receptor.

Operations

Mine site operation would involve noise-producing activities and processes that include extracting rock from the ground (including blasting) and delivering ore to the milling facilities. Routine and preventive maintenance of support facilities and infrastructure would occur in the mine site area for management and safety practices.

Closure

In addition to reclamation activities conducted during mine closure, concurrent reclamation would be performed during operations whenever possible in areas that are no longer required for active mining. Closure earthwork activities would require major grading, contouring, and possible growth media placement using industry-standard heavy equipment; operation of this heavy equipment would in turn cause noise and vibration.

AECOM 2018c lists noise levels emitted by expected mobile and stationary machinery that would be operated at the mine site during construction, operation, and closure.

Impacts Analysis

Sound attenuation with distance and other factors were considered in prediction of noise impacts. Table 4.19-1 presents results of the predicted noise analyses, listing distances within which

AMERICAN OVERSIGHT

adverse noise effects would be expected and considered significant for the indicated NSR types as follows:

- When the predicted mine site noise level would exceed 30 dBA equivalent noise level (L_{eq}) at a location, it would risk causing sleep disturbance for recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient" per Table 3.19-1. This 30 dBA L_{eq} threshold at night is based on World Health Organization (WHO) guidance for sleep disturbance (WHO 1999), assuming that these receptors are not housed, and therefore, fully exposed to the outdoors (e.g., fabric tents, "lean-to" structures, hunting blinds, and other temporary structures assumed to provide no meaningful noise reduction).
- The noise level attributed to the mine site would exceed 45 dBA L_{dn} at a building exterior, and thereby be 10 dBA greater than the existing outdoor ambient sound level at a potential NSR (e.g., a temporarily occupied seasonal shelter).

Table 4.19-1: Distances from Mine Site within which Noise-Sensitive Receptors in Wilderness (35 dBA L_{dn}) would be Impacted

Project Phase	Operational Season/Notes	Distance from Mine Site (feet), where 30 dBA L_{eq} Predicted	Distance from Mine Site (feet), where > 10 dBA over Existing L_{dn} Predicted
Construction	Summer & Winter	17,250	11,900
Operation	Summer & Winter	18,450	12,900
Closure	Summer & Winter	15,900	10,750

Notes:

dBA = A-weighted decibel; Leq = equivalent sound level (e.g., hourly)

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 35 dBA Ldn (wilderness)

The opportunity for noise effects at potential NSR within the indicated distances would last only as long as the project phase under consideration.

4.19.3.2 Transportation Corridor

The facilities associated with the transportation corridor include the subcomponents of surface transportation, air transportation, and water transportation, which are discussed below.

Surface Transportation

The four primary road segments in Alternative 1 are the mine access road, Iliamna spur road, south access road, and Kokhanok Airport spur road. Road segments were studied individually and by phase, as described in the following paragraphs.

Mine Access Road

Noise Sources

Construction

AECOM 2018b (Table 5) provides an estimated roster of equipment required to construct the mine access road. This analysis conservatively assumes that all equipment in AECOM 2018b (Table 5) would be operating and emitting noise from a common geographic point along the road

AMERICAN OVERSIGHT

alignment. As road construction progresses, this acoustical center-point would slowly travel from one endpoint (the mine site) to the other (north ferry terminal). Therefore, an NSR would only be as close to the construction activity as its perpendicular distance to the road alignment.

Operations

During operation, truck traffic along the mine access road would require up to 39 round-trips per day to deliver concentrate, fuel, reagents, and consumables. Given this anticipated average daily truck volume, plus an assumed similar number of light vehicles expected for transport of locally residing mine workers (i.e., not staying in the on-site camp), traffic noise can be estimated with general assessment techniques from Federal Transit Administration (FTA) guidance, with inputs as follows:

- Reference sound exposure levels (SEL) of 82 dBA at 50 feet for the big vehicles, and 74 dBA for the passenger vehicles (pick-up trucks and vans).
- Maximum road speed of 25 miles per hour (mph).
- Speed constants (C_s) of 15 for the large diesel-engine vehicles, and 30 for the passenger vehicles.

With these inputs, the traffic noise estimate, in terms of L_{dn}, is as follows:

- Within a distance of approximately 200 feet from the mine access road, the estimated traffic-attributed noise level would be greater than 45 dBA L_{dn} at a building exterior, and therefore 10 dBA greater than the existing outdoor ambient sound level at a potential NSR (e.g., a temporarily occupied seasonal shelter).

In addition to regular truck traffic volumes, operation of the mine access road would involve regular maintenance activities that vary with the summer and winter seasons. AECOM 2018b (Table 6) provides an estimated roster of equipment required to maintain the road for each of these two seasons. This analysis conservatively assumes that all listed equipment for the season in AECOM 2018b (Table 6) would be operating and emitting noise from a common geographic point along the road. As maintenance progresses, this acoustical center-point would slowly travel from one endpoint (the mine site) to the other (north ferry terminal). Therefore, an NSR would only be as close to the maintenance activity as its perpendicular distance to the roadway alignment.

Closure

The mine access road would be needed for post-mining closure and reclamation activities, and would remain as a long-term asset after the end of mining. Therefore, no noise would be expected related to project closure and reclamation activities associated with the mine access road. However, where there may be borrow pits or staging areas adjoining the road that would undergo reclamation, this analysis assumed the same equipment listed in AECOM 2018b (Table 4) for the Amakdedori port closure would be involved.

Impacts Analysis

There are two Native allotments (AKA 052447 and AKA 006290) with boundaries that are tangential to the road alignment. Within these properties, as well as accessible public lands that adjoin the alignment, the predicted analysis findings are presented in Table 4.19-2, showing distances within which adverse noise effects would be expected, and considered significant for two types of NSR: recreationists and subsistence hunters sleeping outdoors and subject to disturbance; and occupants of structures.

AMERICAN OVERSIGHT

Table 4.19-2: Distances from Mine Access Road within which Noise-Sensitive Receptors in Wilderness (35 dBA L_{dn}) would be Impacted

Project Phase or Activity(ies)	Operational Season/Notes	Distance from Alignment (feet), where 30 dBA L_{eq} Predicted	Distance from Alignment (feet), where > 10 dBA over Existing L_{dn} Predicted
Construction	Summer & Winter	8,800	5,280
Operations	Summer	8,500	5,000
Operations	Winter	7,600	4,500
Closure	Summer & Winter	10,550	6,400

Notes:

dBA = A-weighted decibel

Leq = equivalent sound level (e.g., hourly)

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 35 dBA Ldn (wilderness)

The anticipated noise impacts within the two above-stated distances would be temporary, enduring only for as long as the project phase occurs.

During operation, and with respect to a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the road, the "worst-case" possibility would be a concurrent pass-by of two trucks on the road—traveling in opposite directions. The sleep disturbance criteria in this context would be the aforementioned 45 dBA maximum L_{EQ} (L_{max}) value per WHO guidance (WHO 1999); therefore, the perpendicular distance from the road within which this truck noise might awaken an unhoused receptor is 0.5 mile. Should wide expanses of dense, linearly occluding vegetation or the presence of terrain features like ridgelines or hills obscure the receptor's view of the road, the actual traffic noise L_{max} value should be less at this distance. Put another way, a line-of-sight blocking ridgeline that yields a 10 dBA reduction in the propagated sound would enable the outdoors-sleeping receptor to be up to 1,000 feet away from the road without experiencing sleep disturbance from traffic.

Iliamna Spur Road

Construction

The spur road would connect the mine access road with the existing Portage Road, at a tee-intersection approximately 2 miles north of Iliamna Airport. Construction of the Iliamna spur road would be expected to involve the same type of equipment shown in AECOM 2018b (Table 5); therefore, anticipated noise levels would be similar to those predicted for the mine access road, and the distances at which 30 dBA L_{eq} and 45 dBA L_{dn} occur would also be the same (see Table 4.19-2). Given these distances, noise impacts may be realized depending on the location of potential inhabited structures, recreationists, or subsistence hunters in the Native allotments (AKAA 007347A, 006622A, and 007125B) that are identified as having some portion of their parcels within 0.5 mile of the spur road.

Operations

Because the spur road is expected to experience traffic between the mine site and the communities of Iliamna and Newhalen, the type of traffic would probably be limited to lighter vehicles (e.g., passenger cars, vans) for commuting project workers and visitors. The regular flow

AMERICAN OVERSIGHT

of truck traffic making deliveries to and from the north ferry terminal would tend to avoid this spur; and as a result, the predicted traffic noise levels along the Iliamna spur road would be lower than that of the mine access road. Using the same FTA-based mathematical expression and input parameters, but without the trucks, the traffic noise estimate in terms of L_{dn}, is as follows:

- Within a distance of approximately 20 feet from the spur road, the estimated traffic-attributed noise level would be greater than 45 dBA L_{dn} at a building exterior, and therefore 10 dBA greater than the existing outdoor ambient sound level to a potential NSR (e.g., a temporarily occupied seasonal shelter). This distance is close to the road because the day-night project-attributed traffic noise level would be, without the trucks, much quieter under this condition.

With respect to a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the road, the "worst-case" possibility would be a concurrent pass-by of two vehicles on the road—traveling in opposite directions. The sleep disturbance criteria in this context would be the aforementioned 45 dBA L_{max} value per WHO guidance (WHO 1999); therefore, the perpendicular distance from the road within which an unhoused receptor might be awakened is 1,000 feet. Should linearly occluding forest or ground terrain features block line-of-sight and yield a 10 dBA reduction in the propagated sound, this distance at which sleep disturbance might occur would shorten to 330 feet.

In addition to traffic noise from vehicles on the spur road, noise from regular maintenance activities would also occur during summer and winter seasons, as studied for the mine access road, with the same noise impact potential, depending on distance as shown in Table 4.19-2.

The significant anticipated noise effects associated with project-attributed traffic and road maintenance would continue through operation.

Closure

Any reclamation activities for areas adjoining the Iliamna spur road would be expected to involve equipment similar to the closure roster presented in AECOM 2018b (Table 4), and generate the same predicted potential for noise impact, depending on distance and type of NSR (i.e., housed or unhoused receptor).

South Access Road

Construction

The south access road would connect the south ferry terminal with the Amakdedori port site. Construction of the south access road would be expected to involve the same type of equipment shown in AECOM 2018b (Table 5); therefore, anticipated noise levels would be similar to those predicted for the mine access road, and the distances at which 30 dBA L_{eq} and 45 dBA L_{dn} occur would also be the same (see Table 4.19-2). Given these distances, noise impacts may be realized depending on the location of potential inhabited structures, recreationists, or subsistence hunters in the three Native allotments (AKAA 006264, 006268, and 052505) and the Bureau of Land Management and Alaska Department of Natural Resources (ADNR) lands (24101003, 24103001, and 24103002), respectively, that are identified as having some portion of their parcels within 0.5 mile of the south access road.

Operations

Because the south access road is essentially the southern segment of the mine access road, the type of traffic would largely be the trucks identified in the study of the mine access road operations,

AMERICAN OVERSIGHT

with a few expected lighter vehicles (passenger cars, vans, etc.) for commuting project workers and visitors who may reside in Kokhanok. As a result, the predicted traffic noise levels along the south access road would be comparable to that of the mine access road. Using the same FTA-based mathematical expression and input parameters, but only a fraction (10 percent) of the passenger vehicle traffic as assumed for the Mine Access Road, the traffic noise estimate, in terms of L_{dn}, is as follows:

- Within a distance of approximately 200 feet from the access road, the estimated traffic-attributed noise level would be greater than 45 dBA L_{dn} at a building exterior, and therefore 10 dBA greater than the existing outdoor ambient sound level for a potential NSR (e.g., a temporarily-occupied seasonal shelter).

With respect to a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the roadway, the "worst-case" possibility would be a concurrent pass-by of two trucks on the roadway—with one in each direction. The sleep disturbance criteria in this context would be the aforementioned 45 dBA L_{max} value per WHO guidance (WHO 1999); therefore, the perpendicular distance from the roadway within which an unhoused receptor might be awakened is 0.5 mile. Should linearly occluding forest or ground terrain features block line-of-sight and yield a 10 dBA reduction in the propagated sound, the distance at which sleep disturbance might occur would shorten to 1,000 feet.

In addition to traffic noise from vehicles on the south access road, noise from regular road maintenance activities would also occur during summer and winter seasons, as studied for the mine access road, with the same noise impact potential, depending on distance as shown in Table 4.19-2. The significant anticipated noise effects associated with project-attributed traffic and road maintenance would endure through operation.

Closure

Any reclamation activities for areas adjoining the south access road would be expected to involve equipment similar to the roster presented under closure in AECOM 2018b (Table 4), and generate the same predicted potential for noise impact, depending on distance and type of NSR (i.e., housed or unhoused receptor).

Kokhanok Airport Spur Road

Construction

The spur road would connect the south access road with the community of Kokhanok and its airport. Construction of this spur road would be expected to involve the same type of equipment shown in AECOM 2018b (Table 5); therefore, anticipated noise levels would be similar to those predicted for the mine access road, and the distances at which 30 dBA L_{eq} and 45 dBA L_{dn} occur would also be the same (see Table 4.19-2). Given these distances, noise impacts may be realized depending on the location of potential inhabited structures, recreationists, or subsistence hunters in the lands that abut the planned spur road.

Operations

Because the spur road is essentially a short connection between the existing Kokhanok Airport and its community and the south access road, the type of traffic would probably be limited to lighter vehicles (e.g., passenger cars, vans) for commuting project workers and visitors. The regular flow of truck traffic making deliveries to and from the north ferry terminal would tend to avoid this spur; and as a result, the predicted traffic noise levels along the Kokhanok Airport spur road would be much less than that of the mine access road. Using the same FTA-based

AMERICAN OVERSIGHT

mathematical expression and input parameters, but without the trucks, and only a fraction (10 percent) of the light vehicle traffic as expected on the mine access road on the north side of Iliamna Lake, the traffic noise estimate in terms of L_{dn}, is as follows:

- With respect to a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the roadway, the "worst-case" possibility would be a concurrent pass-by of two vehicles on the roadway—with one in each direction. The sleep disturbance criteria in this context would be the aforementioned 45 dBA L_{max} value per WHO guidance (WHO 1999); therefore, the perpendicular distance from the roadway within which an unhoused receptor might be awakened is 1,000 feet. Should linearly occluding forest or ground terrain features block line-of-sight and yield a 10 dBA reduction in the propagated sound, the distance at which sleep disturbance might occur would shorten to 330 feet.

In addition to traffic noise from vehicles on the spur road, noise from regular road maintenance activities would also occur during summer and winter seasons, as studied for the mine access road, with the same noise impact potential, depending on distance. The significant anticipated noise effects associated with project-attributed traffic and road maintenance would endure through operation.

Closure

Reclamation activities for areas adjoining the Kokhanok Airport spur road would be expected to involve equipment similar to closure presented in AECOM 2018b (Table 4), and generate the same predicted potential for noise impact, depending on distance and type of NSR (i.e., housed or unhoused receptor).

Air Transportation

Already constructed and operating as public airports, existing airfields at Iliamna and Kokhanok would be expected to experience project-related aviation traffic to support construction activities and to provide non-resident transportation to and from the mine site vicinity. However, the Kokhanok Airport would not be used to support project construction until the Kokhanok Airport spur road is completed. Therefore, for the first year of construction, the airstrip at Amakdedori port would temporarily be used as described in the following paragraphs.

Amakdedori Port Airstrip

Construction

On completion, the airstrip at Amakdedori would be expected to experience between 20 and 40 flights per month by a Twin Otter (Bombardier DHC-6 or similar aircraft type) during the May-September periods of the first and second years of project construction. Between these periods, during the winter months, up to 20 flights per month may be required. According to Federal Aviation Administration data, the Twin Otter is estimated to exhibit 67 dBA (at a distance of 6,500 meters from takeoff start roll) during takeoff; and 78 dBA (at 2,000 meters from runway threshold) during approach.

With respect to a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the airstrip, the "worst-case" possibility would be an aircraft takeoff or landing at night. Using the same aforementioned sleep disturbance criterion of 45 dBA L_{max}, the perpendicular distances within which an unhoused receptor might be awakened is 6.5 miles and 4.5 miles for takeoff and approach, respectively. Should linearly occluding forest or ground terrain features block line-of-sight and yield a 10 dBA reduction in the propagated sound, the distance at which sleep disturbance might occur would shorten to 5 miles and 3.1 miles, respectively.

AMERICAN OVERSIGHT

For potential receptors within shelters, where exterior noise levels not exceeding 45 dBA L_{dn} would be expected for avoiding adverse effects with respect to existing outdoor ambient noise levels (35 dBA L_{dn}), perpendicular distances would need to be 3.4 miles for takeoff and 1.8 miles for approach. If terrain-based occlusion of aircraft sound yields 10 dBA of reduction, these distances would shorten to 2.2 miles and 4,900 feet for aircraft takeoff and approach, respectively.

Iliamna Airport

Operations

During airport operations, major noise sources would consist of operating aircraft and on-site facility operations. These are pre-existing sources of noise that acoustically contribute to the outdoor sound environment close to the airport.

For the 12-month period ending December 31, 2015, the airport had 15,400 aircraft operations, an average of 42 per day: 73 percent general aviation, and 27 percent air taxi (AirportIQ™ 5010, 2018). The project would be expected to increase the frequency of fixed-wing and rotary-wing aircraft by an average quantity of 11 aircraft per week, and include Twin Otter and Q400 (Bombardier DHC-8) type aircraft. Assuming the airport's stationary noise-producing noise sources do not change, the increase in noise from the airport would primarily be due to the increase in aviation traffic. The average increase in daily operations of no more than 2 per day due to the project's operation phase represents less than a 5 percent increase in traffic volumes. Unless the size and/or power of project-related aircraft are substantially different than that comprising existing aviation traffic, the per-event sound levels associated with aircraft takeoff, landing, and taxiing would not change, and therefore would not be expected to cause a perceptible difference or adverse effect. Upon closure of the project, and aside from development unrelated to the project that might cause an increase in aviation traffic at Iliamna Airport, noise levels would likely revert to pre-project conditions.

Kokhanok Airport

Operation

During airport operations, major noise sources would consist of operating aircraft and on-site facility operations. These are presumably pre-existing sources of noise that acoustically contribute to the outdoor sound environment close to the airport. However, for the 12-month period ending December 31, 2013, the airport had no aircraft operations (AirportIQ™ 5010, 2018). The project would be expected to add an average quantity of up to 10 Twin Otter–type aircraft operations per week during project construction, and 5 to 10 Twin Otter aircraft operations per week during project operations. Assuming the airport's stationary noise-producing noise sources do not change, the increase in noise from the airport would primarily be due to the increase in aviation traffic. If levels of aircraft operation activity at Kokhanok continue to be modest or non-existent, then these project-attributed operations could be considered relatively new sources of noise, and—for purposes of this analysis—be assessed in a manner similar to what was previously described for the temporary reliance on the proposed Amakdedori port airstrip. Distances within which adverse effects would be anticipated for outdoor subsistence hunters, recreationists, or occupants of shelters and other structures due to Twin Otter takeoffs and landings would be the same as those presented for Amakdedori port.

Closure

Upon closure, anticipated aviation traffic at Kokhanok would likely return to pre-project levels.

AMERICAN OVERSIGHT

Water Transportation

North and South Ferry Terminals

Noise Sources

The ferry terminals would serve as transfer points for cargo conveyed over the lake via an ice-breaking ferry, at an expected average frequency of one round trip per day. Consistent with the project description, this analysis assumes that each terminal has a manned office with a generator and some equipment (e.g., forklifts) to handle loading and unloading of cargo between the moored ferry and trucks. The ferry engine would be offline while such loading/unloading occurs.

Construction

Construction activities associated with the ferry terminals would include ground preparation and development of ferry terminal facilities. This analysis assumes that the intensity of construction activity, as well as type and quantity of equipment and vehicles involved, will resemble AECOM 2018b (Table 5) for the mine access road, and thereby demonstrate an overall reference sound level of 88 dBA L_{eq} at 50 feet.

Operations

This analysis assumes the local power supply (generator) at each ferry terminal would conservatively operate continually (day and night), and represents the dominant site sound source (apart from intermittent forklift operation and related activity during up to twice-per-day ferry loading or unloading), and produces a reference sound level no greater than 70 dBA L_{eq} at a distance of 50 feet.

Closure

The ferry terminals would likely support closure and reclamation. Because activities at these lake ports would continue, the potential for noise impacts would be similar to those discussed under operations. However, it is assumed that once mine site closure and reclamation has been completed, the amount of activity at these ferry terminals would decrease. Any reclamation activities for areas adjoining the ferry terminal sites would be expected to involve equipment similar to closure, as presented in AECOM 2018b (Table 4); and generate the same predicted potential for noise impact, depending on distance and type of NSR (e.g., housed or unhoused receptor).

Impacts Analysis

There is one Native allotment (AKAA 006290) with an easternmost boundary apex that adjoins the northern ferry terminal site. For this property, as well as accessible public lands that adjoin it and the north ferry terminal site on which subsistence hunters and sportsmen may temporarily dwell, the predicted analysis findings are as shown in Table 4.19-3.

AMERICAN OVERSIGHT

Table 4.19-3: Distances from Iliamna Lake Ferry Terminals within which Noise-Sensitive Receptors in Wilderness (35 dBA L_{dn}) would be Impacted

Project Phase or Activity(ies)	Operational Season/Notes	Distance from Alignment (feet), where 30 dBA L_{eq} Predicted	Distance from Alignment (feet), where > 10 dBA over Existing L_{dn} Predicted
Construction	Summer & Winter	8,550	5,000
Operations	Summer & Winter	2,250	1,000
Closure	Summer & Winter	10,600	6,500

Notes:

dBA = A-weighted decibel; Leq = equivalent sound level (e.g., hourly)

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 35 dBA Ldn (wilderness)

The anticipated noise impacts within the two above-stated distances would last only as long as the project phase noise sources occur.

4.19.3.3 Amakdedori Port

Noise Sources

Construction

Construction of the port would involve conventional heavy construction equipment, vehicles, and stationary systems (e.g., air compressors, generators) similar to those listed in AECOM 2018b (Table 3), and expected to prepare and grade the site and construct the port terminal and facilities, including power generation plant and offshore facilities (dock and causeway). Using FTA general assessment techniques to estimate construction noise, it could be assumed that two pieces of equipment, each exhibiting no more than 85 dBA L_{max} (e.g., two simultaneously operating graders on site) at 50 feet and operating at full power, would yield an aggregate average sound level of 88 dBA L_{eq} at 50 feet, and represent the noise from most port construction activities. However, unique to this facility, impact pile-driving would occur during construction that can generate noise levels of 95 dBA L_{max} at 50 feet (FHWA 2006).

Operations

Operation of the port would involve generally persistent stationary noise sources such as on-site power generation and heating, ventilation, and air conditioning systems, punctuated by loading/off-loading activity to handle concentrate containers, other cargo, and fuel from vessels.

Closure

As activities at the port continue to support closure and reclamation, potential noise impacts at the sensitive receptor would be similar to those discussed under the operations above. However, it is assumed that once mine closure and reclamation have been completed, the amount of activity at the port site would decrease.

AECOM 2018b (Table 4) lists noise levels emitted by expected mobile and stationary machinery that would be operated at Amakdedori port during the construction, operation, and closure. Unless otherwise noted, these lists per project phase represent estimates of maximum operating units at one time.

AMERICAN OVERSIGHT

Impact Analysis

The nearest potential NSR to the port would be subsistence hunters and seasonal visitors (recreationists) temporarily inhabiting the surrounding ADNR parcel (ID# 24103002). Such NSR may also dwell on public lands beyond this parcel boundary. Although the equipment and vehicle rosters are different, the technique for estimating noise exposure at NSR due to Amakdedori port operation would be similar to that used for estimating aggregate noise emission from mine site operation, and use the same conservative assumptions. Accounting for sound attenuation with distance and other considered factors, the predicted analysis findings are presented in Table 4.19-4, showing distances within which adverse noise effects would be expected, and considered significant for the same two types of NSR: recreationists and subsistence hunters sleeping outdoors and subject to disturbance; and occupants of structures.

Table 4.19-4: Distances from Amakdedori Port within which Noise-Sensitive Receptors in Wilderness (35 dBA L_{dn}) would be Impacted

Project Phase or Activity(ies)	Operational Season/Notes	Distance from Alignment (feet), where 30 dBA L_{eq} Predicted	Distance from Alignment (feet), where > 10 dBA over Existing L_{dn} Predicted
Construction	Summer & Winter	8,550	4,900
Operations	Summer & Winter	9,750	5,800
Closure	Summer & Winter	10,550	6,400

Notes:

dBA = A-weighted decibel

Leq = equivalent sound level (e.g., hourly)

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 35 dBA Ldn (wilderness)

The anticipated noise impacts at potential NSR within the above-stated distances would be temporary, enduring only as long as the project phase occurs.

With pile-extraction during closure, a subsistence hunter or recreationist who may be sleeping outdoors at some distance from the port may be startled if exposed to 45 dBA L_{max} per WHO guidance (WHO 1999); therefore, the perpendicular distance from the pile-driving activity within which this awakening of an unhoused NSR would occur is 5,100 feet. Should wide expanses of dense, linearly occluding vegetation or the presence of terrain features like ridgelines or hills obscure the receptor's view of the pile-driving activity, the actual noise L_{max} value should be less at this distance. Put another way, a line-of-sight blocking ridgeline that yields a 10 dBA reduction in the propagated sound would enable the outdoors-sleeping receptor to be up to 2,250 feet away from the activity without experiencing sleep disturbance.

4.19.3.4 Natural Gas Pipeline Corridor

For purposes of this noise analysis, the pipeline corridor study is organized as follows:

- Mainline, which includes the natural gas pipeline, temporary construction and operational rights-of-way (ROWs), and temporary work areas outside of the ROW (access roads, construction camps, pipe and equipment storage yards, material sites, and airstrips)

AMERICAN OVERSIGHT

- Above-ground facilities would include the new compressor station at Anchor Point, the main line block valve stations, metering stations, and pig launching and receiving facilities.

Mainline

The distances of the nearest NSR vary for each subcomponent (surface, water, and air) being analyzed; however, the general existing ambient noise level is estimated at 35 dBA L_{dn} (adapted from Table 3.19-3).

Construction

Noise impacts associated with the mainline would occur mainly during construction. Construction-related noise sources would be generated by helicopter traffic, diesel-powered mobile equipment, pipe installation equipment, equipment operating at material sites, and blasting (in the event it would be necessary). Increased noise levels would vary depending on the construction stage, and would be localized and transitory as construction activity proceeds at various locations along the length of the pipeline. Noise impacts for specific construction activities are described below.

The overall project schedule for construction of infrastructure build-out, pipe installation, and ROW stabilization, rehabilitation and reclamation work concurrent with and immediately following pipe installation would take place over a period of 3 to 4 years. The first year would involve ROW civil work and mobilization of material and equipment, including clearing of vegetation (as applicable), preliminary civil construction of access roads, airstrips, barge landings, pipe storage yards, construction campsites, etc. The pipeline installation would occur for a period of 2 to 3 years.

AECOM 2018b (Table 5) lists equipment used for construction of a typical pipeline section, the corresponding noise levels, and season of operation, grouped by construction activities. Because noise impacts and affected sensitive receptors vary with specific construction activities during a certain period of time, as well as the conditions of the affected environment where the activities may be located with respect to potential NSR, the noise impacts are discussed relative to the pipeline major construction activities, as described below.

The equipment rosters presented in AECOM 2018b (Table 5) show the expected assortment of stationary and mobile equipment per construction phase; this analysis predicts distant NSR noise exposure from only the two loudest units operating at full power—in a manner similar to the FTA "general assessment" technique (FTA 2006). By way of example, for the general activities and utility equipment category, the forklift and carrier are each rated at 85 dBA at 50 feet; therefore, the combined representative reference noise level for this phase would be 88 dBA L_{eq} at 50 feet.

Table 4.19-5 lists the distances from the centerline of the pipeline alignment on land in which the indicated sound levels attributed to construction would be exceeded. As consistently used in the preceding analyses, the 30 dBA L_{eq} metric would be the impact criterion applied to recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient," per Table 4.19-1. Correspondingly, the 45 dBA L_{dn} limit (representing a 10 dBA increase over the presumed existing 35 dBA L_{dn} of the pre-project outdoors) applies to such individuals sleeping within structures.

AMERICAN OVERSIGHT

Table 4.19-5: Distances from Construction of the Pipeline Alignment within which Noise-Sensitive Receptors in Wilderness (35 dBA L_{dn}) would be Impacted

Construction Phase or Activity(ies)	Operational Season/Notes	Distance from Alignment (feet), where 30 dBA L_{eq} Predicted	Distance from Alignment (feet), where > 10 dBA over Existing L_{dn} Predicted
General Activities and Utility Equipment (GA&UE)	Summer & Winter	8,550	5,000
GA&UE with helicopter support (40%)	Summer & Winter	19,500	14,000
Civil Construction	Summer & Winter	8,550	5,000
Drilling and Blasting	Summer & Winter	12,600	8,000
Ice Road Construction and Maintenance	Winter	8,550	5,000
Pipe Laying	Summer & Winter	8,550	5,000
River Crossings and HDD	Summer	7,800	4,400
Backfilling and Ground Restoration	Summer & Winter	8,550	5,000
Pipe Cleaning, Pressure Testing and Drying	Summer & Winter	5,100	2,600

Notes:

dBA = A-weighted decibel

HDD = horizontal directional drilling

Leq = equivalent sound level (e.g., hourly)

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 35 dBA Ldn (wilderness)

The anticipated noise effects within the two distances noted in Table 4.19.5 would be considered temporary, lasting only as long as the indicated construction phase activities occur and in the vicinity of the receptors. In other words, pipeline construction activity tends to be intensive at a particular area, and moves away from a stationary NSR as construction progresses.

Where the pipeline makes the east Cook Inlet landfall at Anchor Point, the existing outdoor ambient sound environment is anticipated to be higher (50 dBA L_{dn}), due to road traffic on the nearby Sterling Highway; therefore, the distance buffers within which pipeline construction noise would potentially cause impacts to neighboring NSR are much shorter, as presented in Table 4.19-6. In this sound environment, the outdoor ambient noise is already well above 30 dBA L_{eq}, and would not be expected to have receptors sleeping outdoors. For people sleeping inside their residences in this developed environment, the EPA guidance level of 55 dBA L_{dn} for the NSR exterior serves as the impact threshold for project-attributed noise.

AMERICAN OVERSIGHT

Table 4.19-6: Distances from Construction of the Pipeline Alignment within which Noise-Sensitive Receptors in Anchor Point (50 dBA L_{dn}) would be Impacted

Construction Phase or Activity(ies)	Operational Season/Notes	Distance from Alignment (feet), where 55 dBA L_{dn} Predicted
General Activities and Utility Equipment (GA&UE)	Summer & Winter	2,150
GA&UE with helicopter support (40% AUF)	Summer & Winter	8,300
Civil Construction	Summer & Winter	2,150
Drilling and Blasting	Summer & Winter	4,000
Ice Road Construction and Maintenance	Winter	2,150
Pipe Laying	Summer & Winter	2,150
River Crossings and HDD	Summer	1,850
Backfilling and Ground Restoration	Summer & Winter	2,150
Pipe Cleaning, Pressure Testing and Drying	Summer & Winter	990

Notes:

dBA = A-weighted decibel

HDD = horizontal directional drilling

Ldn = day-night sound level, expressed as dBA; presumes outdoor ambient noise is 50 dBA Ldn

With the exception of helicopter-supported activities and drilling, all listed activity groups in Table 4.19-6 for pipeline construction are expected to cause impactful noise levels within a distance of 2,150 feet from the pipeline alignment. Therefore, it is possible that up to 43 of the potential NSR counted as being within 0.5 mile of the compressor station (in Section 3.19, Noise, Affected Environment) may experience temporary impacts, lasting only as long as construction. Development of a detailed construction noise mitigation plan, including scheduling of noise-producing activities, the proper design and implementation of practical and site-appropriate noise-reducing measures, and sound level monitoring to check for compliance with the outdoor EPA guidance threshold, would help minimize the magnitude of construction noise, and thereby reduce the likelihood, duration, and quantity of impacted NSR.

Construction and installation of the proposed pipeline segments along the bottom of Iliamna Lake and Cook Inlet would be carried out by appropriate equipment and water-borne vehicles sufficiently distant from NSR, and would not cause noise impacts. Section 4.23, Wildlife Values, addresses noise impacts to wildlife.

Operations

Pipeline Operations

There would be no major noise-producing sources along the pipeline corridor during pipeline operation. Gas traveling through the pipeline would not emit audible noise at potential NSR; therefore, there would be no noise impacts associated with pipeline operation.

Periodic Pipeline Maintenance and Inspection

Periodic maintenance and routine inspection would be conducted on the mainline, and noise sources would include pigging. Given the similarity of expected activities, noise level emissions

AMERICAN OVERSIGHT

from pigging would be considered comparable to those of the pipeline cleaning, pressure testing, and drying activities, as described in AECOM 2018b (Table 5), with the potential for impact at NSR depending on the existing sound environment and the proximity (i.e., within the indicated screening distances), per Tables 4.19-5 and 4.19-6. The duration of these impacts would be intermittent throughout the project operation.

Pipeline ROW Maintenance and Safety Inspection

As part of maintenance and safety procedures, the pipeline ROW would be cleared of brush at approximately 10-year intervals, or as required to preserve pipeline integrity and access. AECOM 2018b (Table 6) lists equipment operated for a typical ROW clearing and the corresponding noise levels, and represents an estimate of maximum operating units at one time.

Using the aforementioned FTA-based general assessment technique of estimating construction noise from the two loudest pieces of equipment operating at full power, the resulting reference noise level for pipeline ROW maintenance would be 88 dBA L_{eq} at 50 feet. The predicted analysis findings are as follows:

- Within a distance of approximately 8,550 feet from the pipeline area being cleared, the estimated noise level would be at least 30 dBA L_{eq}, and therefore risk causing sleep disturbance for recreationists and subsistence hunters sleeping outdoors during their seasonal activities on lands considered "wilderness ambient," per Table 3.19-3. At Anchor Point, such receptors would not be expected, and therefore not impacted.
- Within a distance of approximately 5,000 feet, the estimated operations noise level would be at least 45 dBA L_{dn} at a building exterior, and therefore 10 dBA greater than the existing outdoor ambient sound level at a potential NSR (e.g., a temporarily occupied seasonal shelter). For NSR at Anchor Point, where such ROW maintenance may occur, the screening distance would only be 2,150 feet.

The anticipated noise impacts within the two distances noted above would be temporary, and localized to where such activities occur during project operation.

Closure

All disturbed areas (such as the ROW, temporary construction camps, pipe storage yards, material sites, airstrips, roads, barge landings, and other temporary use areas) would be cleaned up, stabilized, prepared for natural revegetation, and reclaimed to their original state. Noise estimates are calculated based on the two loudest equipment units from AECOM 2018b (Table 5) under the backfilling and ground restoration. The two loudest equipment units from the table each have a noise level of 85 dBA at 50 feet, and would therefore combine to a source reference level of 88 dBA L_{eq} at 50 feet. Because this is the same reference level for the pipeline maintenance activity, potential impacts would be anticipated at NSR within the same distances. The significance of these anticipated noise effects would be temporary, localized, and last only through project closure.

Intermittent noise impacts from helicopters used to transport personnel to and from pipeline locations would also be expected. However, because the flight routes and vertical aircraft distances are unknown at this time, resulting noise levels during an NSR fly-over could not be estimated.

AMERICAN OVERSIGHT

Pipeline Aboveground Facilities

Pipeline aboveground facilities consist of a compressor station (Anchor Point), metering stations, mainline valves, and pig launcher and receiver stations. Noise impacts for each of these facilities are described below.

Compressor Station

For purposes of this noise analysis, each compressor station is assumed to feature the following (USACE 2018):

- 1,000-horsepower natural gas compression machines driven by two gas-fired microturbines (one 100 percent unit and a 100 percent backup)
- Outdoor fin-fan cooler
- Unmanned, with fully automated equipment operated by a remote-control system
- Pig launcher and a mainline block valve (as an emergency shutdown or blowdown valve) on the site.

The nearest NSR to the Kenai compressor station would be residents and seasonal visitors of Anchor Point.

Construction

Noise impacts during the construction of the compressor station would be generated during operations of heavy construction equipment. Noise and vibration calculation methodologies and assumptions would be in accordance with the FTA guidance on general assessment for noise impacts (FTA 2006), whereby noise estimates are predicted based on two of the loudest expected equipment units shown under the general activities category of Table 4.19-5 and Table 4.19-6, resulting in 88 dBA L_{eq} at 50 feet. The predicted analysis finding is as follows:

- Within a distance of approximately 2,150 feet, the estimated operations noise level would be at least 55 dBA L_{dn} at a building exterior, and therefore potentially greater than the EPA guidance level for the exterior of an NSR in the community of Anchor Point.

Subsistence hunters and recreationists would not generally be expected to be sleeping outdoors in this developed area of the Kenai Peninsula; thus, they would not be potential NSR with respect to this noise source. The significant anticipated noise effects within the above-stated distance would be temporary, and localized to where such activities occur during construction of the facilities.

Operations

Noise generated at the compressor station during operations would originate mainly from operation of the compressor machines, one microturbine, fin-fan coolers, blowdown processes, and pipeline pig(s). This analysis assumes (USACE 2018):

- The compressors and microturbines would be housed inside buildings or provided enclosures to reduce noise emissions.
- External to these buildings or enclosures, air intakes and combustion exhaust ducting for the power units would feature typical sound-attenuating means.
- In aggregate, sound levels attributed to the enclosed compressors and power units operating at full load would be limited to 68 dBA L_{eq} at a distance of 50 feet (based on

AMERICAN OVERSIGHT

line source propagation from an exterior wall, where the emitted noise is 80 dBA L_{eq} at 3.28 feet from the surface).

- Unenclosed fin-fan coolers would emit up to 88 dBA L_{eq} at a distance of 50 feet, and are the dominant compressor station noise sources.

The predicted analysis finding for compressor station operation noise is as follows:

- Within a distance of approximately 2,150 feet, the estimated operations noise level would be at least 55 dBA L_{dn} at a building exterior, and therefore potentially greater than the EPA guidance level for the exterior of an NSR in the community of Anchor Point.

Subsistence hunters and recreationists would not generally be expected to be sleeping outdoors in this developed area of the Kenai Peninsula; thus, they would not be potential NSR with respect to this noise source. The anticipated noise effects within the above-stated distances would endure as long as the compressor station operates during project operation.

Pipeline pigging is needed for maintenance and testing, and most likely would be performed on an annual basis. The noise from pipeline pigging would be transient in nature, and would only occur at the pig trap, and the short, aboveground pipe segment. The noise from a pipeline blowdown event would be rare, because it would only occur during an emergency pressure relief or blowdown due to an incident requiring a major repair on a pipeline segment or compressor station equipment. Noise from a pipeline blowdown would be loud and transient, lasting for several minutes, until the pressure is relieved.

Closure

Reclamation activities at the compressor station would occur following construction, and at the beginning of closure. Disturbed ground would be graded and stabilized after construction of facilities. At closure, all equipment at the compressor station would be dismantled and transported away for salvage, recycling, or disposal, as appropriate. Noise estimates are calculated based on the two loudest equipment units from AECOM 2018b (Table 5) under backfilling and ground restoration. The two loudest equipment units from the table each have a noise level of 85 dBA at 50 feet, and would therefore combine to a source reference level of 88 dBA L_{eq} at 50 feet. Because this is the same reference level for the pipeline maintenance activity, potential impacts would be anticipated at Anchor Point NSR within the same distances. The significance of these anticipated noise effects would be temporary, localized, and last only through project closure.

Metering Stations

Metering stations would be at the project pipeline tie-in with existing natural gas pipeline infrastructure in the vicinity of the compressor station at Anchor Point. Each of these stations would also have a mainline block valve and a pig launcher and receiver. Noise impacts would generally not be anticipated due to construction, operation, and closure of metering facilities co-located at the compressor stations, where outdoor noise sources such as the unenclosed fin-fan gas coolers are expected to dominate the local sound environment.

Mainline Block Valve Stations

Mainline block valves would be placed at no more than 20-mile intervals along the pipeline route. They would be constructed as part of the pipeline installation, and operate with aboveground features that would be designed to emit low noise levels due to exterior thermal/acoustic lagging materials or insulated housings or enclosures. No noise impacts are anticipated at distances beyond the pipeline ROW when the mainline block valves are conveying gas to the mine site

AMERICAN OVERSIGHT

under normal conditions. Maintenance of these facilities would be considered categorized as pipeline maintenance, which has been previously discussed.

4.19.3.5 Alternative 1 – Variant: Kokhanok East Ferry Terminal

Aside from a relocation of the south ferry terminal to the east of the community of Kokhanok, the Kokhanok east ferry terminal variant avoids a road crossing the Gibraltar River. Regarding noise impact analysis, this variant is identical to Alternative 1.

4.19.3.6 Alternative 1 – Variant: Summer-Only Ferry Operations

Noise impacts with implementation of summer-only ferry operations would be identical to Alternative 1.

4.19.4 Alternative 2

4.19.4.1 Mine Site

Potential noise impacts to NSR with respect to the construction, operation, and closure of the mine site are the same as those for Alternative 1. This section is organized by the subcomponents of the transportation corridor: surface transportation, air transportation, and water transportation.

4.19.4.2 Transportation Corridor

Chapter 2, Alternatives, provides a detailed description of Alternative 2. This section is organized by the subcomponents of the transportation corridor: surface transportation, air transportation, and water transportation.

Potentially affected NSR may include the same property parcels, if occupied, identified for Alternative 2 in Section 3.19, Affected Environment. Along the transportation corridor for Alternative 2, distances within which impacts would be anticipated at NSR would be the same as those as previously discussed in Section 4.19.3, and listed in Tables 4.19-2 and 4.19-3.

4.19.4.3 Diamond Point Port

Assuming the facility is comparable to those of a port at Amakdedori, potential noise impacts to NSR with respect to the construction, operation, and closure of the Diamond Point port would be the same as for Alternative 1.

4.19.4.4 Natural Gas Pipeline Corridor

Distances within which impacts would be anticipated at NSR would be the same as those presented in Section 4.19.3, and listed in Tables 4.19-5 and 4.19-6.

4.19.4.5 Alternative 2 – Variant: Summer-Only Ferry Operations

Implementation of the summer-only ferry operations under Alternative 2 would have the same noise impacts as Alternative 1 during the summer.

4.19.5 Alternative 3

4.19.5.1 Mine Site

Potential noise impacts to NSR with respect to the construction, operation, and closure of the mine site are the same as those for Alternative 1.

AMERICAN OVERSIGHT

4.19.5.2 Transportation Corridor

Potentially affected NSR may include those property parcels, if occupied, identified in Section 3.19, Affected Environment. Along the transportation corridor for Alternative 3, distances within which significant impacts would be anticipated at NSR would be the same as those described for Alternative 1 (Section 4.19.3), and listed in Tables 4.19-5 and 4.19-6. The route passes near the community of Pedro Bay; therefore, the existing outdoor ambient sound environment would not be 35 dBA L_{dn}, but reflect those values shown in Table 3.19-5, and therefore cause the impact distances to reflect use of the EPA guidance-based noise threshold of 55 dBA L_{dn} for the exteriors of occupied residences or seasonal shelters. During construction of the mine access road near the Pedro Bay community, this distance would be 2,250 feet. Maintenance of the road would potentially cause noise impacts to NSR near Pedro Bay at a distance of up to 2,150 feet in summer, and 1,800 feet in the winter.

Expected road traffic would cause noise impact to NSR at a distance of up to 200 feet in an otherwise 35 dBA L_{dn} undeveloped environment; but near Pedro Bay, the distance would shorten to 35 feet. During closure and reclamation activities along the road near the Pedro Bay community, the impact distance would be 3,000 feet.

4.19.5.3 Diamond Point Port

Assuming the facility features and their construction and operation are comparable to those of Amakdedori port (Alternative 1), potential noise impacts to NSR with respect to the construction, operation, and closure of the Diamond Point Port are the same as those for Alternative 1.

4.19.5.4 Natural Gas Pipeline Corridor

Potential noise impacts to NSR with respect to the construction, operation, and closure of the natural gas pipeline corridor should be the same as those for Alternative 1 shown in Section 4.19.3, and listed in Tables 4.19-5 and 4.19-6. The proposed pipeline route passes near the community of Pedro Bay; therefore, the existing outdoor ambient sound environment would not be 35 dBA L_{dn}, but would reflect values shown in Table 3.19-5, and therefore cause the impact distances to reflect use of the EPA guidance-based noise threshold of 55 dBA L_{dn} for the exteriors of occupied residences or seasonal shelters.

4.19.5.5 Key Issues/Impacts Summary

Table 4.19-7 provides summary statements of key issues and impacts from the project on noise.

AMERICAN OVERSIGHT

Table 4.19-7: Summary of Key Issues for Noise Resource

Impact Causing Project Component/Activity	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Note: The following acronyms are used to describe three categories of potentially impacted receivers: • *RSH* = outdoor sleeping Recreationists and Subsistence Hunters in a remote rural or wilderness setting (where 35 dBA day-night sound level [L_{dn}] is the expected existing outdoor ambient sound environment); • *SPR-W* = occupants of Seasonal shelters and Permanent Residences in a remote rural or Wilderness setting (where 35 dBA L_{dn} is the expected existing outdoor ambient sound environment); and • *SPR-D* = occupants of Seasonal shelters and Permanent Residences in a Developed (e.g., Pedro Bay) setting (where exterior noise threshold of 55 dBA L_{dn} per EPA guidance would be expected to apply).

4.19.6 Cumulative Effects

Past, present, and RFFAs in the cumulative impact study area have the potential to contribute cumulatively to impacts on outdoor recreationists, subsistence hunters, and occupants of seasonal and year-long residences. Section 4.1 and Appendix K4.19 detail the past, present, and reasonably-foreseeable future actions that may impact these receivers. There may also be cumulative effects to wildlife in the study area, which has been studied and addressed in Section 4.23, Wildlife Values. The potential future actions are similar to the proposed project in how they may generate noise, and therefore the possibility of sleep disturbance from construction and operations activities, and alter subsistence and recreational hunting, among others. The following RFFAs identified in Section 4.1 were carried forward in this analysis based on their potential to impact outdoor recreationists, subsistence hunters, and occupants of seasonal and year-long residences in the analysis area:

- Pebble project buildout – develop 55 percent of the resource over the 78-year period
- Pebble South/PEB
- Big Chunk South*
- Big Chunk North*
- Fog Lake*
- Groundhog*
- Shotgun*
- Johnson Tract*
- Copper Joe*

**Indicates exploration activities only.*

- Donlin Gold
- Diamond Point Rock Quarry
- Alaska LNG
- Drift River Oil Pipeline
- Cook Inlet Lease Sales
- Onshore Hydrocarbon Exploration*
- Lake and Peninsula Transportation, Infrastructure and Energy Projects

The most important potential future actions included in this analysis are those that contribute to the risk of sleep disturbance for outdoor recreationists and subsistence hunters; the potential for cumulative project activities to raise the outdoor ambient sound level to a degree that may impact hunting activities or the perception of natural soundscape characteristics (and their consistency with recreationist expectations); and the quality of life for residents (both seasonal and permanent) that dwell in the study area. Cumulative rise of ambient or background sound would potentially

AMERICAN OVERSIGHT

mask sounds produced by the hunters, as well as those of the prey, at shorter distances from the listener when all other conditions are otherwise equivalent. Such rise of the outdoor ambient sound level may also be considered a source of annoyance.

However, because noise emission naturally attenuates with distance and other environmental factors (e.g., acoustical air absorption [that varies with air temperature and moisture content], ground surface acoustical absorption, and presence of vegetative ground cover and path-occluding terrain features), an affected receptor would need to be proximate to multiple concurrent cumulative projects for logarithmic addition of sound levels from these combination of sources to cause the resulting increase in outdoor ambient noise to attain impactful levels. If cumulative projects are not concurrent, such as sequential construction activities, then noise emission would not combine, and therefore not create a cumulative effect. Additionally, if only the proposed project is in proximity to the receptor, and other cumulative projects are sufficiently distant, the acoustic contributions from the other projects would have insignificant cumulatively considerable effect.

AMERICAN OVERSIGHT

1.0 PURPOSE AND NEED

1.1 INTRODUCTION

The US Army Corps of Engineers (USACE), Alaska District, Regulatory Division is examining the potential environmental impacts associated with Pebble Limited Partnership's (PLP) submittal of a Department of the Army (DA) Permit application (POA-2017-271). PLP has asked for authorization to discharge fill material into waters of the US (WOUS) and work in navigable waters for the purpose of developing a copper-gold-molybdenum porphyry deposit (Pebble deposit). PLP's proposed discharges and activities are located in the Lake and Peninsula Borough and Kenai Peninsula Borough of Alaska.

1.2 APPLICATION DESCRIPTION

PLP has applied for authorization to discharge dredged and fill material into WOUS as part of development of the Pebble deposit. Authorization for the discharge of dredged and fill material into WOUS is required by Section 404 of the Clean Water Act (CWA) (33 US Code [USC] 1344). PLP has also applied for authorization to work in and place structures in navigable waters of the US (NWUS). Authorization for work and placement of structures in NWUS is required by Section 10 of the Rivers and Harbors Act of 1899 (33 USC 403).

The proposed discharges and work in navigable waters would facilitate the creation of an open-pit mine and associated ore processing facilities for the purpose of producing copper, gold, and molybdenum, and other commodities for sale. Additional elements necessary for this purpose, identified in the application include: the construction of a 29-mile road from the mine site to Iliamna Lake; a 37-mile road from Iliamna Lake to the Cook Inlet at Amakdedori Creek; spur roads to the villages of Iliamna, Newhalen, and Kokhanok; ferry terminals to support an 18-mile ice-breaking ferry crossing; a port facility and lightering locations in Cook Inlet; an 187-mile gas pipeline originating on the Kenai Peninsula and extending across the Cook Inlet to Amakdedori port, terminating at the mine site; and power generation facilities located at the mine and the port site. PLP states that the operating life of the resultant surface mine would be an approximate 20-year period, and that mine closure and monitoring activities would extend for many years thereafter. The complete project description submitted, including updates to applicant's preferred alternative, is provided in Appendix N.

1.3 FEDERAL DECISIONS TO BE MADE

DA authorization is required for the proposed permanent discharges of dredged or fill material into XX acres and temporary discharge of fill into XX acres of WOUS (actual acreage to be inserted prior to DEIS) associated with the construction of the mine and associated roads, port, and natural gas pipeline in wetlands and other WOUS under Section 404 of the CWA. DA authorization is also required for the work and structures associated with construction of the port facilities, ferry terminals, lightering locations and the natural gas pipeline in NWUS. The USACE has set forth implementing regulations in 33 Code of Federal Regulations (CFR) Parts 320-332.

Through review of the application, the USACE identified two additional federal decision makers; the US Coast Guard (USCG), and the Department of the Interior's Bureau of Safety and Environmental Enforcement (BSEE). USCG has authority over locations and clearances of bridges and causeways in or over NWUS. USCG authorization is required for a proposed bridge over the Newhalen River. The USCG has set forth implementing regulations in 33 CFR Parts 114-118. The BSEE oversees safety, environmental protection, and conservation of resources related

AMERICAN OVERSIGHT

to the exploration for and development of offshore resources on the Outer Continental Shelf. BSEE authorization is required for the right of way encompassing the natural gas pipeline between the Kenai Peninsula and the proposed port facility, but only that portion of the right of way that would lie on the Outer Continental Shelf of Cook Inlet. This authority derives from the Outer Continental Shelf Lands Act, as implemented by BSEE regulations at 30 CFR Part 250, Subpart J.

1.4 ENVIRONMENTAL ANALYSIS

All federal permit actions are major federal actions. The USACE has determined that the proposed discharge of fill material into WOUS and/or work in NWUS associated with the application could significantly affect the quality of the human and natural environment. Based on this determination, this Environmental Impact Statement (EIS) has been prepared under Section 102(2)(c) of the National Environmental Policy Act (NEPA) of 1969 (42 USC 4321 et seq.) and its implementing regulations promulgated by the Council on Environmental Quality (40 CFR 1500–1508), and USACE regulations found at 33 CFR 325 Appendix B, NEPA Implementation Procedures for the Regulatory Program. NEPA procedures are designed to ensure that federal agencies identify and assess the reasonable alternatives to proposed actions, along with the environmental consequences of a proposed action and reasonable range of alternatives, in order to avoid or minimize the adverse effects of those actions upon the quality of the human environment.

Information gathered as part of the NEPA process will be used to inform USACE's public interest review determination, required by 33 CFR 320.4. Information will also be used by the USACE to make a determination of the least environmentally damaging practicable alternative under the CWA's Section 404(b)(1) Guidelines (see Appendix F) and any appropriate required compensatory mitigation for unavoidable impacts to WOUS. No discharges of dredged or fill materials are permitted to be authorized by the USACE under the CWA if there is a practicable alternative that would have less adverse impact on the aquatic ecosystem, as long as the alternative does not have other significant adverse environmental consequences.

A joint record of decision (ROD) by the USACE, BSEE, and USCG, issued at the conclusion of the NEPA process, will record each appropriate federal agency's decision(s), identify the alternatives considered in reaching those decision(s), and identify practicable means to avoid or minimize environmental harm (if required).

The USACE has taken the lead, under NEPA, in preparing this EIS. A Notice of Intent to prepare an EIS and a Notice of Scoping for the Pebble Project was published in the Federal Register (FR) on March 29, 2018 (83 FR 13483; pages 13483-13484). The scoping comment period was extended by 60 days to continue through June 29, 2018. Nine public meetings were held during the scoping period. A total of 174,889 submissions were received through June 29, 2018. Further details on the scoping process are found in the Scoping Report (Appendix A).

1.5 PURPOSE AND NEED

A permit applicant's stated purpose and need is used as part of the NEPA process to inform the reasonable alternatives to a proposed action, and the stated need is used by the USACE to determine the overall purpose (and thus, practicable alternatives for the CWA 404(b)(1) evaluation) and to evaluate a proposed project from the public's perspective (under the public interest review criteria). PLP's (the applicant) stated need for the proposed project is, "to meet the increasing global demand for commodities such as copper, gold, and molybdenum."

From the broad, macro-economic scale, the project need is reflected in the worldwide demand for copper. In 2018, the International Copper Study Group projected a small surplus of projected

AMERICAN OVERSIGHT

available copper; however, worldwide demand for copper is projected to exceed the available supply in 2019 (ICSG 2018).

Gold is used for the production of jewelry, electronics and electrical components, official coins, and other uses. In the first 9 months of 2017, domestic consumption of gold used in the production of coins and bars decreased by more than 50 percent; however, gold consumption for jewelry increased slightly, and demand for gold coins and bars increased by 13 percent in comparison to the first 9 months of 2016 (USGS 2018).

Molybdenum is used for the production of ferromolybdenum, metal powder, and various chemical products. Metallurgical application accounted for 87 percent of the total molybdenum consumed. In 2017, US imports for consumption of molybdenum increased by 68 percent from 2016; US exports increased by 37 percent from 2016, mainly owing to an increase in export of molybdenum ores and concentrates and molybdates. Apparent consumption increased by 26 percent in comparison to 2016 (USGS 2018).

The applicant has stated that the proposed project's purpose is to produce commodities, including copper, gold, and molybdenum from the Pebble deposit in a manner that is commercially viable, using proven technologies that are suitable for the project's remote location. According to the applicant, because the area the applicant has leased for mineral development is not served by existing infrastructure, achieving the project purpose requires the construction of facilities for the mining and processing of mineral-bearing rock, as well as construction of support and access infrastructure. The purpose of the natural gas pipeline from the Kenai Peninsula is to provide a long-term stable supply of natural gas to meet the energy needs of the project by connecting to the existing regional gas supply network.

Although the USACE generally focuses on an applicant's stated purpose and need for a proposed project, in all cases the USACE exercises independent judgment in defining the purpose and need from both the applicant's and the public's perspective. The USACE has determined that the applicant's stated purpose is made too narrow by limiting the proposed development to the Pebble deposit. The public's interest in commodities such as copper, gold, and molybdenum does not dictate a particular source of these commodities.

In addition, USACE has determined that the construction of facilities and other infrastructure to support the proposed project is more appropriately evaluated as part of the alternatives, and therefore requires no inclusion in the overall purpose. No specific piece of the proposed infrastructure is required to meet the stated need. An overall project purpose is determined solely by the USACE, while considering the applicant's and the public's perspective, and is used to help identify practicable alternatives (i.e., those that are available and capable of being done after taking into consideration cost, existing technology, and logistics) to be evaluated under CWA 404(b)(1) guidelines. Any overall purpose must seem feasible as well as take into account the need for the type of proposed development.

The USACE has determined that the overall project purpose is to develop and operate a copper, gold, and molybdenum mine in Alaska in order to meet current and future demand.

All,
Attached is the text of the draft Chapter 2 for your consideration as you continue your teams reviews. AECOM will send a link so that you can download all the figures; this document would be too large to send if they were imbedded. At this time, based on the conversation yesterday at the meeting, USACE is not requesting comments prior to the NOA. Thanks.

AMERICAN OVERSIGHT

2.0 ALTERNATIVES INCLUDING APPLICANT'S PROPOSED ALTERNATIVE

The Council on Environmental Quality's (CEQ's) regulations describe the alternatives section as the "heart of the Environmental Impact Statement," and require federal agencies to "rigorously explore and objectively evaluate all reasonable alternatives and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated." (40 Code of Federal Regulations [CFR] 1502).

Alternatives screening is also pertinent to Clean Water Act (CWA) 40 CFR Part 230 Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material (hereafter identified as 404(b)(1) guidelines), which require the analysis of practicable alternatives to the proposed discharge. The 404(b)(1) guidelines define a practicable alternative as one that is "available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes" (40 CFR 230.10(a)(2)).

For actions subject to the National Environmental Policy Act (NEPA), where the US Army Corps of Engineers (USACE) is the permitting agency, the analysis of alternatives required for NEPA environmental documents would in most cases provide the information for the evaluation of alternatives under the 404(b)(1) guidelines. The alternatives development process for the proposed Pebble Project (the project) considers a broad range of alternatives in sufficient detail to address both NEPA and CWA Section 404(b)(1) requirements.

Chapter 2 summarizes the alternatives development process, lists alternatives eliminated from further consideration, and describes the alternatives carried forward for detailed analysis in the Environmental Impact Statement (EIS).

2.1 ALTERNATIVES DEVELOPMENT PROCESS

2.1.1 Public Input on Alternatives

As part of scoping, the public was encouraged to provide specific suggestions for alternatives that should be considered in preparing the EIS. The following guidelines for providing input on alternatives were communicated in scoping materials:

1. Any suggestions should fulfill the overall project purpose in consideration of the applicant's objectives with a focus on reducing potential adverse environmental impacts.
2. You can suggest alternatives specific to components for developing the mine (e.g., mining methods, water treatment, tailings management), the port site, the transportation corridor and modes (e.g., rail), and the natural gas pipeline.
3. You can suggest changes in location of project components (e.g., road, port site, mine components).
4. You can suggest potential mitigation measures and conditions of development that may reduce environmental impacts.
5. Be as specific as possible and provide the reason for making your suggestions (e.g., construction of a rail connection may eliminate truck traffic and reduce dust levels).

Specific suggestions for alternatives that were provided by the public, stakeholders, and agencies during scoping have been fully considered in the alternatives development process.

AMERICAN OVERSIGHT

2.1.2 Screening for Full Range of Alternatives

Appendix B details each step of the alternatives development process for the Pebble Project EIS. A summary of the screening of alternatives is provided below.

The EIS team screened alternative options around four criteria:

- Purpose and need,
- Reasonable under CEQ guidance,
- Practicable under CWA 404(b)(1) Guidelines, and
- Environmental impacts.

The criteria screening steps were followed sequentially. If an option clearly did not meet one of the screening criteria, it was dismissed from further consideration, and did not proceed to the subsequent screening tests.

2.2 ALTERNATIVES CARRIED FORWARD FOR DETAILED ANALYSIS

CEQ regulations require the consideration of a No Action Alternative [40 CFR 1502(e)]. In this case, the No Action Alternative would assume that the mine, transportation facilities, port, and pipeline would neither be permitted nor constructed as currently proposed.

PLP's Proposed Action for analysis in this EIS is Action Alternative 1 – Applicant's Proposed Alternative.

As a result of this alternatives development process, two action alternatives were identified for detailed analysis in the EIS: Action Alternative 2 – North Road and Ferry, and Action Alternative 3 – North Road Only. These two alternatives vary from the Proposed Action in key engineering design, siting, and operational features, which address concerns raised in scoping, and provide a reasonable range of alternatives for comparison.

2.2.1 No Action Alternative

The No Action Alternative would result from federal agencies with decision-making authorities on the project not issuing permits under their respective authorities. The USACE would not issue a permit for development of proposed project components that require the discharge of dredged and fill material in Waters of the US (WOUS), and work and structures in Navigable Waters of the US (NWUS). The US Coast Guard (USCG) Bridge Administration Program would not issue approval for proposed bridges over waters that the USCG considers navigable. The Department of the Interior's Bureau of Safety and Environmental Enforcement (BSEE) would not issue a right-of-way (ROW) for the proposed natural gas pipeline on the outer continental shelf. Federal regulatory authorities are described in Chapter 1, Purpose and Need.

Under the No Action Alternative, PLP would retain the ability to apply for continued mineral exploration activities under the State's authorization process, as well as any activity that would not require Federal authorization. Current State-authorized activities associated with mineral exploration and reclamation and scientific studies would be expected to continue at similar levels. PLP would be required to fully restore and remediate any remaining sites at the conclusion of their exploration program. If reclamation approval is not granted immediately after the cessation of reclamation activities, the State may require continued authorization for ongoing monitoring and reclamation work as deemed necessary by the State of Alaska.

The No Action Alternative is intended to be used as a baseline to facilitate the comparison of impacts between the Proposed Action and other action alternatives analyzed in detail in the EIS. Baseline conditions for all resources are described in the affected environment sections of

AMERICAN OVERSIGHT

Chapter 3. Impacts from the proposed project (beneficial or adverse) would not occur under the No Action Alternative.

The No Action Alternative does not meet the Purpose and Need of the project.

2.2.2 Action Alternative 1 – Applicant's Proposed Alternative

This section summarizes the Proposed Action for the project. Detailed information about engineered facilities and operations for the project from initial construction through closure and reclamation is included in Appendix N. Mitigation measures, Best Management Practices (BMPs), and environmental protections that are integral to the project are described in Chapter 5, Mitigation.

PLP's October 2018 Project Description (PLP 2018d), the Pebble Project Department of the Army Application for Permit POA-2017-271 and supporting documents (PLP 2017), various responses to Request for Information (RFIs) as cited herein, and associated Geographic Information System (GIS) data provided by PLP form the basis for the description of Alternative 1. PLP's October 2018 Project Description supersedes any prior iterations of the Pebble Project description.

PLP proposes to develop the Pebble copper-gold-molybdenum porphyry deposit (Pebble deposit) as an open-pit mine, with associated infrastructure. The project is in a sparsely populated region of southwest Alaska near Iliamna Lake, in the Lake and Peninsula and Kenai Peninsula boroughs. The Pebble deposit is approximately 200 miles southwest of Anchorage and 60 miles west of Cook Inlet. The closest communities are the villages of Iliamna, Newhalen, and Nondalton, each approximately 17 miles from the Pebble Deposit. See Figure 2-1.

The project is comprised of four primary components: the mine site at the Pebble deposit location, the Amakdedori port on the western shore of Cook Inlet, a transportation corridor connecting these two sites, and a natural gas pipeline corridor connecting to existing infrastructure on the Kenai Peninsula. See Figure 2-1 showing the natural gas pipeline corridor and Figure 2-2 showing the general project layout of Alternative 1.

AMERICAN OVERSIGHT

Figure 2-1: Regional Map

AMERICAN OVERSIGHT

Figure 2-2: Alternative 1 – General Project Layout

AMERICAN OVERSIGHT

The proposed operating life of the project is 20 years. Construction would last for approximately 4 years, followed by a commissioning period and 20 years of mineral processing. A construction overview is provided in Appendix N. Mining pre-production would start during construction with removal of overburden and waste rock material, and active mining from the pit would continue through the 20-year operations period. The project would have an operating schedule of two 12-hour shifts per day, 365 days per year, and employ approximately 850 to 2,000 personnel for operations and construction, respectively.

Other project details are listed below and summarized in the following sections.

- A total of 1.44 billion tons of material mined over the life of the project.
- Final pit dimensions of 6,800 feet in length, 5,600 feet in width, and 1,970 feet in depth.
- Mining rate up to 73 million tons per year, average rate of 70 million tons per year.
- Milling rate up to 66 million tons per year.
- Average annual copper-gold concentrate production (dry concentrate) of 613,000 tons.
- Average annual molybdenum concentration production (dry concentrate) of 15,000 tons.
- Final bulk tailings storage facility (TSF) capacity of 1,140 million tons.
- Temporary storage of 155 million tons of pyritic tails in the pyritic TSF.
- Temporary storage of up to 50 million tons of PAG and/or Metal Leaching (ML) waste rock in the pyritic TSF until closure.
- Power plant generating capacity of 270 megawatts (MW).
- An 84-mile transportation corridor from the mine site to a year-round port site located on Cook Inlet near the mouth of Amakdedori Creek consisting of:
    - A 29-mile private two-lane unpaved road from the mine site to a ferry terminal on the north shore of Iliamna Lake.
    - An 18-mile lake crossing using an ice breaking ferry to a ferry terminal on the south shore of Iliamna Lake.
    - A 37-mile private two-lane unpaved road from the south ferry terminal to Amakdedori port.
    - Lightering of concentrate between Amakdedori port and offshore lightering locations for loading onto bulk carriers.
- Unpaved spur roads from the transportation corridor to the communities of Iliamna, Newhalen, and Kokhanok.
- A port facility and jetty with docking for lightering and supply barges.
    - Annual vessel traffic of up to 27 concentrate vessels and 33 supply barges.
- A 187-mile gas pipeline from the Kenai Peninsula across Cook Inlet to the project site with a compressor station on the Kenai Peninsula.

2.2.2.1 Mine Site

The fully developed mine site would include the open pit, bulk TSF, pyritic TSF, overburden stockpiles, material sites, water management ponds (WMPs), milling and processing facilities, and supporting infrastructure such as the power plant, water treatment plants (WTPs), camp facilities, and storage facilities. See Figure 2-3 showing the mine site layout. The site is currently undeveloped and not served by any transportation or utility infrastructure. Figure 2-4 presents a digital simulation of the mine site at the end of mining, before closure. Simulations presented in Chapter 2 were generated by Resolution 3D LLC using a fully digital process based on actual

AMERICAN OVERSIGHT

terrain scans, three dimensional mapping, and modelling and rendering software to present alterations to the landscape from proposed facilities (PLP 2018-RFI 034d).

Mining Methods and Phasing

The mine would be a conventional drill, blast, truck, and shovel operation with an average mining rate of 70 million tons per year, and an overall stripping ratio of 0.12 ton of waste per ton of mineralized material.

The open pit would be developed in stages, with each stage expanding the area and deepening the previous stage. The final dimensions of the open pit would be approximately 6,800 feet long and 5,600 feet wide, with depths to 1,970 feet. See Figure 2-5 showing the open pit design.

Mining would occur in two phases: pre-production, and production. The mine operation would commence during the last year of the pre-production phase, and extend for 20 years during the production phase. During this period, 1,300 million tons of mineralized rock and 150 million tons of waste rock and overburden would be mined. Non-potentially acid-generating (NPAG) waste rock would be used in construction of the tailings embankments. The PAG waste rock would be stored in the pyritic TSF until closure, when it would be back-hauled into the open pit. Fine- and coarse-grained soils would be stored southwest of the pit and north of the TSF embankments, and would be used for reclamation during mine closure.

The pre-production phase consists of dewatering the pit area and mining of non-economic materials overlying the mineralized material from the initial stage of the open pit. Dewatering would begin approximately 1 year before the start of pre-production mining. Approximately 33 million tons of material would be mined during this phase.

The production phase encompasses the period during which economic-grade mineralized material would be fed to the metallurgical process plant that produces concentrates for shipment and sale. The production phase is planned to last for 20 years. Mineralized material would be mined, and would be fed through the process plant at a rate of 180,000 tons/day. The open pit would be mined in a sequence of increasingly larger and deeper stages. Approximately 1.4 billion tons of material are planned to be mined during the production phase.

Blasting

Initial operations during the pre-production phase may use pre-packed emulsion blasting agents or a mobile bulk emulsion manufacturing plant. After the explosives plant is completed, emulsion-based ammonium nitrate and fuel oil (ANFO) explosives would be used as the primary blasting agent.

Blasting events during the pre-production phase would occur approximately once per day. The frequency would increase during the production phase, with events occurring as often as twice per day.

Waste Rock and Overburden Storage

Waste rock is mined material with a mineral content below an economically recoverable level that is removed from the open pit, exposing the higher-grade production material. Waste rock would be segregated by its potential to generate acid. NPAG and non-ML waste rock may be used for embankment construction. PAG and ML waste rock would be stored in the pyritic TSF until mine closure, when it would be back-hauled into the open pit.

AMERICAN OVERSIGHT

Figure 2-3: Alternative 1 – Mine Site Layout

AMERICAN OVERSIGHT

Figure 2-4: Alternative 1 – Digital Simulation of Mine Site

AMERICAN OVERSIGHT

Figure 2-5: Alternative 1 Open Pit Design

AMERICAN OVERSIGHT

During the pre-production phase, approximately 33 million tons of non-mineralized and mineralized material would be removed from the open pit. Non-mineralized waste and overburden would be stockpiled, or used in construction. Mineralized waste would be stockpiled and relocated to the pyritic TSF once complete; or if grades are sufficient, stockpiled for milling once the mill is complete. Material would be stockpiled within the pit footprint, or in designated stockpiles, as appropriate.

Overburden is the unconsolidated material lying at the surface. At the Pebble deposit, the overburden depth ranges from 0 to 140 feet. Overburden removal would commence during the pre-production phase, and would recur periodically during the production phase at the start of each pit stage. The overburden would be segregated and stockpiled in a dedicated location southwest of the open pit. A berm built of non-mineralized rock would surround the overburden to contain the material and increase stability. Overburden materials deemed suitable would be used for construction. Fine- and coarse-grained soils suitable for plant growth would be stockpiled for later use as growth medium during reclamation. Growth medium stockpiles would be stored at various locations around the mine site, and stabilized to minimize erosion potential.

Mineral Processing

Mineral processing facilities would be located at the mine site. Blasted mineralized material from the open pit would be fed to a crushing plant, and then conveyed to a coarse ore stockpile, which in turn feeds a grinding plant in the process plant. In the grinding plant, it would be reduced to the consistency of very fine sand. The next step is froth flotation, in which the copper and molybdenum minerals are separated from the remaining material to produce concentrates. The concentrates are then filtered for shipment.

The copper-gold concentrate would be loaded into covered bulk shipping containers, and the molybdenum concentrate would be packaged in bulk bags and loaded into shipping containers for off-site transport using the proposed transportation corridor described under Section 2.3.2.2. Other economically valuable minerals—such as palladium and rhenium—would be present in the concentrates, and may be recovered at the refineries. See Figure 2-6 showing the process flow diagram.

Over the life of the project, approximately 1.3 billion tons of mineralized material would be fed to the process plant at a rate of 180,000 tons/day. On average, the process plant would produce approximately 613,000 tons of copper-gold concentrate per year, containing approximately 318 million pounds of copper, 362,000 ounces of gold, 1.8 million ounces of silver, and approximately 15,000 tons of molybdenum concentrate, containing about 14 million pounds of molybdenum.

Tailing Storage Facilities

Separate TSFs for the bulk and pyritic tailings would be located primarily in the North Fork Koktuli (NFK) watershed but would also have some footprint in the South Fork Koktuli (SFK) watershed (See Figure 2-3).[1] The TSFs would be designed to meet or exceed the standards of the updated 2017 Guidelines for Cooperation with the Alaska Dam Safety Program (ADSP) prepared by the Alaska Department of Natural Resources (ADNR). The TSFs would be designed to the standards

[1] Bulk tailings are comprised of relatively inert, non-acid-generating fine-grained ground waste rock that remains after economic minerals and pyritic materials have been extracted through ore processing at the mine site. See also pyritic tailings.
Pyritic tailings are comprised of potentially acid-generating fine-grained ground waste rock containing the naturally occurring mineral pyrite.

AMERICAN OVERSIGHT

of a Class I hazard potential dam (the highest classification). Total TSF capacity would be sufficient to store the 20-year mine life tailings volume (1.3 billion tons).

AMERICAN OVERSIGHT

Figure 2-6: Alternative 1 – Process Flow Diagram

AMERICAN OVERSIGHT

Approximately 88 percent (1,140 million tons) of the tailings would be bulk tailings, and approximately 12 percent (155 million tons) would be pyritic tailings.

The unlined bulk TSF has two embankments: the main and south embankments. The pyritic TSF would be lined, and has three embankments: north, south, and east. Starter embankments for both facilities would be constructed as part of the initial TSF construction. The main embankment of the bulk TSF would function as a permeable structure to maintain a depressed zone of saturation in the embankment, and tailings mass in proximity to the embankment. A basin underdrain system would be constructed at various locations throughout the bulk TSF basin to provide preferred drainage paths for seepage flows. The pyritic TSF would be a fully lined facility. See Figure 2-7 for the proposed TSF layouts.

The pyritic TSF, which would also contain the PAG waste, would have a full water cover during operations, while the bulk tailings cell would have a relatively small supernatant pond, located away from the embankments, to promote large tailings beach development upstream of the embankments.

The bulk TSF downstream embankment slopes would be maintained at approximately 2.6 horizontal:1 vertical (H:V), including buttresses established at the downstream toe of the main embankment. The final embankment crest elevation would be approximately 1,730 feet above sea level for bulk TSF. Embankment heights, as measured from lowest downstream slope elevation, would be 545 feet (main) and 300 feet (south). See Figure 2-8 showing the bulk TSF embankment cross sections.

The pyritic TSF embankment slopes would be maintained at 2.6H:1V. The final crest elevation would be 1,710 feet above sea level. The north embankment height would be 425 feet, the south embankment height would be 305 feet, and the east embankment height would be 315 feet. See Figure 2-9 showing the pyritic TSF embankment cross section.

Tailings Deposition

Each tailings stream would be delivered to its respective TSF using two pump stations: one in the process plant, and one booster station positioned approximately mid-way along the pipeline route. The bulk tailings would be discharged via spigots spaced at regular intervals along the interior perimeter of the bulk tailings cell to promote beach development, which would allow the supernatant pond to be maintained away from the main embankment.

PAG waste rock would be placed in a ring around the interior of the pyritic TSF. Pyritic tailings from the cleaner scavenger flotation circuit would be discharged into the pyritic TSF at sub-aqueous discharge points, with the level maintained just below the upper bench level for the PAG waste being stored. The sub-aqueous discharge is necessary to prevent oxidation and potential acid generation.

Construction

A "Certificate of Approval to Construct a Dam" is required from ADNR for the construction of impounding structures meeting the minimum height or impounding thresholds. The TSFs, seepage collection ponds, and WMPs would be jurisdictional dam structures regulated by ADSP. The certificate would include any special conditions or limitations on the construction.

The embankments would be constructed using suitable rockfill or earthfill materials, including quarried rock, NPAG, and non-ML waste rock excavated from the open pit, if available, and stripped overburden.

AMERICAN OVERSIGHT

Figure 2-7: Alternative 1 – Tailings Storage Facility Layout

AMERICAN OVERSIGHT

Figure 2-8: Alternative 1 – Bulk Tailings Storage Facility Embankment Cross Sections

AMERICAN OVERSIGHT

Figure 2-9: Alternative 1 – Pyritic TSF Embankment Cross Sections

AMERICAN OVERSIGHT

The main Bulk TSF embankment would be constructed using the centerline construction method with local borrow materials. The centerline construction method provides a high level of embankment stability while reducing the embankment material requirements associated with the downstream method. The south Bulk TSF embankment would be constructed using the downstream construction method to facilitate lining of the upstream face.

The pyritic TSF embankments would be constructed using the downstream method. The embankments would be constructed using select borrow materials, and include a liner bedding layer, overlain by a liner, on the upstream slope and over the entire internal basin. Basin underdrains would collect and convey any seepage to the downstream seepage collection ponds.

TSF embankments would be constructed in stages throughout the life of the project, with each stage providing the required capacity until the next stage is completed. A 'Certificate of Approval to Modify a Dam' is required from ADSP for each construction lift. Planned embankment raises would be evaluated each year, and sized according to a review of the process plant throughput, actual tailings settled densities (TSF ponds are typically sounded to establish the size of the supernatant pond and the density of the deposited tailings in the TSF), and water storage requirements.

Main Water Management Pond

The main WMP is the primary water management structure at the mine site. It would be a fully lined facility, and would be constructed using quarried rockfill materials. The embankment would be approximately 190 feet high, with an overall downstream slope of approximately 2H:1V, and an upstream slope of 3H:1V to accommodate the liner. It would be constructed to its final height during the initial construction period. The main WMP embankment design concept requires that any potential weak foundation conditions encountered in the overburden materials are addressed by excavating that material. Any potential mitigation requirements (including the removal of the overburden if required) would be addressed based on the geotechnical and hydrogeological information collected for the area during site investigations.

Infrastructure

Due to the remote location and the absence of existing infrastructure, the project would be required to provide basic infrastructure, as well as the support facilities typically associated with mining operations. These facilities would require reasonable access from the Pebble deposit, and situated foremost for stability and safety. Supporting infrastructure and facilities include:

- Power generation capacity and distribution infrastructure: a plant with a 270-MW capacity fired by natural gas.
- Shops: a truck shop complex housing a light-vehicle maintenance garage, a heavy-duty shop, a truck wash building, a tire shop, and a fabrication and welding shop. An oil/water separation system would be designed for water collected from the wash facility and floor drains.
- Onsite access roads: several access roads in the mine site area, including a road from the gatehouse to the mine site, and secondary roads linking with the various facilities around the mine.
- Personnel camps: a main construction camp to accommodate 1,700 workers, later refurbished for 850 permanent single-occupancy rooms for the operations phase.
- Potable water supply: a series of groundwater wells north of the mine site to supply potable water and distributed through a pump and piping network.

AMERICAN OVERSIGHT

- Communications: fiber-optic cable connecting to existing fiber-optic infrastructure in the region, or a dedicated fiber-optic cable laid in conjunction with the gas pipeline.
- Laboratories: Two laboratories, the metallurgical laboratory and assay laboratory, would operate at the mine site during the Production Phase. Each laboratory would be equipped with fume hoods (with exhaust treatment, if required) and drains connected to a central receiving tank. Chemical wastes would be disposed of in accordance with all applicable laws and regulations.
- Fire and emergency response: Freshwater supply tanks for fire suppression distributed via an insulated pipeline system, a fire truck and ambulance, and equipment to response to oil spills would be located at the mine site. Crews would be appropriately trained for such response.

Temporary Facilities

Laydown areas and access roads for construction would be placed within the future footprint of the open pit to minimize impacts. The temporary construction camp at the mine would be situated near the mill laydown area. Construction crews would use this camp and the permanent accommodations complex when it is complete. As construction is completed and crew sizes reduce, they would transition to the temporary camp only. This would enable the accommodations complex to be refurbished to single-room occupancy for the mine operations staff.

All temporary construction facilities would be removed after construction; and the sites, unless being used for permanent facilities, would be reclaimed.

Material Management and Supply

Fuel, lubricants, tires, and blasting agents would be the primary materials used in mining. Reagents would be used in low concentrations throughout the mineral processing plant and are primarily consumed in the process. Table 2-1 lists common mining supplies, processing reagents, and materials, along with typical packaging for transportation.

Table 2-1 Mining Supplies, Processing Reagents, and Materials

Material/Supply/Reagent	Use	Shipping/Preparation
Diesel fuel	Vehicles and blasting	6,350-gallon ISO tank-containers
Lubricants	Vehicles and equipment	Drums and totes in containers
Ammonium nitrate prill	Blasting	Bulk container
Primers, detonators, and detonating cord	Blasting	Specialized packaging as required
Blasting emulsion ingredients	Blasting	Specialized packaging as required
Packaged explosives	Blasting	Specialized packaging as required
Haulage truck and other tires	Vehicles	Bulk containers/break bulk
Ground-engaging tools	Drilling and loading	Bulk containers
Calcium Oxide (quick lime)	pH modifier; depresses pyrite in the copper-molybdenum flotation process.	Calcium oxide pebbles (80 percent) shipped in specially adapted shipping containers. Pebbles would be crushed and mixed with water to form lime slurry at the lime plant.
Sodium Ethyl Xanthate	Copper collector; used in the rougher flotation circuit.	Pelletized reagent shipped in 1-ton bags. Mixed with process water to

AMERICAN OVERSIGHT

Table 2-1 Mining Supplies, Processing Reagents, and Materials

Material/Supply/Reagent	Use	Shipping/Preparation
		form 20 percent solution and stored in collector storage tank. Mix and storage tanks vented externally with fans.
Fuel Oil (Diesel)	Used in the flotation process.	Shipped in tanker trucks and stored in the main head tank in the copper-molybdenum concentrator area.
Sodium Hydrogen Sulfide (NaHS)	Copper depressant used in the copper-molybdenum separation processes.	Pelletized reagent shipped in 1-ton bags. Mixed with process water to form 20 percent solution and stored in the NaHS storage tank.
Carboxy Methyl Cellulose	Depressant; anionic polymer used to depress clay and related gangue material in the bulk cleaner flotation circuit.	Pelletized reagent shipped in 1-ton bags. Mixed with process water in the agitated dispersant tank to form 20 percent solution and stored in dispersant storage tank.
Methyl Isobutyl Carbinol	Frother; maintains air bubbles in the flotation circuits.	Shipped in 20-foot specialized ISO containers and stored in the frother storage tank.
Depressant (sodium silicate)	Clay or silica gangue mineral depressant used in the copper-molybdenum separation process.	Pelletized reagent shipped in 1-ton bags. Mixed with process water to form 20 percent solution and stored in the sodium silicate storage tank.
Anionic polyacrylamide	Thickener aid.	Pelletized reagent shipped in 1-ton bags. Vendor package preparation system comprised of a bag breaking enclosure to contain dust, dry flocculent metering, and a wet jet system to combine treated water with the powdered flocculent in an agitated tank for maturation. Prepared in small batches and transferred to a flocculent storage tank.
Polyacrilic acid	Anti-scalant for the lime production process.	Liquid shipped in 35-cubic-foot specialized container tanks in protected rectangular framework.
Nitrogen	Nitrogen used in the molybdenum flotation circuit to depress copper sulfides.	Provided by a vendor-supplied pressure swing adsorption nitrogen plant. This equipment separates nitrogen from air for use in the mineral-process plant.

ISO = International Organization for Standardization

General supplies and bulk reagents would typically be stored in, or adjacent to, the areas where they would be used. The location of the explosives storage and emulsion manufacturing plant is based on the need to minimize transfer distances, and to provide a safety buffer between the explosives plant and other facilities. Average annual quantities of fuel, mining, milling, and miscellaneous consumables are listed in Table 2-2.

AMERICAN OVERSIGHT

Table 2-2 Supplies Quantities

Supply	Average Annual Quantity
Fuel	16 million gallons
Ammonium Nitrate	17,500 tons
Grinding Media, Reagents, and Miscellaneous Supplies	250,000 tons

The main mine site fuel storage area would contain fuel tanks in a dual-lined and -bermed area designed to meet regulatory requirements. Sump and truck pump-out facilities would be installed to handle any spills. There would also be pump systems for delivering fuel to the rest of the mine site. Dispensing lines would have automatic shutoff devices, and spill response supplies would be stored and maintained on site wherever fuel would be dispensed. Fuel would be dispensed to a pump house in a fuel storage area for fueling light vehicles. It would also be dispensed to the fuel tanks in the truck shop complex, which are used for fueling mining equipment. These tanks would also be in a lined and bermed secondary containment area.

Lubricants would be packaged in drums and/or totes and stored on site in a secondary containment area.

As a safety precaution, ammonium nitrate prill would be stored and prepared for use at a location approximately 0.75 mile southeast of the final pit rim. Electrical delay detonators and primers would be stored in the same general area, but in a separate magazine located apart from each other and separate from the prill. All facilities would be constructed and operated to meet mine safety and health regulations as set forth in 30 CFR 77.1301. Small amounts of pre-packaged blasting agents and minor amounts of other explosives may be used for specific purposes.

Reagents would arrive at the mine site by truck in 20-ton containers, depending on the reagent. They would be stored in a secure bulk reagent storage area and segregated according to compatible characteristics. The reagent storage area would be sufficient to maintain a 2-month supply at the mine site. Reagents would be used in very low concentrations throughout the mineral processing plant and are primarily consumed in the process; low residual reagent quantities remain in the tailings stream and would be disposed in the TSF where they would be diluted and decompose. The metallurgical and assay laboratories would also use small amounts of reagents. Any hazardous reagents imported for testing would be transported, handled, stored, reported, and disposed of as required by law, in accordance with manufacturers' instructions, and consistent with industry best practices.

Water Management

About 2 years before process plant startup, the pit area would begin to be dewatered through groundwater withdrawal from approximately 30 groundwater wells installed around the pit perimeter. Dewatering would continue throughout operations as the pit is deepened until collection of flow is more efficient from ditches. During closure, water level in the pit would be managed via pumping of groundwater wells. Extracted water would be pumped into the open-pit WMP (Knight Piésold 2018e).

All runoff water contacting the facilities at the mine site and water pumped from the open pit would be captured to protect the overall downstream water quality. Mine site water management systems would be designed for the entire lifecycle of the project; from initial construction through the pre-production phase, operation, and closure. The project would develop a comprehensive water management plan that strategically discharges surplus treated water to downgradient

AMERICAN OVERSIGHT

streams in a manner that reduces the effect of stream flow fluctuations, and minimizes impacts to fish habitat.

Water Balance Model

The Pebble Water Balance Model is comprised of three primary modules: the Watershed Module, the Groundwater Module, and the Mine Plan Module. These three modules, which are all numerical water balance models, are very different, yet complementary. They collectively provide the means of quantifying the numerous water flows in the streams, in the ground, and in the various pipes, ponds, and mine structures associated with the mine development. The Watershed Module focuses on water flows throughout the NFK, SFK, and Upper Talarik Creek (UTC) drainages. The Groundwater Module focuses on the detailed simulation and understanding of groundwater flows in those drainages, and serves to inform the watershed module, and vice versa. The Mine Plan Module focuses on mine site water inflows and uses. Complementing the water balance modules is an instream fish habitat-flow model, which was used to assess the effects of changes in water flow to the fish habitat in the adjacent streams. These models are further described in Appendix N.

Pre-production Phase Water Management Plan

The water management and sediment control plan during the pre-production phase would consist of multiple aspects focusing on minimizing contact water volumes. Runoff and associated sediment control measures would be managed with BMPs and adaptive control strategies. Where water cannot be diverted, it would be collected, treated, and discharged. PLP's water management plan is further described in Appendix N.

Pre-production Phase Water Treatment

Minimal water storage would be available on site until initial construction activities are completed. Therefore, prior to completion of the TSF embankments and water management structures, all water that does not meet water quality standards would be treated and released. Water from the following sources and activities are expected to require treatment prior to release:

- Pre-production phase pit dewatering (dewatering of the overburden aquifer near the pit may require treatment).
- Water, primarily from precipitation, accumulating in the open pit during pre-production phase mining.
- Runoff from TSF embankment construction.
- Runoff from excavation for site infrastructure such as the process plant, camps, power plant, or storage areas would be routed to settling ponds prior to release.
- Prior to the operations WTPs being brought on-line, modular WTPs would be used to treat contact water that does not meet discharge requirements.

Production Phase Water Management Plan

The water management and sediment control plan during the production phase focuses on minimizing contact water. Runoff and associated sediment control measures would be managed with BMPs and adaptive control strategies. Where water cannot be diverted, it would be collected for use in the mining process, or treated and discharged. PLP's water management plan is further described in Appendix N.

Water collection, management, and transfer would be accomplished through a system of water management channels, ponds, and pump and pipeline configurations. These systems would be

AMERICAN OVERSIGHT

designed to handle the large flows that occur during spring freshet and late summer/fall rains. Spare parts for pump systems would be kept on site to maintain continuous and effective water management. Leak detection systems that report to a central control system would be employed, as would monitoring systems to control pump cycling, high and low water-level switches, no-flow (or low-flow) alarms, vibration overheating alarms, and other systems as appropriate to monitor water management systems.

Production Phase Water Treatment

Water collected around the mine area and Amakdedori port site would require treatment prior to discharge to the environment. Treatment methods would include a mixture of settling for sediment removal, chemical additions to precipitate trace elements, filtration, reverse osmosis, and evaporation to meet final discharge criteria.

The mine area would have two WTPs: the open pit WTP (WTP #1), and the main WTP (WTP #2). Both would be constructed with multiple independent treatment trains, which would enable ongoing water treatment during mechanical interruption of any one train.

The main WTP would treat water from the main WMP. The open-pit WTP would treat water from the open-pit WMP. See Figures 2-10 and 2-11 illustrating the main WTP treatment process and open-pit WTP treatment process, respectively. WTP discharge locations are shown on Figure 2-3.

Closure/Post-Closure Phase Water Management Plan

Closure and post-closure water management would address both the immediate physical closure of the site and associated reclamation activities, as well as the long-term post-closure period and associated maintenance and monitoring activities.

The water management plan during the closure and post-closure phases can be summarized as follows:

Years 0-15:

- The open-pit WTP would be reconfigured to treat contact water.
- Excess and seepage water from the bulk TSF would be pumped to the main WMP.
- Seepage water from the pyritic TSF would be pumped to the main WMP.
- Surplus water from the main WMP would be treated at the main WTP, and released to the downstream environment.
- Surplus water from the open pit would be pumped to the open-pit WTP to maintain the placement of the PAG waste rock in the dry.
- Treated water from the open-pit WTP would be released to the downstream environment.
- The open-pit WMP would be reclaimed.

Years 16 until the pit is full (approximately Year 20):

- The main WTP would be decommissioned once it is no longer required.
- The pyritic TSF and associated seepage collection ponds would be reclaimed, and surface water runoff from the area discharged to the downstream environment.
- The main WMP would be reclaimed, and surface water runoff from the area discharged to the downstream environment.
- Bulk TSF and seepage collection pond water would be pumped to the open pit.

AMERICAN OVERSIGHT

- The open pit fills to the maximum management level.
- The basis for this analysis is that no water would be treated during this phase; however, an adaptive management strategy would be used, and water would be directed to the open-pit WTP for treatment, and released if required to maintain downstream flows.

Year 20 until the bulk TSF consolidation is complete (approximately Year 50):

- Bulk TSF seepage and runoff water would be pumped to the open pit.
- Water levels in the open pit would be maintained below the main management level by treating and releasing surplus water from the open pit.

Post-Closure:

- Runoff water would be directly discharged from the reclaimed bulk TSF to the NFK catchment once it has been demonstrated to meet water quality criteria.
- Bulk TSF seepage water would be pumped to the open pit.
- Water levels in the open pit would be maintained below the main management level by treating and releasing surplus water from the open pit.

Closure/Post-Closure Water Treatment

Water treatment during this phase would use the facilities as outlined above for the Closure/Post-Closure Phase Water Management Plan. Water quality would be closely monitored, and changes and adjustments to the treatment process would be made as needed. The reclamation and closure bond package would include provisions for periodic replacement of water treatment facilities and ongoing operating and monitoring costs over the long-term, post-closure period.

Waste Management and Disposal

A landfill and incinerator would be constructed and operated at the mine site for domestic waste handling (see Figure 2-3). Domestic refuse would be disposed of in the on-site landfill, or shipped off-site to appropriate disposal sites. Wastes suitable for burning, including putrescible wastes, would be incinerated on site.

Scrap steel would be shipped off-site to appropriate disposal sites. Waste oils not suitable for burning, including lubricants, would be collected into drums, sealed, and stored in containers for shipment to be recycled or disposed of off-site at an approved facility. Miscellaneous hazardous wastes that may accumulate on site, such as paint, used solvents, and empty reagent containers with residual chemicals, would be managed and shipped off site to approved facilities according to applicable BMPs and regulations.

Separate sewage treatment plants would be located at the camp and the process plant. Plans for each plant would be reviewed and approved by the Alaska Department of Environmental Conservation (ADEC) prior to construction.

Grey water from camp facilities would be treated in a WTP. The WTP would be designed to remove biological oxygen demand, total suspended solids (TSS), total phosphate, total nitrogen, and ammonia to meet ADEC domestic waste-discharge criteria. Treated water would be discharged to the TSF.

The process plant sewage WTP would receive effluent that may have metallic residues from the workers' change house and associated laundry. This WTP would be designed for metals removal in addition to biological oxygen demand, TSS, total phosphate, total nitrogen, and ammonia to meet ADEC domestic waste-discharge criteria. The treated water would be discharged to the TSF. Sludge from both plants would be stabilized and disposed of on site.

AMERICAN OVERSIGHT

The disposal plan for closure would be developed in accordance with Alaska Department of Environmental regulations. Inert mine site materials, such as geomembrane material, piping, and pumps, would be drained and cleaned, as appropriate, and placed into a facility that would be permitted within the submerged waste rock dump in the pit or within the footprint of the reclaimed pyritic tailings facility. Material that has residual value or is not suitable for onsite disposal would be hauled offsite for disposal (PLP 2018-RFI 055a).

Closure and Reclamation

Reclamation and closure of the project falls under the jurisdiction of the ADNR Division of Mining, Land, and Water, and the Alaska Department of Environmental Conservation. The Alaska Reclamation Act (Alaska Statute 27.19) is administered by the ADNR; it applies to state, federal, municipal, and private land and water subject to mining operations. Except as provided in an exemption for small operations, a miner may not engage in a mining operation until the ADNR has approved a reclamation plan for the operation. The landowner participates in the planning process with regard to determining and concurring with the designated post-mining land use.

The project has committed to a design-for-closure philosophy that considers closure and post-closure site management requirements during all operating phases. Examples include:

- Segregated storage facilities for bulk and pyritic tailings. Bulk tailings would remain in place at closure.
- A lined pyritic TSF. PAG and ML waste rock would be stored with pyritic tailings in the lined pyritic TSF during operations. At closure, the stored waste rock would be backhauled to the pit and the pyritic tailings pumped to the pit for sub-aqueous storage in the pit lake. Storage of PAG/ML waste rock and pyritic tailings in the pit lake would avoid post-closure management of the pyritic TSF.

AMERICAN OVERSIGHT

Figure 2-10: Alternative 1 – Main Water Treatment Plan Process Schematic

AMERICAN OVERSIGHT

Figure 2-11: Alternative 1 – Open Pit Water Treatment Plant Process Schematic

AMERICAN OVERSIGHT

Physical Reclamation and Closure

The physical site closure work would commence as operations end.

- Active mining and pit dewatering would stop. Pit water levels would be maintained to provide safe access for placement of pyritic tailings and PAG waste rock.
- Pyritic tailings and PAG waste rock would be placed into the pit for long-term storage below water. Once the material has been transferred to the open pit, the water would be allowed to rise to the maximum management level. The mill, pyritic TSF, main WMP, and other infrastructure not required for post-closure would be removed and/or reclaimed.
- The bulk tailings would have a dry closure and be allowed to fully consolidate. Once runoff is demonstrated to meet water quality criteria, it would be directly discharged to the NFK catchment area. Bulk TSF seepage water would be pumped to the open pit.
- The open-pit water level would be maintained at a level to ensure inward flow of surrounding groundwater, and prevent contact water from getting into the groundwater.
- Once physical closure activities are completed, site access infrastructure would be reconfigured to support long-term post-closure activities.

All mill and support facilities not required for post-closure, including the pyritic TSF, main WMP, and open-pit WMP embankments and liners, would be dismantled and removed. Concrete pads and foundations would be broken up so that they do not act as an impermeable impediment to water flows.

Inert materials would be disposed of in an on-site monofill that would be sited within the disturbed footprint, while others would be shipped off site for disposal as appropriate. Disturbed areas would be recontoured, graded, ripped, and scarified. Top soil and growth media would be placed as needed, and sites would be seeded for revegetation. Surface runoff from the disturbed areas would be collected; and either treated in the WTPs, or directed to the pit lake until it is found to be suitable for direct discharge to the downstream drainages.

A spillway would be constructed from the bulk TSF. Late in the operating phase, tails in the bulk TSF would be spigoted to allow for surface drainage toward the closure spillway. As milling operations cease, free water would be pumped from the surface of the bulk tails, and they would be allowed to consolidate until the surface is suitable for equipment traffic on the surface. The tails would be re-graded as needed to facilitate drainage. A capillary break and growth media would be placed over the surface of the tails prior to seeding for revegetation. Growth media would also be placed on the bulk TSF embankments prior to seeding for revegetation.

Seepage water from the bulk TSF embankment seepage collection systems would be collected and directed to the pit lake.

Post Closure Management

The pit lake would fill during the closure period. Surface runoff from the walls would result in leaching of accumulated metals from the walls. Water quality is expected to be acidic, with elevated metals due to overall oxidation of the pit walls. Pit lake water quality would be monitored, and appropriate precautions would be taken to manage wildlife activity on the lake. Once the level of the pit lake has risen to about 890 feet in elevation, water would be pumped from the pit, treated as required, and discharged to the environment.

Long-term discharge from the bulk TSF seepage collection systems would be pumped to the pit lake.

AMERICAN OVERSIGHT

Financial Assurance

Prior to commencing construction, the project Reclamation and Closure Plan approval and associated financial assurance mechanisms would need to be in place. The Reclamation and Closure Plan and financial assurance obligations would be updated on a 5-year cycle, in accordance with regulatory requirements, to address any changes in closure and post-closure requirements and cost obligations.

A detailed reclamation and closure cost model would be developed to address all costs required for both the physical closure of the Project and the funding of long-term post-closure monitoring, water treatment, and site maintenance. The estimate would include the costs of closure planning and design, and mobilization of third-party equipment to site; detailed estimates of equipment and labor requirements for physical closure; capital, sustaining capital, and operating costs for water treatment and other long-term post-closure operations; and appropriate indirect costs and contingencies developed following ADNR guidance.

2.2.2.2 Transportation Corridor

The transportation corridor, which would connect the mine site to Amakdedori port on Cook Inlet, has three main components (see Figure 2-12):

- Mine access road: A private, unpaved, two-lane road extending approximately 29 miles south from the mine site to a ferry terminal on the northern shore of Iliamna Lake (includes a short spur near the mine site near UTC) (see Figure 2-13);
- Ferry crossing: An ice-breaking ferry to transport materials, equipment, and concentrate 18 miles across Iliamna Lake to a ferry terminal on the southern shore near the village of Kokhanok; and
- Port access road: A private, unpaved, two-lane road extending approximately 37 miles southeast from the south ferry terminal to Amakdedori port on Cook Inlet (see Figure 2-14).

Separate spur roads, approximately 11 miles in total length, would connect the transportation corridor to the villages of Iliamna, Newhalen, and Kokhanok. See Figure 2-15 showing the typical access road cross section. Apart from a small network of local roads near the villages, the transportation corridor area is undeveloped.

Road System

The main access road would be a private 30-foot-wide gravel road, which would enable two-way traffic, and would be capable of supporting anticipated development and operational activities during construction and truck haulage of concentrate from the mine to the port.

A total of 97 streams would be crossed by the Alternative 1 road system. Crossing structures would include nine bridges, six of which would be single-span, two-lane bridges that range in length from approximately 30 to 125 feet. There would be one large (575 feet) multi-span, two-lane bridge across the Newhalen River, and one large (470 feet) multi-span, two-lane bridge across the Gibraltar River. NOTE TO REVIEWERS: CLARIFICATION REQUESTED FROM PLP REGARDING THE NUMBER OF BRIDGES—GIS DATA DOES NOT MATCH WHAT IS SPECIFIED IN THE UPDATED PROJECT DESCRIPTION. Road culverts at stream crossings are divided into categories based on whether the streams are fish-bearing. There would be a total of 88 culverts; of these, 35 are designated as fish passage culverts. Culverts at streams without fish would be designed and sized for drainage only, in accordance with Alaska Department of Transportation and Public Facilities (ADOT&PF) standards. Culverts at streams with fish would be designed and sized for fish passage in accordance with ADOT&PF and Alaska Department of

AMERICAN OVERSIGHT

Fish and Game (ADF&G) standards. See Figures 2-16 to 2-18 showing typical water body crossing structures.

AMERICAN OVERSIGHT

Ferry

The location of the mine site is physically separated from the marine terminal location by Iliamna Lake, which is roughly 75 miles long and up to 20 miles across, with no existing roadway networks around it. PLP's Proposed Action includes use of an all-season ice-breaking ferry to cross the lake, which would reduce the miles of roadbed that would be required for construction of a new road around the lake.

A custom-designed ferry would transit Iliamna Lake between the north and south ferry terminals, carrying inbound supplies from Amakdedori port to the mine site, and returning with copper-gold and molybdenum concentrates, backhauled waste, and empty shipping containers. The one-way ferry trip is about 18 miles, and would take approximately 3 hours to complete in ice conditions, or 1.5 hours in open water. On average, one round trip per day across the lake would be required. Figures 2-19, 2-20, and 2-21 present digital simulations of the ferry vessel, the north ferry terminal, and the south ferry terminal, respectively. Figures 2-22 and 2-23 show the north ferry terminal layout and cross sections, respectively. Figures 2-24 and 2-25 show the south ferry terminal layout and cross sections, respectively.

The vessel would be designed to operate year-round, in all ice conditions. Cargo would be carried on the vessel deck. The vessel would be symmetrical forward and aft with two icebreaking bows, allowing operation in open water or ice in either direction without the need to turn the vessel around at each terminal.

The hull would be subdivided by watertight bulkheads so that even if one compartment is damaged and flooded, the vessel would remain afloat, upright and stable, and operational, capable to return to shore facilities for repairs. Fuel and other potential contaminants would be stored in tanks inside the hull and away from the shell to prevent spills, in the unlikely event of damage to any of the hull's compartments.

Bilge water would be pumped through oil/water separation equipment installed on the vessel, and then discharged back to Iliamna Lake. The sludge from the system would be transferred to a shore storage tank, and ultimately transported to the mine site for disposal in the mine site incinerator.

The ferry terminals would initially serve as trans-shipment points for construction barge traffic across Iliamna Lake, using small temporary barges until the ferry is assembled. The south ferry terminal site includes the ferry assembly site. The ferry would be assembled from pre-fabricated components barged to Amakdedori port, and then transported across the road. The assembly site would remain intact to enable regular vessel surveys and maintenance as required.

The permanent facilities at the ferry terminals would include container handling and storage facilities, office and maintenance buildings, and local power supply. Each ferry terminal facility would have space for a minimum of 2 days of storage of the average concentrate container traffic. An access ramp would be built out from shore as a rock and aggregate causeway structure to provide approximately 40 feet of roadway surface for trucks and forklifts to access the ferry.

During normal operations, the ferry would be moored with a pair of lines to bollards at the end of the causeway. When the ferry is parked, it would be moored to a set of buoys outside of the causeway.

Material Sites

Construction materials would be excavated from borrow material sites (MS) along the main access road (See Table 2-3). Material from these sites would also be used for construction and maintenance of access and spur roads. Field review has not identified PAG material at any of the proposed sites. If PAG is identified at a site evaluation prior to use, the material site would be moved. The amount of material estimated to be required for the road and pipeline is approximately 7.9 million cubic yards. Final volumes of these gravel materials and specific location of material sites and development plans for these sites would be part of the final project design. NOTE TO REVIEWERS: REQUESTED AN UPDATED DATA SET FOR MATERIAL SITES FOR ALL ACTION ALTERNATIVES.

Table 2-3 Alternative 1 Material Site Quantities Estimates

Site	Quantity (cubic yards)	Size (acres)	Type	Blasting Required (Yes/No)	Use

Water Extraction Sites

Potential water extraction sites and quantities to support project construction and operations are provided in Table 2-4. Final estimated quantities for specific uses would be determined during final design (PLP 2018 – RFI 022). Temporary water use authorizations would be applied for by either the appropriate contractor or PLP. NOTE TO REVIEWERS: REQUESTED AN UPDATED DATA SET FOR WATER EXTRACTION SITES FOR ALL ACTION ALTERNATIVES.

Temporary Facilities

A key component of the construction plan is to establish year-round access across Iliamna Lake using the permanent ice-breaking ferry. A temporary road would be constructed within the permanent alignment from the Amakdedori port site to the first material site, approximately 3 miles from the port site, to support construction. Pioneer road construction would extend the road toward the South Ferry Terminal near Kokhanok.

Once access is gained to Iliamna Lake, small barging equipment would be used on the lake to establish beachheads at the two ferry terminal sites. The beachheads at the ferry terminal sites would enable road construction to advance from those points. Temporary bridges would be used at the smaller crossings.

Temporary camps would be established at the ferry landings to support road construction; and at the south ferry landing, assembly of the ferry. These camps would remain in place until the natural gas line construction is complete. The north ferry landing camp would likely be augmented using existing facilities in Iliamna and Newhalen. Until the access road crossing the Newhalen River is complete, the crews would be shuttled to their workplaces by boat or by helicopter.

All temporary construction facilities would be removed after construction; and the sites, unless being used for permanent facilities, would be reclaimed.

Transportation Corridor Operations and Materials Transport

To facilitate efficient cargo movement and optimize ferry space, most material would be transported in shipping containers. At each ferry terminal, a container yard with forklift trucks would be provided to stage empty and loaded containers for loading on/off the ferry, and truck transfer. Some cargo would be handled as break-bulk if it does not fit into containers.

AMERICAN OVERSIGHT

Inbound project cargo and consumables would be transported using standard International Organization for Standards (ISO) containers for ocean freight (either 20- or 40-foot size). Diesel fuel would be transferred from Amakdedori port to the mine site using ISO tank-container units, which have a capacity of 6,350 gallons. Copper-gold concentrate would be loaded into specialized bulk cargo containers, each containing about 38 tons of concentrate, with removable locking lids. Truck/trailer units would be designed to haul up to three loaded containers per trip.

Daily transportation of concentrate, fuel, reagents, and consumables would require up to 35 round trips per day for each leg of the road, including three loads of fuel per day. The ferry would require one round trip across the lake per day. Figure 2-26 presents a digital simulation of a haul truck on the proposed access road.

Physical Reclamation and Closure

The road system would be retained as long as required for the transport of bulk supplies needed for long-term post-closure water treatment and monitoring. As operations end, the Iliamna Lake ferry facilities would be removed, and all supplies would be transported across the lake using a summer barging operation.

AMERICAN OVERSIGHT

Figure 2–26: Digital Simulation of Haul Truck

AMERICAN OVERSIGHT

2.2.2.3 Amakdedori Port and Lightering Locations

Port Design

The proposed project includes construction of Amakdedori port, a year-round port near Amakdedori Creek on the western shore of Cook Inlet (see Figure 2-27). The port site area is currently undeveloped, and not served by any transportation or utility infrastructure.

The proposed port site would include shore-based and marine facilities for the shipment of concentrate, freight, and fuel for the project. The shore-based facilities would include separate facilities for the receipt and storage of containers for concentrate and freight. Other facilities would include fuel storage and transfer facilities, power generation and distribution facilities, maintenance facilities, employee accommodations, and offices. The shore-based complex would be constructed on an engineered fill pad at an elevation sufficient to address tidal surge from major storms and potential tsunamis.

The marine component includes an earthen access causeway extending out to a marine jetty located in 15 feet of natural water depth. One side of the jetty would be occupied by a roll-on/roll-off barge access berth; a separate berth for loading lightering barges would be on the opposite side. The jetty is expected to be constructed as a sheet pile cell structure filled with granular material. A floating dock, on the jetty but separate from the cargo-handling berths, would be provided for ice-breaking tug moorage. Dredging of the port site would not be required. See Figure 2-28 for cross sections of the Amakdedori port.

The natural gas pipeline from the Kenai Peninsula (discussed under Section 2.3.2.4, below) would come ashore at Amakdedori port. An offtake would distribute natural gas to the port power generation facility.

Lightering Locations

Copper-gold concentrate containers would be loaded onto lightering barges at Amakdedori port, and then transported to one of two lightering locations for transfer to bulk carriers. The primary lightering location is approximately 12 miles offshore east of the proposed Amakdedori port; the alternative lightering location is approximately 18 miles east-northeast of the proposed Amakdedori port between Augustine Island and the mainland. Wave heights in this area are reduced by Augustine Island, and it would be used when required by sea conditions. Figure 2-29 presents a digital simulation of concentrate transfer operations at a lightering site.

Figure 2-30 shows the proposed mooring system that would be installed at each lightering location. Vessels would not drop anchor each time they return to the location. Six floating mooring buoys would be used to secure the bulk vessel during loading, and each of these buoys would be attached to permanent anchors set on the sea floor using a pattern similar to that shown on Figure 2-30. On arrival, the bulk carriers would attach mooring lines to the floating buoys, anchoring themselves in place (PLP 2018-RFI 081).

The layout for the permanent anchors (10 to 12) set on the seabed would be finalized in detailed design, but typically consists of a large weight, such as a rock/concrete-filled 40x8x8-foot shipping container that is lowered to the sea floor (see Figure 2-31). Alternatives that might be used if sea floor conditions are not suitable for the use of gravity anchors as outlined include (PLP 2018-RFI 081):

1. Large spade anchors (similar to a conventional boat anchor).
2. Spiral screw anchors that would be twisted into the seabed using a hydraulic drill. This does not work in areas of rock or hard cobbles.

AMERICAN OVERSIGHT

3. For areas of rock seabed, anchors may be drilled into the seabed.
4. Depending on the ground conditions at the designated mooring area, the anchoring system may involve drilling into the subsurface rock as an alternative to a gravity anchor system. The mooring spread measures approximately 2,300 by 1,700 feet, but the impact footprint on the sea bottom is limited to the ten anchor locations.

AMERICAN OVERSIGHT

Temporary Facilities

During the initial construction effort at Amakdedori port, a beachhead would be established using small landing craft–style barges for access. It would consist of a temporary camp, environmental protection features, the port site airstrip, and service facilities. Temporary diesel generators would be used for power supply. While this work is under way, crews would be housed on vessels moored near the site.

A temporary construction camp at the port would be located in an area that would be used for port operations, and would not require a separate footprint. The camp would house the crews for the pioneer road construction. Once the road is through to Iliamna Lake, an existing camp at Kokhanok would be used for road crews and for the crew establishing the ferry landings.

All temporary construction facilities would be removed after construction; and the sites, unless being used for permanent facilities, would be reclaimed.

Port Operations and Materials Transport

Incoming supplies such as equipment, reagents, and fuel would be barged to Amakdedori port, and then transported by truck to the mine site. To a lesser extent, some supplies, such as perishable food, may be transported by air to the Iliamna Airport and trucked to the mine site. Figure 2-32 shows a digital simulation of barges at Amakdedori port.

Copper-gold concentrate would be transported from the mine site to Amakdedori port by truck in covered bulk cargo containers, and stored between vessel sailings on a dedicated laydown pad adjacent to the jetty. The concentrate would be lightered by barge from Amakdedori port to Handysize bulk carriers at offshore mooring points. The containers would be lifted by crane into the open hold of the receiving ship. Once inside the hold, the container lid would be opened, and the container turned upside down to unload the concentrate into the ship's hold. The container would be lowered as close as possible to the bottom of the hold to minimize the drop distance and the potential for dust generation during ship loading. About ten trips by the lightering barges would be required to load a bulk carrier, which would be anchored for 4 to 5 days at the lightering location. The bulk carrier ships would transport the concentrate to out of state smelters. This containerized bulk handling system minimizes dust emissions and the risk of spills.

The empty containers would be cleaned of any residue on the outside while at the port, and then returned to the laydown pad. They would then be returned to the mine site and reused for transporting concentrate.

Up to 27 Handysize ships would be required annually to transport concentrate. Up to 33 marine linehaul barge loads of supplies and consumables would be required annually. Two ice-breaking tug boats would be used to support marine facility operations.

The Amakdedori port site would be equipped for fire and emergency response. Water for fire suppression would be stored in freshwater supply tanks at the port and distributed via insulated pipeline system. An ambulance would be located at the port and a pump truck would be used to deliver fire suppression water. Equipment would also be installed to respond to oil spills, and crews would be appropriately trained for such response.

AMERICAN OVERSIGHT

Figure 2-32: Alternative 1 – Digital Simulation of Barges at Amakdedori Port

AMERICAN OVERSIGHT

Water Management

The WTP at Amakdedori port would treat surface runoff from the port facilities, including truck-wash bays. The treatment process would include dissolved metal oxidation using potassium permanganate, followed by co-precipitation with ferric chloride. Water from the co-precipitated solids would flow into flocculators/clarifiers to separate out solids. The clarified water would then be treated with sodium hydrogen sulfide, sodium hydroxide, and ferrous sulfate to further co-precipitate remaining metals under reducing conditions. The solids that are removed would be thickened and disposed of appropriately. The treated water would be suitable for discharge.

A potable WTP and a sewage treatment plant would also be sited at Amakdedori port.

A groundwater well for the port site is planned. The precise location for the well would be identified during detailed design. The well would be sited on uplands far enough from the shore so as to avoid any potential for saltwater intrusion, and water would be piped to the site from the wellhead (PLP 2018-RFI 022a).

Physical Reclamation and Closure

Physical site closure work would commence as operations end. At that time, the Amakdedori port facilities would be removed, except for those required to support shallow draft tug and barge access to the dock for the transfer of bulk supplies.

2.2.2.4 Natural Gas Pipeline

Natural gas, sourced through the existing natural gas supply infrastructure for the Cook Inlet area, would be the primary energy source for the project.

Natural Gas Pipeline Corridor and Ancillary Facilities

The natural gas would be supplied to Amakdedori port and the mine site by pipeline (Figure 2-33). The pipeline would connect to the existing gas pipeline infrastructure near Anchor Point on the Kenai Peninsula and would be designed to provide a gross flow rate of approximately 50 million standard cubic feet per day. A fiber optic cable would be ploughed in, or buried in a shallow trench, adjacent to the pipeline.

A metering station would be constructed at the offtake point that connects to a compressor station sited on a land parcel on the eastern side of the Sterling Highway. Figure 2-34 shows a digital simulation of the proposed compressor station. The steel pipeline would be designed to meet all required codes, and would be a nominal 12 inches in diameter.

The compressor station would feed a 104-mile subsea pipeline that would be constructed using heavy-wall nominal 12-inch-diameter pipe designed to have negative buoyancy and provide erosion protection against tidal currents. Horizontal directional drilling (HDD) would be used to install pipe segments from the compressor station out into waters that are deep enough to avoid navigation hazards. From this point, the heavy-wall pipe would be laid on the sea floor, and anchored or supported as required.

The pipeline would come ashore at Amakdedori port, where natural gas would be fed to the port site power station and used for site heating. The natural gas corridor from Amakdedori port to the mine site would consist of three sections. The first section would follow the access road to the south ferry terminal. The pipeline would be buried in a trench adjacent to the road. At the south ferry terminal, gas would be fed from the pipeline to the facilities for power supply and facility heat. At this point, the pipeline would enter Iliamna Lake for the next section, an approximate 18-mile lake crossing. The design of this section of the pipe, transitions, and burial would be similar to the

AMERICAN OVERSIGHT

Cook Inlet crossing. The pipeline would come ashore at the north ferry terminal. Natural gas would be used to provide power and heat at ferry terminal facilities. From this point, the pipeline would follow the road route to the mine site.

The segments of the natural gas pipeline and fiber-optic cable constructed along the access roads would be buried adjacent to the road alignment (see Figure 2-15). For river crossings, the pipeline would either use HDD or be attached to the bridge structures. See Figures 2-35 and 2-36 for the typical open-cut and HDD crossings, respectively.

AMERICAN OVERSIGHT

Figure 2-33: Alternative 1 - Natural Gas Pipeline Alignment

AMERICAN OVERSIGHT

Figure 2-34: Digitation Simulation of Compressor Station

AMERICAN OVERSIGHT

Figure 2–35: Alternative 1 – Typical Pipeline Open Cut Water Body Crossing

AMERICAN OVERSIGHT

Figure 2-36: Alternative 1 – Typical Pipeline HDD Crossing

AMERICAN OVERSIGHT

Long-term corrosion protection and control would be provided by an external coating on the pipeline and components, combined with an impressed current and/or galvanic current cathodic protection system. The cathodic protection system would be installed and activated, as soon as is practical, after pipe installation to maximize the effect of corrosion protection. Anode bed and rectifier locations would be determined based on specific local conditions and field observations. Metering stations and pig launching and receiving facilities would be located at the compressor stations and offtake points as appropriate. Mainline sectionalizing valves would be installed as required by code, with a spacing of no more than 20 miles for the onshore sections of the pipeline.

On completion of construction, the natural gas pipeline would be pressure–tested, and all mechanical, civil, structural, and electrical installations would be checked to ensure that they are installed according to design, and can operate safely.

Pipeline test methods would at a minimum include hydrostatic testing and x-raying welds. No chemicals would be added to the water used for hydrostatic testing. Hydrostatic testing would be conducted during the summer construction season. Disposal methods and locations would be developed in accordance with the Alaska Pollutant Discharge Elimination System (APDES) General Permit AKG320000 – Statewide Oil and Gas Pipelines prior to filing a Notice of Intent (NOI) for coverage. Specific BMPs for the test water discharge would be developed, as required by the general permit.

Material sites and water extraction sites for road and pipeline construction are discussed above under Section 2.2.2.2, and listed in Tables 2-3 and 2-4, respectively.

Physical Reclamation and Closure

The natural gas pipeline would be maintained until such time as it is no longer required to provide energy to the project site. If no longer required, the pipeline would be pigged and cleaned and either abandoned in place or removed, subject to regulatory review and approval at the decommissioning stage of the project. Surface utilities associated with the pipeline would be removed and reclaimed.

2.2.2.5 Action Alternative 1 – Summer Only Ferry Operations Variant

This variant considers ferry operations only in the summer when Iliamna Lake is free of ice. Changes to the mine site, transportation corridor, and port components with incorporation of this variant are described below. This variant does not involve changes to the natural gas pipeline component.

Mine Site

Storage of concentrate at the mine site would be needed during the winter months until Iliamna Lake is free of ice to resume the movement of cargo. Storage would be through a container-based system with a laydown area at the mine site (PLP 2018-RFI 065). Storage would occur during the months that Iliamna Lake was iced over, up to 6 months. The sewage tank pad would be relocated to provide space for the additional laydown space in proximity to the mill. See Figure 2-37 for the mine site layout showing the concentrate storage area and relocated sewage tank pad.

AMERICAN OVERSIGHT

Figure 2-37: Alternative 1 Summer Only Ferry Operations Variant – Mine Site Layout

AMERICAN OVERSIGHT

Transportation Corridor

The ferry would only operate in the summer. Trucks would only operate when the ferry was running, which would double the number of round trip truck moves to 78 per day each side of the ferry (PLP 2018-RFI 065).

Amakdedori Port

Concentrate would be stored at the port site during the winter months until Iliamna Lake is free of ice to resume the movement of cargo. Storage would be through a container-based system with a laydown area at the port site (PLP 2018-RFI 065). Storage would occur during the months that Iliamna Lake was iced over, up to 6 months. See Figure 2-38 showing the concentrate storage laydown area at Amakdedori port.

2.2.2.6 Action Alternative 1 – Kokhanok East Ferry Terminal Variant

This variant considers an alternate ferry terminal site east of Kokhanok: the Kokhanok east ferry terminal site (See Figure 2-39). Changes to the transportation corridor and natural gas pipeline components with incorporation of this variant are described below. This variant does not involve changes to the mine site and port components.

Transportation Corridor

The ferry would cross to one ferry terminal site variant (PLP 2018-RFI 078), the Kokhanok east ferry terminal site, and a private unpaved access road would extend 27 miles from the Kokhanok east terminal to Amakdedori port. A separate spur road, approximately 5 miles, would connect the transportation corridor to the village of Kokhanok.

The layout of Kokhanok east ferry terminal would be similar to the Kokhanok west ferry terminal (See Figure 2-40). The one-way ferry trip is about 27 miles, and would take approximately 4.5 hours to complete in ice conditions, or 2.25 hours in open water. On average, one round trip per day across the lake would be required.

The port access road would not require a crossing of the Gibraltar River, and would also have less overall stream crossings. A total of 8 waterbodies would be crossed along the access road and spur road under this variant. Crossing structures would include one bridge and seven cross-drainage culverts. Typical bridge and culvert designs would be the same as described above. NOTE TO REVIEWERS: REQUESTED DETAILS ON BRIDGE SPANS FOR THIS VARIANT.

New material sites are proposed along the port access road from the Kokhanok east ferry terminal (Table 2-5). These would replace three material sites identified along the port access road from the Kokhanok west ferry (MS-A##, MS-A##, and MS-A## identified in Table 2-3), which would no longer be required with this variant. The material sites under this variant are larger, resulting in an increase of ### cubic yards and 125 acres. NOTE TO REVIEWERS: REQUESTED AN UPDATED DATA SET FOR MATERIAL SITES FOR ALL ACTION ALTERNATIVES.

Table 2-5 Kokhanok East Variant Material Site Quantities Estimates

Site	Quantity (cubic yards)	Size (acres)	Type	Blasting Required (Yes/No)	Use
Port Access Road (Kokhanok East Ferry Terminal)					
MS-K01		80

AMERICAN OVERSIGHT

Figure 2-39: Alternative 1 Kokhanok East Ferry Terminal Variant

AMERICAN OVERSIGHT

Figure 2-40: Alternative 1 Kokhanok East Variant - Ferry Terminal Layout

AMERICAN OVERSIGHT

New water extraction sites are proposed along the port access road from the Kokhanok east ferry terminal and the Kokhanok spur road (Table 2-6). These would replace ## water extraction sites identified along the port access road from the Kokhanok west ferry (WE-##, WE-##, and WE-## identified in Table 2-4), which would no longer be required with this variant. NOTE TO REVIEWERS: REQUESTED AN UPDATED DATA SET FOR WATER EXTRACTION SITES FOR ALL ACTION ALTERNATIVES.

Table 2-6 Kokhanok East Variant Water Extraction Sites and Quantities

Water Extraction Site	All-Season (Yes/No)	Water Body Type	Use	Years of Use	Extraction	
					Rate (gpm)	Annual Volume (gal)
Kokhanok Village Spur Road						
WES-KE36	Yes	lake	Road and pipeline construction	life of mine	1,000	8M
Port Access Road (Kokhanok East Ferry Terminal)						
WES-KE37	Yes	lake	Road and pipeline construction	3	500	3M
WES-KE38	Yes	stream	Road and pipeline construction	3	500	3M
WES-KE39	Yes	lake	Road and pipeline construction	3	500	3M

Natural Gas Pipeline

The natural gas pipeline alignment would follow the spur road into Kokhanok, and then follow an existing road alignment to the point where it departs the shoreline to tie into the proposed route from the Kokhanok west ferry terminal site (Figure 2-37). The total pipeline length with this variant would be 185 miles.

2.2.2.7 Action Alternative 1 – Pile-Supported Dock Variant

This variant considers construction of an access trestle and pile-supported dock at Amakedori port, instead of an earthen access causeway and jetty. See Figure 2-41 for the conceptual pile-supported dock layout. The conceptual structure would consist of 76 trestle piles and 177 dock piles, for a total of 253 piles. All piles would be 48 inches in diameter, with a 1.5-inch wall thickness. The piles would be vibrated into place and then driven to refusal with an impact hammer. The total dock area would be approximately 14 acres, and the footprint of pilings would be approximately 3,200 square feet. No fill would be required under this variant.

This variant does not involve changes to the mine site, transportation corridor, or natural gas pipeline components.

2.2.3 Action Alternative 2 – North Road and Ferry

Alternative 2 – North Road and Ferry (Alternative 2) is being considered as an alternative that reduces the total length of road required along a mine access route.

The Alternative 2 access route includes a road alignment from the mine site along the northern shore of Iliamna Lake to Eagle Bay; a ferry from Eagle Bay to Pile Bay; and a road alignment to a port at Diamond Point (Figure 2-42).

AMERICAN OVERSIGHT

Alternative 2 descriptions will refer to Alternative 1 for components that would not change, and describe components that differ. Variants to the alternative (such as the summer-only ferry option) that were identified during the alternatives development process are incorporated into the project component descriptions.

2.2.3.1 Mine Site

The mine site layout and processes under Alternative 2 (Figure 2-43) would be the same as Alternative 1, with the exception of the construction methods for the north embankment of the bulk TSF. Under Alternative 2, the north bulk TSF embankment would be constructed using the downstream method with buttresses, instead of the centerline method proposed under Alternative 1.

Under this alternative, the overall downstream slope would be 2.6H:1V, and the upstream slope 2H:1V. The north embankment crest would be raised approximately 15 feet to an elevation of 1,745 feet (embankment height approximately 570 feet) to provide equivalent bulk TSF storage capacity. The centerline would shift approximately 40 feet upstream. The embankment fill would increase from 78 million cubic yards (yd^3) to 124 million yd^3, and the impoundment footprint area would increase by 119 acres (PLP 2018-RFI 075a). See Figures 2-44 and 2-45.

2.2.3.2 Transportation Corridor

The transportation corridor under Alternative 2 would connect the mine site to the Diamond Point Port in Iliamna Bay (Figure 2-46). It has three main components:

- Mine access road: A private, unpaved two-lane road extending 36 miles east from the mine site to a ferry terminal on the northern shore of Iliamna Lake at Eagle Bay (see Figure 2-47).
- Ferry crossing: An ice-breaking ferry to transport materials, equipment, and concentrate 29 miles across Iliamna Lake to a ferry terminal on the eastern shore at Pile Bay.
- Port access road: A controlled access, unpaved two-lane road extending 18 miles southeast from the east ferry terminal to the Diamond Point Port site in Iliamna Bay (see Figure 2-48).

This corridor would act as the main access route to and from the mine for the transportation of materials, equipment, and concentrate. The ferry, truck transportation, and the Diamond Point port would operate year-round. The general descriptions for temporary facilities, transportation corridor traffic, and material transport, and physical reclamation and closure, would be the same as Alternative 1, but would occur at the locations described under this alternative. The exception is that it is reasonable to assume that the Diamond Point port would be maintained and operated to transfer freight and boats by another entity at closure instead of being removed, as is proposed for the Amakdedori port under Alternative 1. Freight and boats are currently transferred through nearby Williamsport, but the all-tide Diamond Point port would be an upgrade over the existing high-tide-only Williamsport facility.

AMERICAN OVERSIGHT

Figure 2-47: Alternative 2 – Mine Access Road

AMERICAN OVERSIGHT

Figure 2-48: Alternative 2 – Port Access Road

AMERICAN OVERSIGHT

Road System

The main access road design would be the same as Alternative 1; a 30-foot-wide gravel road to enable two-way traffic, and capable of supporting anticipated development and operational activities during construction and truck haulage of concentrate from the mine to the port. The corridor would be north of Iliamna Lake, where it would connect with the existing Williamsport-Pile Bay Road in the vicinity of Pile Bay, and then continue to the Diamond Point port site on Cook Inlet. The road would bypass all but 5 miles of the existing Williamsport-Pile Bay Road.

A total of ## streams would be crossed by the Alternative 2 road system. Crossing structures would include # bridges and ## culverts (# of which would be designed as fish passage culverts). Typical bridge and culvert designs would be the same as described for Alternative 1. NOTE TO REVIEWERS: REQUESTED UPDATED WATER BODY CROSSING DATA SET FOR ALTERNATIVE 2.

Ferry

The ferry vessel would be the same as Alternative 1. It would carry inbound supplies from the lake portion of the route from Diamond Point port to the mine site, returning with copper-gold and molybdenum concentrates, backhauled waste, and empty containers. The one-way ferry trip is about 29 miles, and would take approximately 5 hours to complete in ice conditions, or 2.5 hours in open water. On average, one round trip per day across the lake would be required.

The north shore ferry terminal would be at Eagle Bay, and would have a similar layout, facilities, and operations as Alternative 1. The Pile Bay Ferry Terminal would be south of the start of the Pile Bay-Williamsport Road on the east shore of Iliamna Lake (See Figure 2-49).

AMERICAN OVERSIGHT

2.2.3.3 Diamond Point Port and Lightering Locations

Alternative 2 port site and lightering locations are described below. The general descriptions for temporary facilities, water management, and physical reclamation and closure would be the same as Alternative 1, but would occur at the locations described under this alternative. Under Alternative 2 a temporary airstrip would not be constructed at the port site. However, improvements to the existing airstrip near Pile Bay may be necessary for limited use during construction.

Port Site

Alternative 2 includes construction of Diamond Point port, a year-round port at Iliamna Bay (Figure 2-50). Similar to the Proposed Action, the proposed port site would include shore-based and marine facilities for the shipment of concentrate, freight, and fuel for the project. The shore-based facilities would include separate facilities for the receipt and storage of containers for concentrate and freight. Other facilities would include fuel storage and transfer facilities, power generation and distribution facilities, maintenance facilities, employee accommodations, and offices. The shore-

AMERICAN OVERSIGHT

based complex would be constructed on an engineered fill pad at an elevation sufficient to address tidal surge from major storms and potential tsunamis.

The marine component would be similar to the Amakdedori port design under Alternative 1; consisting of an earthen access causeway extending out to a marine jetty. The jetty is expected to be constructed as a sheet-pile cell structure filled with granular material. Figure 2-51 shows a digital simulation of the Diamond Point port.

The shallow approach at this port site would require dredging. Initial estimates would be for dredging up to a 20-foot depth because the existing water depth is shallower than at Amakdedori port. Dredged channels are typically more prone to sedimentation, requiring maintenance dredging; therefore, dredging deeper reduces the frequency of maintenance dredging. Dredged material would either be used in construction of the causeway and dock, or disposed of onshore. The total volume of dredged material for the 20-foot channel would be 650,000 cubic yards, of which a minimum of 50 percent is estimated to be used in the barge dock construction, which would require approximately 615,000 cubic yards of fill for construction. Any rocks encountered in the channel would be moved to the side of the channel, or used in the dock construction. Any remaining dredged material and any material from maintenance dredging would be disposed of on-shore in a bermed facility on uplands west of the dock site (PLP 2018-RFI 032 and PLP 2018-RFI 063).

An offtake from the natural gas pipeline (discussed under Section 2.3.3.4, below) would distribute natural gas to the port power generation facility.

Lightering Locations

Two offshore lightering stations would be used to lighter the ore concentrate to moored bulk carriers (Figure 2-50). The primary location in Iniskin Bay would be used unless high winds, waves, ice, or other factors preclude its use. If the primary location is not suitable under given conditions, the alternate location shown on Figure 2-50 could be used if conditions there are more favorable. The lightering location in Iniskin Bay is generally protected from wave action, and heave is not expected to be a problem for loading at this location, except under extreme weather conditions.

The proposed mooring system would be the same as described for Alternative 1.

2.2.3.4 Natural Gas Pipeline Corridor

The Alternative 2 natural gas pipeline corridor is described below. All other components of the pipeline would be the same as described for Alternative 1.

AMERICAN OVERSIGHT

Figure 2-50: Alternative 2 – Diamond Point Port and Lightering Locations

AMERICAN OVERSIGHT

Figure 2-51: Alternative 2 – Digital Simulation of Diamond Point Port

AMERICAN OVERSIGHT

Natural Gas Pipeline Corridor and Ancillary Facilities

Natural gas would be supplied to Diamond Point port and the mine site by pipeline (Figure 2-52). As with Alternative 1, the pipeline would connect to the existing gas pipeline infrastructure near Anchor Point on the Kenai Peninsula, and would be designed to provide a gross flow rate of approximately 50 million standard cubic feet per day. A fiber-optic cable would be ploughed in, or buried in a shallow trench, adjacent to the pipeline. A metering station would be constructed at the offtake point that connects to a compressor station on a land parcel on the eastern side of the Sterling Highway. The steel pipeline would be designed to meet all required codes, and would be a nominal 12 inches in diameter.

The pipeline across Cook Inlet would be constructed as described for Alternative 1, but the alignment would come ashore at Ursus Cove. From Ursus Cove, it would be routed north running overland to Cottonwood Bay. A 150-foot temporary construction ROW would be requested to allow for adjustment of the final route to suit terrain. Access for construction would be by barge landings from each end of the ROW. The ROW would be reduced to a 50-foot permanent operations ROW following completion of pipeline construction. The pipeline would be installed in a trench to cross Cottonwood Bay using a barge mounted excavator in inundated areas, or low ground pressure equipment and mats in tidal areas, to excavate the trench. The pipeline would come ashore at Diamond Point port, where natural gas would be fed to the port site power station and used for site heating.

From Diamond Point port, the pipeline would be buried in a trench that follows the general Alternative 3 north access road alignment with minor (see Section 2.2.4.2 below). For segments that follow the Alternative 2 access road alignment, the pipeline would be buried in a trench adjacent to the road prism (see Figure 2-15). For segments that do not follow the road alignment PLP would secure the ROW easements from land owners. A 150-foot temporary construction ROW would be requested to allow for adjustment of the final route to suit terrain. The ROW would be reduced to a 50-foot permanent operations ROW following completion of pipeline construction. Three construction access points would be required (see Figure 2-52), and would be reclaimed after construction. See Figure 2-53 for typical sections showing summer construction of the pipeline along segments not adjacent to access roads.

The pipeline alignment would be monitored by air (helicopter and/or drone) to check for any ROW issues and/or leaks. The pipeline would also be inspected by pig as part of the regular maintenance and inspection program. Any work that needs to be performed would be supported by air, or by low-pressure ground vehicle access along the ROW and/or from the lake (PLP 2018-RFI 080).

2.2.3.5 Action Alternative 2 – Summer Only Ferry Operations Variant

This variant considers ferry operations only in the summer when Iliamna Lake is free of ice. Changes to the mine site and transportation corridor with incorporation of this variant under Alternative 2 are described below. This variant does not involve changes to the port or natural gas pipeline components.

Mine Site

Storage of concentrate at the mine site would be needed during the winter months until Iliamna Lake is free of ice to resume the movement of cargo. Storage would be through a container-based system with a laydown area at the mine site (PLP 2018-RFI 065). Storage would occur during the months that Iliamna Lake was iced over, up to 6 months. See Figure 2-54 showing the concentrate storage laydown area at the mine site.

AMERICAN OVERSIGHT

Figure 2-52: Alternative 2 – Natural Gas Pipeline Route

AMERICAN OVERSIGHT

Figure 2-53: Alternative 2 – Natural Gas Pipeline Typical Section for Pipeline Segment Not Adjacent to Access Road

AMERICAN OVERSIGHT

Figure 2-54: Alternative 2 Summer Only Ferry Operations Variant – Mine Site Layout

AMERICAN OVERSIGHT

Transportation Corridor

The ferry would only operate in the summer. Trucks would only operate when the ferry was running, which would double the number of round trip truck moves to 78 per day each side of the ferry (PLP 2018-RFI 065).

With this variant, storage of concentrate would be needed during the winter months until Iliamna Lake is free of ice to resume the movement of cargo. Storage would be through a container-based system with a laydown area along the Pile Bay-Williamsport Road due to limited available space at Diamond Point port (PLP 2018-RFI 065). Storage would occur during the months that Iliamna Lake was iced over, up to 6 months. See Figure 2-55, which shows the concentrate storage laydown area along the Alternative 2 transportation corridor.

2.2.3.6 Action Alternative 2 – Pile-Supported Dock Variant

This variant would construct an access trestle and pile-supported dock at Diamond Point port, instead of an earthen access causeway and jetty. See Figure 2-56 for the conceptual pile-supported dock layout. The conceptual structure would consist of 44 trestle piles and 474 dock piles, for a total of 518 piles. All piles would be 48 inches in diameter, with a 1.5-inch wall thickness. The piles would be vibrated into place and then driven to refusal with an impact hammer. The total dock area would be approximately 102 acres, and the footprint of pilings would be approximately 6,500 square feet. Dredging would similar to what is described for Alternative 2 with an earthen fill dock and jetty.

This variant does not involve changes to the mine site, transportation corridor, or natural gas pipeline components.

2.2.4 Action Alternative 3 – North Road Only

Alternative 3-North Road Only (Alternative 3) is being considered as an alternative that addresses alternative transportation corridor and natural gas pipeline routes that were carried forward from screening, and eliminates the need for ferry transportation across Iliamna Lake.

The Alternative 3 access route includes a north road alignment from the mine site to a port at Diamond Point on Cook Inlet. See Figure 2-57.

Alternative 3 descriptions will refer to Alternative 1 or 2 for components that would not change, and describe components that differ. Variants to the Proposed Action that were identified during the alternatives development process are incorporated into the project component descriptions.

2.2.4.1 Mine Site

The mine site layout and processes under Alternative 3 would be the same as described for Alternative 1.

2.2.4.2 Transportation Corridor

The transportation corridor under Alternative 3 would connect the mine site to Diamond Point port in Iliamna Bay (Figure 2-58). The project transportation corridor would consist of a double-lane road north of Iliamna Lake, the north access road, which would act as the main access route to and from the mine for the transportation of materials, equipment, and concentrate (Figure 2-59). There would be no ferry transportation across Iliamna Lake. The truck transportation and Diamond Point port would operate year-round.

Physical reclamation and closure would be the same as described for Alternative 2.

Road System

The north access road design would be the same as Alternative 1; a private 30-foot-wide gravel road to enable two-way traffic, and capable of supporting anticipated development and operational activities during construction and truck haulage of concentrate from the mine to the port.

A total of 116 waterbodies would be crossed by the Alternative 2 road system. Crossing structures would include 17 bridges and 99 culverts (36 of which would be designed for fish passage). Typical bridge and culvert designs would be similar to those described for Alternative 1. NOTE TO REVIEWERS: REQUESTED DETAILS ON BRIDGE SPANS FOR THIS ALTERNATIVET.

Material Sites

Potential material sites Alternative 2 are shown in Table 2-9. NOTE TO REVIEWERS: REQUESTED AN UPDATED DATA SET FOR MATERIAL SITES FOR ALL ACTION ALTERNATIVES.

Temporary Facilities

Temporary facilities associated with Alternative 3 are assumed to be the same as described for Alternative 1 for access roads. There would not be a ferry, so temporary facilities associated with ferry terminals would not apply.

Transportation Corridor Traffic and Materials Transport

Trucks, containers, and truck traffic would be the same as Alternative 1. There would be no ferry traffic under Alternative 3.

2.2.4.3 Diamond Point Port and Lightering Locations

Alternative 3 includes construction of Diamond Point port, marine components, and lightering locations, as described for Alternative 2.

2.2.4.4 Natural Gas Pipeline Corridor

The natural gas pipeline component would be similar to Alternative 2. It would be approximately 1 mile longer than the Alternative 2 natural gas pipeline corridor because it would follow the entire North Road access route from Diamond Point to the mine site (see Figure 2-57); buried in a trench adjacent to the road. Additionally, the three construction access points described for Alternative 2 would not apply to Alternative 3.

2.2.4.5 Alternative 3 – Concentrate Pipeline Variant

This variant considers the concept of delivering copper and gold concentrate from the mine site to Diamond Point port using a pipeline instead of trucking along the north access road. Two options are addressed under this variant: one for the concentrate pipeline only, and another for a return water pipeline with the concentrate pipeline concept. Changes to the mine site, transportation corridor, and port with incorporation of this variant under Alternative 3 are described below. This variant does not involve changes to the natural gas pipeline component or the trucking of molybdenum concentrate.

Mine Site

With this variant, an electric pump station would be sited at the mine site, and would use positive displacement pumps in the 1,000-horsepower range. See Figure 2-60, which shows the location of the concentrate pumphouse at the mine site.

With incorporation of a concentrate pipeline only (no return water pipeline) and the corresponding treatment and discharge of the filtrate at the port site (discussed below), the amount of water

AMERICAN OVERSIGHT

available for release to surrounding drainages at the mine site would be reduced by approximately 1 to 2 percent, on average.

Transportation Corridor

The concentrate pipeline would follow the Alternative 3 access road route, and would be buried in the same trench as the gas pipeline (see Figures 2-61 and 2-62). The molybdenum concentrate, which represents approximately 2.5 percent of the total concentrate production, would still be transported in containers loaded on trucks.

The pipeline would consist of a single, approximately 6.25-inch-diameter API 5L X60 grade (or similar) steel pipeline with an internal high-density polyethylene (HDPE) liner to prevent corrosion. A cathodic protection (zinc ribbon or similar) system would be included for prevention of external corrosion. A pressure-based leak detection system, with pressure transmitters along the pipeline route, would monitor the pipeline for leaks. Two electric pump stations would be required: one at the mine site, and one at an intermediate point. Both pump stations would use positive displacement pumps in the 1,000-horsepower range, and the intermediate one would require appropriate power generation facilities (1 to 2-MW range). Rupture discs at the intermediate and terminal stations and pressure monitoring would be used to protect the pipeline from overpressure events. Aboveground sections of the pipeline would use heavy-wall pipe or casing as needed for additional protection. Manual isolation and drain valves would be spaced at intervals no greater than 20 miles apart (PLP 2018-RFI 066).

The pipeline would transport a mixture of 55 percent concentrate and 45 percent water by mass, which equates to a water consumption rate from the mine site of approximately 0.6 cubic foot per second (cfs). Additional water would be intermittently used for flushing the line during maintenance activities. Storage for water and slurry would be provided at the intermediate and terminal stations. Concentrate handling and dewatering facilities would be required at the port facility (PLP 2018-RFI 066).

During construction, steel pipe lengths would be welded together into segments, and the HDPE liner (smaller-diameter pipe) then pulled through each segment of steel pipe, ensuring a tight fit for the HDPE liner pipe. These lined segments are then bolted together using flange connections that connect both the inner HDPE liner pipe and the steel outer pipe. Lined concentrate pipelines cannot be built as a continuous welded segment over the entire length due to the requirement to pull the tight-fitting HDPE liner through the inside of the steel pipe. Welded segments can be up to 2,000 to 2,500 feet in length, typically allowing for river crossings that do not include flange connections.

The concentrate pipeline would be buried in the same trench as the gas pipeline, with approximately 36 inches of cover, or deeper in areas where needed to prevent freezing. The trench would be adjacent to the access road, facilitating access for construction, inspection, and maintenance. The road corridor width would be increased by less than 10 percent under most construction conditions. At major stream crossings, the pipeline would be attached to the vehicle bridges. Smaller crossings would use HDD, or trenching if appropriate. Decisions on the appropriate methodology for individual crossings would be made in consultation with ADF&G. Major river crossings would have isolation valves and pressure and temperature monitoring instrumentation installed.

AMERICAN OVERSIGHT

Figure 2-61: Alternative 3 Concentrate Pipeline Variant – Concentrate Pipeline Route

AMERICAN OVERSIGHT

Figure 2-62: Alternative 3 Concentrate Pipeline Variant – Typical Road Section

AMERICAN OVERSIGHT

Diamond Point Port

Use of a concentrate pipeline would require concentrate handling, dewatering, and treatment facilities at Diamond Point port (See Figure 2-63). The port facility footprint and activity at the port site would increase due to the requirements of dewatering the concentrate, storing water and concentrate, and treating and discharging the filtrate water. The dewatered concentrate would be stored in bulk in a large storage building, and the concentrate lightering scheme would be revised to accommodate the bulk concentrate. The lightering system would use bulk handling (i.e., conveyers) of concentrate to load the bulk carriers, with appropriate controls to address the potential for concentrate dust emissions associated with storage, loading, and unloading.

The moisture content of the concentrate after dewatering would be 8 percent, resulting in a requirement to treat an average of approximately 220 gallons of filtrate water per minute. Water produced from sources such as pipeline flushing, or process-contacted stormwater, would also require treatment. The port water treatment facility would therefore be designed for a treatment capacity of up to 350 gallons per minute (gpm) (~ 0.8 cfs). The water quality characteristics of the slurry filtrate water and port area stormwater streams are expected to exceed discharge criteria for pH and metals concentrations to marine waters. The treatment of this stream would consist of chemical addition for pH adjustment and metals precipitation, followed by clarifiers for bulk suspended solids removal. Following clarification, additional metals precipitation would be accomplished by addition of sodium hydrogen sulfide, and either multimedia filtration or ultrafiltration. The filtered water would be discharged through an outfall pipeline and diffuser into surrounding marine waters. All discharge water would meet appropriate marine discharge criteria. Solids and/or brine captured in the clarification process and the filtration backwash would be trucked to the mine site, or barged to an offsite disposal facility as appropriate.

Concentrate Pipeline Operations Variant Option with Return Water Pipeline

Changes from the concentrate pipeline variant described above, with incorporation of a return water pipeline, are as follows:

1. The return water pipeline would be placed in the same trench as the slurry and natural gas lines, adjacent to the road, so the trench would be widened by a few feet (see Figure 2-62). This pipeline would need to be sized to accommodate water from flushing operations, resulting in a return water size of approximately 8 inches. This would also be a HDPE-lined steel pipeline with appropriate corrosion protection and other controls, as discussed above.
2. The Diamond Point Port footprint would not change substantially. The WTP would be removed, but other process and storage infrastructure would remain, and a return water pump station and associated generation capacity would be required at the port site. The return water line would not require an intermediate pump station.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

2.2.5 Summary of Differences Between Action Alternatives

Table 2-11 summarizes the primary differences between the action alternatives. The table does not summarize all the components of each alternative, but instead lists the parts of the Proposed Action that would differ in other alternatives. Figure 2-64 illustrates the primary differences between the action alternatives.

NOTE TO REVIEWERS: TABLE 2-11 TO BE PREPARED FOR THE DEIS—PENDING REQUESTED GIS DATA TO COMPLETE.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

Figure 2-64: Alternatives Comparison

AMERICAN OVERSIGHT

2.3 ALTERNATIVES ELIMINATED FROM FURTHER CONSIDERATION

Appendix B describes the options that were considered, provides details on the screening of each option, and explains the rationale for dismissal of options. Over 70 alternative options were evaluated in Appendix B, including alternative mining methods, alternative water treatment, alternative access routes, and alternative locations for project component facilities.

The technical and economic practicability of options was evaluated carefully, and these factors were most often the basis for eliminating options. Environmental impacts were assessed at a screening level; some options were eliminated because they would increase the overall adverse environmental impacts, or would add no environmental benefit when compared with the corresponding components of the proposed project. Others were not carried forward as options because they were more properly characterized as potential mitigating measures. Mitigation measures are addressed in Chapter 5, Mitigation.

The alternative options considered and eliminated from further analysis, based on the screening process outlined above, are presented in Tables 2-12 through 2-23, which are organized by various elements of the proposed project (e.g., mine location and layout, access, tailings, and management). The tables provide a brief description of each option that was considered and dismissed.

Table 2-12: Mine Location and Layout Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Location – Whistler Project	LOC-002	***Description*** – The Whistler mineral property is a gold-copper porphyry deposit located in the Yentna mining district northwest of Anchorage. Molybdenum resources have not been reported at Whistler.
Location – Pyramid Project	LOC-003	***Description*** – Pyramid is a copper-gold-molybdenum porphyry deposit located on the southwestern tip of the Alaska Peninsula southwest of Anchorage. Exploration to date at the Pyramid property has characterized only inferred resources.
Location – Outside of Alaska	LOC-004	***Description*** –This option involves acquisition, development, and operation of a copper-molybdenum massive sulfide deposit located outside of Alaska.
Location – within Alaska	LOC-005	***Description*** –This option involves development and operation of a multi-metals massive sulfide deposit located in Alaska.
Layout – Mine Layout Option 1	LAY-002	***Description*** – This option is based on a mining plan that requires stockpiling capacity for lower-grade ore (LGO) that is processed late in the mine life. A single tailings storage facility (TSF) with separate cells for bulk and pyritic tailings would be constructed in the North Fork Koktuli (NFK) West site, with an internal embankment between the cells. The pyritic TSF would be lined. The bulk TSF would not be lined. Potentially acid generating (PAG) waste and LGO would be stored in a lined facility in the NFK East site. The main water management pond (WMP) would be constructed north of the NFK East site. The bulk TSF would have a dry closure. The pyritic TSF would have a wet closure. The LGO/PAG waste storage facility would be reclaimed.
Layout – Mine Layout Option 2	LAY-003	***Description*** – This option is based on a mining plan that would send all ore directly to the mill. The TSF would be constructed in the NFK West site, and consist of a single cell with an internal area to store the pyritic tailings so that they remain subaqueous. A lined WMP with space to store PAG waste would be constructed in the NFK East site. The tailings would have wet closure, and the WMP would be reclaimed.

AMERICAN OVERSIGHT

Table 2-12: Mine Location and Layout Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Mine Size – EPA Restricted Mine Size	LAY-004	***Description*** – This option would restrict the size of the mine to what the EPA found appropriate in the 2014 Watershed Assessment.
Mine Size – Smaller Mine Pit Size	LAY-005	***Description*** –This option examines the smallest mine size considered by the EPA in the 2014 Watershed Assessment. Under this option, 0.23 billion metric tons of ore would be mined, with a throughput of 31,100 metric tons per day (tpd).
Mine Size – Larger Mine to Develop More of the Known Deposit	LAY-006	***Description*** –This option would increase the mine site and duration of operations to develop more of the known and inferred resource of the overall deposit.

Table 2-13: Mining Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Mining Type – Underground Mining	MNG-002	***Description*** – This option would develop the resource using underground mining methods.
Mining Type – Surface and Underground Mine	MNG-003	***Description*** – This option would develop the resource using both open-pit and underground mining methods.
Material Handling – In-Pit Crushing and Conveying	MNG-005	***Description*** – This option would use in-pit crushing and conveying methods for material handling that would begin several years into the start of operations, and operate through the end of the mine life.
Truck Fuel – Liquefied Natural Gas	MNG-007	***Description*** – Under this option, liquefied natural gas (LNG) would be produced using an on-site plant and used to power the haul trucks.

Table 2-14: Processing Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Facility Location– Off-site Ore Processing	PRO-002	***Description*** – Off-site ore processing would involve transporting all ore away from the project area for processing. This would involve transportation of 180,000 tons of ore from the mine site to the mill site daily.
Facility Location /Process Type – On-site Ore Processing (Metal Production)	PRO-003	***Description*** – On-site ore processing would construct a smelter and produce metals on site (copper, gold, and molybdenum) instead of a concentrate product.

AMERICAN OVERSIGHT

Table 2-15: Throughput Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
50,000 tons per day	TPD-002	***Description*** – Mine throughput of 50,000 tons per day (tpd), with a mine life of 71 years.
115,000 tons per day	TPD-002a	***Description*** – Mine throughput of 115,000 tpd, with a mine life of 31 years.
160,000 tons per day	TPD-003	***Description*** – This throughput option of 160,000 tpd would require construction of a large, lined pad for storing PAG waste rock and LGO (PAG waste rock would be returned to the completed pit at closure, and LGO would be processed during the later years of mine operations). This option was replaced by the 180,000-tpd throughput as the Proposed Action.
320,000 tons per day	TPD-004	***Description*** – Mine throughput of 320,000 tpd over an 11-year mine.

Table 2-16: Gold Recovery Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Secondary Gold Recovery	GR-002	***Description*** –This option involves construction of a cyanide leach circuit at the mine site to process the pyritic tails. A cyanide leach circuit could recover additional gold from the process.

Table 2-17: Power Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Power Source – Renewable Energy	POW-002	***Description*** – Under this option, PLP would construct and power the mine using renewable energy resources such as wind turbines and run-of-river hydropower. Also considered under this option is supplementing the natural gas power plant production with renewables.
Power Source – Purchase Power from Existing Grid	POW-003	***Description*** – Under this option, power would be purchased from existing third-party providers and transmitted to the site via a High-Voltage Direct Current transmission. The nearest connection would be on the Kenai Peninsula, 120 miles from the mine site and across Cook Inlet.
Power Source – Use Alternative Fuel Sources/Delivery Methods	POW-004	***Description*** – The most likely alternative energy sources would be diesel fuel and LNG, both of which could be delivered to the proposed Amakdedori port via barge. Transportation from the port to the Mine Site could be by truck or pipeline.
Power Plant Location – Off-site with High-Voltage Transmission Lines	POW-006	***Description*** –This option would require a new power plant to be built at an alternative location such as the Kenai Peninsula or Amakdedori. High-voltage transmission lines would be constructed and used to transmit the power to the mine site.
Gas Source – Pipeline to a Source on the West Side of Cook Inlet	POW-008	***Description*** – This option would follow an alternative route to the north to access existing natural gas supplies such as Beluga on the western side of Cook Inlet.

AMERICAN OVERSIGHT

Table 2-17: Power Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Gas Source – Connect to Donlin Gold Gas Pipeline	POW-009	***Description*** –Under this option, the pipeline would follow an alternative route to the north, allowing it to connect to the proposed Donlin Gold Mine natural gas supply pipeline.
Gas Source – Northern Gas Pipeline Route to Kenai Peninsula (Direct Route to Iliamna Bay)	POW-011	***Description*** – Under this option, the pipeline route would follow a more direct route to Iliamna Bay and Diamond Point than POW-010.
Gas Source – Other	POW-012	***Description*** – A scoping comment requested evaluation of alternative pipeline routes, but did not suggest specific locations.

Table 2-18: Access Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Access Road – West Access Route	ACC-004	***Description*** – Under this option, the road would go from the mine site around the western end of Iliamna Lake and continue to the Amakdedori port site on Cook Inlet. This option would not require a ferry.
Access Road – Bristol Bay Access Route (Road Only)	ACC-005	***Description*** – This road option is a road-only access route from the mine site to a port site on Bristol Bay. This option would not require a ferry.
Ferry Terminal Location – North Shore East Ferry Terminal	ACC-006a	***Description*** – This ferry terminal site option would include the construction of a ferry terminal on the north shore of Iliamna Lake The site is slightly east of the North Shore Ferry Terminal Site (ACC-006) in the same bay.
Ferry Terminal Location – Iliamna and Kokhanok Ferry Terminals	ACC-007	***Description*** – Under this option, a north shore ferry terminal would be located in or near the communities of Newhalen and Iliamna, but away from the Newhalen River. The Iliamna spur road would therefore be the main mine access road route to connect the mine site to this ferry terminal. A south shore ferry terminal would be located north of the Kokhanok Airport. The road from this ferry terminal to Amakdedori port would avoid crossing the Gibraltar River.
Ferry Terminal Location – Utilize Alternative Ferry Terminal Sites	ACC-012	***Description*** – The suggested option requested consideration of alternative ferry sites and locations compared to the Proposed Action, but did not specify locations.
Port Location – Knoll Head/Iniskin Bay Port Site	ACC-015	***Description*** – This port site would be located at Knoll Head in Iniskin Bay, and is associated with the North Access Routes (ACC-002 and ACC-003).
Port Location – Fortification Bluff/Rocky Point Port Site	ACC-016	***Description*** – Under this option, the port location would be at Fortification Bluff/Rocky Point, which is approximately 15 miles north of Amakdedori, and would require 26 additional road miles from the port access road route to this port site, compared to the Proposed Action.
Port Location – Williamsport Port Site	ACC-017	***Description*** – The port location would be at the existing Williamsport location in Iliamna Bay. This option would require improvements to the existing port facilities.

AMERICAN OVERSIGHT

Table 2-18: Access Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Port Location – Utilize Alternative Port Sites	ACC-018	***Description*** – A scoping comment requested consideration of alternative port sites and locations compared to the Proposed Action, but did not suggest specific locations.
Port Operations– Shore-Side Loading	ACC-021	***Description*** –Bulk carriers would be loaded directly at the port site (rather than at lightering locations), and would require a deep draft navigation channel and turning basin of approximately 50 feet of water depth.
Other Access Options – Mandatory Bridges at Stream Crossings	ACC-024	***Description*** – This option would make it mandatory for bridges to be built any time the access route crosses a stream or river that supports anadromous fish.
Other Access Options – Revised Project Alignment via Micro-Siting	ACC-025	***Description*** – Use micro-siting practices to avoid local impacts to wetlands, stream crossings, guiding, lodges, wildlife, visual resources, archeological, and historical resources.

Table 2-19: Concentrate Transport Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Concentrate Transport – Rail	CTR-003	***Description*** – This option would require the construction of a railroad from the mine site for the transportation of ore concentrate.

Table 2-20: Reclamation and Closure Access Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Closure – Iliamna Airport and Existing Roads	RCA-002	***Description*** –This option would use existing infrastructure (Iliamna Airport and Pile Bay-Williamsport Road) for all mine reclamation and closure transportation needs after operations. The mine access road would be reclaimed. A variant to maintain the mine road system north of Iliamna Lake and reclaim the road south of the lake was also considered and eliminated.

Table 2-21: Tailings Management Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Storage Method – Slurry Tailings Storage	TSF-002	***Description*** – This option considers slurry tailings for the bulk TSF instead of the thickened tailings method. Slurry tailings were considered for the bulk TSF instead of the thickened tailings method that is proposed. Slurry tailings are a water-like material moved by pipeline. The slurry typically has a solids content of 10 to 40 percent, and can flow downgradient by gravity.
Storage Method – Paste Tailings Storage (for Bulk Tailings only)	TSF-003	***Description*** – This option considers paste tailings for the bulk TSF instead of the thickened tailings method. This option is only applicable to the bulk tailings, and not the pyritic tailings that would need to stay saturated to prevent acid rock drainage (ARD) generation and metal leaching. Paste tailings are essentially thickened tailings, thickened with high-density thickeners, cement, and other additives to a toothpaste-like material. Paste tailings are mostly used as backfill in underground mine workings where

AMERICAN OVERSIGHT

Table 2-21: Tailings Management Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
		transport and placement of the paste is aided by gravity, and are typically not disposed of in TSFs.
Storage Method – Dry Stack Tailings (for Bulk Tailings only)	TSF-004	***Description*** – This option considers dry stack tailings for the bulk TSF instead of the thickened tailings method. This option of dry-stack tailings is only suited for bulk tailings because the pyritic tailings need to stay saturated to prevent ARD generation and metal leaching. Filtering tailings removes water using mechanical filters, and results in tailings with 75 to 85 percent solids content. This creates a soil-like material or "dry cake" that is transported by conveyor or truck to a "dry stack" TSF. These TSFs do not require dams, unless possibly for perimeter berms. The tailings are placed by bulldozers and compactors, as is done in conventional earthwork construction.
Storage Method – Submarine Disposal Storage	TSF-005	***Description*** – This option would place the tailings and other mine waste in a water body such as a lake to maintain a saturated condition into perpetuity. The concept is to discharge tailings by gravity to a location and depth where they are not likely to oxidize and leach out toxic metals, and where marine life is less abundant.
Storage Method – Remove or Make All Tailings Inert	TSF-006	***Description*** –This option would involve transporting all of the tailings from the project area to another disposal area, or making the tailings inert to eliminate the ARD and metal leaching potential.
Storage Method – Truck Tailings to Canada	TSF-007	***Description*** –This option would involve transporting all of the tailings from the project area to a disposal area in Canada.
Tailings Dam – Upstream Construction	TSF-010	***Description*** – Under this option, use of upstream tailings dam construction is considered. Tailings dams built by the upstream method of construction are raised by using rock, soil, and tailings in various combinations as dam fill. A starter dam is first built in the same manner as a centerline or downstream dam. Trapezoidal-shaped raises are built on top of each other at an offset toe-to-crest design, moving the dam crest and centerline upstream so that the upstream part of the dam is situated over tailings in the TSF.
Storage Method – Emergency Storage for TSF	TSF-011	***Description*** –This option would require an emergency storage/overflow containment area to minimize risk of tailings spills from excessive buildup of water in the TSF.
Tailings Production – Blended Bulk/Pyritic Tails	TSF-013	***Description*** – Under this option, bulk and pyritic tailings streams would be combined into one for the purpose of having a single TSF.
Bulk Tailings Basin – Lined	TSF-015	***Description*** – This option has the bottom of the bulk TSF fully lined so that the bulk tailings would not be in contact with the ground surface.
Pyritic Tailings Basin – Unlined	TSF-017	***Description*** – Under this option, the pyritic TSF would be unlined.
TSF Location – NFK North TSF Location	TSF-019	***Description*** – This option would store pyritic tailings about 2 miles north of the proposed open pit.
Combined TSF and Operating Pond	TSF-021	***Description*** – This option would add the operating pond (part of the main WMP) to the bulk TSF. It would result in additional water stored in the bulk TSF, and would eliminate the need for or reduce the size of the main WMP.

AMERICAN OVERSIGHT

Table 2-21: Tailings Management Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
		The objective would be to perform all bulk tailings and water management operations at one facility, instead of two facilities.
Cook Inlet Drainage TSF Locations	TSF-022	***Description*** – This option would transport the ore to Cook Inlet drainages where it would be milled. Seven drainages were considered for TSF locations, six above Kamishak Bay and one above Iniskin Bay. Due to the amount of material that would need to be transported it would be necessary to build and operate a railroad between the mine site and the mill.
Store and Release Cover on Bulk TSF	TSF-024	***Description*** – This option considers use of a Store and Release cover (SRC) on the bulk TSF. SRCs are designed to retain precipitated water within inert material overlying the tailings, from where the water is removed by evapotranspiration. SRC systems are typically most effective in warm, semi-arid climates where there is no, or limited, net precipitation (annual evaporation exceeds precipitation), even if there may be elevated levels of precipitation in some seasons (e.g. monsoon areas). Typical SRC systems consist of a layer of soil (usually well graded with significant fines) with dense vegetation coverage on top.

Table 2-22: PAG Waste Rock Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Storage Method – Store PAG in LGO stockpile	PAG-002	***Description*** – This option would store PAG with the LGO stockpile.
Storage Method – Separate WRF Storage	PAG-003	***Description*** – This option would involve the construction of a separate permanent facility for waste rock.

Table 2-23: Water Treatment and Air Options Eliminated from Further Consideration

Option	Option #	Option Origination and Description
Enhanced Water Treatment	WTP-002	***Description*** –This option would require the water quality of all discharged water to be the same as receiving water. Additional water treatment steps would likely be required to achieve this.
Enhanced Water Treatment – Zero Metal Discharge	WTP-003	***Description*** – This option would require there to be zero metal content in discharged water.
Enhanced Water Treatment – Reverse Osmosis	WTP-004	***Description*** –This option would require reverses osmosis processing for water treatment at both water treatment plants (WTPs) (the main WTP and the open-pit WTP).
Airtight Structure for Emissions Collection	AIR-001	***Description*** – This option calls for the development and construction of an airtight structure that covers the mine site. Any fumes, dust, or gasses would be cleaned before the air can be re-released into the atmosphere.

K3.17 HYDROGEOLOGY

This appendix contains additional information regarding baseline studies and technical information on the following topics described in Section 3.17:

- Hydrogeological characterization programs
- Aquifer properties and hydraulic conductivity
- Groundwater flow systems
- Site water balance model
- Mine site groundwater model

K3.17.1 Hydrogeological Characterization Programs

Hydrogeological data were collected during the course of several field programs between 2004 and 2012, which involved logging of borings, installation of pumping wells, piezometers, and monitoring wells, permeability testing, streamflow gauging, monitoring of meteoric inputs and routine monitoring of groundwater levels, and collection of streamflow and groundwater quality data.

Boreholes were advanced using a variety of drilling techniques, including mud rotary, air rotary ODEX, and rotary sonic, with sampling and logging conducted according to standard methods defined by the American Society for Testing and Materials (ASTM), and consistent with best industry practice.

Instrumentation installed prior to 2008 included the following: 39 nested monitoring wells at 21 locations, 240 nested piezometers at 103 locations, 216 single piezometers, one deep multi-level groundwater instrumentation system, nine cross-hole aquifer test wells at eight locations, and 70 piezometers installed as part of the wetlands program. In 2011, an additional 43 boreholes were drilled in the deposit area for geotechnical purposes, and several response tests were conducted to determine bedrock permeability. In 2012, an additional 18 boreholes were drilled to further investigate hydrogeology.

Piezometers were installed to depths of up to 232 feet below ground surface (bgs) to collect information on stratigraphy, hydraulic conductivity, and groundwater levels. Vertical groundwater gradients were also characterized where a cluster of piezometers was installed near the same location. Piezometers were also installed as part of the geotechnical characterization program for the purposes of water level monitoring and permeability testing.

Between 2004 and 2008, nine pumping wells were installed using air rotary drilling techniques and telescopic well screens, targeting the most permeable features encountered during drilling. In 2012, four additional pumping wells were installed using sonic drilling techniques to understand the requirements for pit dewatering, but these wells have not yet been tested.

Single-well response tests were completed by displacing groundwater in the well and monitoring recovery until water levels stabilized. Prior to commencement of each test, static water levels were measured and pressure transducers installed. Falling and rising head slug tests were conducted on monitoring wells and piezometers to determine the hydraulic conductivity of the surrounding overburden or bedrock formations.

In 2006, a multi-level piezometer system (WB-1) was installed in the Pebble deposit area in a borehole drilled to a depth of 4,050 feet bgs for mineral exploration purposes. After flushing the borehole, an assembly of 50 hydraulic head measurement ports and 24 sampling ports were installed to facilitate monthly monitoring of hydraulic head and groundwater quality to significant

AMERICAN OVERSIGHT

depths below the deposit. Cross-hole testing was also completed to allow for measurement of hydraulic conductivity for a larger volume of rock, as compared to response testing and packer testing.

Larger-scale pumping tests were conducted in three areas, including the area around the Pebble deposit, at four locations downgradient of the Pebble deposit near the South Fork Koktuli (SFK) River and in the North Fork Koktuli (NFK) River drainage area (watershed). Pumping tests were conducted in both overburden and bedrock using air lift pumping techniques for between 6 and 24 hours. Step tests were completed to determine the specific capacity of the pumping wells and a pumping rate for the constant-rate tests. Water levels and pumping well discharge were monitored in both the pumping wells and nearby monitoring wells using pressure transducers and manual water level meters during both pumping and recovery phases to allow for determination of aquifer properties.

In 2010, an additional multi-level piezometer system (WB-3) was installed to a depth of approximately 600 feet to improve characterization of the area between tributaries NK1.190 and SK1.190. The primary objective was to characterize groundwater levels and gradients, and confirm groundwater flow directions. In 2012, a third multi-level system (WB-4) was installed in the pre-Tertiary bedrock in the western portion of the Pebble deposit area to a depth of 2,250 feet. The primary objective was to characterize groundwater levels and gradients in the deposit area.

Monthly water level monitoring was conducted in monitoring wells from 2005 through 2012 using manual water level probes; or calculated based on piezometric pressure measurements by vibrating wire piezometers and at measurement ports in the multi-level piezometer systems.

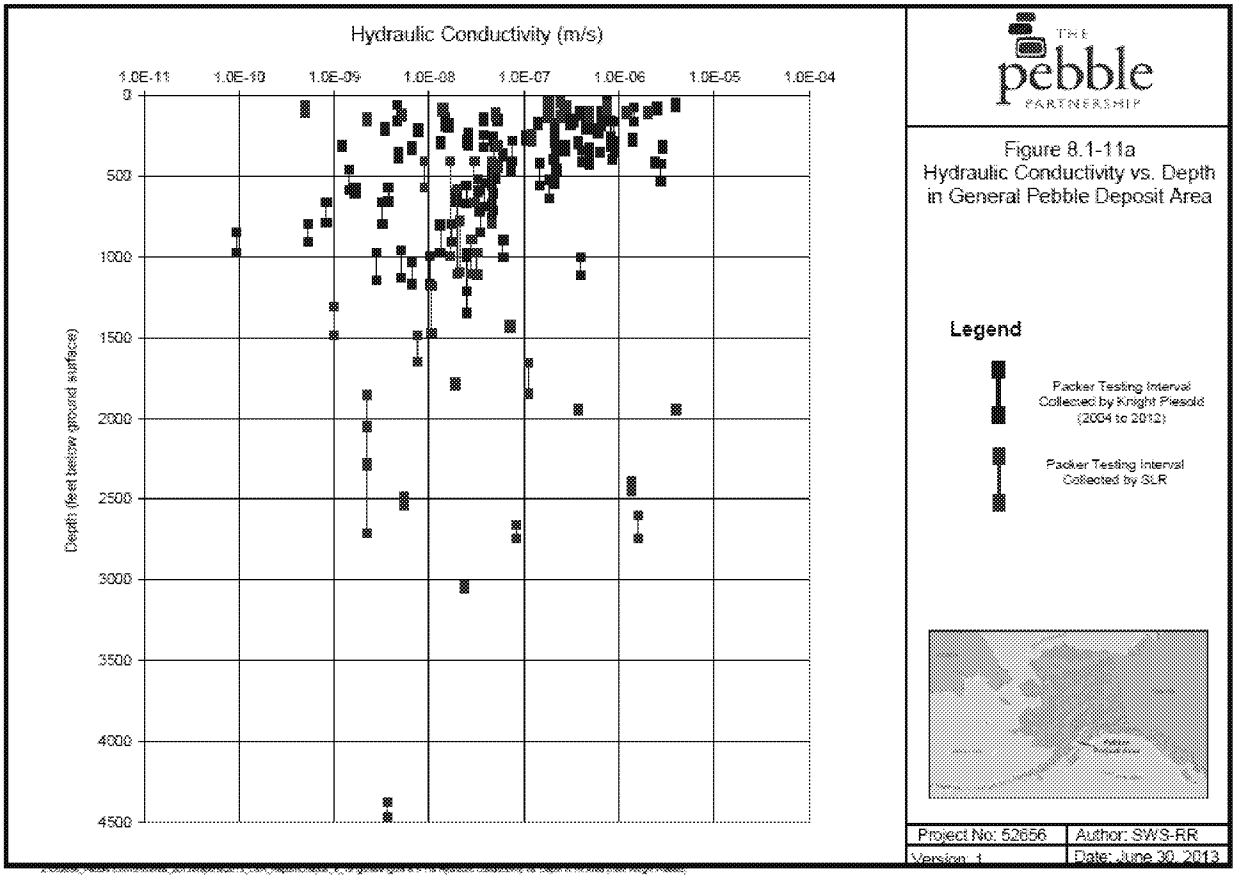
In support of the characterization of the physical groundwater flow system, a groundwater quality characterization program was also conducted. The program involved sampling of groundwater and seepage quality on a quarterly schedule, and is described in Section 3.18, Water and Sediment Quality. Field chemistry and flow measurements were collected at weirs to support development of the site water balance and water quality modeling.

K3.17.2 Aquifer Properties – Hydraulic Conductivity and Storativity

Table K3.17-1 and Figure K3.17-1 through Figure K3.17-3 provide a summary of hydraulic conductivity testing conducted at the mine site, based on individual testing results presented in Schlumberger (2015).

Table K3.17-1: Summary of Hydraulic Conductivity Testing Results

Hydrostratigraphic Unit	Statistic	Hydraulic Conductivity (m/s)				
		Pebble Deposit Area	Frying Pan Lake Area	South Fork Koktuli Area	North Fork Koktuli Area	Upper Talarik Area
Overburden	Number of Tests	33	6	45	22	4
	Geometric Mean	2.23×10^{-5}	6.40×10^{-5}	1.00×10^{-4}	9.74×10^{-5}	1.05×10^{-5}
	Median	3.00×10^{-5}	3.25×10^{-4}	4.00×10^{-4}	3.00×10^{-4}	1.45×10^{-5}
	Maximum	1.30×10^{-3}	8.70×10^{-4}	1.00×10^{-3}	1.78×10^{-3}	4.24×10^{-5}
	Minimum	5.10×10^{-8}	6.10×10^{-8}	7.00×10^{-8}	7.80×10^{-9}	1.60×10^{-6}
Bedrock	Number of Tests	52	10	20	50	8
	Geometric Mean	1.78×10^{-5}	4.38×10^{-6}	2.00×10^{-5}	9.68×10^{-7}	1.86×10^{-6}



AMERICAN OVERSIGHT

Figure K3.17-3: Hydraulic Conductivity Profile for Deep Bedrock

Source: Schlumberger 2015, Figure 8.11.c

Based on a total of 110 response tests, the hydraulic conductivity of overburden ranges from 7.8×10^{-9} to 1.78×10^{-3} meters per second (m/s) in the mine site. The hydraulic conductivity of overburden is similar throughout the mine site, with geometric mean values between 1.05×10^{-5}

AMERICAN OVERSIGHT

m/s and $1.0x10^{-4}$ m/s for each area. Hydraulic conductivity values for overburden materials in the Pebble deposit and Upper Talarik Creek (UTC) areas were an order of magnitude lower than those measured in the rest of the mine site based on the median values, likely due to the presence of silty deposits in this area.

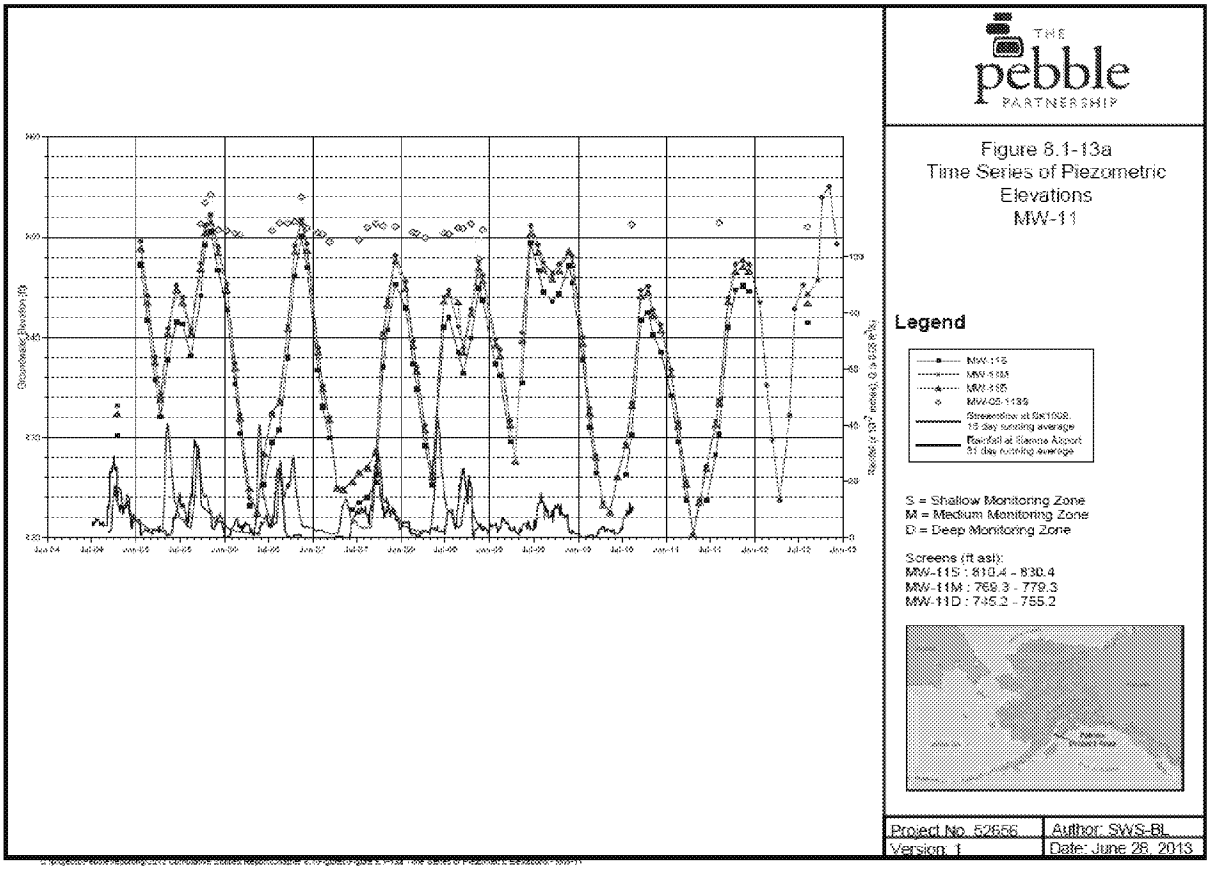
Based on a total of 140 response tests, the hydraulic conductivity of bedrock ranges from $9.4x10^{-9}$ to $3.0x10^{-3}$ m/s in the mine site. Similar to overburden, the hydraulic conductivity of the bedrock is about the same throughout the mine site, with geometric mean values between $9.7x10^{-7}$ and $2.0x10^{-5}$ m/s. Hydraulic conductivity values for bedrock in the Pebble deposit and SFK areas are about 1 to 2 orders of magnitude higher than those measured in the NFK and UTC areas, possibly due to the presence of batholith granodiorite in parts of these areas.

Larger-scale hydraulic conductivity values were also assessed by conducting a total of nine pumping tests, and found that the hydraulic conductivity of overburden was almost 10 times higher than values derived from response tests (Schlumberger 2011). Pumping rates ranged from approximately 10 to 356 gallons per minute (gpm), and water level responses were observed at significant distances from the pumping well, allowing for a more robust analysis of transmissivity (hydraulic conductivity) and storativity (specific yield) parameters for individual aquifers than possible using response testing and packer testing alone. Detailed analyses and results are presented in Schlumberger (2011: Table 8.1-6). Calculated transmissivity values ranged from $8.0x10^{-5}$ to $1.1x10^{-1}$ m/s, indicating the aquifers are capable of conveying moderate to large quantities of groundwater. Calculated storativity values ranged from $1x10^{-5}$ to $2.5x10^{-2}$, which indicates the ability of individual aquifers to store water is moderate to high overall, but is limited for some aquifers. This indicates that response testing underestimates the hydraulic conductivity of the aquifer, which may be due to restrictions placed on pumping associated with the well screen, surrounding sand filter pack, and/or borehole damage during drilling. Pumping test results for wells completed in bedrock were similar to those for response tests.

Hydraulic conductivity values were also measured by conducting borehole packer testing and Lugeon tests as part of geotechnical investigations to depths of up to 4,500 feet near the Pebble deposit, and at depths of up to 400 feet outside of the deposit area. The highest values were typically measured in the upper 500 feet, but similar values were also measured at considerable depths. Overall, bedrock hydraulic conductivity values are lower at depth than shallow bedrock in the deposit area.

Deep bedrock was investigated through the installation of three Westbay multi-level groundwater monitoring systems (WB-1, WB-3, and WB-4) at three locations to depths of 4,054 feet, 600 feet and 2,250 feet, respectively.

K3.17.3 Groundwater Flow Systems



Hydrographs of monitoring well (MW) MW-11 (SFK Flats area) and MW-5 (Pebble deposit area) are presented on Figure K3.17-4 and Figure K3.17-5 to illustrate seasonal and vertical groundwater level fluctuations. These examples show groundwater levels from three to four different screened intervals over a 9-year period compared to precipitation and stream flow.

The water table typically lies at the greatest depths below upland areas, and is near the surface in valley bottoms. The lowest groundwater levels were typically recorded in late winter immediately prior to spring freshet, while the highest water levels were typically observed during spring freshet or during fall rains, with water levels fluctuating on the order of 10 feet to 20 feet seasonally. Vertical groundwater gradients were found to be variable in both time and with depth, and generally support the conceptual model of compartmentalized groundwater flow. Similar to groundwater levels, measured discharge from seeps varied by a factor of between 3 and 10 seasonally, with a median flow of 44 gpm.

AMERICAN OVERSIGHT

Based on the results of tritium analysis, the majority of the groundwater in mine site aquifers likely recharged after 1972, which indicates that groundwater moves through the aquifers relatively quickly. This interpretation is supported by the measurement of relatively high hydraulic conductivities in overburden and shallow bedrock, and the seasonal behavior of groundwater levels in response to rainfall and snowmelt.

K3.17.4 Site Water Balance Model

A detailed description of the site baseline Water Balance Model (WBM) is provided in Schlumberger (2011: Appendix 8.1I). The model was also used to validate the meteoric data and the variability in precipitation across the site. Continuous streamflow records from a total of 12 gauging stations were used to calibrate the model from 2004 to 2008. Sub-catchments were delineated and drainage areas calculated for each gauging station. Inputs to the model and calibration are further described in Section 3.16, Surface Water Hydrology.

The results of the WBM indicate that groundwater recharge varies from 11 to 23 inches per year for the NFK River, UTC, and SFK River drainage areas. The majority of groundwater that recharges in each catchment tends to discharge to surface within the same drainage, with the exception of the inter-catchment transfer of approximately 6 inches per year that occurs between the SFK River and UTC drainages.

In 2018, the water balance model has been recalibrated and climate variability was incorporated to a larger degree than earlier baseline efforts with development of a 76-year synthetic record of monthly temperature and precipitation as described in the hydrometeorology report (Knight Piésold 2018g).

AMERICAN OVERSIGHT

K3.17.5 Mine Site Groundwater Model

The groundwater model domain encompasses the majority of the mine site and sub-catchments that were included in the WBM. The complex site geology was translated into the groundwater model using a five-layer structure, with three layers to represent variably thick overburden units, one layer to represent the uppermost 50 feet of bedrock, and one layer for the underlying bedrock to an elevation of -200 feet amsl.

Because groundwater levels and flow exhibit strong seasonality, the model was developed as a transient model with a simulation period of 37 months, from December 2004 to December 2007, to coincide with the WBM. The primary objective was to simulate the behavior of the groundwater flow system in the upper reaches of the SFK River, the UTC tributary UT1.190, and the upper reaches of the NFK River. The calibration effort was focused on the SFK River area, where data are most abundant.

The calibrated groundwater model produced water table elevations that follow the same general pattern as field measurements, and also reproduced inter-catchment flows between the SFK River catchment and UTC catchment UT1.190. A total of 220 piezometers, with up to 35 measurements prior to 2008 each, were used to calibrate hydraulic heads and calculate hydraulic head residuals to judge the calibration of the model. Focus was placed on calibrating the model to periods of time when the aquifer was stressed during pumping tests.

Simulated groundwater elevations were very similar to measured groundwater elevations, as shown in Schlumberger (2011: Figure 8.1-20), whereby an ideal calibration is represented by equivalent modeled and measured hydraulic heads to produce a straight line. Hydraulic heads in bedrock beneath upland areas are predicted to be slightly lower by the model than measurements. When plotted over time, hydraulic head residuals continually increased in some areas, highlighting opportunities for model refinement; while in other areas, the model produced uniform residuals over the simulation period.

Calculated calibration statistics produced a Root Mean Squared Error (RMSE) of 3 percent, with values ranging between 4 and 12 percent for the focus areas of calibration, suggesting that calibration could be improved in the SFK discharge and tributary UT1.190 areas. RMSE values ranged from 5 to 25 percent for areas in the model domain that were not the focus of calibration. Lower RMSE values generally indicate a good match between the model and actual field data. The largest errors at the mine site typically occurred in the bedrock layers. The model was generally able to reproduce measurements of groundwater elevations over time, but was unable to reproduce the range of measured seasonal hydraulic head fluctuations near Frying Pan Lake, where fine sediments may not be adequately reflected in the numerical groundwater model. Although the average direction of vertical flow between overburden and bedrock was well simulated by the model, the seasonality of vertical hydraulic head differences was not well replicated by the model, and will be the focus of the next phase of calibration.

Recharge and discharge rates estimated by the groundwater model agreed fairly well with estimates calculated in the WBM. However, additional refinements are planned for some areas in the SFK River catchment where the WBM and groundwater model were not in agreement. The groundwater model simulates the exchange of water between streams and groundwater, and model estimates were compared with streamflow measurements during periods of time when flows were low, and primarily groundwater-derived. Overall, the groundwater model was able to reproduce measured hydraulic head calibration targets, and was in general agreement with recharge rates, inter-catchment flows, and local groundwater discharge rates estimated by the WBM with a reasonable degree of accuracy.

K3.18 WATER AND SEDIMENT QUALITY

This appendix contains supplemental technical information on the following topics related to baseline surface water, groundwater, and substrate/sediment quality discussed in Section 3.18:

- Water and sediment quality criteria used to compare to existing and predicted future conditions.
- Geochemistry sampling program, rationale, data summaries, and time period predictions.
- Surface water data tables and trend analyses for the mine site, north access route, and Iliamna Lake.
- Water quality information for Cook Inlet at Iliamna/Iniskin estuary north of Amakdedori port.
- Groundwater well completions and data summary for the mine site.
- Sediment quality data for the mine site and north access route.

K3.18.1 Criteria

This section provides a description of water and sediment quality criteria used in comparison to baseline and predicted future data to assess where conditions might exceed standards for protection of aquatic resources or human health.

K3.18.1.1 Surface Water Quality Criteria

In Alaska, surface water quality is regulated by Alaska Department of Environmental Conservation (ADEC) under 18 Alaska Administrative Code (AAC) 70, Water Quality Standards (WQS). Table K3.18-1 provides a list of the most stringent applicable WQS.

US Environmental Protection Agency (EPA) provides oversight of WQS selection under the Clean Water Act (CWA) (65 Federal Regulations [FR] 24643). In 2004, EPA partially approved revisions to the WQS, while taking no action on Alaska's proposed acute and chronic freshwater aquatic life criteria for mercury and selenium. Therefore, the new aquatic life criteria for mercury and selenium will not be in effect for CWA purposes until a decision is made by EPA about whether these criteria can be approved. In the interim, the previously approved aquatic life criteria for mercury (2.4 micrograms per liter [µg/l] acute and 0.012 µg/l chronic, both as total recoverable) and selenium (20 µg/l acute and 5 µg/l chronic, both as total recoverable) will remain the applicable CWA standards.

In instances where the Alaska WQS have been approved by EPA, water quality in this section is described in relation to Alaska WQS, which include use classifications, numeric and narrative water quality criteria, and an anti-degradation policy. The usage classification system designates the beneficial uses that each waterbody in the state of Alaska is expected to support. In Alaska, all waterbodies are designated for all protected water use classes unless otherwise stated (18 AAC 70.050). The water quality data presented in this appendix are compared to the most stringent applicable State of Alaska water and sediment quality standards (for all designated water uses) listed in Table K3.18-1.

Table K3.18-1: Criteria Used for Comparison to Water and Sediment Quality Data

Water Quality[a]				Sediment Quality[b]	
Parameter[c]	Unit	Most Stringent Criteria	Basis	TEL	PEL
pH	-	6.5 - 8.5	WQS-GP	-	-
TSS	mg/L	20	ELG-MA	-	-
DO	mg/L	> = 7.0	WQS-GP	-	-
Turbidity (NTU)	NTU	<= 5 NTU above natural turbidity	WQS-WS	-	-
Alkalinity	µg/L	> = 20,000	WQBEL-ALC	-	-
Ammonia as N (NH3)	mg/L	4.36	WQBEL-ALC	-	-
Hardness (as CaCO3)	mg/L	~=100		-	-
Sulfate	mg/L	250	WQS	-	-
Alkalinity as CaCO3	mg/L	20	ALC	-	-
Total ammonia as N	mg/L	0.18	ALC	-	-

Notes:

a: Water quality limits are based on the lowest 15th percentile hardness of the three proposed discharge locations.

b: Sediment quality units = parts per billion

c: WQBEL is the most stringent among total and dissolved criteria for all metals, unless otherwise specified.

d: ADEC has determined that the WAD cyanide method is to be used for analysis and the result is to be applied to the free cyanide criterion.

Abbreviations:

WQBEL: Water Quality Based Effluent Limit

ELG: Effluent Limitation Guideline

(H): Hardness dependent criterion

(S): Selenite + Selenate dependent criterion

WQS: Water Quality Standards

HH: Human Health

ALA: Aquatic Life, Acute

ALC: Aquatic Life, Chronic

DW: Drinking Water

MA: Monthly Average

GP: Growth and Propagation of Fish

IR: Irrigation water

WS: Water supply

Criteria for some dissolved metals, including cadmium, chromium, copper, lead, nickel, silver, and zinc, are hardness-dependent, meaning that the acceptable concentrations of these metals depend on the hardness of the water. Hardness is a measure of the concentration of polyvalent cations in the water, such as calcium (Ca2+) and magnesium (Mg2+). The polyvalent cations that contribute to water hardness reduce the bioavailability of certain trace metals by competing with the trace metal ions for binding sites within organisms. The extent of this effect varies according to which dissolved metals are present, and their oxidation states. To account for the

AMERICAN OVERSIGHT

influence of water hardness on the bioavailability and potential toxicity of certain dissolved metals, the numeric water quality criteria for those metals are calculated so that the allowable concentrations of the metals increase in proportion to the hardness of the water (ADEC 2008a). Therefore, the numeric water quality criteria for hardness-dependent parameters vary depending on the measured (or predicted) hardness value for the specific water in question. Hardness parameters are based on the lowest 15th percentile of hardness measured at the three proposed discharge locations for the project, which are located in tributaries to the North Fork Koktuli (NFK), South Fork Koktuli (SFK), and Upper Talarik Creek (UTC) (Figure 2-3).

The ADEC numeric water quality standard for ammonia depends on both the temperature and the pH of the water, but not hardness.

K3.18.1.2 Groundwater Quality Criteria

As specified in 18 AAC 70.050(a)(2), groundwater is protected for all uses in Class (1)(A), including drinking, culinary, and food processing; agriculture, including irrigation and stock watering; aquaculture; and industrial uses. ADEC also regulates discharges to groundwater under 18 AAC 72 (wastewater disposal); releases to groundwater from contaminated sites under 18 AAC 75 (oil and hazardous substances); and discharge of non-domestic wastewater to groundwater, or discharge of groundwater to surface water, under 18 AAC 83 (APDES program).

Drinking water from groundwater sources is regulated by 18 AAC 80 (ADEC 2012c) and by EPA (2013k, 2017c). EPA sets standards for approximately 90 contaminants in drinking water. These standards include National Primary Drinking Water Regulations, which become legally enforceable Maximum Contaminant Levels (MCLs) for public water systems in Alaska once adopted by 18 AAC 80. Primary standards protect public health by limiting the levels of contaminants in drinking water. Secondary Drinking Water Standards are unenforceable federal guidelines regarding taste, odor, color, and certain other effects of drinking water. EPA MCLs for certain constituents (e.g., aluminum, chloride, iron, manganese, pH, sulfate, total dissolved solids [TDS], and zinc) are Secondary Drinking Water Regulations that set non-mandatory water quality standards.

Because groundwater at the mine site is intended to be extracted and discharged to surface waterbodies, or could migrate to surface waterbodies or groundwater drinking water sources, the most stringent of either WQS aquatic life criteria or drinking water standards (Table K3.18-1) are used for the purposes of comparison to existing and future groundwater conditions.

K3.18.1.3 Sediment Quality Criteria

There are no regulations established for chemical concentrations in sediment. Sediment Quality Guidelines (SQGs) recommended by ADEC (2013d) for use at contaminated sites were used for comparison purposes to project area data (Table K3.18-1). These include Threshold Effects Levels (TELs) and Probable Effects Levels (PELs) published in NOAA Screening Quick Reference Tables for both fresh and marine water sediment (Buchman 2008). TELs are concentrations below which adverse effects of benthic organisms are expected to occur rarely, and PELs represent concentrations above which effects are expected to be frequent.

K3.18.2 Geochemistry

This section contains additional technical information on the following topics related to geochemical characterization of the Pebble deposit and its potential for weathering and release of constituents to water and sediment resources:

AMERICAN OVERSIGHT

- Geochemical data summary
- Waste rock characteristics
- Tailings analyses
- Construction rock fill
- Open pit block model

The geochemical evaluation presented in Section 3.18 primarily relies on data presented in SRK (2011a, 2018a, 2018b, 2018c, and 2018d). These data were developed using representative overburden, rock cores, and metallurgical waste (tailings) samples from the Pebble east and west zones (PEZ and PWZ), and rock core samples from borings drilled in three proposed construction rock quarry areas. Geochemical characterization includes sample mineralogy and static and kinetic tests including acid base accounting (ABA), metal mobility, humidity cell, subaqueous leach columns, stored bag weathering, and field barrel tests.

A total of 1,080 overburden and pre-Tertiary and Tertiary rock core samples from various rock and alteration types within the Pebble deposit, 60 tailings samples from metallurgical process test runs, and 138 rock core samples from boreholes drilled at the proposed construction quarries have been tested to date. Of the 1,080 rock samples tested, 685 were assigned by PLP geologists to a hydrothermal alteration zone within the deposit. A summary of the rock and tailings samples geochemically characterized is provided in Table K3.18-2.

Table K3.18-2: Summary of Rock and Tailings Geochemical Testing Program

Test	Waste Rock Test Count					Tailings Test Count
	Pebble West Zone		Pebble East Zone		Overburden	
	Pre-Tertiary	Tertiary	Pre-Tertiary	Tertiary		
Acid-base Accounting	500	145	202	200	26	103
Mineralogya	19	13	15	13	0	20

K3.18.2.1 Waste Rock Geochemical Characteristics

The objectives of the geochemical characterization program were to predict the weathering and leaching behavior of rock, tailings, and other materials that would be produced during mining and processing. Data produced from geochemical testing are used to predict the chemistry of waters that contact the rock exposed in the open pit, and the waste rock and tailings stored in the TSFs, and determine their ARD/ML potential.

AMERICAN OVERSIGHT

Samples for geochemical testing were selected from the numerous exploration cores drilled to outline the deposit. The samples included all the main Pebble deposit rock types, and adjacent rock types that might be removed during mining. As of 2018, the program had included analysis of over 1,000 rock samples from the Pebble deposit, and 26 samples of overburden materials. In addition, almost 60 tailings samples comprised mostly of rougher, cleaner scavenger, pyritic, and gold plant tails, from test processing of ore composites have also been characterized. To date, limited geochemical testing has been performed on the representative concentrate because possible designs for a metallurgical process are still at an investigative stage.

The rock samples were tested for mineral abundance using transmitted and reflected light microscopy, and ARD potential, bulk chemical composition, and constituent mobility. Geochemical tests have included ABA, sequential net acid generation, shake flask extractions, meteoric water mobility, humidity cells, subaqueous (saturated) leach columns, and on-site field weathering (barrel and bag) tests to evaluate rates of oxidation, acid generation, acid neutralization, and element leaching.

In some mineralized deposits, rock type alone can be a good indicator of whether a rock will potentially produce ARD and/or ML. There are two main geological divisions at the proposed mine site. The mineralization is hosted by sedimentary and volcanic rocks of pre-Tertiary age. After the pre-Tertiary occurrence of mineralization, those rocks were partially eroded, then covered by other sedimentary and volcanic rock later in the Tertiary period. The later Tertiary age rocks at the mine site generally do not contain copper, gold, or other metals that would be economically viable to recover at the present time (SRK 2011a and 2011b; SRK 2018a).

For the proposed project, the neutralization potential (NP) and acidification potential (AP) terms were developed through extensive study of the chemistry and mineralogy of the various rock types at the site. This included ABA using the modified Sobek et al. (1978) method on more than 1,000 rock samples collected from drill holes blanketing the proposed mine area. The mineralogical characterization included analysis of samples by thin section, Rietveld X-ray diffraction (XRD), and/or ion microprobe to determine carbonate and sulfide mineral compositions. Based on mineralogical analysis, the NP in the pre-Tertiary rocks was found to be mainly dolomite, with lesser amounts of calcite, ankerite, and magnesite. NP in Tertiary rocks is primarily derived from calcite. Siderite was found in both the pre-Tertiary and Tertiary rocks, but does not contribute to NP. The AP was found to be mainly pyrite and chalcopyrite, and lesser amounts of molybdenite. Pyrite is the predominant source of acidity in both pre-Tertiary and Tertiary rocks.

ABA is a series of laboratory tests designed to estimate a rock's AP and NP. Both AP and NP are expressed in units of tons of calcium carbonate equivalent per 1,000 tons of material (tCaCO3/kt) to allow direct comparisons. Corrections are made when the respective minerals are not all pyrite or calcite. Table K3.18-3 provides a summary of the ABA results for waste rock grouped by lithologic type. ABA determined that the pre-Tertiary mineralized sedimentary and plutonic rocks at the proposed mine site are predominantly potentially acid generating (PAG). The AP of these rocks is relatively high because they contain several percent pyrite, as indicated by the total sulfur content of greater than 1 percent, and they have limited NP. The distribution of pyrite (and consequently acid generating potential) was found to be influenced by the hydrothermal alteration zones overprinted on the deposit.

In contrast, the majority of the Tertiary age and younger rocks that comprise the cover and overburden materials at the proposed mine site are considered non-PAG because they have less than 1 percent pyrite, low total sulfur concentrations less than 0.1 percent, and excess NP because carbonate minerals are abundant. However, a small proportion of the Tertiary volcanic rocks were found to be PAG.

AMERICAN OVERSIGHT

The most common measure of whether a rock is non-PAG or PAG is its ratio of NP to AP. To develop an understanding of weathering and leaching processes that might affect rocks exposed during mining (e.g., pit walls and stockpiled waste rock and tailings), additional laboratory and field geochemical tests were conducted. Laboratory tests included humidity cell, subaqueous (saturated) column, stored bag, and field barrel tests.

Humidity cell test results were used to confirm ABA criteria for segregating PAG from non-PAG rocks and waste, based on the NP to AP ratio. Analysis of the ABA and humidity cell data indicates that PAG and NAG rocks can be distinguished using an NP/AP ratio of 1.4 (SRK 2018a), and is applicable to pre-Tertiary, Tertiary, and overburden materials. Humidity cell test data obtained for periods up to 8 years allow interpretation of long-term acid generation potential and neutralization rates as the rocks are oxidized and leached during wet and dry cycles. Humidity cell tests also help to estimate the potential lag or delay in the onset of ARD using the sulfide oxidation and release rates and pH profiles. The delay occurs because acid-neutralizing minerals (e.g., calcite, feldspars, and micas) are not depleted instantly as acid is formed, but are consumed at different rates depending on their reactivity and abundance.

Results show that pre-Tertiary rocks with low NP/AP ratios (less than 0.3) have little neutralization potential and are estimated to generate acid within 1 to 6 years (SRK 2018a). Pre-Tertiary rocks with NP/AP ratios of 1 have higher neutralization potential, which delays the estimated onset of acid generation to 8 to 20 years (SRK 2018a). These estimated times to onset of ARD are considered underestimates because they are based on data developed under controlled laboratory conditions. Paste pH results for aged rock cores stored at the site suggest that acidification may be delayed up to 40 years. Given differences in the test conditions, laboratory and field tests suggest that oxidized pre-Tertiary mineralized rock may take up to several decades for acidification to occur.

Element release rates determined from kinetic tests were mainly a function of leachate pH rather than the concentration of elements in the samples. Leaching of copper accelerated as pH decreased; therefore, the potential for metal release is linked to the potential for acid generation, and ABA data can be used to assess the potential for copper leaching. However, for some elements (e.g., arsenic, molybdenum, and selenium), release can be environmentally significant under neutral pH conditions. Tests on some samples of Tertiary rock showed elevated leaching of these elements under non-acidic conditions. These leaching data, along with baseline water quality data, are being used with other inputs to develop geochemical source terms for water quality modeling and water treatment planning (SRK 2018c).

AMERICAN OVERSIGHT

K3.18.2.2 Tailings and Supernatant Geochemical Characteristics

A total of 59 tailings samples from concurrent metallurgical process test runs have been geochemically characterized. Samples analyzed included rougher tails and rougher tail blends from various hydrothermal alteration zones, blends of rougher and pyritic tails, and first cleaner scavenger, pyrite rougher, combined rougher, and gold plant tails. Most of the tailings samples tested represent rougher tails, which will be the most volumetrically abundant tailings. All of the tailings samples were analyzed using ABA and total metals methods. ABA tests included paste pH, total, sulfate, and sulfide sulfur, AP, Sobek and modified NP, fizz test, total inorganic carbon, and carbon dioxide. Total metals were determined using a four-acid digestion. A subset of samples were analyzed using optical mineralogy and x-ray diffraction methods and humidity cell, subaqueous column leach column, and field barrel tests.

Mineralogy determinations indicate that the rougher tailings are dominated by potassium and plagioclase feldspars (about 67 percent), quartz (about 12 percent), muscovite and biotite (about 13 percent), carbonate minerals (about 4 percent), and trace hematite, pyrite, and rutile. ABA tests indicate that the rougher tails have total sulfur contents ranging between 0.3 and 1.3 percent, primarily as sulfide sulfur. Other tailings products (pyritic tails, blends with pyritic tails, and gold plant tails) had total sulfur contents up to 31.6 percent (gold plant tails), which are also dominated by sulfide sulfur. AP ranged from 0.9 to 980 kilograms $CaCO_3$ per ton ($kgCaCO_3/t$). NP was generally less than 20 $kgCaCO_3/t$, with a maximum NP of 54 $kgCaCO_3/t$.

Figure K3.18-1 provides an AP versus NP graph for the tailings. While some tailings samples are classified as non-PAG, a large number of samples are considered PAG. The sulfide sulfur content of the tailings exerts a strong control on the NP/AP ratio, where NP/AP values below 2 are associated with sulfide sulfur contents greater than 0.2 percent. The rougher tails typically have low to moderate total sulfur and are predicted to be non-PAG, provided the sulfide content remains below 0.2 percent. The pyritic and gold plant tailings have higher sulfide contents and are often classified as PAG.

Tailings supernatant analyses are summarized in Table K3.18-4. Results indicate that the supernatants have a pH of 8, are dominated by major ions (Ca, Mg, Na, K, sulfate, and alkalinity), and generally low trace metal concentrations (Mn, As, Co, Cu, Mo, Ni, Sb, Se, and Zn).

AMERICAN OVERSIGHT

K3.18.2.3 Construction Rockfill Geochemical Characteristics

Construction rockfill will be obtained from quarries in Cretaceous-age granodiorite located outside of the footprint of the proposed mine. To evaluate the potential needs to manage the rock geochemistry and to estimate contact water quality, PLP tested rock from boreholes in three proposed quarry locations designated A, B, and C. The first phase of testing involved continuous sampling of core by PLP at 10-foot intervals from two boreholes drilled in each quarry, for a total of six boreholes. The core was tested using a multi-element scan (including sulfur) following a four-acid digestion. A total of 138 samples were analyzed: 50 samples from quarry A, 41 samples from quarry B, and 47 samples from quarry C. The results obtained to date are summarized in SRK (2018c) and provided in Table K3.18-5.

The results demonstrate that the quarry rock is dominated by unmineralized granodiorite, which would be geochemically suitable for use as construction fill due to its low metal leaching and ARD potential and is classified as non-PAG. It is expected that weathering of the granodiorite would be expected to yield contact water chemistry comparable to that observed in natural surface water and groundwater. However, hydrothermally altered zones with elevated metal concentrations may have the potential for leaching of metals and possibly ARD potential, and would need to be segregated using an operational monitoring program and not used as construction fill.

Table K3.18-5: Statistical Summary by Quarry for Selected Elements

Quarry	n	Statistic (percentiles)	As (mg/kg)	Cu (mg/kg)	Mo (mg/kg)	S (%)	Se (mg/kg)	Zn (mg/kg)

K3.18.2.4 Open Pit Block Model

Because of the geochemical variability in the rocks, assessment of impacts resulting from geochemical processes requires consideration of the disposition and fate of the material that would be mined each year. The annual area mined can be estimated by developing an open pit block model. A block model is a computer model that shows the three-dimensional distribution of rock types and their likely order of excavation within the open pit as mining progresses. The

AMERICAN OVERSIGHT

mined rock is assessed based on its PAG and non-PAG characteristics, and whether the material would be processed and end up in tailings, or not processed and set aside as waste rock.

[Note: This section will be updated when requested information on the open pit block model is received.]

K3.18.3 Surface Water Quality

K3.18.3.1 Data Tables

This section contains baseline surface water data for parts of the project area that would be most affected by project activities. These include:

- Table K3.18-6 through Table K3.18-9: surface water data for the NFK and SFK watersheds, UTC, and Frying Pan Lake, respectively. These waterbodies would receive discharge from mine site water treatment plants (WTPs).
- Table K3.18-10 and Table K3.18-11: surface water data for the western and eastern parts of the north access route transportation corridor, respectively.
- Table K3.18-12: water quality data for Iliamna Lake, which would be crossed by project ferry traffic.

Baseline data for other mine area surface waterbodies are available in Pebble Environmental Baseline Documents (EBDs) (ERM [2018: Tables 9.1-15 through 9.1-24] and Schlumberger et al. [2011: Tables 9.1-31 through 9.1-36]), and incorporated here by reference.

Table K3.18-6 through Table K3.18-11 provide the range of detected results, along with the mean and standard deviation of each detected analyte. Table K3.18-12 provides a summary of the Iliamna Lake data as a range of mean values for groups of sampling stations in the following locations: north ferry terminal, south ferry terminal, Iliamna village area, and east end of Iliamna Lake. Results exceeding the most stringent criteria listed in Table K3.18-1 are shown in bold on the data tables.

Mine Site

Table K3.18-6 through Table K3.18-9 summarize data used for characterization of surface water quality at the mine site.

Transportation Corridor

Table K3.18-10 and Table K3.18-11 summarize data used for characterization of surface water quality along the upland area of the west and east parts of the northern access route, respectively, which are pertinent to Alternatives 2 and 3. The samples were divided on the basis of geology: samples west of GS-11A (Figure 3.18-4) are located in an area of Quaternary surficial deposits over volcanic and sedimentary rocks, while samples to the east are located in an area of exposed intrusive bedrock (Schlumberger et al. 2011a).

Table K3.18-12 summarizes surface water quality data for Iliamna Lake, which are grouped as follows: near the mouth of UTC (Alternative 1 North ferry terminal area), Iliamna village area (pertinent to Alternatives 1 and 2–Eagle Bay ferry terminal area), Pedro Bay area (pertinent to Alternatives 2 and 3, pipeline and road routes, respectively), and Pile Bay (pertinent to Alternative 2 ferry terminal) (Figure 3.18-5).

K3.18.3.2 Trend Analysis at Mine Site

Some differences in water quality between watersheds and trends in water quality along streams were noted. Table K3.18-13 through Table K3.18-15 summarize observed spatial trends in the NFK, SFK, and UTC, respectively. Tau values represent the correlation coefficient, or how strongly the data trend. Negative tau values indicate an inverse relationship between constituents and distance downstream, and positive tau values indicate that constituents increase in concentration as distance downstream increases.

Statistical methods were employed to determine whether spatial trends in constituents increase or decrease in a statistically significant way, or remain stable (no significant trend in data). P-values, or probability values, represent the probability that the null hypothesis (i.e., no significant trend in data for a given model) is true. When analyzing data, a p-value of 0.05 is the threshold for statistical significance. Trends with a p-value calculated to be less 0.05 are statistically significant, indicating that observed spatial trends are real. Field and physical parameters with p-values calculated to be greater than 0.05 display trends that are not statistically significant, and indicate a stable spatial distribution of data.

K3.18.3.3 Cook Inlet: Iliamna/Iniskin Estuary

This section contains additional water quality information for the portion of Cook Inlet north of Kamishak Bay that pertains to the port area for the north access route under Alternatives 2 and 3.

Salinity Gradient. Water quality in the Iliamna/Iniskin estuary, located about 30 miles north of the Amakdedori port site, was studied in 2004 through 2012 by Pentec et al (2011) and Hart Crowser (2015). Water quality in this area appeared to be dominated by tidal exchange with Cook Inlet and Kamishak Bay, with smaller, localized effects from freshwater inputs and local wind waves. Observed gradients in salinity between the inner (lower salinity) and outer (higher salinity) portions of Iliamna Bay are consistent with this conclusion. Average salinity was observed to decrease from the outer stations of Iliamna Bay to the inner stations. This is likely a result of freshwater inputs at the head of Iliamna Bay. Salinity decreases from spring to late

AMERICAN OVERSIGHT

summer, and increases again in the fall, thereby providing an additional indicator of the influence of regional water on the bays. A certain amount of stratification was observed during both the spring snowmelt season and during the warmer summer months, particularly during calmer weather and in more sheltered portions of the bays.

Snowmelt or significant rain events create a freshwater surface lens a few inches deep in areas adjacent to freshwater inputs; these lenses rapidly diminish as a result of tidal and wind driven mixing.

Suspended Particulates/Turbidity. Analysis of available data indicates that turbidity is generally moderate, and does not exhibit any obvious trends that indicate point-source inputs. Average turbidity for the Iliamna/Iniskin stations ranged between 3.1 and 75 Nephelometric Turbidity Units (NTU). Monthly mean turbidity was relatively constant over the study period, with occasional high turbidity corresponding to months in which generally windy conditions prevailed.

Organics and Inorganics. Analyses of hydrocarbon concentrations in marine water from the Iliamna/Iniskin estuary in 2004, and of metal and trace element concentrations in 2008 to 2012, showed little to no connection to anthropogenic effects. With the exception of boron and iron, concentrations of inorganic constituents were less than water quality criteria recommended by the EPA and others for marine habitat (Buchanan 2008), many by orders of magnitude. Boron exceeded the chronic marine water quality criterion at all sample stations, and iron was elevated at one of four sample locations in bottom waters only. Organic constituents were similarly at low levels, and appeared to be derived from biologic, petrogenic, and anthropogenic sources.

The data provide some support for a relationship between increased concentrations of inorganic constituents and TSS, but demonstrate no strong patterns with respect to depth in the water column, to geography, or to tidal elevation.

K3.18.4 Groundwater Quality

The following baseline groundwater data tables are provided in this appendix:

- Table K3.18-16 provides a list of wells completed within and outside of the deposit area, along with watershed, screened intervals, and lithologies.
- Table K3.18-17 provides the results of groundwater quality testing summarized as a range of mean values for individual wells within each lithologic group. Results exceeding the most stringent criteria listed in Table K3.18-1 are shown in bold.

Notes:

a: Nested wells refer to multiple screened wells residing within a single borehole at varying depths.

b: Relative depth: D=deep, M=medium, S=shallow

Source: Schlumberger 2015b

c: Numbers in parentheses represent depth to the bottom of the well in feet. Screen length is typically 10 ft.

d: Bedrock contact refers to the disturbed and weathered region of bedrock which can be up to 50 ft thick. These regions have been documented under the lower slopes and valley bottoms throughout the project area (Knight Piésold 2018a).

K3.18.5 Sediment Quality

The following baseline groundwater data tables are provided in this appendix:

- Table K3.18-18 provides a summary of the sediment quality data collected at the mine site.
- Table K3.18-19 provides a summary of the sediment quality data collected in Iliamna Lake as a range of mean values for sampling stations in the following areas: Iliamna village area, and Pedro and Pile bays at the east end of the lake (Alternatives 2 and 3).

K4.18 WATER AND SEDIMENT QUALITY

This appendix contains additional technical information on the following topics related to mine site impacts to surface water, groundwater, and substrate/sediment quality described in Section 4.18:

- Water quality modeling
- Water treatment plant (WTP) methodologies

K4.18.1 Water Quality Modeling

This section provides a description and analysis of modelling conducted at the mine site to estimate the chemical content of water stored in onsite facilities and provide source information for preliminary design of WTPs.

K4.18.1.1 Operations

A water balance model for the operations period of the mine was developed by Knight Piésold (2018a) using GoldSim® software and is based on the conceptual 20-year life of mine footprint shown on Figure 4.16-1. The water balance model is comprised of three modules, the watershed, groundwater, and mine plan modules. The mine plan module is representative of the movement of water in the mine system and it uses inputs from the watershed and groundwater modules. The mine plan module estimates the amount of water to be managed at the mine site during the operations phase of the mine under a full range of historic climate conditions. Climate variability is incorporated in the model using a 76-year synthetic time series of monthly temperature and precipitation values to simulate the cyclical nature of the climate record. The model generated 76 unique sets of monthly water flow and storage results for each year. Three of these model runs were selected to represent dry, average, and wet climate conditions and illustrate the range of potential flows for the mine site under these varying conditions. Details regarding the water balance model inputs and assumptions are provided in Knight Piésold (2018a). Table K4.18-1 (Knight Piésold 2018a: Table 4.3) summarizes average predicted monthly and annual total release from the WTPs to downstream of the mine site for relatively dry, average, and relatively wet climate conditions. The annual average flows for dry, average, and wet periods range from 20 to 29 to 32 cfs, respectively.

A water quality model for the operations period was also developed in GoldSim® by Knight Piésold (2018a) using a mass balance approach to estimate constituent loading in and out of each of the mine facilities, including the water balance model developed in GoldSim®. The water quality model is used to predict the influent water quality to the water treatment plants and the water quality in the water management ponds (WMPs), under varying climate conditions. The water quality model is coupled with the water balance model to estimate constituent loads under completely mixed, steady-state conditions during operations at the mine site. The model was developed using a mass balance approach considering the inflow, outflow, and storage flow volumes and constituent concentrations in the WMPs to calculate constituent loads. Geochemical source term inputs for the water quality model were developed by SRK Consulting (Canada) Inc. (SRK) (2018a). Table K4.18-2 provides the predicted water quality from various geochemical sources at the mine site that were used as inputs to the water quality model.

AMERICAN OVERSIGHT

Table K4.18-3 shows the predicted water quality in mine site facility ponds during operations from the Knight Piesold (2018a) water quality model. Values in the table represent the maximum monthly predicted concentrations for the 50th percentile flow values and the 95th percentile source term concentrations for flows going to the WTPs from each facility for the final year of operations. Water quality feeding the WTPs is primarily controlled by the constituent concentrations from open pit WMP for WTP#1 and the main WMP for WTP#2. The water quality predictions for WTP#1 are dominated by loading from open pit dewatering. The maximum predicted concentrations in the open pit WMP occur during the summer months because of the in-pit stockpile loads from the open pit. The influent water quality to WTP #1 is expected to gradually worsen each year of mine activity as more pre-Tertiary age rock is exposed to oxygen and water. Thus, pit wall runoff in early years of mining is expected to be of better quality than at end of mine life (i.e., after 20 years). To be conservative, the water quality estimate for end of mine life was used in all simulations to represent all years of mining.

The main WMP manages surplus water from the mine site. The majority of the loading to the main WMP is primarily from the bulk and pyritic tailings storage facilities (TSFs). The maximum predicted concentrations in the main WMP are, however, less than in the bulk and pyritic TSFs because of the continuous removal of loads from the main WMP via reclaim water that is directed to the process plant and to WTP#2. The bulk tailings slurry water drives the loading in the bulk TSF supernatant pond. Similarly, the pyritic tailings slurry water drives the majority of loading in the pyritic TSF, with both sludge reject and reverse osmosis (RO) reject flows from the WTPs contributing to the loading. The flushing load from potentially acid generating (PAG) waste rock in the pyritic TSF provides loading to the pyritic TSF supernatant pond; however, the load from the PAG waste rock is not as great as that from the tailing slurry water. Water collected at the mine site that does not meet discharge water quality criteria would be treated in the WTPs prior to discharge to the environment. Treated water in excess of process requirements would be released to the environment in the North Fork Koktuli (NFK) and South Fork Koktuli (SFK) rivers and the Upper Talarik Creek (UTC) watersheds at flows protective of the environment to the extent possible given the capacities of the WTPs and need for process water use onsite. Impacts on flows in these watersheds are discussed in Section 4.16, Surface Water Hydrology, and Section 4.24, Fish Values.

K4.18.1.2 Closure and Post-Closure

The closure strategy for the mine site is to decommission and reclaim facilities that leave the mine site in a stable condition that complies with regulations and closure criteria and prevents unnecessary degradation of the land and water resources. To assess closure effectiveness, a water balance and water quality model for the closure and post-closure periods of the mine was developed by Knight Piésold (2018d) using GoldSim® software and is based on a four-phase closure plan as outlined below:

- Phase 1 – reclamation of quarries and bulk TSF, backfilling of open pit by closure year 15.
- Phase2 – bulk TSF and quarries reclaimed, backfilling of open pit complete, reclamation of pyritic TSF and main WMP, no water treatment in closure years 16 through approximately 20.
- Phase 3 – pyritic TSF and main WMP reclaimed, ongoing treatment of surplus water in open pit in closure years 20 through 50.
- Phase 4 – post-closure long-term conditions.

The closure and post-closure water balance model was developed similar to the operations model to estimate water flow volumes for the various facilities during the closure phases under

AMERICAN OVERSIGHT

varying historical climate conditions. Details regarding the closure and post-closure water balance and quality model inputs and assumptions are provided in Knight Piésold (2018d).

Notes:

a: End of mine life maximum monthly 50th Percentile results based on 76 realizations of model simulations.

b: Model input concentrations provided by SRK (dated 20 June 2018).

AMERICAN OVERSIGHT

c: Model assumes loading from in-pit stockpile in the open pit during summer months.

d: Tailings pond adjustment values were applied for Al, SO4, Fe, Cu and Mn in the bulk and pyritic TSFs.

e: Model assumes return of sludge and reject flows from WTP#1 and WTP#2 to the pyritic TSF via the pyritic tailings line. WTP effluent, sludge, and reject concentrations were provided by HDR (dated 4 January 2018).

f: Model assumes loading from PAG waste rock in the pyritic TSF as a flushing term provided by SRK (dated 20 June 2018).

g: pH was not modelled; pH values are based on the range of pH source terms provided by SRK (dated 20 June 2018).

h: TDS values were calculated by summing alkalinity, Cl, F, SO4, Ca, Mg, K, Na, and Si.

i: Bold values indicate exceedances of most stringent water quality parameters (Table K3.18-1).

j: Hardness values were calculated based on the equation, hardness (CaCO3) = calcium concentration (mg/l) x 2.497 + magnesium concentration (mg/L) x 4.118.

AMERICAN OVERSIGHT

The primary water sources during closure include the main WMP, the WTPs, and the open pit. The results of the closure and post-closure water balance model are summarized in Figure K4.18-1 through Figure K4.18-3. Figure K4.18-1 shows the estimated 10th, 50th, 90th, and 99th percentile open pit water surface elevations during closure. The approximate elevations of the PAG waste rock and pyritic tailings are also shown for reference. Figure K418-1 shows that it will take 19 to 21 years to fill the open pit to the maximum management (MM) level depending on climatic conditions. The MM level is set at 890 ft msl, 10 ft below the not to exceed (NTE) level of 900 ft (Piteau 2018), so that the open pit can store the probable maximum flood (PMF) without encroaching on the NTE level. The NTE level is set below the static groundwater level so that the open pit functions as a hydraulic sink maintaining groundwater flow towards the pit. The average annual water surplus from the open pit is about 3 cfs. Surplus water from the open pit will be pumped and treated to maintain the water surface elevation below the MM level throughout post-closure.

Figure K4.18-2 shows the estimated 10th, 50th, 90th, and 99th percentile pond volumes for the main WMP in early closure. The results depicted on this figure indicate that the main WMP has the capacity to manage the surplus water from the mine site during closure phases 1 and 2, when the bulk and pyritic TSF are being reclaimed. The water in the main WMP is estimated to operate below the maximum operating pond capacity at all times during closure.

Table K4.18-4 and Figure K4.18-3 show the estimated average annual flows and flow volumes from the WTPs during closure. With the exception of phase 2 when no water treatment would be required (pyritic TSF and main WMP are empty and pit lake still rising), these results indicate that the total amount of water treatment required is greatest during the early closure phases when the mine site footprint is larger, and lowest during closure phase 4 once all the mine facilities are reclaimed and the only water being treated is surplus pumped from the open pit to maintain water levels. The total flow releases from the WTPs is estimated to vary from a high of 58 cfs during closure phase 1 to a low of 3 cfs during closure phase 4. The total flow released downstream of the mine site is a combination of freshwater from the diversion channels, surface runoff from reclaimed facilities, and treated water from the water treatment plants. The WTP flows are estimated to vary with historical climatic patterns.

A closure and post-closure water quality model was developed in GoldSim by Knight-Piésold (2018d). It is coupled with the closure and post-closure water balance model to calculate constituent loads in the various mine facilities under completely mixed, steady-state conditions. Details regarding the predicted water quality model inputs and assumptions in closure and post-closure are provided in Knight-Piésold (2018d).

The maximum monthly predicted constituent concentrations within each facility for the four project closure and post-closure phases are provided in Tables K4.18-5 through K4.18-8. The bolded values in these tables indicate where predicted constituent concentrations exceed the discharge water quality criteria, and will therefore require treatment at the water treatment plants. Figure K4.18-4 shows the 50th percentile water quality predictions (based on 95th percentile source terms) for alkalinity, antimony, copper, cadmium, molybdenum, manganese, sulfate, and zinc for the bulk TSF supernatant pond at the end of closure phase 3 and the beginning of closure phase 4. The predicted water quality in closure Year 50 meets discharge water quality criteria for all parameters modeled except for alkalinity which has a minimum criterion of 20 mg/L. The water quality of the supernatant pond will be monitored and surplus water from precipitation events will only be discharged from the bulk TSF to the downstream NFK catchment once it meets discharge water quality criteria.

AMERICAN OVERSIGHT

Figure K4.18-4: Bulk TSF Pond Water Quality Predictions – Closure Phases 3 and 4

AMERICAN OVERSIGHT

K4.18.1.3 Pit Lake

Once mining ceases, partial dewatering of the open pit would be continued to maintain pit wall stability to allow some PAG waste rock to be moved from the pyritic TSF to the pit until the waste rock buttresses the lower walls of the pit. The pyritic tailings would then be re-slurried and pumped to the open pit for sub-aqueous disposal. The water level in the open pit will be maintained to allow controlled placement and management of the PAG waste rock while keeping a water cover over the pyritic tailings. Backhauling of the PAG waste rock would end approximately 14 years into closure and the pyritic tailings transfer would end about 15 years into closure. Dewatering of the open pit would cease at the end of closure phase 1 once the transfer of these materials is complete. Once dewatering ceases, groundwater behind the pit walls would begin to rise to create a pit lake. The open pit would then be allowed to fill with surface water runoff and groundwater, but would be kept at the designated maximum management level (890 ft msl) so that groundwater continues to flow into the open pit and it remains as a hydraulic sink. The maximum management level also allows sufficient storage for the PMF.

Surface runoff into the pit lake could cause metals to leach from the pit walls. In addition, contaminated groundwater would flow into the pit. As a result, water quality in the pit lake would be expected to be acidic, with elevated concentrations of total dissolved solids (TDS), sulfate, and some metals (Sb, As, Cd, Cu, Pb, Mn, Hg, Mo, Ni, Se, and Zn) released from the oxidation of sulfide minerals in the pit walls and the natural concentrations of metals found in the mineralized rock that exceed water quality standards. The predicted water quality in the pit lake after closure is provided in Table K4.18-5 through Table K4.18-8.

[Note: Additional information on pit lake modeling, lake stratification, and its effects on water quality will be added following completion of response to RFI 021c.]

K4.18.2 Water Treatment Methodologies

This section contains additional technical information on the water treatment methodologies and WTPs that would operate at the mine site during the operations and closure phases. A high-level review of current WTP design was conducted to assess the effectiveness of the planned water treatment approach at meeting water treatment goals. The results of that review are detailed in a memo prepared by AECOM and dated October 18, 2018 (AECOM 2018i), and summarized in the discussion below.

Water treatment during operations: Two WTPs are planned during operations: WTP#1 and WTP#2. WTP#1 would treat water from the open pit WMP and discharge treated water to the environment, and WTP#2 would treat water from the main WMP and discharge most to the environment, and a limited amount would be used as process water for the power plant and mill site.

Variable water treatment rates would be required to manage surplus water from the mine site under differing climate conditions, with higher treatment rates during extended wet periods and lower treatment rates during extended dry periods. The treatment rates for WTP#1 and WTP#2 would be dictated by the volumes of water stored in the open pit WMP and the main WMP, respectively (Knight Piésold 2018a).

Water treatment during closure: Two WTPs are planned for operation at various stages during closure: WTP#2, and WTP#3, which would be converted and re-designated from the open pit WMP (WTP#1). WTP#2 would continue to treat water from the main WMP through phase 1 of closure (years 0 to 15), at which point it would be decommissioned. WTP#3 would treat surplus water from the open pit while PAG waste rock and pyritic tailings are being

AMERICAN OVERSIGHT

transferred (phase 1), and while the surplus water from the bulk TSF supernatant pond and main seepage collection pond (SCP) are collected within the open pit between years 20 and 50 (phase 3). WTP#3 would also operate as necessary during phase 4 (year 50 and beyond) to maintain the water level in the open pit below the not-to-exceed level, and to manage any additional surplus water from the bulk TSF main SCP. No water treatment would be necessary during phase 2 (years 16 to 20) as no discharge to the environment is planned as the open pit fills (Knight Piésold 2018d).

Specific details of the operation and treatment process that would be employed by each WTP are discussed in the following sections.

The operation of the WTPs would utilize an automated control system using supervisory control and data acquisition (SCADA) to monitor and adjust treatment operations. The SCADA system would also provide information and alarms to the treatment plant operations staff. Specific details of the operational strategy and control system are not available at this time and would typically be completed in a later phase of project engineering.

K4.18.2.1 Main Water Treatment Plant

The main WTP (WTP#2) would operate during the production phase, and through phase 1 of closure, and would treat water from the main WMP which would receive water from the bulk and pyritic TSF ponds and the bulk TSF main embankment SCP (Knight Piésold 2018d, HDR 2018a). WTP#2 would have four treatment trains to meet the influent flow of 29 cfs and enable ongoing water treatment during mechanical interruption of any one train (HDR 2018a). Key treatment steps would occur in the following sequence (HDR 2018a):

1. Dissolved metals would be oxidized with air, ferric sulfate, and potassium permanganate, followed by co-precipitation with lime. Flocculators/clarifiers would be used to separate out co-precipitated solids. Co-precipitation of metals is a common treatment strategy in mining and is currently used in multiple locations. The process can experience upset if the chemical addition processes are not monitored and adjusted.
2. The clarified water would flow into a membrane feed tank, where sodium hydrogen sulfide or an organosulfide would be added to complete the precipitation process. Supplemental lime and sulfuric acid would be added as needed to maintain pH for optimal precipitation and membrane feed. Organosulfide is a process to precipitate trace metals and has been used in similar applications in other industries. The process can be disrupted due to competition if the upstream co-precipitation process is not properly maintained, leading to excessive metal ions that compete for the sulfide reactant.
3. Ultrafiltration membranes would be used to filter precipitated metals and protect downstream high-pressure membranes. Ultrafiltration is a barrier process for solids that has been used in similar applications at other mining and industrial locations. The process can be disrupted by fouling if the membrane system is not properly monitored and maintained, or if the upstream processes are upset in a manner that results in excessive solids in the influent.
4. High-pressure membranes (nanofiltration) would provide removal of metals, calcium, magnesium, and sulfate. Filtrate from the high-pressure membranes may require an alkalinity adjustment before discharge. Nanofiltration is a TDS removal process that has been used in similar applications at other mining and industrial locations. The process can be disrupted if the membrane system is not properly monitored and

AMERICAN OVERSIGHT

maintained, or if the upstream processes are upset in a manner that results in excessive TDS in the influent.

5. Reject from the high-pressure membranes would have a high concentration of sulfate and other divalent ions. To prevent overloading the mine water balance with sulfate, some sulfate must be removed from the reject before its disposal in the TSF. Sulfate would be removed as calcium sulfate process. Precipitated calcium sulfate solids would be disposed of in the pyritic TSF. Water quality analysis has indicated that the conditions in the pyritic TSF should prevent redissolution of the calcium sulfate solids. Lime softening is common method to reduce calcium and sulfate that has been used at other mining and industrial applications. The process can be upset by high levels of TDS.
6. Decant from the calcium sulfate precipitation process would contain high levels of TDS. It would be necessary to split the decant stream as follows:
   A. Approximately three-quarters of the decant stream would be returned to the beginning of the WTP for reprocessing. This approach is common in lime softening and allows for additional precipitation of calcium and sulfate, but it may also result in significant return of TDS that could negatively impact the process.
   B. The remainder of the decant stream will be concentrated with a reverse osmosis (RO) system. RO filtrate would be blended with nanofiltration permeate for discharge. Concentrated RO reject water would be sent to an evaporator for further concentration of the TDS. The liquid stream of the concentrated TDS will be transferred to the pyritic TSF. The evaporate is condensed and the condensate blended with treated water from the nanofiltration membranes (step 4) for discharge. This methodology is not regularly practiced due to the high cost of evaporation. Further, there may be concern that high TDS water return could increase the TDS of decant from the pyritic TSF.

K4.18.2.2 Open Pit Water Treatment Plant

The open pit WTP (WTP#1) would operate through production to treat water from the open pit WMP, which would receive water primarily from dewatering of the pit. WTP#1 would have two treatment trains to meet the influent flow of 14 cfs and enable ongoing water treatment during mechanical interruption of any one train (HDR 2018a). Water in the open pit WMP is expected to be significantly lower in TDS than the main WMP (Knight Piésold 2018d). Key treatment steps would occur in the following sequence:

1. Dissolved metals would be oxidized with potassium permanganate, followed by co-precipitation with ferric chloride. Sodium hydroxide and hydrochloric acid would be added as needed to maintain pH for optimal precipitation. Flocculators/clarifiers would be used to separate out the co-precipitated solids.
2. Clarified water would then be treated with sodium hydrogen sulfide, sodium hydroxide, and ferrous sulfate to further co-precipitate remaining metals under reducing conditions.
3. Water from the sulfide reaction tanks would be filtered to remove precipitated metals. The sulfide reaction will primarily impact dissolved metals and is not expected to significantly alter the other properties of the water such as pH or alkalinity. The filtered water is expected to be suitable for discharge.
4. Clarifier solids and filter backwash would be thickened and transferred to the TSF.

AMERICAN OVERSIGHT

5. Water from the sulfide reaction tanks would be filtered with ultrafiltration (UF) membranes to remove precipitated metals. Reject from the UF membranes would be thickened and transferred to the pyritic TSF.
6. A portion of the UF membrane filtered water would be treated by RO to remove selenium, and that treated stream will be recombined with the main effluent to achieve acceptable discharge limits.
7. Reject brine from the RO process, which would be high in selenium, would be further treated with a biologic reactor to separate selenium as a solid precipitate. Selenium solids would be separated in flocculators/clarifiers, thickened with other solids, and transferred to the pyritic TSF.

K4.18.2.3 Closure Water Treatment Plant

During closure, WTP#1 would be reconfigured and re-designated as WTP#3, with the open pit partially backfilled with materials that were temporarily stored in the pyritic TSF during operations (HDR 2018a). WTP#3 would treat surplus water from the open pit while PAG waste rock and pyritic tailings are being transferred during phase 1 of closure (closure years 0 through 15), and while the surplus water from the bulk TSF and main SCP are collected in the open pit to form the pit lake during phase 3 of closure (closure years 20 through 50). WTP#3 would also operate as necessary during phase 4 of closure (closure year 50 and beyond) to maintain the water level in the pit lake and to manage any additional contact water from the bulk TSF or main SCP (Knight Piésold 2018d). Current preliminary design information for WTP#3 does not identify changes in treatment processes.

K4.18.2.4 Water Quality of WTP Discharge

The predicted quality of discharge water from both WTPs in operations is provided in Table K4.18-9, and from the WTP in closure in Table K4.18-10. Based on a comparison of the data to most stringent discharge limits shown in Table K3.18-1, discharge water is currently expected to meet Alaska Department of Environmental Conservation (ADEC) criteria. However, based on the independent review conducted of the water treatment approach (AECOM 2018i), there is some concern that waste products high in selenium and salt placed in the pyritic TSF may, over time, lead to increased TDS concentrations in the main WMP, and thereby affect the inflow conditions to the main WTP (WTP#2). Such a change in condition of the inflow to the WTPs may warrant additional WTP design consideration, or development of adaptive management strategies to ensure that mine site WTPs are capable of and effective at meeting treatment goals over the duration of time that treatment will be required.

K4.18.3 Dust Deposition Methodologies

This section describes the methodology used to calculate potential increases in surface water from both direct deposition to waterbodies and runoff from dust in soil. The methodology for calculating incremental increases in the top inch of soil from dust deposition is provided in Appendix K4.14, Soils.

Potential increases of metal concentration in soil at the mine site were estimated using AERMOD modeling data for airborne metals concentrations (hazardous air pollutants [HAPs]) and dust deposition provided by Pebble Limited Partnership (PLP) (PLP 2018-RFI 009). The Environmental Protection Agency (EPA) defines ambient air as the portion of the atmosphere, external to buildings, to which the general public has access (40 CFR 50.1 (e)). For this reason, airborne metal concentration was modeled along the mine site's ambient air boundary to find the maximum cumulative concentration of metals bordering the ambient environment. Dust deposition was modeled by extrapolating from the upper-bound airborne concentration to calculate deposition values (PLP 2018-RFI 009). The incremental increase metals concentration in mine site soil over the 20 year life of the mine was calculated using the following:

$$Cs = 100 t_D * \left(\frac{D}{Z_S * B_D}\right);$$

AMERICAN OVERSIGHT

(Equation K4.14-1 [EPA 2005])

where Cs is the average soil concentration of the constituent of potential concern (COPC) over the exposure duration (mg COPC/kg soil), D is the yearly dry deposition rate, tD is the time period over which deposition occurs (years), Zs is the soil mixing zone depth (cm), BD is the soil bulk density (g/cm3), and 100 is a unit conversion factor. By adding this to baseline soil concentrations, the predicted constituent soil concentration was calculated after the 20-year life of the mine due to operational dust fall.

K4.18.3.1 Sediment/Substrate

Baseline sediment quality data are presented in Appendix K3.18. Dust deposition impacts to sediment/substrate quality at the mine site were calculated following the same approach as for soils, outlined in Appendix K4.14, Soils. Baseline dry weight sediment quality data for the mine site (Appendix K3.18) was used for this analysis, as well as the same default parameters for sediment bulk density and mixing zone. Table K4.18-11 provides the results of dust deposition impacts to sediment quality, including the percent increase in metals concentration and total estimated concentration of metals in sediment after the 20-year life of mining operations.

Air deposition represents the primary source of site-related contamination to waterbodies, with metals partitioning to both sediment and surface water. The equation used below conservatively assumes all of the metals from air deposition partition to sediment. Although this modeling does not account for overland runoff, metals' contributions from this pathway to nearby waterbodies are expected to be minor, as most of the site is covered with vegetation (not paved or bare soil), minimizing the potential for overland transport. Furthermore, baseline metals concentrations in soil and sediment are similar; therefore, any soil particles washing off into the waterbody would not likely introduce higher metals concentrations than are already present in the waterbody (i.e., mixing of similar concentrations would result in similar concentrations).

e: Bold values indicate exceedances of the most stringent water quality criteria (Table K3.18-1).

AMERICAN OVERSIGHT

K4.18.3.2 Surface Water

Table K418-12 provides the results of the estimated increase in metals concentrations in surface water from dust deposition at the mine site. The 20-year total and dissolved concentrations due to dust deposition were calculated as follows:

$$Total\ SW_{20yr} = \frac{SD_{20yr}}{R_{total}};\ Dissolved\ SW_{20yr} = \frac{SD_{20yr}}{R_{dissolved}}$$

(Equation K4.18-1)

where SW_{20yr} is the surface water concentration (total and dissolved respectively) after 20 years of operations, SD_{20yr} is the sediment concentration after 20 years of operations, and R is a site-specific relationship representing the ratio of sediment to surface water. R is defined as follows:

$$R_{total} = \frac{SD_{BL}}{SW_{BL(total)}};\ R_{dissolved} = \frac{SD_{BL}}{SW_{BL(dissolved)}}$$

(Equation K4.18-2)

where SD_{BL} is the baseline sediment concentration and SW_{BL} is the baseline surface water concentration. This approach allows the estimation of impacts to surface water quality for the length of mining operations. This methodology was applied to mine site related surface water sources including the NFK, SFK, UTC, and Frying Pan Lake. Mean values of sediment and surface water metals concentrations were used for this analysis. This approach was developed as a semi-quantitative approach to be analogous to the EPA surface water pathway approach using chemical-specific soil-water partition coefficients (K_d) (e.g., Allison and Allison 2005).

f: Bold values indicate exceedances of the most stringent water quality criteria (Table K3.18-1).

AMERICAN OVERSIGHT

K4.18.3.3 Groundwater

Table K4.18-13 displays baseline and predicted soil concentrations of HAPs metals due to dust compared to ADEC migration to groundwater levels. The ADEC levels represent soil concentrations at which there is potential risk for substances to leach to groundwater and potentially result in a completed human health exposure pathway (ADEC 2017). This approach was used to examine potential impacts to groundwater from dust deposition.

Table K4.18-13: Predicted Change in Groundwater Quality from Dust Deposition

Analyte	Baseline[a]	Soil Concentration Post-Dust Deposition			Comparative Action Levels[d]
	Soil Concentration Mean (mg/kg)	Incremental Increase over 20 Years (mg/kg)[b,c]	Baseline + 20 Years Dust Deposition	% Increase after 20 years	Migration to Groundwater (mg/kg)

AMERICAN OVERSIGHT

3.17 HYDROGEOLOGY

This section addresses hydrogeology – the study of distribution and movement of groundwater in soil, sediment, and rock beneath the ground surface. Groundwater is water that is held in the openings (pore space) of soil and sediment and in openings (faults, joints, fissures) in bedrock. Groundwater recharge (input) may occur through precipitation migrating to the groundwater (e.g., snowmelt, rainfall). In addition, surface water features (e.g., streams, ponds) may "leak" water into the ground and then to the groundwater. Groundwater discharge (output) is generally to surface water features (e.g., streams, ponds, seeps). Whether surface water features contribute to groundwater (losing stream) or receive groundwater flow (gaining stream) depends on factors such as precipitation, groundwater and surface water levels, the ability of the subsurface material to transmit water (permeability), and may vary seasonally as water levels fluctuate with seasonal precipitation, or vary because of other influences such as pumping groundwater from nearby wells.

It is important to characterize the existing hydrogeology and define how the local groundwater flow system interacts with the regional (deeper) groundwater flow system, as well as characterize the nature and degree of interactions between groundwater and surface water to inform the understanding and characterization of aquatic, fish resource, and wetlands habitat.

Hydrostratigraphic units, groundwater flow systems, and aquifer properties are discussed in this section for the areas that could be most affected by the project. Section 3.16, Surface Water Hydrology addresses water use–both surface water and groundwater use to avoid redundancy. The mine site baseline and closure/post-closure groundwater models are also addressed in this section. Appendix K3.17 provides additional technical information to support or explain in greater detail the hydrogeological characterization programs (i.e., baseline studies), the methods of technical review, and conclusions presented in the body of the Environmental Impact Statement (EIS). Appendix K3.17 is frequently referenced where applicable. In addition, other sections in the EIS that support development of the hydrogeology discussion are cross-referenced to avoid redundancy.

3.17.1 Mine Site

This section describes existing hydrogeologic conditions in the mine site area (Figure 3.17-1) that are anticipated to be the most affected by project activities. For example, dewatering associated with the open pit would create a zone of influence around the area of the open pit where groundwater levels and groundwater quantity, groundwater/surface water interactions, and surface water flows would be affected. Other influences on groundwater and surface water levels and flow may include: groundwater seepage, and flow pathways away from the tailings storage facility (TSF) and water management ponds.

3.17.1.1 Hydrogeological Characterization Programs

Over the course of several field programs between 2004 and 2012 Schlumberger (2011 and 2015) collected hydrogeologic data (as well as geologic and groundwater quality data) on the mine site using various methods including: geologic mapping and characterization (Section 3.13, Geology), drilling and borehole logging, well and piezometer installation, pumping tests, permeability tests, streamflow measurements at gaging stations (See also Section 3.16, Surface Water Hydrology), monitoring of meteoric inputs (e.g., rainfall, snowfall), and routine measurement of groundwater levels.

AMERICAN OVERSIGHT

Figure 3.17-1: Mine Site Hydrogeology Study Area

AMERICAN OVERSIGHT

EPA-0135-0003538

These studies provide baseline data regarding hydrogeologic conditions at the mine site that form the basis of this EIS. Appendix K3.17 summarizes the data collection programs and methods. Details of these programs and data summaries are provided in Schlumberger (2011, 2015).

Figure 3.17-2 depicts locations of observation (i.e., monitoring) wells and piezometers, Figure 3.17-2 also depicts known groundwater seeps. Seeps occur as groundwater discharge to the surface where natural topography intersects the water table (groundwater surface). A seep can also occur if an excavated slope were to intersect the water table (e.g., at a road cut).

The objective of the previous studies was to determine key aspects of the local and regional groundwater flow systems including:

- Aquifer properties of the overburden and bedrock.
- Groundwater levels and gradients.
- Groundwater flow directions and rates.
- Interaction of local groundwater flow systems and regional flow system.
- Interaction and seasonality of groundwater and surface water systems.

The results of these characterization programs form the basis for a baseline water balance model (Schlumberger 2011, Appendix 8.1I), a baseline groundwater flow model (Schlumberger 2011, Appendix 8.1J), a groundwater model at the end of mining and post-closure (Piteau Associates 2018), and water balance and quality models for operations, closure, and post-closure (Knight Piésold 2018a, 2018b). The hydrogeologic characterization data and model results are used to inform water management planning, processes, and facility design for all phases of the project and provide the basis for this EIS.

3.17.1.2 Hydrostratigraphic Units

Topography is characterized by hills separated by wide valleys with elevations ranging to 2,500 feet amsl in the mine site to 46 feet amsl at Iliamna Lake. Weathered (highly fractured) bedrock is exposed at higher elevations (uplands), and below about 1,400 feet amsl, the valleys are covered with overburden, generally composed of glacial deposits, with some areas overlain by alluvial deposits. Composition of the overburden material varies both laterally and with depth, typical of areas where material has been transported and deposited by both ice and water, with interbedding and gradations between types of material (see Section 3.13, Geology). Figure 3.17-3 shows a schematic representation of the site-wide groundwater flow system and hydrostratigraphic units.

For the overburden, the grain size and size distribution (sorting or grading) of the sand and gravel particles are key characteristics used to define a hydrostratigraphic unit, or aquifer. For bedrock in the project area, aquifer characteristics are controlled by weathering (a high degree of fracturing from repeated freeze/thaw cycles in the upper bedrock), and in deeper bedrock by fault zones. The weathered bedrock is more permeable than the deeper more competent bedrock. The distribution and characteristics of the overburden and bedrock aquifers in the areas that would be most affected by the project are summarized in Table 3.17-1 by South Fork Koktuli (SFK), North Fork Koktuli (NFK), and Upper Talarik Creek (UTC) watersheds.

AMERICAN OVERSIGHT

Figure 3.17-2: Monitoring Well, Piezometer, and Seep Locations

AMERICAN OVERSIGHT

Figure 3.17-3: Schematic Representation of Site-Wide Groundwater System

AMERICAN OVERSIGHT

Geologic cross-sections (based on data obtained from drill holes) were developed to illustrate the subsurface distribution of hydrostratigraphic units in overburden and bedrock at the mine site (Schlumberger 2015: Appendix 8.1B). The cross-sections also show the model layers incorporated into the numerical groundwater flow model. Locations of four representative hydrogeologic cross-sections are shown on Figure 3.17-4. Hydrogeologic cross-sections are provided as Figure 3.17-5 through Figure 3.17-8 as follows:

- Figure 3.17-5: Cross-section E-10 – southwest-northeast section across the area between the Pebble deposit area and Frying Pan Lake.
- Figure 3.17-6: Cross-section L-1 – an approximately 10-mile section from the south side of the Pebble deposit area, along the SFK River through Frying Pan Lake, and across the drainage divide to the headwaters of Tributary UT1.190.
- Figure 3.17-7: Cross-section S-1 – north-south cross-section across the SFK River at the western end of the study area.
- Figure 3.17-8: Cross-section M1 – northwest-southeast cross-section across the NFK River, across the TSF main embankment pond and seepage collection pond to the east end of the TSF main embankment.

The cross-sections illustrate that the surficial geology (overburden) varies both laterally and with depth, which is consistent with regional geologic mapping and borehole logging. Shallow groundwater flow patterns in the overburden at seasonal low levels are illustrated in Figure 3.17-9.

The following narrative describes the hydrogeologic characteristics of areas that would be most affected by the project.

3.17.1.3 Hydrogeologic Characterization of the SFK and NFK River and UTC Drainages

Hydrogeology Overview

The hydrogeology of the mine site is largely comprised of adjacent uplands underlain by permeable weathered and fractured bedrock, talus, rubble, and solifluction deposits. The weathered and fractured bedrock, which is up to 50 feet thick, provides a pathway for elevated rates of groundwater recharge beneath these bedrock ridges. The upland weathered bedrock areas have limited groundwater storage capacity, which results in flashy streamflows and low groundwater baseflows. Below the weathered bedrock, bedrock permeability generally decreases with depth, but includes some higher permeability zones associated with faults. Many of the faults act as flow barriers, while others appear as flow conduits resulting in compartmentalized groundwater flow with the bedrock at depth. The compartments limit regional groundwater flow within the deep bedrock (Knight Piésold 2018a).

The lower upland slopes and valley bottoms are filled primarily with glacial deposits with some overlying alluvium deposits (overburden). The glacial deposits include low and high permeability sediments deposited as end, lateral, and recessional moraines, ground moraines, outwash sands and gravels, and glacio-lacustrine (glacial lake) deposits. The weathered bedrock is also found beneath the lower slopes and valley bottoms. Most of the groundwater storage occurs in the overburden which sustains winter base flow along most of the streams and rivers in the main valleys (Knight Piésold 2018a).

EPA-0135-0003548

Groundwater flow occurs along local and/or intermediate flow paths. There is limited regional groundwater flow to the surrounding outlying lowlands. The groundwater flow pattern is dominated by flow within the weathered bedrock from the uplands toward the overburden sediments in the valleys. The majority of groundwater flow occurs in the overburden deposits. Groundwater in the valley sediments typically flows downstream along the axis of the valley, predominantly in permeable sands and gravels and the underlying weathered and fractured bedrock. Except for some cross-catchment flow between the SFK River and UTC, most of the recharge water remains within each watershed and is discharged to streams along the valley bottoms. The large differences in overburden and weathered bedrock permeabilities, coupled with the varying topographic gradients in each watershed, result in variable local recharge rates (Knight Piésold 2018a).

Hydrogeologic Characterization across the SFK River Drainage South of the Pebble Deposit

Hydrogeologic cross-section E-10 (Figure 3.17-5), a southwest to northeast trending section, shows the hydrostratigraphy across the SFK River drainage south of the Pebble deposit and north of Frying Pan Lake. The overburden deposits consist of interbedded gravels, sands, silts, and clays that overlie the underlying weathered bedrock. Groundwater recharge rates in the SFK drainage basin (Areas 2 through 5 and 8) calculated using the site-wide water balance model ranged from 11.8 inches per year at the mine site (Area 3) to 46.8 inches per year along the SFK River downstream of Frying Pan Lake (Area 5) and averaged 24.2 inches per year (Schlumberger 2011).

Groundwater in this area flows from the upland recharge areas toward the valley floor where it discharges to the SFK River. Groundwater primarily flows through the overburden aquifers of sands and gravels and the uppermost 10 to 50 feet of weathered (fractured) bedrock before discharging to the SFK River. Groundwater gradients in the vicinity of the Pebble deposit are vertically upward with a minimal horizontal component, indicating that groundwater in the vicinity of the deposit locally discharges to the upper reaches of the SFK River, and is unlikely to flow across groundwater divides or migrate appreciable distances down the valley before discharging to surface water.

The weathered bedrock is highly fractured from physical weathering and is much more permeable than the more competent bedrock below. Deeper bedrock is less weathered and exhibits lower hydraulic conductivity values (a measure of the rate of water flow through the rock) to depths of at least 600 feet. Groundwater is controlled in the deeper bedrock by cross-cutting fractures and faults. Although fractures and faults are widespread in the deep bedrock, the features are often infilled with fine-grained fault gouge (blocking the flow) and are offset relative to one another (cross-cutting). The faults and fractures have resulted in formation of groundwater compartments (compartmentalized flow) in the deeper bedrock, thereby limiting the potential for substantial regional groundwater flow (Knight Piésold 2018l).

Hydrogeologic Characterization along the SFK River Drainage South of the Pebble Deposit

Hydrogeologic cross-section L-1 (Figure 3.17-6), a northeast-southwest trending section, also shows the hydrostratigraphy along the SFK River drainage south of the Pebble deposit and north of Frying Pan Lake. Overburden thickens from the Pebble deposit area toward Frying Pan Lake. Groundwater levels in shallow weathered and fractured bedrock (upper 50 feet of bedrock) exhibit stronger seasonal fluctuations than the overburden of sand and gravel. Groundwater gradients in the upper weathered bedrock are upward following periods of groundwater recharge in the upland areas, and downward during the months prior to seasonal

AMERICAN OVERSIGHT
EPA-0135-0003549

recharge events of heavier precipitation. This supports the conceptual model of groundwater flow involving recharge to the exposed weathered and fractured bedrock aquifer in upland areas, with subsequent migration toward valley bottoms, where the groundwater is eventually discharged to overlying surficial deposits or streams. A bedrock high (i.e., an area where the bedrock is higher than the surrounding bedrock surface; similar to a hill in surface topography) acts as a barrier to groundwater flow and the presence of low-permeability sediments at the downstream end of Frying Pan Lake generally limits discharge from Frying Pan Lake to the underlying groundwater flow system.

Hydrogeologic Characterization of the Frying Pan Lake Area and the Upper Reaches of Tributary UT1.190

The hydrogeology of the region from Frying Pan Lake to upper reaches of Tributary UT1.190 is also shown further south on hydrogeologic cross-section L-1 (Figure 3.17-6) Several overburden aquifers have been identified in this area and overburden thickness under Frying Pan Lake is about 150 feet thick. Just upstream of Frying Pan Lake are surficial aquifers of mainly clean sand and gravel. An intermediate aquifer is interpreted to occur in the overburden between silty deposits under most of the valley floor that thins to the east and south. A deeper overburden aquifer of sands and gravels overlies the weathered and fractured bedrock and thickens toward Frying Plan Lake, but is not continuous with the deep overburden aquifer in the Pebble deposit area. The most areal extensive aquifer in this area is the weathered and fractured shallow bedrock aquifer.

South of Frying Pan Lake, silty layers are absent along the SFK River where overburden consists of sand and gravel. Overburden is relatively thin as compared to beneath the lake and is permeable beneath most valley floors, with valley walls dominated by colluvium (coarse material originating from the slopes, such as angular pieces of bedrock) and shallow weathered and fractured shallow bedrock, with the exception of some local thin till deposits (a mixture of many grain size gradations, deposited by glacial ice).

Groundwater recharge in the Frying Pan Lake area is derived locally from the weathered and fractured shallow bedrock on uplands and on valley sides where recharge occurs on local topographic highs with discharge to ponds and streams. The valley floor is likely a groundwater discharge area; however, data indicate that during seasonal dry periods some of the valley floor recharges the lower sand and gravel aquifer and uppermost weathered and fractured shallow bedrock aquifer.

Groundwater at Frying Pan Lake is shallow and exhibits upward groundwater movement (groundwater discharge) toward the lake, while groundwater levels downstream of the lake are up to 60 feet below the stream bottom, indicating strong downward groundwater gradients and losses from the stream.

The results of groundwater level monitoring and a water balance assessment (Schlumberger 2011) suggests that approximately two-thirds of the groundwater flowing through the deep overburden aquifer downstream of Frying Pan Lake remains in the SFK River drainage, while the remaining one-third of the groundwater crosses the surface water drainage divide and contributes to groundwater flow in tributary UT1.190, and discharges to UTC. Figure 3.17-10 depicts the divergent groundwater flow along SFK River to UTC in the deep groundwater aquifer. The divergent groundwater flow pattern occurs during seasonal low and high water periods.

AMERICAN OVERSIGHT

Hydrogeologic Characterization of the SFK River Discharge Area

Hydrogeologic cross-section S-1 (Figure 3.17-7) shows the hydrostratigraphy along the SK1.190 drainage from north to south across the SFK River. The upper slopes are underlain by weathered and fractured bedrock. The mid slopes are mapped as colluvium and drift of the Pre-Brooks Lake glaciation. A 125 feet thick outwash gravel deposit occurs along the valley axis with adjoining terrace gravels. Response tests and sediment descriptions indicate that the gravels are very permeable ($3x10^{-5}$ to $6x10^{-4}$ meters per second [m/s]) in this area. The main aquifer along this portion of the SFK River is outwash sands and gravels and the terrace deposits and alluvium that infill the valley (Valley Aquifer).

Meteoric recharge is expected along the weathered and fractured bedrock ridges and through the overburden in the valley bottom. A large portion of precipitation falling on the outwash sand and gravels and the terrace deposits along the valley floor is expected to recharge the aquifer. Additional recharge occurs from stream channels as they flow into the valley, particularly from the large catchments, SK1.190 and SK 1.210. Similar but less concentrated recharge of groundwater is expected adjacent to the valley sand and gravel deposits where runoff and shallow groundwater exit the adjacent slopes.

A relatively large groundwater flow enters the SFK discharge area from the SFK River Flats area (Area 5). At times when the groundwater level is high, groundwater might discharge to the streambed near the boundary between Areas 5 and 4. However, during low-flow periods, the SFK River streambed is dry upstream of the confluence with tributary SK1.190. Additional water recharges the groundwater system in this area, both as direct recharge from rainfall and snowmelt and as run-on from adjoining slopes.

Immediately downstream of the confluence with tributary SK 1.190, groundwater discharges into the bottom of the stream channel. This discharge results from a reduction of the aquifer thickness and width in this area, and additional water contributed to the aquifer from SK1.190 and SK1.210. In the dry season, where little to no visible surface water flow is observed upstream of the confluence with tributary SK l.190, surface water flows in the SFK River ranges up to 50 cfs about 2.4 miles downstream of the confluence with SK1.190.

Hydrogeologic Characterization of the NFK River Drainage for Tributary NK1.190 (also known as Area G/ Bulk TSF drainage) Drainage Area 14

Hydrogeologic cross-section M-1 (Figure 3.17-8) shows the hydrostratigraphy from the upland slopes adjacent to the NK1.190 drainage northwest along the lower portion of the NK1.190 drainage and across the NFK River upstream of its confluence with NK1.190. The upland slopes are underlain by weathered and fractured bedrock and covered with a thin mantle of colluvium. Overburden is thin over much of the valley; however, several borings intercepted up to 100 feet of overburden. Response tests indicate that the overburden and the weathered and fractured shallow bedrock are very permeable.

Groundwater recharges on the upper slopes with some discharging to numerous sustained seeps at a range of elevations with the balance of groundwater flowing downward toward the stream channel in the center of the valley. Groundwater likely migrates downstream under the valley floor in the overburden and weathered and fractured shallow bedrock. Because the overburden is expected to be thin along the valley floor, most groundwater likely discharges to the streambed contributing to stream baseflow. Groundwater levels are expected to be near ground surface over much of the catchment and at or above the ground surface near the stream channel.

AMERICAN OVERSIGHT

Upstream of stream gage NK100C (see Section 3.16, Surface Water Hydrology, Figure 3.16-4), the headwater drainage area for the NFK River is overlain by glacial drift and materials deposited at the bottom of former glacial lakes that have resulted in relatively thin, but laterally continuous aquifers. A terminal glacial moraine is near the confluence of the main stem NFK River and Tributary NK1.190. At this location, the surficial deposits transition to coarser grained glacial outwash materials where the NFK River recharges the underlying aquifer.

The thin overburden limits groundwater recharge in this area. The average groundwater recharge rate calculated using the site-wide Water Balance Model (WBM) is 11 inches per year, the lowest rate of the three watersheds in the project area (groundwater recharge in the SFK watershed is estimated at 24 inches per year and UTC watershed at 16 inches per year).

Hydrogeologic Characterization of the NFK East (also known as Area E, Pyritic TSF)

Two aquifers are identified in this area: overburden aquifer of sand and gravel that underlies glacial till (which is less porous and permeable) and the shallow weathered and fractured bedrock. Groundwater recharge is derived at higher elevations on hillsides and hill tops where weathered and fractured bedrock is close to the surface or exposed. Groundwater flows downslope toward the valley and discharges in seeps in weathered and fractured bedrock and the sands and gravels of the valley floor. Many seeps have been identified along hillsides in this area and are likely caused by high recharge on the upper slopes and the variability of hydraulic conductivity and thickness of the weathered and fractured bedrock.

Hydrogeologic Characterization of the UTC Drainage

The only project features within the UTC drainage are the water treatment plant #1 (WTP#1) discharge and a portion of the mine site access road. Primary aquifers in this area are sands and gravels of glacial outwash upstream of gage UT100E and the shallow weathered and fractured bedrock.

Groundwater recharge is locally recharged on the hilltops and hillsides of weathered bedrock. Upstream of UT100E, UTC and tributaries contribute additional recharge to groundwater (losing streams). Recharge occurs through precipitation infiltrating the upper hillslopes and migrating downslope in the highly fractured shallow bedrock unit. The calculated average groundwater recharge rate is 14 inches per year. Where downslope groundwater movement is restricted by low-permeability sediments or discontinuities in the flow system, groundwater discharges to ground surface as seeps; seeps are abundant in this drainage, and often occur high on the hillslopes. Overburden deposits are variable in this drainage, and include silty sand and gravel to clean sand (low percentage of clay and silt) in the upper portion of the UTC drainage.

In the intermediate reaches of the drainage between UT1.135 and UT1.190, a large area has been filled with deltaic, glacial outwash, ice-contact sands, and sand and gravel. This area is inferred to be a groundwater recharge area. Tributary UT1.190 joins the UTC drainage downstream of the groundwater recharge area, and is inferred to transmit the majority of groundwater that migrates east from the SFK River drainage area across the surface water drainage divide into the UTC drainage area. Most of the groundwater moves downgradient in the sand and gravel units and the weathered upper bedrock. Steep vertical gradients have been observed in some areas, suggesting the presence of fine sediments that restrict downward movement of groundwater.

Upstream of UT 100B, groundwater inflow originating from the SFK drainage discharges into the UTC groundwater system (crossing under the surface watershed divide between SFK and

AMERICAN OVERSIGHT
EPA-0135-0003552

UTC). This flow is primarily through the intermediate aquifer in the SFK Flats area described in Table 3.17-1 and depicted on Figure 3.17-10.

AMERICAN OVERSIGHT

Table 3.17-1: Summary of Hydrostratigraphic Units

Drainage/ Catchment	Area/ Sub-Catchment (*Project Facility*)	Overburden or Bedrock	Aquifers	Description	Hydraulic Conductivity (K)
South Fork Koktuli Drainage	Pebble Deposit Area (*Open Pit*)	Overburden	Surficial Aquifer (multiple)	Clean sand (very little silt or clay) or sand and gravel. Beach, delta, and fan deposits.	K in overburden ranged from $5x10^{-8}$ to $1x10^{-3}$ m/s; geometric mean of $2x10^{-5}$ m/s; median of $3x10^{-5}$ m/s K in weathered bedrock ranged from $4x10^{-7}$ to $1x10^{-3}$ m/s; geometric mean of $2x10^{-5}$ m/s; median of $2x10^{-5}$ m/s
			Intermediate Aquifer	Sand and gravel between silty deposits. Located in two bedrock lows	
			Deep Aquifer	Sands and gravels in bedrock low on east side of deposit to depths of 163 ft. Based on pumping tests at PW-08-9 (Figure 3.17-2).	
		Bedrock	Weathered Bedrock Aquifer	Upper 10 to 50 ft of bedrock. Felsenmeer[1] or rock block field where exposed.	
			Upper Bedrock Aquifer	Below weathered bedrock, from 50 to 600 feet in depth. Considerably less permeable than weathered bedrock aquifer.	
			Fault Zones	Faults function as both conduits and barriers to groundwater flow (i.e., compartmentalized flow).	
	Frying Pan Lake Area (*South WTP Discharge*)	Overburden	Surficial Aquifer (multiple)	Clean sand; sand and gravel. Largest is fan delta upstream of Frying Pan Lake.	K in overburden ranged from $6x10^{-8}$ to $9x10^{-4}$ m/s; geometric mean of $6x10^{-5}$ m/s; median of $3x10^{-4}$ m/s K in weathered bedrock ranged from $2x10^{-8}$ to $9x10^{-5}$ m/s; geometric mean of $4x10^{-6}$ m/s; median of $9x10^{-6}$ m/s
			Intermediate Aquifer	Sand and gravel between silty deposits. Under most of the valley floor. Thins to the east and south.	
			Deep Aquifer	Sand and gravel overlying bedrock, in valley thalweg. Thickens toward Frying Pan Lake. Not continuous with deep aquifer in Pebble deposit area.	
		Bedrock	Weathered Bedrock Aquifer	Uppermost 10 to 30 feet of bedrock. Most consistent aquifer in area.	
	South Fork Koktuli Flats (from Frying Pan Lake, 5.5 miles downstream along SFK River)	Overburden	SFK Valley Aquifer	Clean sand and gravel moraine downstream of Frying Pan Lake. Continuous with outwash, terrace, and alluvium[4] sand and gravel deposits in valley to west.	K in overburden ranged from $7x10^{-8}$ to $1x10^{-3}$ m/s; geometric mean of $1x10^{-4}$ m/s; median of $4x10^{-4}$ m/s K in weathered bedrock ranged from $1x10^{-8}$ to $3x10^{-3}$ m/s; geometric mean of $2x10^{-5}$ m/s;
			SFK Channel Aquifer	Alluvium and terrace gravels along the channel from downstream of Frying Pan Lake to bedrock high to the east.

3.17.1.4 Aquifer Properties – Hydraulic Conductivity and Storativity

Hydraulic conductivity (K) (expressed in meters per second [m/s]) describes the movement of water through pore spaces or fractures in subsurface material and depends on permeability and saturation of the material (e.g. silt, sand, bedrock). Hydraulic conductivities were measured at wells using response and pump tests within areas of the project to characterize groundwater movement and interactions between aquifers (whether overburden or bedrock) and surface waterbodies. A response (or slug) test is conducted by inserting a slug of known volume into a well or piezometer and measuring the rate of rise or fall of the water level as it returns to its original (static) level. These data are used to calculate local hydraulic conductivity at an individual well. A pump test involves pumping water from a well at a steady rate and measuring the drawdown (over time) of the water level at the well being pumped and in other observation wells (wells not being pumped) or piezometers in the area. Drawdown decreases with radial distance from the pumping well and increases as the length of time pumping continues. Packer (or Lugeon) tests measure the hydraulic conductivity of discrete intervals within a boring that are isolated with movable, inflatable packers. The rate of water is injected into the interval between two packers is measured and used to estimate hydraulic conductivity. Storativity (specific yield) is essentially a measure of how well the aquifer stores water (how much water the aquifer will hold or expel with changes in water level, or, technically, a change in hydraulic head). Results of pump tests provide information to estimate storativity of aquifers in the mine site area.

Results of technical review and analysis of previous hydrogeologic data are provided in Appendix K3.17. A summary of aquifer properties is provided below.

Overburden hydraulic conductivity values range from $8x10^{-9}$ to $1x10^{-3}$ m/s, which reflects the heterogeneous nature of the interbedded glaciofluvial sediments. The hydraulic conductivity of overburden is similar throughout the mine site, with median values ranging from $1x10^{-5}$ (UTC) to $4x10^{-4}$ m/s (SFK River Flats). Hydraulic conductivity values for overburden materials in the Pebble deposit ($3x10^{-5}$ m/s) and UTC ($1x10^{-5}$ m/s) areas were an order of magnitude lower than those measured in the SFK River, NFK River, and Frying Pan Lake areas, based on the median values, likely due to the presence of silty glacial deposits in these areas. A summary of the hydraulic conductivity measurements in overburden and bedrock within and outside the Pebble deposit is shown in Figure 3.17-11 and Figure 3.17-12, respectively.

In addition, results of pump tests in overburden indicate hydraulic conductivity was almost 10 times (one order of magnitude) higher than values derived from response tests (Schlumberger 2011, 2015). Pump test results estimate the hydraulic conductivity over a larger area than response tests and are generally assumed to be more reflective of the areal hydraulic conductivity. Results of the pump tests indicate the overburden aquifers are capable of conveying moderate to large quantities of groundwater. Results also indicate the ability of individual overburden aquifers to store water is moderate to high overall, but is limited for some aquifers. Results of pump tests in bedrock were similar to those for response tests.

AMERICAN OVERSIGHT

Figure 3.17-10: Deep Groundwater Elevations – Seasonal Low Water

AMERICAN OVERSIGHT

EPA-0135-0003558

Similar to overburden, the hydraulic conductivity of the bedrock also varies widely throughout the mine site, ranging from $9x10^{-9}$ to $1x10^{-3}$ m/s which reflect varying degrees of weathering and fracturing with depth. Bedrock hydraulic conductivity generally decreases with depth. Median hydraulic conductivity values measured with response tests in bedrock in the Pebble deposit ($2x10^{-5}$ m/s) and SFK River ($5x10^{-5}$ m/s) areas are about 1 to 2 orders of magnitude higher than those measured in the NFK ($9x10^{-7}$ m/s), Frying Pan Lake ($9x10^{-6}$ m/s), and UTC ($5x10^{-6}$ m/s) areas, possibly due to the presence of less weathered and fractured bedrock in these areas (Section 3.13, Geology). A summary of the hydraulic conductivity measurements in bedrock vs depth within and outside the Pebble deposit is shown in Figures 3.17-13 and 3.17-14, respectively.

Packer (or Lugeon) tests were conducted to measure the hydraulic conductivity in the deeper bedrock to depths up to 4,500 feet, but depths generally less than 1,000 feet. In the Pebble deposit, deeper bedrock hydraulic conductivities ranged from $1x10^{-10}$ to $4x10^{-6}$ m/s. The highest hydraulic conductivity measurements were in the upper 500 of bedrock, but are less than those in the shallow weathered bedrock where the response test results ranged from $4x10^{-7}$ to $1x10^{-3}$ m/s. Outside the Pebble deposit, deep bedrock hydraulic conductivities were measured to depths up to 400 feet, but most were at depths less than 200 feet. Deep bedrock hydraulic conductivities in these areas ranged from $1x10^{-9}$ to $1x10^{-5}$ m/s.

3.17.1.5 Groundwater Flow Systems

Hydrogeologic characterization indicates that the majority of water that recharges the groundwater system in each of the three main watersheds generally discharges in that same watershed.

AMERICAN OVERSIGHT

AMERICAN OVERSIGHT

EPA-0135-0003563

Input to the groundwater flow system includes groundwater recharge (e.g., precipitation) and leakage from surface water features. Precipitation in the vicinity is primarily the result of marine storm systems with the most precipitation occurring from late summer to early winter. Precipitation is greater on upland areas than in lowland areas due to orographic effects. Precipitation data and additional climate data is addressed in Section 3.20, Air Quality.

The primary output from the groundwater flow system at the mine site includes discharge to surface water features, including seeps. In general, the water table reflects the ground surface topography, whereby it is deepest below ridge tops, and nearer ground surface in valley bottoms.

Groundwater generally flows from upland areas typically through the weathered and fractured bedrock to valley bottoms filled with glacial and fluvial sediments comprising the overburden, eventually discharging to surface water (streams, rivers, and lakes). The majority of the groundwater flow is in the most permeable overburden, which includes outwash sands and gravels (glaciolacustrine and glaciofluvial sediments, see Section 3.13, Geology), and the uppermost 50 feet of bedrock that is weathered and highly fractured by physical and chemical weathering. Groundwater seeps are observed in some areas where fine-grained sediments restrict downward groundwater flow causing perched zones that discharge along outcrop faces. Groundwater flow in deep bedrock is limited by lower hydraulic conductivity that occurs in the upper 50 feet. Although permeability in bedrock from faults and fractures has been identified, the flow pathways along the faults are localized and appear to terminate in the study area. Therefore, the faults and fractures in bedrock are not anticipated to function as preferential groundwater flow pathways at the deeper regional scale.

Groundwater level monitoring and interpreted contours (Figure 3.17-9) indicate three groundwater divides in the study area as follows:

1. Between the UTC Creek drainage and the NFK drainage.
2. Near the Pebble deposit between the SFK River drainage and the UTC drainage.
3. Between the SFK River drainage and the tributary UT1.190 drainage.

Although the groundwater divides generally align with surface water drainage divides, there is evidence of some groundwater exchange between drainage basins from the SFK River drainage to the tributary UT1.190 drainage area (Schlumberger 2015).

Data from two monitoring wells were used to characterize general seasonal and vertical groundwater level fluctuations: monitoring well (MW) MW-5 in the Pebble deposit area and MW-11 in the SFK Flats area (Figure 3.17-15 and Figure 3.17-16; Schlumberger 2015). Lowest groundwater levels were recorded in late winter; highest water levels were typically recorded during spring freshet or fall rain events. Groundwater levels seasonally fluctuated approximately 10 to 20 feet. Similar to groundwater levels, measured discharge from seeps seasonally varied by factors between 3 and 10. Vertical hydraulic gradients were variable over the seasons and with depth – which supports the concept of compartmentalized groundwater flow.

A more detailed discussion regarding groundwater flow systems is provided in Appendix K3.17.

3.17.1.6 Site-Wide Water Balance Model

A WBM is essentially a means to calculate inflow, outflow, and water storage and can be used to predict and manage water supply. The site-wide WBM was developed to inform the characterization of mine site hydrology, understand the nature and extent of interactions between groundwater and surface water, and provide estimates of groundwater recharge to support calibration of the mine site groundwater flow model.

AMERICAN OVERSIGHT

Figure 3.17-16: Time Series of Piezometric Elevation at MW-11, South Fork Koktuli Flats Area

AMERICAN OVERSIGHT

EPA-0135-0003566

The WBM is also used to estimate water flows during site operations and during the mine closure and post-closure phases. The WBM was calibrated (adjusted) to 4.5 years of continuous streamflow data at six SFK River, three NFK River, and three UTC gaging stations and a long-term synthetic series of temperature and precipitation data for the period 1942 to 2017 based on data from mine site and regional weather stations.

The site-wide WBM results are briefly summarized below. The site WBM is described in detail in Schlumberger (2011 and 2015) and Knight Piésold (2018a and 2018b). The average annual estimated precipitation for the catchments in the water balance ranged from 40 to 55 inches. Nine of the 14 catchments had estimated annual unit flows that ranged from 1.4 to 6.9 cfs/mi^2, averaging about 2.8 cfs/mi^2. Average annual groundwater recharge varied from 11 to 24 inches per year for the NFK River, UTC, and SFK River drainage areas. Groundwater recharge in individual catchments ranged from 4.7 to 46.8 inches per year. The majority of groundwater tends to discharge to surface water within the same drainage basin, with the exception of groundwater transfer between the SFK Flats Area (Area 5) to the UTC drainage along UT1.190 (Area 7) estimated to be 6 inches per year, or about one-third of the total underflow in the SFK Flats Area.

3.17.1.7 Mine Site Groundwater Flow Model

A three-dimensional numerical groundwater flow model was developed to simulate baseline groundwater conditions as described in detail in Schlumberger (2011, Appendix 8.1J). A numerical model is a computer simulation of local and regional groundwater flow. The model was constructed with three layers to represent flow in the overburden, the shallow weathered and fractured bedrock, and the deeper competent bedrock. Transient (time varying) recharge and discharge estimates from the site-wide water balance model as well as measured groundwater levels and measured hydraulic conductivities were used as model input. Groundwater levels at wells and flows at seeps and along streams were used as calibration targets.

The model was calibrated (adjusted) to total recharge and discharge rates obtained from the site-wide WBM described above. The total groundwater recharge and discharge calculated by the site-wide WBM includes meteoric recharge and losses from streams to the underlying groundwater flow system. The groundwater model was calibrated to observed groundwater elevations, estimated groundwater recharge, and estimated groundwater discharge obtained from the site-wide WBM. The baseline groundwater model is important because it is used to predict potential effects caused by the project by incorporating project specific information (variables) to address activities (such as pit dewatering and recovery). The groundwater model can address the comprehensive effects of the project at various phases. The groundwater model simulates the exchange of water between streams and groundwater, and model estimates were compared with streamflow measurements during periods of time when flows were low, and primarily groundwater-derived.

A subsequent model was developed by Piteau Associates (2018) to assess groundwater flow conditions at the end of mining and during long-term post-closure. The model was used to assess seepage from the bulk and pyritic TSFs and the water management ponds, the effect of dewatering the open pit (including its groundwater inflow rate and zone of influence), and the reduction of groundwater discharge to UTC. The model was also used to assess groundwater flows after mining ceases, including the time to form an open pit lake and the amount water needed to maintain the open pit lake as a hydraulic sink. The model results are presented in Piteau Associates (2018).

AMERICAN OVERSIGHT

3.17.1.8 Groundwater and Surface Water Interaction

The Pebble mine region is overlain with glacial till, and has significant groundwater-surface water interactions. Groundwater and surface water interaction was characterized based on detailed streamflow surveys and the site-wide WBM. Figure 3.16-4 (see Section 3.16, Surface Water Hydrogeology) depicts stream gage locations.

The surface water flow surveys were conducted during periods of low streamflow, and are described in detail in Knight Piésold (2015) and Section 3.16, Surface Water Hydrogeology. These surveys included eight gages in the NFK River drainage basin, 12 gages in the SFK River drainage basin, and 12 gages in the UTC drainage basin. Based on the results of the streamflow surveys, gaining and losing stream reaches were identified, and possible explanations for the variability in flows between gages were provided. The majority of the stream reaches were found to be receiving groundwater discharge from the underlying aquifer (i.e., gaining); however, the NFK River was found to be losing water to the underlying aquifer between gages NK100B and NK100LF1. The SFK River was found to be losing water to the underlying aquifer(s) from SK100G to SK100F, from SK100F to SK100C, and between SK100B and SK100LF10. Figure 3.17-17 shows the gaining and losing stream segments.

3.17.2 Transportation Corridor and Amakdedori Port

3.17.2.1 Hydrogeological Characterization

The sections below summarize the available baseline hydrogeological data for the transportation corridor, spur roads, and Amakdedori port site. The road corridor spans multiple drainage basins; starting at the southeastern edge of the Nushagak River drainage in the mine site, across the greater Kvichak River drainage (including Iliamna Lake) to the Aleutian Range divide, and then into the greater Cook Inlet drainage east of the divide.

The northernmost segment of the transportation corridor (northern half of the mine access road) is in the well-studied UTC drainage. Limited data are available for the southern segment of the mine access road. No known hydrogeological investigations have been conducted along the south access road or Amakdedori port site.

Climatic factors influencing groundwater across the corridor are the same or similar to those described above for the mine site. There are no glaciers or known permafrost in the transportation corridor or port site.

3.17.2.2 Hydrostratigraphic Units

The transportation corridor begins at the mine site, which straddles the drainage divide between the SFK and UTC drainage basins. Glacial sands and gravels generally host multiple surficial and intermediate aquifers that likely contains most of the groundwater, while the weathered and fractured shallow bedrock aquifer stores significantly less groundwater (Schlumberger 2015, Appendix 8.1B).The northern half of the mine access road is mostly in the UTC drainage, where groundwater occurs in surficial aquifers of glacial sediment and in weathered and fractured shallow bedrock.

The southern half of the mine access road parallels First Creek (west of the road route), a tributary basin that drains southward into the main UTC drainage about 4 miles upgradient of Iliamna Lake. Hydrogeologic data for this area are limited. Bedrock and surficial geology along this stretch of the mine access road are similar to the corridor to the north, with Tertiary volcanic bedrock and thick deposits of surficial glacial sediments (see Section 3.13, Geology). Based on the similar geologic setting and topography across the mine access road, hydrostratigraphic

AMERICAN OVERSIGHT

units in the transportation corridor are likely similar. Permeable sands and gravels, which make up the abundant glacial till and outwash across this stretch of the mine access road, as well as lake terrace and beach deposits within one to two miles of the north ferry terminal (Detterman and Reed 1973), likely host surficial and/or intermediate aquifers. It is possible that weathered and/or fractured bedrock stores additional groundwater at depth.

No known hydrogeological investigations have been conducted south of Iliamna Lake, and hydrostratigraphic units have not been delineated for this area. Lake terrace and beach deposits that occur in the south ferry terminal area (Detterman and Reed 1973) likely host shallow groundwater. The geologic setting along the rest of the south access road and the Kokhanok spur road is somewhat distinct from that north of Iliamna Lake. Jurassic age intrusive bedrock is commonly exposed at the surface, and glacial sediments are less abundant. The water table approaches the surface in lowland areas, as evidenced by abundant kettle ponds and wetlands. Glacial deposits are significantly thinner along the south access road corridor compared to the mine access road, but likely host shallow aquifers where present (Glass 1999). Shallow groundwater is likely present in surficial alluvium, alluvial fan, marine terrace, and beach deposits near Amakdedori port (Detterman and Reed 1973). The degree of weathering and fracturing in bedrock is not well known along the south access road, and it is unknown if bedrock fractures host significant groundwater. It is also unknown if local fault zones host groundwater, or if they contain fine-grained fault gouge that may impede groundwater flow.

3.17.2.3 Aquifer Properties: Hydraulic Conductivity and Storativity

The northern half of the mine access road is in the UTC drainage, where groundwater occurs in aquifers of surficial glacial sediments and in fractured shallow bedrock. The permeability of the glacial sediments allows groundwater to pass through relatively easily. The hydraulic conductivities are thus moderately high, ranging from $2x10^{-6}$ to $4x10^{-5}$ m/s in this area (Schlumberger 2015). The modest variation of hydraulic conductivity by one order of magnitude is to be expected with the lateral diversity of the glacial deposits, which vary in permeability largely depending on the amount of silt present.

Shallow, weathered, and fractured bedrock along the northern segment of the mine access road has hydraulic conductivities that range from $2x10^{-7}$ to $2x10^{-5}$ m/s (Schlumberger 2015). These hydraulic conductivities are similar to those for silty sands and sand aquifers. Because this bedrock is fractured, groundwater is able to flow through the cracks in the rock relatively easily, at rates similar to those of the overlying glacial sediments. However, deeper, unweathered, and less fractured bedrock does not readily transmit or store groundwater.

To the south, the corridor parallels the First Creek tributary basin, which drains southward into the main UTC drainage above Iliamna Lake. No detailed studies have been conducted on aquifer properties here, but a similar geologic setting suggests that groundwater occurs in both surficial sedimentary aquifers and weathered and fractured shallow bedrock, as it does to the north.

No data on hydraulic conductivity or aquifer storage are available along the transportation corridor south of Iliamna Lake.

AMERICAN OVERSIGHT

Figure 3.17-17: Gaining and Losing Stream Segments

AMERICAN OVERSIGHT

3.17.2.4 Groundwater Flow Systems

Groundwater flow systems in the northern portion of the corridor have complex surface water/groundwater interactions (Schlumberger 2015). The UTC drainage has both gaining and losing reaches as groundwater migrates generally southeast across the area. Farther south along the mine access road, the water table remains near the ground surface in lowland areas, and groundwater/surface water interaction likely occurs, as has been demonstrated in and around the mine site. Existing data and regional groundwater trends suggest a generally southerly flow of groundwater along the southern half of the mine access road (Schlumberger 2015, Appendix 8.1B).

There are no known groundwater studies in the transportation corridor south of Iliamna Lake. Groundwater flow along the south access road corridor likely parallels surficial flow, following general hydrologic trends. In the Kvichak drainage, groundwater is expected to flow northwest toward Iliamna Lake. Across the Aleutian Range divide in the Tuxedni-Kamishak drainage, groundwater likely flows southeast towards Kamishak Bay. Near Amakdedori port, shallow groundwater in surficial deposits and bedrock (where present) likely flows from hill slopes towards Amakdedori Creek and swamp deposits near the southern end of the road, then parallels creek flow south and southeast towards Kamishak Bay. Groundwater flow beneath beach deposits at the port site may have a diurnal directional component due to large tidal fluctuations.

3.17.2.5 Groundwater and Surface Water Interaction

Groundwater/surface water interactions have not been studied in the transportation corridor or at Amakdedori port. However, groundwater/surface water is likely to interact similar to the mine site. Studies in the mine site suggest that groundwater discharge to streams or rivers prevails, and that where it is occurring, groundwater base flow is highest in the winter, and lowest (on a volume basis) during the spring and summer runoff events. In general, groundwater/surface water interactions will not have any significant areal effect on road or pipeline construction, other than the possible need to temporarily dewater some stream or lowland crossings as construction proceeds (see Chapter 4.17, Hydrogeology).

3.17.3 Pipeline Corridor

No specific hydrogeologic studies have been conducted in the natural gas pipeline corridor and data are the same as those discussed above for the transportation corridor, with the exception of Kenai Peninsula at the east pipeline shore approach and tie-in. Groundwater beneath Kenai Peninsula is known to occur in multiple aquifers in thick glacial and alluvial deposits above Tertiary sedimentary bedrock (Karlstrom 1964; Nelson and Johnson 1981). Groundwater flow is generally to the west toward Cook Inlet, and seeps commonly occur along Cook Inlet bluff, where fine-grained glacial lake deposits form aquitards and support perched groundwater zones. Private groundwater wells drilled on top of Cook Inlet bluff at elevations of approximately 200 feet produce water at depths between 8 and 30 feet below ground surface (ADNR WELTS 2018). Deeper aquifers are also locally present in glacial deposits and sedimentary bedrock at depths between 50 and 120 feet (USGS 1967; Nelson and Johnson 1981).

3.17.4 Groundwater Use

See Section 3.16 for all discussion of water use, both surface and groundwater.

3.18 WATER AND SEDIMENT QUALITY

This section describes existing conditions related to surface water, groundwater, and sediment quality of the project components. Geochemistry at the mine site is also described as it relates to the potential for release of chemicals into water from mining activities. Information on water and sediment quality criteria that are used to compare to existing and future conditions are provided in Appendix K3.18.

Evaluation factors to be considered by the US Army Corps of Engineers (USACE) in making determinations under CWA 404(b)(1) Subpart C include the following physical and chemical characteristics of the aquatic ecosystem. These are addressed in this and other sections of the Environmental Impact Statement (EIS) as noted below:

- **Substrate.** Substrate includes sediment at the bottom of waterbodies as well as wetland soils. Baseline characteristics of waterbody substrate (sediment) within the four project components are summarized below and additional details are provided in Appendix K3.18. Baseline information on wetland substrate is provided in Section 3.22, Wetlands/Special Aquatic Sites, and Section 3.14, Soils. Removal and disposal of dredged marine sediment under the northern route is addressed in Section 4.18.
- **Suspended Particulates/Turbidity.** Measurements of total suspended solids (TSS) and turbidity in water are summarized in the surface water quality sections of this chapter and additional details are provided in Appendix K3.18.
- **Water Quality.** Water quality data are summarized in the surface water quality sections of this chapter and additional details are provided in Appendix K3.18.
- **Current Patterns and Water Circulation.** Flow patterns, circulation in open waterbodies, and the interaction between surface water and groundwater flow are addressed in Section 3.16, Surface Water Hydrology, and Section 3.17, Hydrogeology.
- **Normal Water Fluctuations.** Annual and seasonal stream discharge fluctuations and tidal ranges in Cook Inlet are presented in Section 3.16, Surface Water Hydrology.
- **Salinity Gradients.** Salinity trends are described below, and additional details are provided in Appendix K3.18.

3.18.1 Mine Site Area

3.18.1.1 Geochemistry

Rock chemistry typically drives water quality, facility design, and water treatment requirements at hard rock mines (ADNR 2014). The open pit, Bulk tailings storage facility (TSF), pyritic TSF, and water management ponds at the mine site pose the most significant risk to water quality because they expose fresh rock to oxidation and leaching processes that may generate acidic drainage and leach metals that could impact water. The geochemistry of the rock that would be mined and exposed at the Pebble deposit is described in this section, followed by a summary of existing data for surface water, groundwater, and sediment at the mine site.

The Pebble deposit is a copper-gold-molybdenum porphyry deposit formed when older sedimentary and igneous rocks were intruded by a granitic magma laden with hot fluids carrying dissolved copper, gold, molybdenum, and silver, as well as quantities of rhenium and palladium. As the fluids cooled, concentrations of sulfide minerals, chalcopyrite ($CuFeS_2$), molybdenite (MoS_2), and pyrite (FeS_2), hosting the copper, molybdenum, gold, and silver metals, precipitated

AMERICAN OVERSIGHT

in quartz veins and disseminated throughout the granitic and adjacent sedimentary and igneous rocks.

Geochemical Processes

In the natural environment, rocks are broken down to create soil layers through exposure to air and water in a process called chemical weathering. During weathering, minerals in the rocks react with air (oxidation) and water (dissolving into solution) to release some of their constituents (ions) into the surrounding environment. The ions that go into solution may be transported away by overland runoff, streams, and groundwater. Therefore, weathering processes in rock can have a large influence on water quality. If a mineralized deposit is buried beneath other rocks, sediment, and soil, it naturally weathers very slowly. However, when a mineralized deposit isexposed at the surface, the weathering process can increase substantially due to exposure to rain, snow, and air.

Both ore and non-ore rocks contain minerals that can produce acid during weathering, the most common acid-generating mineral being pyrite (FeS_2), which contains iron and sulfur. The sulfur in pyrite reacts with oxygen and water to form sulfuric acid. The resulting acidic water is known as acid rock drainage (ARD), which in turn accelerates the weathering process further. Metals and other potentially harmful constituents can also be released during weathering in a process called metal leaching (ML). Most metals are released more rapidly in acidic water; however, some other constituents, including metalloids such as arsenic, molybdenum, and selenium, and salts such as sulfate, can be released into the environment even if the water draining the rock has a neutral or basic pH (Smith 2007). Acid generation can be counteracted if there are minerals present that neutralize the acid, such as calcite. The neutralization is generated through a reaction of calcite with the sulfuric acid. In the presence of those minerals, acidification is typically delayed until the neutralizing minerals are exhausted.

The purpose of geochemical characterization at the proposed mine site is to identify the potential of the rocks in and surrounding the mineralized deposit to produce ARD and/or ML that could affect water quality in surface water and/or groundwater. The characterization process involves studies of the mineralogy of the rocks, the quantities of minerals with potential to generate or neutralize acid, the amounts of leachable constituents in the rocks, and the rates of weathering and release of these minerals and constituents expected both during mining and after mining ceases. Geochemical characterization was undertaken as part of environmental baseline studies over a number of years to evaluate the potential for ARD and/or ML for the project (SRK 2011a, 2011b, 2018a, 2018 b, 2018c). A summary of the results of these studies follows, and additional details are provided in Appendix K3.18.

Geochemical Characterization

The objectives of the geochemical characterization program were to predict the weathering and leaching behavior of rock, tailings, and other materials that would be produced during mining and processing. Data produced from geochemical testing are used to predict the chemistry of waters that contact the rock exposed in the open pit, and the waste rock and tailings stored in the TSFs, and determine their ARD/ML potential.

Sampling and Testing Program. Samples for geochemical testing were selected from the numerous exploration cores drilled to outline the deposit. A summary of the geochemical testing program is provided in Table K3.18-2. The samples included all the main Pebble deposit rock types and adjacent rock types that might be removed during mining. As of 2018, the program had included analysis of over 1,000 rock samples from the Pebble deposit, and 26 samples of overburden materials. In addition, almost 60 tailings samples, comprised mostly of angular,

AMERICAN OVERSIGHT

pyritic, and gold plant tailings, from test processing of ore composites have also been characterized. To date, limited geochemical testing has been performed on the representative concentrate because possible designs for a metallurgical process are still at an investigative stage.

The rock samples were tested for mineral abundance using transmitted and reflected light microscopy, ARD potential, bulk chemical composition, and constituent mobility. Geochemical tests have included acid-base accounting (ABA), sequential net acid generation, shake flask extractions, meteoric water mobility, humidity cells, subaqueous (saturated) leach columns, and on-site field weathering (barrel and bag) tests to evaluate rates of oxidation, acid generation, acid neutralization, and element leaching. Selected geochemical data are summarized in data tables in Appendix K3.18, and described below.

Acid-Generating Potential. In some mineralized deposits, rock type alone can be a good indicator of whether a rock will potentially produce ARD and/or ML. There are two main geological divisions at the proposed mine site. The mineralization is hosted by sedimentary and volcanic rocks of pre-Tertiary age. After the pre-Tertiary occurrence of mineralization, those rocks were partially eroded, then covered by other sedimentary and volcanic rock later in the Tertiary period. The later Tertiary age rocks at the mine site generally do not contain copper, gold, or other metals that would be economically viable to recover at the present time (SRK 2011a and 2011b).

A summary of ABA data is provided in Table K3.18-3. ABA testing has determined that the pre-Tertiary mineralized sedimentary and plutonic rocks at the proposed mine site are predominantly potentially acid generating (PAG). The acid-generating potential (AP) of these rocks is relatively high because they contain several percent pyrite, as indicated by the total sulfur content of >1 percent, and they have limited neutralization potential (NP). The distribution of pyrite (and consequently AP) was found to be influenced by the hydrothermal alteration zones overprinted on the deposit. In contrast, the majority of the Tertiary age rocks that comprise the cover and overburden materials at the proposed mine site are considered non-PAG because they have <1 percent pyrite, low total sulfur concentrations, and excess NP because carbonate minerals are abundant. However, a small proportion of the Tertiary age volcanic rocks were found to be PAG.

Weathering and Leaching Rates. To develop an understanding of weathering and leaching processes that might affect rocks exposed during mining (e.g., pit walls and stockpiled waste rock and tailings), additional laboratory and field geochemical tests were conducted. Laboratory tests included humidity cell, subaqueous (saturated) column, stored bag, and field barrel tests. Humidity cell test data obtained for periods up to 8 years allow interpretation of long-term acid generation potential and neutralization rates as the rocks are oxidized and leached during wet and dry cycles. Humidity cell test results were used to confirm ABA criteria for segregating PAG from non-PAG rocks and waste, based on the NP/AP ratio. The ABA and humidity cell data indicate that PAG and non-PAG rocks can be distinguished using an NP/AP ratio of 1.4 (SRK 2011a), and are applicable to pre-Tertiary, Tertiary, and overburden materials.

Humidity cell tests also help to estimate the potential lag or delay in the onset of ARD using the sulfide oxidation and release rates and pH profiles. The delay occurs because acid-neutralizing minerals (e.g., calcite, feldspars, and micas) are not depleted instantly as acid is formed, but are consumed at different rates depending on their reactivity and abundance. Results show that pre-Tertiary rocks with low NP/AP ratios (less than 0.3) have little neutralization potential and are estimated to generate acid within 1 to 6 years (SRK 2018a). Pre-Tertiary rocks with NP/AP ratios of 1 have higher neutralization potential, which delays the estimated onset of acid generation to 8 to 20 years (SRK 2018a). These estimated times to onset of ARD are

AMERICAN OVERSIGHT

considered underestimates because they are based on data developed under ideal laboratory conditions. Actual conditions in the field, with colder temperatures, and long winters, are likely to be less conducive to acid formation. Paste pH results for aged rock cores stored at the site suggest that acidification may be delayed up to 40 years. Given differences in the test conditions, laboratory and field tests suggest that oxidized pre-Tertiary mineralized rock may take up to several decades for acidification to occur.

Element release rates determined from kinetic tests were mainly a function of leachate pH rather than the element content of the samples. Leaching of copper accelerated as pH decreased; therefore, the potential for metal release is linked to the potential for acid generation, and ABA data can be used to assess the potential for copper leaching. However, for some elements (e.g., arsenic, molybdenum, and selenium), release can be environmentally significant under neutral pH conditions. Tests on some samples of Tertiary rock showed elevated leaching of these elements under non-acidic conditions. These leaching data, along with baseline water quality data, were used with other inputs to develop geochemical source terms for water quality modeling and water treatment planning (SRK 2018c). Additional information regarding how the data were used in water quality modeling is provided in Section 4.18.

Tailings. Ore processing based on a conventional flotation process to recover chalcopyrite and molybdenite, the primary copper and molybdenum minerals, followed by treatment of pyrite to recover gold, would result in a low sulfide bulk tailing concentrate and a high-sulfide (pyrite-rich) tailing concentrate, respectively. Metallurgical process testing has produced a range of representative tailings products. Geochemical testing of approximately 60 tailings samples indicates that the most volumetrically abundant product, bulk tailings, which would be produced under most of the processing approaches being considered, typically contains low to moderate total sulfur and can be categorized as non-PAG, provided the total sulfur remains below 0.2 percent. The ARD potential for the bulk tailings is lower than that of mineralized rock because most of the sulfur is removed to recover the economic minerals and separate out the pyritic tails while concentrating neutralizing minerals in the bulk tailings. Element leaching from the rougher tailings occurred at low rates, and unfiltered process supernatants were found to contain low levels of potential constituents relative to water quality standards. The pyrite and gold plant tailings have higher sulfide contents are often classified as PAG, and leach metals at higher rates. Appendix K3.18 provides additional information on the geochemical characteristics of the tailings and supernatant.

Pit Block Model. Because of the geochemical variability in the rocks, assessment of impacts resulting from geochemical processes requires consideration of the disposition and fate of the material that would be mined each year. The annual area mined can be estimated by developing a block model (i.e., a computer model that shows the three-dimensional location of each type of rock and the likely order of mining.) Rock material is assessed based on its PAG and non-PAG characteristics and whether the material would be processed and end up in tailings, or not processed and set aside as waste rock, to design waste management strategies.

Based on the results obtained from integrating the geochemical studies with the block model, the majority of the rocks that would be mined from the deposit do not have the potential for acid generation, and could be considered substantially acid neutralizing. However, some rocks do have the potential to leach certain non-acid constituents; mainly arsenic and sulfate. These results, and their influence on the existing baseline water quality at the site of the proposed mine, are discussed in more detail in the next few sections. [Note: This text will be updated when requested information on the open pit block model is received.]

AMERICAN OVERSIGHT

3.18.1.2 Surface Water Quality

The Pebble deposit is located in the headwaters of the Upper Talarik Creek (UTC) and South Fork Koktuli (SFK) River drainages, and adjacent to the headwaters of the North Fork Koktuli (NFK) River drainage. The NFK River is on the north side of the project area. The Kaskanak Creek (KC) drainage lies south of the SFK River drainage.

Sampling Program. Water quality studies were conducted by Schlumberger et al. (2011) and ERM (2018a) to quantify chemical and physical parameters that describe the quality of the water at the mine site and surrounding areas that would potentially be impacted by the proposed action and alternatives. Water quality data were collected for rivers, lakes, and seeps in the project area, and throughout a 965 square mile area that includes the NFK River, SFK River, and UTC (Figure 3.18-1).

A comprehensive network of sampling stations was established in the project area for sampling surface water from streams, lakes, and seeps. Stream samples were collected from 44 locations during 50 sampling events from April 2004 through December 2008 (Schlumberger et al. 2011). Lake and pond samples were collected from 19 lakes once or twice per year during 2006 and 2007. Seep samples were collected from 11 to 127 sample locations (depending on the year), two to five times per year.

Altogether between 2004 and 2008, over 1,000 samples were collected from streams, more than 600 samples from seeps, and approximately 50 samples from lakes. Additional samples were also collected during the supplementary water quality study period, which occurred from 2008 and 2013 (ERM 2018a).

Several tables are provided in Appendix K3.18 showing a summary of surface water quality data compared to criteria for waterbodies most pertinent to potential future impacts at the mine site. These include data for NFK, SFK, UTC, and Frying Pan Lake (Table K3.18-6 through Table K3.18-9). Additional water quality details on seeps and other lakes and streams in the mine site study area are provided in ERM (2018a: Tables 9.1-15 through 9.1-24) and Schlumberger et al. (2011: Tables 9.1-31 through 9.1-36), and are incorporated by reference into the discussion below.

Overview of Sampling Results. The results of these analyses indicate that the baseline surface water resources can generally be characterized as cool, clear waters with near-neutral pH that are well-oxygenated, low in alkalinity, and generally low in nutrients and other trace elements. Water types ranged from calcium-magnesium-sodium-bicarbonate to calcium-magnesium-sodium-sulfate. Water quality data occasionally exceeded the maximum criteria for concentrations of various trace elements in some individual sample measurements; however, in no instance did the mean concentration of trace elements exceed the most stringent water quality guidelines. Cyanide was occasionally present at detectable concentrations in a limited number of samples. Cyanide detected in those samples is believed to be of natural origin, based on the distribution and lack of anthropogenic sources. Cyanide can occur naturally as a product of anabolism in some plants, bacteria, and fungi (CDC 2013). Additionally, there were consistently detectable concentrations of dissolved organic carbon. No detectable concentrations of petroleum hydrocarbons, polychlorinated biphenyls (PCBs), or pesticides were found.

AMERICAN OVERSIGHT

Figure 3.18-1: Surface Water Quality Sample Locations, Mine Site Area

AMERICAN OVERSIGHT

Some differences in water quality between watersheds and trends in water quality along streams were noted. These are summarized below and in tables in Appendix K3.18. Higher concentrations of copper, molybdenum, nickel, zinc, and sulfate were present in SFK than in NFK, consistent with SFK's proximity to the Pebble deposit area. Total dissolved solids (TDS), pH, sodium, alkalinity, hardness, nitrogen (nitrate+nitrite), and nickel concentrations were greatest in the UTC drainage. The uppermost reach of UTC passes through a portion of the general deposit area, and also had significantly higher concentrations of all of these naturally occurring constituents than in NFK. TSS, potassium, chloride, iron, and arsenic concentrations were highest in KC, while cadmium and lead concentrations were highest in the NFK drainage. These characteristics of KC and NFK likely indicate that these parameters are unrelated to the deposit area, and represent water quality signatures that are distinct from the other drainage areas.

The following paragraphs discuss some of the specifics of the sample results and trends observed in the NFK, SFK, and UTC. Data summaries for these streams are provided in Tables K3.18-6 through K3.18-8, and trend analysis data in Table K3.18-13 through Table K3.18-15.

Total Dissolved Solids. The mean levels for TDS in streams, by watershed, ranged from 37 to 51 milligrams per liter (mg/L), which is 10 percent or less of the most stringent Alaska Department of Environmental Conservation (ADEC) water quality maximum criterion. Of the three streams that originate close to the deposit area, UTC and SFK had significantly higher TDS levels than NFK. Furthermore, a decrease in TDS levels with distance along the stream was more pronounced in the SFK and UTC watersheds than in the NFK watershed. Higher TDS in the UTC and SFK watersheds with decreasing trends downstream were expected, because the deposit area lies within their watersheds, and the oxidation of sulfide minerals associated with the deposit would release dissolved solids. The mean levels for TDS in lakes and seeps were similar to those for streams, with values of 49 and 42 mg/L, respectively.

Total Suspended Solids and Turbidity. Mean TSS values ranged from 1.19 mg/L to 3.21 mg/L in the NFK and UTC, respectively. The highest value for TSS was in KC, and the lowest was in the NFK. Mean TSS values did not exceed the most stringent water quality criteria for any rivers in the mine site area; however, at least one exceedance was recorded in a sample collected at the UTC. The mean for TSS in lakes and seeps was similar to that for streams.

pH. The pH values in surface water were close to neutral. The mean pH for streams by watershed ranged from 6.7 to 7.0. The mean pH values for lakes and seeps were 7.2 and 6.5, respectively. Because of the exposed Pebble deposit and seasonally fluctuating groundwater conditions in the area (see Section 3.17, Hydrogeology), it is possible that the oxidation of sulfide minerals release acid in this area; however, based on the mean pH data, carbonate minerals may be providing some pH buffering. Although the mean pH values fell within the range for pH specified in the most stringent ADEC criteria (6.5 to 8.5), 34 percent of all individual water quality samples did not meet the water quality criteria for pH. Recorded pH values ranged from 3.31 to 9.33 with the lowest pH recorded in the NFK and the highest recorded in UTC. The frequency of this trend in seeps was at least double that of streams, depending on the watershed.

Alkalinity. The alkalinity of the surface water samples was low. Mean alkalinity for streams, by watershed, ranged from 17 to 32 mg/L. Mean alkalinity for lakes and seeps was 19 and 23 mg/L, respectively. Alkalinity was the parameter that was most frequently detected outside the range of the most stringent ADEC criterion. In all, 43 percent of all surface water samples were below this value. The frequency with which alkalinity values for lakes and seeps were below the minimum criterion was 10 to 20 percent higher than the frequency for streams.

AMERICAN OVERSIGHT

Temperature. Mean water temperature in streams ranged from 4.0 to 4.8 degrees Celsius (°C), depending on the watershed. The standard deviation of temperature values measured in each watershed was approximately equal to the mean of the values, indicating a high level of variability. Lakes in the mine site area were considerably warmer, with a mean temperature of 12°C, and seeps slightly cooler, with a mean temperature of 3.4°C.

An example of seasonal stream temperature variability is shown on Figure 3.18-2, which depicts water temperature in NFK at a location about 15 miles downstream of the mine site. Daily water temperatures range from about 6 to 16°C in summer months, and from about 1 to 7°C in spring and fall during breakup and before freeze-up (USGS 2018).

The period of temperature record at the USGS site is from October 2013 to present. While long-term water temperature trends are not available, these may vary as a subdued expression of long-term air temperature trends. Mean annual temperature trends in the region indicate that air temperatures have increased approximately 3°C over the past 50 to 60 years related to large-scale climate oscillation (Knight Piésold 2012, 2018a), trends that are predicted to continue into the next century (SNAP 2018).

Dissolved Oxygen. Dissolved oxygen (DO) concentrations in streams were very similar in all watersheds, with mean concentrations that ranged from 10.2 to 10.5 mg/L. These values are close to the theoretical solubility of oxygen of 12.3 mg/L at 900 feet above mean sea level (amsl) and a water temperature of 4°C. Although most samples indicated high DO, 7 percent of the samples had DO concentrations lower than the most stringent ADEC minimum criterion.

Major Ions. Groundwater type can be characterized by the presence and predominance of specific ions, including anions and cations. The water type of most samples from streams in the mine site area ranged from calcium-magnesium-sodium-bicarbonate to calcium-magnesium-sodium-bicarbonate-sulfate. The cation composition was dominated by calcium and was relatively consistent. The anion composition had a wider range, with most stream samples being dominated by carbonate. The average water type of the lakes and seeps was generally the same as the streams; however, the seeps had a slightly greater range of water types, and the distribution of water types was slightly different. Specifically, the seeps included samples with a higher proportion of sulfate, and the samples also were distributed more evenly across the spectrum of anion composition, rather than being weighted toward the bicarbonate end of the spectrum.

Nutrients. Nutrients, which included total ammonia, total nitrogen (nitrate+nitrite), total phosphorous, and orthophosphate, had generally low concentrations, especially in lakes and seeps. Orthophosphate was generally not present at detectable levels, with one exception in the KC watershed. Total ammonia was detected in 19 to 36 percent of surface water samples, and mean concentrations ranged from 0.03 to 0.05 mg/L, depending on source (streams, lakes, or seeps). Nitrogen and phosphorous were detected in 66 to 98 percent of surface water samples, depending on the sample source. Mean concentrations of nitrogen ranged from 0.1 to 0.3 mg/L, and mean concentrations of total phosphorous ranged from 0.02 to 0.04 mg/L. None of the nutrient concentrations exceeded the most stringent ADEC maximum criterion. The coefficients of variation for nutrients were high compared to most other parameters, often in the range of 1 to 2.

AMERICAN OVERSIGHT

Figure 3.18-2: Daily Water Temperatures in NFK River

AMERICAN OVERSIGHT

Trace Elements. The trace elements aluminum, antimony, arsenic, barium, cadmium, copper, iron, lead, manganese, molybdenum, mercury, nickel, and zinc were detected in surface water, although at low concentrations. The frequency of detection depended on the watershed, and on whether the sample was collected from a stream, a lake, or a seep. Total and dissolved aluminum, barium, copper, iron, manganese, and molybdenum were typically the most frequently detected trace elements in the streams and lakes; the frequency of detection generally ranged from 85 to 100 percent, depending on sample source (streams, lakes, or seeps). The most frequently detected elements in the seeps were generally the same as those for the streams and lakes, but the frequency of detection was lower in the seeps (53 to 99 percent, rather than 85 to 100 percent). Exceptions to this general pattern included a frequency of detection for total and dissolved arsenic in KC of more than 98 percent. The trace elements arsenic, lead, nickel, and zinc had an intermediate frequency of detection in most waters sampled, with the exception of zinc, which had a higher frequency of detection (98 percent) in lakes. Cadmium had the lowest frequency of detection.

Some trace element concentrations in stream samples exceeded the most stringent ADEC maximum criteria. These are described below in relationship to watersheds (trend analyses for data within individual watersheds are provided in Appendix K3.18):

- Copper from the SFK watershed exceeded the water quality criterion most frequently, with total and dissolved copper exceeding the criterion in 42 and 34 percent of samples, respectively. In contrast, copper had one of the lowest frequencies of exceedance in other watersheds. The relatively high frequency of exceedance in the SFK watershed is probably related to proximity of the deposit.
- Total aluminum exceeded the most stringent ADEC maximum criterion in 12 to 22 percent of the stream samples from the SFK, UTC, and KC watersheds; and in 6 percent of the samples from the NFK watershed. In contrast, dissolved aluminum exceeded the criterion in only 1 percent of the stream samples, and only in the UTC watershed; therefore, aluminum exceedances seem to be almost exclusively associated with suspended solids.
- Total lead exceeded the most stringent criterion in 8 to 16 percent of the stream samples, and was generally the next most frequently exceeded criterion after total aluminum. Dissolved lead exceeded the criterion in 1 to 6 percent of the stream samples, and was second only to copper for frequency of exceedance for dissolved elements.
- Total manganese exceeded the criterion in 15 percent of stream samples from the SFK and UTC watersheds, in 3 percent of the samples from the NFK watershed, and in none of the samples from the KC watershed. Similar to aluminum, manganese exceedances appear to be associated with suspended solids.
- Concentrations of total antimony, cadmium, iron, mercury, and zinc for the stream samples rarely exceeded the criteria (0.3 to 4 percent).
- In samples from lakes and seeps, exceedances of the most stringent maximum criteria included total and dissolved aluminum, total and dissolved copper, total and dissolved iron, total and dissolved nickel, total and dissolved lead, total and dissolved cadmium, and dissolved manganese.

Cyanide was occasionally detected in the surface water samples. Total cyanide was detected in 2 to 15 percent of all samples, depending on sample source (streams, lakes, or seeps), and weak acid dissociable cyanide was detected in 5 to 13 percent of all samples. Concentrations of weak acid dissociable cyanide in samples were compared with the most stringent ADEC

AMERICAN OVERSIGHT

maximum criterion, and exceeded this criterion in 1 to 3 percent of the stream samples, depending on the watershed.

Dissolved organic carbon was detected in 93 to 100 percent of the stream samples, and the mean concentrations ranged from 1 to 2 mg/L, depending on the watershed.

Concentrations of petroleum hydrocarbons, volatile and semi-volatile organic compounds, polychlorinated biphenyls, and pesticides were not detected.

3.18.1.3 Groundwater Quality

Mine Site Monitoring Wells. A total of 77 groundwater monitoring wells with depths up to 200 feet below ground surface were installed in the project area. Two additional drill holes (DH-8417 and GH10-220) were used for sampling deep bedrock in the deposit area at depths ranging from 210 to 4,050 feet. Table K3.18-16 provides a list of wells completed within and outside of the deposit area, along with depth and bedrock lithology. The location of the wells is shown on Figure 3.17-2. The results of groundwater quality testing are summarized in Table K3.18-17 and discussed below based on mean values for wells grouped by lithology (ERM 2018a). These data were used in the Knight Piésold (2018a) Operations Water Management Plan to predict the water quality of pit dewatering water going to water management ponds (WMPs) and influent to the water treatment plants (WTPs) (see Section 4.18).

Groundwater samples from depths of 200 feet or less were characterized by mean levels of TDS ranging from less than 90 mg/L to over 150 mg/L (higher in bedrock wells); mean pH values between 4.4 and 7.3; mean DO concentrations ranging from 2.6 to 9.1 mg/L; and mean concentrations of trace elements above the most stringent ADEC water quality maximum criteria for several constituents (aluminum, copper, iron, lead, and manganese).

Concentrations of TDS in groundwater generally decreased with distance from the deposit area, and results from deep drill hole DH-8417 (mean of 835 mg/L) suggest that concentrations of TDS increase with depth (Knight Piésold 2018a). Monitoring wells MW-14D in the SFK watershed and P08-69D in the NFK watershed were the only wells showing a relatively high TDS level that was not consistent with this general pattern. While data from well MW-14D are somewhat anomalous, they could be interpreted to suggest that the deposit has influenced groundwater quality.

Most of the groundwater samples had a composition that ranged from calcium-bicarbonate to calcium-magnesium-bicarbonate and calcium-sodium-bicarbonate. Some samples from relatively close to the deposit area had a higher proportion of sulfate, suggesting that the groundwater in this area is influenced by oxidation of the sulfide minerals that are associated with the deposit. As the sulfide minerals oxidize, iron, sulfuric acid, and probably trace elements are released. The acid is neutralized by carbonate minerals such as calcite and dolomite, which release calcium, magnesium, manganese, carbonate, and usually some trace elements. This series of geochemical reactions increases the concentration of TDS and the proportion of sulfate in the groundwater.

Although sulfides appear to be oxidizing locally in the deposit area, the groundwater is not acidic overall. The lowest mean pH value of 4.4 was recorded at only one well location in shallow bedrock. In the remaining wells, mean pH values ranged from 6.7 to 7.9, indicating broadly that the groundwater is not acidic. Eight wells (six completed in overburden, two in bedrock) had mean pH values greater than 7.0, and three of these wells (all completed in overburden) had the highest mean TDS concentrations observed.

The DO measured in the groundwater was generally high. Twenty-seven wells had mean DO concentrations of 8 mg/L or greater. Wells with relatively high TDS, measured in filtered

AMERICAN OVERSIGHT

samples, also generally showed relatively high concentrations of arsenic, barium, and molybdenum compared with other wells in the analysis area. All of the wells with more than two trace metals at relatively high concentrations were located closer to the deposit area.

Some systematic differences in concentrations were observed with depth, as indicated by the differences in concentration between wells that were completed in overburden and those completed in bedrock (Table K3.18-17). Specifically, the concentrations of antimony, arsenic, copper, iron, manganese, and molybdenum tended to be higher in wells completed in bedrock than in wells completed in overburden. Conversely, the concentrations of DO and nickel tended to be lower in bedrock wells than in overburden wells.

Drinking Water Wells. There are currently no drinking water wells at the mine site (ADNR-WELTS 2018). During exploration activities, personnel typically stay in Iliamna and utilize local water supplies in that community (described below).

3.18.1.4 Substrate/Sediment Quality

This section describes baseline information on waterbody substrates at the mine site. Baseline information on wetland substrate is provided in Section 3.22, Wetlands, and 3.14.2.3, Soil Chemistry. Baseline physical and chemical data on substrate/sediment from the major drainages and other waterbodies at the mine site were collected between 2004 and 2008 (Knight Piésold 2011; SLR Alaska 2011; R2 et al. 2011; HDR Alaska 2011; SLR Alaska et al. 2011; Three Parameters Plus and HDR 2011). Sample locations are shown on Figure 3.18-3. The National Uranium Resource Evaluation (NURE) program also collected a variety of substrate samples across the region in 1977 (Grossman 1998). NURE data include basic physical substrate descriptions and thorough chemical analyses, as well as reporting of potential contaminant sources, and are included below.

Physical Characteristics. Waterbody substrate data coverage within the mine site includes the SFK, NFK, and UTC drainages. Streambed sediment from these drainages is dominated by medium to coarse gravels, to small cobbles, with boulders present in stretches of rapids. In areas of low water velocity and pools, sands and silts are more common, and organic sediments are present in some areas (Knight Piésold 2011; R2 et al. 2011). The NURE data collected from the region include basic physical substrate descriptions and thorough chemical analyses, as well as reporting evidence for potential local contaminant sources. Twelve samples of pond substrate collected by NURE within approximately 20 miles of the mine site were all reported as mud/fine sediment (Grossman 1998). Limited data from the shores of Frying Pan Lake show a sand, silt, and gravel substrate (R2 et al. 2011).

AMERICAN OVERSIGHT

Figure 3.18-3: Sediment Quality Sample Locations, Mine Site Area

AMERICAN OVERSIGHT

Chemical Quality. Between 2004 and 2007, a total of 198 samples of sediment from lakes, ponds, seeps, and major and minor drainages in the analysis area were sampled and analyzed for their content of naturally occurring trace elements, anions, cations, and organics (SLR Alaska 2011). A summary of the data is provided in Table K3.18-18. Samples collected from wetland substrates are included in the summary of soil chemical quality in Section 3.14, Table 3.14-2 and Table 3.14-3.

Of the 26 trace elements for which samples were analyzed, all were present above detection limits in at least some of the samples, with aluminum, iron, calcium, and magnesium present at substantially higher concentrations than the other elements. Mercury content of sediment samples from the mine site was the lowest level detected, at a mean concentration of 0.040 milligrams per kilogram (mg/kg). Comparing sediment from the major drainages, copper was the only element showing significant variation, likely due to the difference in rock composition across drainages. Copper concentrations were particularly high in SFK sediment, likely due to copper-rich bedrock at the headwaters. In comparison to sediment quality guidelines (SQGs) (Table K3.18-1), the highest detected concentrations of four metals (arsenic, chromium, copper, and nickel) exceeded concentrations that may have an adverse effect on benthic organisms [both the threshold effects level (TEL) and higher probable effects level (PEL)]. These samples were from sediment in the SFK drainage (for arsenic and copper) and UTC drainage (for chromium and nickel). The mean concentration of arsenic exceeded the TEL across the study area.

Sediment from ponds and minor drainages in the mine site area showed higher concentrations of anions and cations such as sulfate, ammonia, and sodium than did other waterbodies. Total cyanide concentrations were the lowest of the analyzed anions on average, with a mean concentration of 0.39 mg/kg (SLR Alaska 2011). Of the 12 pond sediment samples analyzed by the NURE within 20 miles of the mine site area, none showed evidence of contamination (Grossman 1998).

Analyses of several organic compounds (GRO, DRO, VOCs, SVOCs, and PAHs) were performed on one mine site pond sample to identify the potential presence of naturally occurring hydrocarbons. Of the compounds analyzed, DRO, RRO, and 12 of 18 PAHs were detected. Because of the remote undeveloped nature of the area, these compounds are likely present due to the biogenic breakdown of aquatic plants, historic wildfires, or volcanic activity (e.g., Abdel-Shafy and Mansour 2015). Total organic carbon (TOC) was detected in all 34 samples tested, with a mean concentration of 6.05 percent.

3.18.2 Transportation Corridor

The 84-mile long proposed access corridor would cross numerous streams within the Bristol Bay and Cook Inlet watersheds, and includes an 18-mile crossing of Iliamna Lake. The corridor originates in the Nushagak watershed at the mine site, and traverses the Kvichak watershed on the north side of the Alaska Peninsula; both are within the greater Bristol Bay watershed (Figure 3.16-1). The south end of the corridor terminates in the Tuxedni-Kamishak bays watershed of the greater Cook Inlet watershed. More detailed descriptions of these watersheds are provided in Section 3.16, Surface Water Hydrology.

3.18.2.1 Surface Water Quality

Mine Access Road. Surface water quality data described above for the UTC drainage at the mine site are pertinent to the upper part of the mine access road. Stream data for UTC is summarized in Table K3.18-8, and spatial trends are presented in Table K3.18-15. Although exceedances were measured in some samples, mean concentrations of all measured

AMERICAN OVERSIGHT

constituents for the UTC were below the most stringent water quality standards. Additionally, field studies in 2018 included turbidity measurements at stream crossing sites. Field study measurements indicate that all stream crossings along both the mine access road and the Iliamna spur road yield turbidity below the minimum detection level for the instrument used (65 cm turbidity tube; 7-11 Nephelometric Turbidity Units [NTU] detection level) (PLP 2018-RFI 036).

Newhalen River and North Access Route. A total of 16 surface water sampling stations were established and sampled by Schlumberger et al. (2011) along the north access route extending east from the Newhalen River (Figure 3.18-4). About 12 samples were collected at each station over a 2-year period in 2004 and 2005. One of the stations, located on the Newhalen River upstream of the proposed Newhalen Bridge, is pertinent to both the proposed transportation corridor under Alternative 1 and the northern access route under Alternatives 2 and 3. Table K3.18-10 and Table K3.18-11 provide a summary of the surface water quality data for the western and eastern parts of the northern access route, respectively. Data are described below for both the Newhalen River and collectively for all stations along the northern access route.

The surface water was characterized by: low levels of TDS (2 to 126 mg/L for all stations, 18 to 45 mg/L for Newhalen River); mostly near-neutral pH (4.6 to 8.8 for all stations, 6 to 7.8 for Newhalen River); and high DO concentrations (9 to 19 mg/L for all stations, 9 to 17 mg/L for Newhalen River). Additionally, TSS for all stations ranged from 0.2 to 51.6 mg/L and 0.5 to 9.1 mg/L for Newhalen River. During months when surface water samples were collected, temperatures ranged from 0.1 to 23ºC for all stations, and 1 to 16ºC at the Newhalen River station. The full annual range of water temperatures could not be characterized because samples were not collected during some winter months (November, December, or January).

The cation composition of the water samples was dominated by calcium and was consistent between sampling events. The anion composition was typically dominated by bicarbonate, but varied over time. Concentrations of nutrients were low; specifically, most ammonia and phosphorous concentrations were below detection limits. Total nitrogen (nitrate+nitrite) averaged 1 mg/L for all stations and 0.37 mg/L for the Newhalen River. Collectively for all stations, concentrations of the trace elements aluminum, copper, lead, and zinc were above the most stringent ADEC maximum criteria in a few cases. Only aluminum was above the most stringent criterion in about half of the Newhalen River samples.

Iliamna Lake. A total of 176 surface water samples were collected at nine stations in northeast Iliamna Lake (May to October) between 2005 and 2007 (HDR 2011a). Stations located near Alternative 1 include one near the mouth of UTC and four near Iliamna village; four additional sites were located at the east end of the lake. Samples were collected at multiple depths at five of the nine locations (Figure 3.18-5). Ambient water measurements included dissolved oxygen, temperature, specific conductance, oxidation reduction potential, pH, turbidity, and water clarity. Table K3.18-12 provides a summary of the lake water quality data. Samples were collected and analyzed at various locations in four different regions: UTC, Iliamna Village Area, Pedro Bay Area, and at Pile Bay. The UTC drainage and Iliamna Village area sample locations represent water quality information for proposed action, and the Pedro Bay area and Pile Bay area lend relevant water quality insight for transportation alternatives utilizing mine access along the northeast side of Iliamna Lake.

The sample data for all sites suggest that Iliamna Lake has water quality conditions similar to the natural conditions of other regional lakes. Aluminum, copper, iron, lead, manganese, and alkalinity were detected at concentrations that were outside the most stringent ADEC water quality criteria; however, mean concentrations did not exceed water quality criteria. Cation and anion dominance was generally characteristic for temperate lakes. Concentrations of major ions

AMERICAN OVERSIGHT

did not vary with depth, suggesting that the water at the sampling sites were well mixed. The concentrations of several major ions and TDS were lower earlier in the summer, peaked in September, and declined again in October. These temporary increases are likely associated with the influence of inflow from streams and precipitation.

Regional variations in constituent concentrations were observed for some trace elements including aluminum, cobalt, copper, iron, lead, and manganese. In particular, significant variation was observed in the mean concentration of aluminum. Mean concentrations of total aluminum varied greatly between locations; mean concentrations at Pile Bay were over ten times that of the UTC area. Chromium, cobalt, copper, iron, lead, and manganese also showed some notable variation (about 50 percent change) in mean concentrations. Samples collected at UTC consistently yielded lower concentrations than other locations for these trace metals.

HDR Investigators noted that concentrations of nutrients and major ions found during the 2005 to 2007 study were similar to concentrations from a study conducted at Iliamna Lake nearly 40 years before. The single exception was sodium, which was present at nearly twice the concentration found in the earlier study. However, only a few ions (copper, lead, aluminum, iron, manganese, and alkalinity) had concentrations outside benchmarks established by ADEC for freshwater. The investigators attributed the latter to geological influences, and noted their consistency with previous studies conducted at Iliamna Lake and other area watersheds (HDR 2011a).

Field data collected in 2017 added three additional sample locations assessing the surface water quality near the proposed ferry terminals in Iliamna Lake. Samples were taken near the surface and near the bottom of the lake. These data did not yield any exceedances of the most stringent water quality criteria (Table K3.18-1) for total or dissolved metals, or any conventional parameters tested (GeoEngineers 2018a, Table 6a).

South Access Road. Water quality data are limited along the proposed south access road. Field studies in 2018 recorded turbidity measurements at stream crossings along the south access road at levels below the instrument detection level (7-11 NTU) for all but two stream crossings, at which turbidity levels of 24 and 13 were recorded. Turbidity measurements at the Gibraltar River crossing were also below the instrument detection level (PLP 2018-RFI 036).

Drinking Water Sources. Three communities around Iliamna Lake have community surface water systems as their primary drinking water source, including Nondalton, Kokhanok, and Igiugig (Figure 3.16-1). Nondalton uses infiltration galleries from Six Mile Lake (which drains into the Newhalen River); Kokhanok draws water from Iliamna Lake; and Igiugig has one active intake in the Kvichak River, just downstream of Iliamna Lake. No state data is available on drinking water sources for Pile Bay and Williamsport (ADEC 2018; ADNR-WELTS).

Past water system violations in these communities reported by ADEC (between 1995 and 2018) are mostly monitoring violations that represent failure to collect a sample. Water quality constituent exceedances are rare and have included coliform, iron, manganese, arsenic, lead and copper (ADEC 2018).

3.18.2.2 Groundwater Quality

Drinking Water Wells. The village of Newhalen uses both community and private groundwater wells as drinking water sources, while Iliamna and Pedro Bay rely on private groundwater wells. Drinking water wells were sampled at four locations (Newhalen, Nondalton, Iliamna, and Pedro Bay) in 2004 and 2005 to assess regional water quality across the transportation corridor (Schlumberger et al. 2011a). These wells were similar in quality, with exceedances of drinking water quality standards for total arsenic in Newhalen, Nondalton, and Pedro Bay; and pH

AMERICAN OVERSIGHT

exceedances in Newhalen and Pedro Bay. Newhalen has had numerous monitoring violations from failure to collect a sample since 1995, but rare exceedance violations have only been registered for coliform (ADEC 2018).

Mine Access and South Access Roads. Groundwater quality beneath the proposed 84-mile transportation corridor can be characterized as similar to that of the mine site and port. Along the northern mine access road in the Nushagak and Kvichak watersheds, the groundwater quality of the transportation corridor is similar to that of the mine site. Trend analysis of the mine site groundwater system (discussed above) suggests that TDS concentrations decrease with distance from the mine site. The northern mine access road traverses a series of shallow intermittent surficial deposits, including glacial, glaciofluvial, and alluvial deposits (Detterman and Reed 1973). The south access road would traverse flat ground and low hills, much of which is bare rock covered with a thin layer of soil (AECOM 2018h). There are few known potentially groundwater-bearing surficial deposits along the south access road, with few intermittent glaciofluvial and alluvial surficial deposits (Detterman and Reed 1973). This terrain suggests that shallow groundwater occurrences along this route would be limited. Groundwater quality beneath the south access road is likely similar to that of the port site.

North Road. The northern access route would cross a variety surficial deposits, all of which have the potential to be groundwater bearing. These are intermittent in the eastern part of the route and thicker in the western part of the route (Detterman and Reed 1973; Schlumberger et al 2011a). Groundwater quality and characteristics can be influenced by these surficial deposits and bedrock geology, which is complex throughout the Cook Inlet basin (Brabets 1999). A single groundwater quality sample was collected in Pedro Bay near the northern access route and was similar in quality to wells sampled at Newhalen, Nondalton, and Iliamna (Schlumberger et al. 2011a).

AMERICAN OVERSIGHT

Figure 3.18-5: Surface Water and Sediment Sample Locations, Iliamna Lake

AMERICAN OVERSIGHT

3.18.2.3 Substrate/Sediment Quality

Physical Characteristics. Stream substrate intersected by the transportation corridor includes a wide range of fine to coarse sediments (Grossman 1998). Stream sediments at the northern end of the road corridor are dominated by sand and silt, with some stretches high in gravel and cobbles, while other stretches are rich in organic matter (PLP 2018-RFI 036). Limited substrate data along the Iliamna spur road shows that some stream crossings are dominated by gravel and cobbles, while others are high in fine-grained sand, silt, and organic matter. Along the mine access road south of the intersection with the Iliamna spur road, substrates are dominantly silt, sand, and gravel (PLP 2018-RFI 036). No substrate data is available for streams along the southern portion of the mine access road.

A small number of nearshore and deeper water sediment samples from Iliamna Lake were collected in 2005 and 2006 (Figure 3.18-5). Substrate offshore of the north ferry terminal near the mouth of UTC was described as consisting of small gravel. Lake sediment analyzed near Iliamna village was described as fine-grained material (HDR Alaska 2011). Sediment samples collected near the proposed ferry terminals in Iliamna Lake in 2017 consist primarily of underdeveloped sand-gravel beaches with intermittent cobble, and larger rocks, and occasional outcrops of bedrock (GeoEngineers 2018a).

Stream substrates along the south access road show similar diversity to those north of Iliamna Lake. Sand and silt are the dominant sediment size, with a high percentage of organic matter present as well. Sampled streams have a higher percentage of boulders and less gravel south of Iliamna Lake. Sediment at the proposed location of the Gibraltar River bridge is dominated by gravel and cobble substrate. Sediments in drainages with proposed crossings by the other four bridges along the south access road tend to be more coarse-grained, with a higher percentage of cobbles and boulders (PLP 2018-RFI 036). Samples of substrate from four ponds within approximately 5 miles of the southern access road were all recorded as mud/fine sediment (Grossman 1998).

Chemical Quality. Sediment in streams intersected by the transportation corridor show little to no known existing contamination (Grossman 1998). Of 12 pond substrate samples analyzed by NURE within approximately 20 miles of the mine access road, none showed evidence of contamination (Grossman 1998).

Table K3.18-19 provides a summary of Iliamna Lake sediment quality data collected in 2005 and 2006. Sediment quality measurements for Iliamna Lake were examined at the Iliamna village area (four sample locations), Pedro Bay area (three sample locations), and at Pile Bay (one sample location). Minor variations in sediment content occur between the three areas; however, mean constituent concentrations only exceeded TELs for cadmium in the Iliamna village area and for copper at the Pile Bay location. In these instances, concentrations did not reach the probable effects level. Sediment samples collected from two locations near Iliamna village (Figure 3.18-5) were analyzed for trace elements and other constituents (HDR Alaska 2011). Sediment data showed levels for copper, lead, aluminum, iron, and manganese that exceed ADEC freshwater sediment criteria (same as SQGs). This is likely due to the highly mineralized nature of the local geology, and is similar to chemistry in other area lakes.

Of four pond substrate samples analyzed by NURE within approximately 5 miles of the south access road, none showed any evidence of contamination (Grossman 1998).

AMERICAN OVERSIGHT

3.18.3 Marine Ports

3.18.3.1 Surface Water Quality

The discussion of marine water quality below presents regional information, as well as data collected in northern Kamishak Bay (2004 to 2012) and offshore of the Amakdedori port site (2018) that are pertinent to Alternative 1. Additional details of marine water quality in the Iliamna/Iniskin estuary north of Kamishak Bay that are pertinent to the Diamond Point port (Alternatives 2 and 3) are provided in Appendix K3.18.

Suspended Particulates/Turbidity. Cook Inlet basin is an expansive watershed surrounding the 180-mile-long Cook Inlet waterbody. Covering more than 38,000 square miles of southern Alaska, it receives water from six major watersheds and many smaller ones. More than 10 percent of the basin is covered by glaciers, and suspended sediment loading in glacier-fed rivers without lakes is significant, leading to generally high suspended sediment load in some portions of Cook Inlet.

Hart Crowser (2015) provides physical and chemical data from the Ursus Cove area at the north end of Kamishak Bay (about 17 miles northeast of Amakdedori), which are likely similar to the Amakdedori port site because of its exposure to lower Cook Inlet oceanographic conditions. Turbidity in the sampled areas at the north end of Kamishak Bay ranged from near 0 to 13 NTU, probably reflective of varying exposures to wave activity. Turbidity was described as generally moderate, except near the shoreline during windy periods, and did not exhibit any obvious trends that would indicate point-source inputs (Hart Crowser 2015). TSS was 5 mg/L at both surface and bottom, indicating a well-mixed and relatively clear water column.

The amount of suspended solids and accompanying turbidity in waters adjacent to the proposed Amakdedori port site would be a function of seabed composition (e.g., silt, mud, sand). Extrapolation of onshore geophysical survey data (Zonge 2017) and NOAA (2015) nautical chart information for the approach to the port site suggest that the seabed in this area consists of sand and gravel with scattered boulders. This suggests that suspended solids are of naturally low concentrations and that water is relatively clear (i.e., low turbidity). Field studies conducted in 2018 at four offshore locations near the Amakdedori port site (two near-bottom and two near-surface samples) measured no exceedances of the marine screening criteria or the most stringent water quality criteria for TSS with an average of 15.3 mg/L (GeoEngineers 2018a, Table 5). However, under energetic wave conditions, any loose sediment on the seabed would be stirred upward into the water column, thereby temporarily increasing suspended solids and turbidity.

Salinity Gradient and Temperature. The Amakdedori port site is on the open coast of Kamishak Bay. As such, water properties such as salinity and temperature can be expected to be similar to those of lower Cook Inlet (Muench and Schumacher 1980). However, some freshening of surface waters in the immediate vicinity of Amakdedori Creek might occur; while under southerly winds, greater freshening could occur as a result of flows from sources to the south, such as McNeil and Kamishak rivers. The extent of any freshening is dependent on flows from those sources and the persistence of southerly winds. The freshening of surface waters would be manifest as a thin, low-salinity lens overlying saltier water, which would be mixed quickly into the water column by any wave action produced by brisk winds.

Hart Crowser (2015) temperature and salinity data from the Ursus Cove area are likely to be similar to the Amakdedori port site, although they may be influenced by freshening from upland sources through Ursus Lagoon. For the 2012 sampling period (August), mean water temperatures ranged from 12.9 to 14 ^{0}C, while mean salinities ranged from 22.8 to 25.7 parts per thousand. The small range in data for both temperature and salinity suggest a fairly

AMERICAN OVERSIGHT

homogenous water column. Temperature exhibited seasonal warming up to mid-summer and then subsequent cooling, but was also a function of water depth, indicating the role of insolation as a factor in temperature trends. Salinity decreased from spring to late summer, reflecting the influence of upland sources on coastal waters, and then increased in autumn months.

Organics and Inorganics. The area surrounding Cook Inlet north and east of the port site is a relatively populated and industrialized region of Alaska. Therefore, its waters are influenced to some degree by urban (and a small amount of agricultural) runoff, oil and gas activities (e.g., accidental spills, discharges of drilling muds and cuttings, production waters, and deck drainage), effluent from municipal wastewater treatment facilities, oil and other chemical spills, offal from seafood processing, and other regulated discharges. Waters free from contaminants, however, are considered a principal component of the Cook Inlet beluga whale critical habitat in the Amakdedori port area. Hence, the comparatively low levels of contaminants documented in Cook Inlet beluga whales, as well as in chemical analyses of water and sediment in the area, suggest that contaminant concentrations in lower Cook Inlet are low (NMFS 2016).

Hydrocarbon concentrations sampled in 2004 at the northern end of Kamishak Bay, as well as metal and trace element concentrations collected in 2008, showed little to no effect from anthropogenic sources. The majority of organic constituents tested were not detected (Hart Crowser 2015: Table 34-7). Inorganics analyzed in both surface water and bottom water at a depth of about 50 ft in northern Kamishak Bay (Hart Crowser 2015: Table 34-8, Station MRC20) showed that none exceeded National Recommended Water Quality Criteria (USEPA 2009). In samples collected offshore of the Amakdedori port site, exceedances of marine water screening levels were measured in boron for both total and dissolved metal concentrations at all locations. Additionally, total iron concentrations exceeded the marine screening level for all sample locations (GeoEngineers 2018a, Table 5).

3.18.3.2 Groundwater Quality

Aquifer systems found in small drainages around the Cook Inlet region, such as those in the Amakdedori and Diamond Point port areas, include groundwater occurrences in saturated fractures in bedrock which provide water to streams near the port areas during winter (Glass 1999). Aquifers are primarily situated within glacial and fluvial deposits overlying sedimentary and low-grade metamorphic bedrock. Glacial deposit aquifers have been described as irregular in distribution and highly variable in composition and flow (Brabets et al.1999).

The thickness of surficial deposits in the Amakdedori port area are believed to range from about 50 to 100 ft thick in the port area based on geophysical survey results (Zonge 2017). Potential groundwater-bearing surficial deposits in the Diamond Point area would be limited to alluvium and alluvial fan deposits in the small drainage west of Diamond Point, and morainal deposits in uplands west of the proposed terminal (Detterman and Reed 1973). There are no existing drinking water wells in either port area. Potable water supplies for seasonal work at the Diamond Point quarry come from temporary mobile sources (ADNR 2014).

3.18.3.3 Substrate/Sediment Quality

Physical Characteristics. Studies in upper and lower Cook Inlet provide a general characterization of seafloor substrate and sediment depositional processes in the region. Lower Cook Inlet is a tidal embayment with a substrate of abundant glacial sediments, predominantly cobbles, pebbles and sand, with minor amounts of silt and clay (Sharma and Burrell 1970). Large ice-rafted boulders are also present in some areas (Thurston and Choromanski 1994). Over 40 million tons of sediment is discharged per year into the inlet by surrounding major drainages (Rember and Trefry 2005). Sediment transport in some areas of upper Cook Inlet has

AMERICAN OVERSIGHT

been shown to be exceptionally high, with 10,000 to over 100,000 cubic yards of sediment moving in and out of the Port of Anchorage area in a matter of days or weeks (USACE 2013). A combination of shallow water, high tidal fluctuations, and strong currents constantly mobilize seafloor sediments in the inlet, keeping sediments in suspension, resulting in highly turbid water, and inhibiting deposition of fine-grained sediments (Rember and Trefry 2005). Fine sediments introduced by major rivers feeding into upper Cook Inlet are carried in suspension, and have been shown to be deposited as far as 150 miles south in lower Cook Inlet (ADL 2001).

The shoreline at Amakdedori is a wave-dominated coastal berm largely composed of weathered cobbles, boulders, and exposed bedrock rising from the intertidal zone. Amakdedori Creek alluvial fan-delta deposits extend about 1,000 feet offshore into Kamishak Bay (PLP 2018-RFI 039). Seafloor sediment at and around the Amakdedori port location is primarily comprised of subtidal gravel and beach complex (GeoEngineers 2018a, Figure 2). Bathymetry in Kamishak Bay around the Amakdedori port location was investigated through a multi-beam survey in 2017, which indicated that the seafloor is relatively smooth with a gentle slope (60 feet over 5.6 miles). Results from three boreholes indicate that sub-bottom sediment consists primarily of fine silty sand with occasional course gravel and shell fragments, and a fines content ranging from 14 to 19 percent. Sediment samples from the estuarine environments of Iliamna and Iniskin bays, about 30 miles northeast of the port site, revealed substrates of fine sediment (SLR Alaska et al. 2011).

Waterbody substrate data from the onshore environment at the Amakdedori port site are limited. Sediment from two ponds, one about 0.5 miles north and the other approximately 3 miles south, was described as mud/fine sediment (Grossman 1998).

Chemical Quality. Data on regional sediment chemical quality in Cook Inlet are sparse. Limited data from dredging operations and sediment sampling suggest that sediments generally have low concentrations of contaminants (USACE 2013; ADL 2001). Low levels of hydrocarbons have been detected at multiple sites in the inlet, potentially connected with offshore oil development, past oil spills, or natural oil seeps within the region. Glacial sediments, which are continually transported into the inlet by the major drainages, may also bring metals and hydrocarbons from upstream sources into Cook Inlet. Municipal discharges and seafood processing also contribute potential contaminants to Cook Inlet substrate. Extreme tidal fluctuations and strong currents constantly disperse and dilute potential pollutants in the inlet (ADL 2001).

Sampling of offshore sediment has been conducted at two locations near the Amakdedori port site. Sediment quality data was analyzed for concentrations of inorganic and organic chemical concentrations. Field results indicate that concentrations of metals fell below the TEL for all measured quantities except for manganese and nickel. An exceedance of nickel in marine sediments was detected in one sample collected from subtidal sands/fines, but mean concentrations did not exceed the marine TEL. Manganese concentrations exceeded the marine TEL for both sampled locations in subtidal sands/fines, and yielded a mean concentration of 380 mg/kg, exceeding the marine TEL (GeoEngineers 2018a, Tables 7a and 7b).

Samples of fine sediment were collected from the offshore estuarine environments of Iliamna and Iniskin bays near Diamond Point. Some of the samples showed arsenic, copper, nickel and zinc levels higher than the threshold of biological effect, and measurable hydrocarbons. There is current development in the Diamond Point area, and minor marine vessel traffic at Williamsport at the head of Iliamna Bay. Estuarine sediments are generally more fine-grained than offshore of Amakdedori, which is more exposed to open water. Fine-grained sediments generally retain

AMERICAN OVERSIGHT

chemical pollutants more than coarse-grained sediments, due to higher surface area-to-volume ratios.

Chemical substrate data from the onshore environment at the Amakdedori port site are limited. Sediment from two ponds, one within 0.5 miles to the north and one about 3 miles south of the port site, were analyzed by NURE and were reported to have no contamination (Grossman 1998).

3.18.4 Natural Gas Pipeline Corridor

3.18.4.1 Surface Water Quality

Surface water quality data for the onshore part of the natural pipeline corridor are summarized above under Section 3.18.2, Transportation Corridor. Water quality information for Cook Inlet and Kamishak Bay pertinent to the pipeline is summarized above under Section 3.18.3.1, Marine Ports. The pipeline would tie into the existing natural gas supply at a compressor station near Anchor Point. This would result in no additional stream or waterbody crossings on the Kenai Peninsula. The closest stream to the horizontal directional drilling (HDD) part of the corridor is about 200 ft to the north (PLP 2017, Figure G-012).

3.18.4.2 Groundwater Quality

Summary groundwater quality information pertinent to the natural gas pipe corridor can be found above under "Transportation Corridor." The only additional sections of pipeline that do not match the road alternatives would be at the east end of the pipeline on Kenai Peninsula, and the short section from Ursus Cove to Diamond Point under Alternatives 2 and 3.

As described in Section 3.17, Hydrogeology, groundwater beneath Kenai Peninsula is known to occur in thick glacial and alluvial deposits (Karlstrom 1964; Nelson and Johnson 1981). Seven private groundwater wells are currently located a distance of 600 to 1,600 ft away from the HDD part of the pipeline terminus. Groundwater quality data is not publically available on private wells (ADNR WELTS 2018).

There would be limited shallow groundwater occurrence within a narrow strip of alluvial deposits along the short pipeline corridor between Ursus Cove and Diamond Point (Detterman and Reed 1973). No groundwater quality data has been collected in this area.

3.18.4.3 Substrate/Sediment Quality

Physical Characteristics. A description of nearshore Cook Inlet physical substrate characteristics is provided above under "Marine Ports." Field studies indicate that the substrate in the western portion of Kamishak Bay is primarily comprised of subtidal gravel with intermittent reef and sand/fine substrate in the region near the port location (GeoEngineers 2018a, Figure 2). Publicly available information regarding the substrate of Cook Inlet in areas further offshore is sparse. Substrate in the vicinity of mooring facilities could include flows from Augustine Volcano, which have been documented to occur every few 100 years (Section 3.15, Geohazards).

Water depths in the center of Cook Inlet range from about 50 to over 500 feet (NOAA nautical chart #16660). Numerous oil and natural gas pipelines currently span the bottom of Cook Inlet. Pipeline damage has previously been documented from boulders moved on the seafloor by strong tides and currents.

Chemical Quality. Seafloor substrate in lower Cook Inlet generally has low toxicity (Little 2001). Chemical quality of sediment in the nearshore parts of Kamishak Bay and Iliamna/Iniskin

AMERICAN OVERSIGHT

estuary are summarized above under "Marine Ports." Sediment quality data for the offshore part of the pipeline route are limited as described previously. Sediment sampled from one stream in the Kenai Peninsula area near the east end of the pipeline did not show evidence of contamination (Grossman 1998).

AMERICAN OVERSIGHT

4.17 HYDROGEOLOGY

4.17.1 No Action Alternative

Under the No Action Alternative, the project would not be undertaken; there would be no mine site, transportation corridor, port development, or natural gas pipeline corridor.

Under the No Action Alternative, PLP would have the same options for exploration activities that currently exist. There are many valid mining claims in the area, and these lands would remain open to mineral entry and exploration. It is possible for permitted exploration to continue under this alternative (PLP 2018-RFI 073).

In the event PLP concludes their exploration program, or in the event of revocation or termination of the associated state permits, PLP would be required to fully restore and remediate the project site as per state regulations. Groundwater along the transportation corridor, pipeline corridor, and at the Amakdedori port would remain in its current state. There would be no effects on existing private wells. In summary, there would no direct or indirect impacts on baseline groundwater conditions from implementation of the No Action Alternative.

4.17.2 Action Alternative 1 – Applicant's Proposed Alternative

4.17.2.1 Mine Site

Groundwater conditions were modeled by Piteau Associates (2018a). The analysis addressed two general areas: 1) the tailings storage areas (bulk and pyritic TSF) and the main WMP; and 2) the pit area. Analysis of groundwater conditions was conducted for the pit capture zone and the zone of influence. The capture zone is the area in which groundwater recharge is captured by a groundwater "sink." The zone of influence is the area in which a hydraulic stress influences groundwater elevations. The zone of influence is often larger than the capture zone because groundwater elevations can be affected outside the groundwater divide that defines the capture zone. Groundwater flow conditions were assessed for operations (at end of mining) and post-closure. The post-closure was defined as the time at which the pit lake reached its maximum closure level.

Piteau Associates (2018a) used the groundwater flow model to simulate the effect of open pit dewatering at the end of mining and the recovery of groundwater level and pit lake formation during closure and post-closure. Piteau Associates (2018a) estimates that the cone of depression at the end of mining would extend approximately 2,500 to 10,000 feet from the crest of the open pit depending on the hydraulic character of the affected aquifers. Once mining ceases, groundwater in the open pit would be allowed to slowly rise, resulting in a permanent pit lake in about 21 years. The groundwater level in the pit would be maintained to create a permanent groundwater sink to prevent pit lake water from discharging to the environment. The presence of a permanent groundwater sink at the pit will continue to locally influence groundwater flow in the immediate vicinity of the pit; however, the influence on groundwater flow would be less than the pit in its fully dewatered state. Piteau Associates (2018a) estimates that the post-closure cone of depression will extend 2,000 to 4,000 feet or less during post-closure. The input parameters and assumptions are described in greater detail in Piteau Associates (2018a) and Knight Piésold (2018n).

Pit Dewatering

Dewatering of the open pit would be required to facilitate mining. Construction of the open pit would require lowering groundwater levels in the pit area through dewatering to establish stable

AMERICAN OVERSIGHT

pit walls and provide dry working conditions. Although a specific dewatering design has not been developed at this point, the ultimate pit dewatering design would be based on a series of interim pit phases that successively expand and deepen the pit. This phase approach would allow the pit dewatering program to be adjusted, based on the operational performance of each preceding phase.

Dewatering is typically accomplished by placement of dewatering wells around the proposed pit perimeter; wells in the pit bottom as mining progresses; and horizontal drains along the pit walls. Dewatering results in a groundwater "cone of depression" because the water table is lowered in the pit, and extends beyond the pit area into the adjacent bedrock, glacial, and alluvial aquifers (see Section 3.17, Hydrogeology). The cone of depression would deepen and widen as pit excavation progresses and dewatering continues, and would last as long as the dewatering system is operated during construction and operation of the mine. Groundwater levels would ultimately need to be lowered below the base of the final mine pit depth, which is estimated to be up to 2,200 feet below grade.

The initial pre-production dewatering well field is conceptualized to consist of approximately 30 operating wells installed at a depth of 150 feet, and spaced about 200 feet apart around the starter pit perimeter. The wells would initially be pumped at a rate of 50 gallons per minute (gpm), with a total rate of approximately 1,500 gpm. The estimated groundwater inflow to the pit at the end of mining is estimated to be about 2,200 to 2,400 gpm (Piteau Associates 2018), with a maximum of 2,700 gpm (Knight Piésold 2018a). The well field at the end of mining is expected to include approximately 30 wells at 500-foot spacing around the pit perimeter. Sumps in the pit would capture precipitation and/or groundwater not captured by the dewatering system.

Water in the open pit would be managed using a storage pond and runoff controls. Groundwater inflows to the open pit would be pumped to the open pit water management pond (WMP) for storage and treatment prior to discharge. Runoff from areas upslope of active mining would be intercepted, and diverted around the open pit to the extent possible (see Section 4.16, Surface Water Hydrology). Direct rainfall, snowmelt, and runoff from the open pit walls would be collected and pumped using in-pit pumps to the open pit WMP for storage and treatment prior to discharge.

Creation of a cone of depression around the proposed pit would locally change groundwater flow patterns so that groundwater flows radially towards the pit. Groundwater/surface water interactions and surface water flows would also be impacted by pit dewatering. Groundwater discharge to seeps, streams, ponds, or lakes in or adjacent to the proposed pit may cease or be reduced, resulting in lower surface water base flows or pond or lake levels. Some stream segments, ponds, or lakes in the immediate pit area may be eliminated as the water table is lowered in the immediate pit area during construction and mining operation.

The Pebble deposit straddles a watershed and groundwater divide between the headwaters of the Upper Talarik Creek (UTC) and South Fork Koktuli (SFK) River. Groundwater dewatering impacts related to the proposed project are expected to be largely confined in the upper reaches of the SFK watershed, but may locally impact groundwater flow across the divide in the bedrock aquifer from the headwaters of the UTC watershed (Section 3.16, Surface Water Hydrology) (Piteau Associates 2018a), depending on the extent of the cone of depression around the pit. Streamflow reduction during operations and closure is addressed in Section 4.16, Surface Water Hydrology; and water quality is described in Section 4.18, Water and Sediment Quality.

The primary impact to groundwater flow would be in the alluvial, glacial, and bedrock aquifers in the open pit footprint and cone of depression. Groundwater flow in these aquifers would radially flow towards the pit, and be captured by the dewatering system. The groundwater impact would grow as mining proceeds to depth, and the cone of depression surrounding the pit becomes

AMERICAN OVERSIGHT

wider and extends to depth. Piteau Associates (2018a) estimates that the cone of depression at the end of mining would extend approximately 2,500 to 10,000 feet from the crest of the open pit, depending on the hydraulic character of the affected aquifers.

Once mining ceases, dewatering would be discontinued and groundwater in the open pit would be allowed to rise. Groundwater flow into the pit would initially be fast, but would slow as water level rises. It is estimated it will take 19 to 21 years for the groundwater in the pit to reach the maximum management (MM) level (890 feet above mean sea level [amsl]) (not-to-exceed level would be 900 feet amsl) (Knight Piésold 2018n). Knight Piésold (2018d) estimates an average annual pit water surplus of 3 cfs. This excess water would be managed by pumping and treating groundwater to maintain the MM level in the pit lake and prevent pit lake water from discharging into the environment. This would result in a permanent pit lake. The presence of a permanent groundwater sink at the pit would continue to locally influence groundwater flow in the immediate vicinity of the pit; however, the influence on groundwater flow would be relatively small compared to active mining operations. Piteau Associates (2018a) estimates that the post-closure cone of depression would extend 2,000 to 4,000 feet or less during post-closure.

Potable Well Supply

Potable water would be supplied by a series of groundwater wells north of the mine site, outside of the estimated cone of depression around the proposed open pit. The wells would be pumped at a rate to provide sufficient potable water for mine site personnel living and working at the site. The potable water supply wells would also be used for fire-fighting, if needed. As described in the Project Description (PLP 2018) and Knight Piésold (2018e), a 250-person camp would initially be built to support early site construction activities. This camp would then be supplemented by the main camp, which would accommodate about 1,700 workers during construction. The main camp would be converted at the end of construction into a permanent facility expected to house 850 workers. Assuming an average water requirement of 50 gallons per day (gpd) per person to support the camps (ADNR 2014), and an additional 10 gpd per person for the other facilities, a maximum daily volume of 102,000 gallons is expected to be required. The total average water flow requirement rate during construction for the camps is estimated to be about 80 gpm. This average demand is expected to be met by the installation of a single pumping well with two backup wells to allow for regular downtime and maintenance. During operations, the potable water requirement would be reduced to about 35 gpm. The potable water would be distributed through a pump-and-piping network to supply fresh water to holding tanks at the camps and other facilities. The holding tank capacity would be sufficient for a 24-hour supply. Impacts from pumping at the potable water supply well have not been modeled, but the well is expected to have negligible impact on local groundwater flow, based on expected aquifer conditions.

Water Management Ponds

The main and open pit WMPs would be constructed at the mine site to manage water removed during pit dewatering, manage water from the milling and concentrating operations, and manage surface water runoff collected in the mine site. These ponds would be lined and equipped with underdrains to prevent leakage of water with potentially elevated particulate and constituent concentrations to the underlying groundwater. Water in the WMPs ponds would be treated as needed and used in the milling operations. The water may also be used in tailings disposal operations (to create a tailings slurry). Surplus water would be treated to discharge standards and released downstream of the mine site at specified discharge areas (Figure 4.16-1) to mitigate surface water flow water balances downstream of the mine site (Section 4.16, Surface Water Hydrology). Groundwater flow would be minimally impacted by the construction of the

AMERICAN OVERSIGHT

WMPs and local reduction in recharge caused by the presence of the liner. The WMPs are expected to have no adverse impact on groundwater quality, because they would be lined to prevent leakage of impacted water to the subsurface (Section 4.18, Water and Sediment Quality). The WMPs may help restore downgradient groundwater flow to maintain existing flow conditions as surplus water is treated and discharged downstream of the mine site.

Tailings Storage Facilities

Bulk TSF

Non-acid generating bulk flotation tailings generated during milling operations would be stored in an unlined bulk tailings storage facility (bulk TSF) at the mine site. The bulk TSF would be constructed in the NFK watershed, with a series of embankments to impound the tailings and entrained and ponded water; and an underdrain system and grout curtain to manage seepage water draining from the tailings. The thickened bulk flotation tailings discharged to the TSF would settle, and water would be collected in a tailings decant pond (i.e., supernatant pond). Seepage water draining from the tailings would be collected by the underdrain system, and routed to a lined seepage control pond. Piteau Associates (2018a) estimates the bulk TSF would discharge approximately 0.7 cfs at the end of mining, which would be collected in the north and south seepage collection ponds (Figure 4.16-1). Water collected in the seepage control pond would be used for tailings dust control, or transferred to the main WMP for subsequent use in ore processing. Surplus water would be treated to discharge standards and released downstream of the mine site. Construction of the bulk TSF would locally impact surface water features at the site, and potentially impact groundwater/surface water interactions; this impact is expected to be small in extent (e.g., near the vicinity of the bulk TSF), but permanent. The underdrain system is expected to minimize vertical seepage into native materials below the bulk TSF. Potential impact to groundwater quality as a result of seepage from the bulk TSF area is described in Section 4.18, Water and Sediment Quality. The grout curtain would locally impact groundwater flow in the overburden and shallow bedrock, but would not affect regional flow patterns. Tailings seepage that is not captured could create a local groundwater mound beneath the TSF that could have a local influence on groundwater flow.

Pyritic TSF

The potentially acid-generating (PAG) pyritic tailings and PAG waste rock would be stored submerged in a separate lined impoundment equipped with underdrains to minimize oxidation and the potential release of acidic contact waters to the environment (pyritic TSF). Groundwater flow would be minimally impacted by the construction of this impoundment through local reduction in recharge cause by presence of the liner. The pyritic tailings would be placed at the bottom of the open pit at the end of mining, and submerged in the pit lake to prevent oxidation. The pyritic TSF liner and embankments would be removed at closure, and the site reclaimed to its approximate pre-mining state (Section 4.16, Surface Water Hydrology describes closure in greater detail) (Knight Piésold 2018d). Therefore, groundwater flow in this tributary drainage is expected to essentially return to pre-mining conditions post-closure (Section 4.16, Surface Water Hydrology).

4.17.2.2 Amakdedori Port

Shallow Groundwater Interception

Excavations across the port footprint may be required during port and dock construction. Due to the apparent high water table in glacial, glaciofluvial, alluvial, and estuarine deposits in the area,

AMERICAN OVERSIGHT

which is likely hydraulically connected to Amakdedori Creek, some excavations would likely intercept shallow groundwater. Impacts would be limited to within the port footprint or soil borrow areas for dock construction, and would occur only during construction.

Groundwater Use

Based on limited hydrogeologic information at the port site, shallow glacial and fluvial sediments in the area are likely to host groundwater (Glass 1999). A groundwater well is planned to supply potable water for port personnel and/or fresh water for operations. The precise location for the well would be identified during detailed design. The well would be sited on uplands far enough from the shore to avoid any potential for saltwater intrusion, and water would be piped to the site from the wellhead (PLP 2018-RFI 022a). It is anticipated that such a well would have a local impact on groundwater flow and quantity depending on rate and frequency of drawdown caused by pumping. The duration of impacts would be long-term, lasting through the life of the project. Water use is described in more detail for both surface water and groundwater in Sections 3.16 and 4.16, Surface Water Hydrology.

4.17.2.3 Transportation Corridor

Shallow Groundwater Interception

The transportation corridor is designed to avoid wetlands and stream crossings where feasible, and its alignment would be optimized for the most amenable soil and geotechnical conditions. Local groundwater flow impacts may occur along the corridor where the roadway is constructed across wetlands that may be supported by groundwater inflow.

Some road segments would likely require road cuts to maintain proper road grade. These are represented by wide areas of the road footprint on hillslopes (PLP 2017: Figures T-001 through T-046), which are prevalent throughout much of the access and spur road corridors. Due to the likelihood of shallow groundwater being present across the road corridor, it is possible that road cuts could intersect groundwater in some areas and cause a local effect on groundwater flow as drainage controls (construction BMPs) direct potential seepage away from the road.

Surface Water Extraction

Surface water/groundwater interaction is likely along much of the corridor, as demonstrated in the mine site vicinity. Approximately 50 million gallons of surface water would be extracted from 21 water extraction sites along the road corridor, mostly for use in road construction activities (PLP 2018-RFI 022) (Figure 4.16-8). This water would be extracted at specific permitted locations along the road corridor over months to years of construction (see Section 4.16, Surface Water Hydrology). Due to the abundance of groundwater in the region, the extraction of surface water for road construction would not likely have measurable impact on groundwater flow where there is interaction with surface water.

4.17.2.4 Natural Gas Pipeline Corridor

Shallow Groundwater Interception

Although no specific studies have been conducted on hydrogeology along most of the pipeline corridor, the water table is likely close to the surface along most of the corridor, as evidenced by abundant wetlands and kettle ponds and exposed bedrock. Groundwater along the corridor is likely held in shallow aquifers of glacial sediment, as demonstrated in similar geologic terrain at

AMERICAN OVERSIGHT

the mine site (see Section 3.13, Geology). Therefore, a large percentage of the buried pipeline could intersect shallow groundwater.

Potential impacts to groundwater would likely involve interception of shallow groundwater during trenching activities, which could be captured and locally routed along the trench backfill. Modifications to groundwater flow would occur mostly in the immediate vicinity of the trench. Impacts could extend beyond the life of the project, because the pipeline would be abandoned in place. Low-permeability trench plugs, considered a typical BMP for pipeline installation (e.g., USACE 2018), would be installed to minimize movement of groundwater along the trench, reduce erosion along the trench backfill, and alteration of the natural groundwater flow path.

Potential contamination of shallow groundwater and surface water could occur during pipeline construction from inadvertent spills of fuel and fluids from heavy machinery and trenching equipment operating in close proximity to the water table. Section 4.18, Water and Sediment Quality, describes potential impacts of project activities on groundwater quality, and spills are addressed in Section 4.27, Spill Risks.

Horizontal Directional Drilling

On the Kenai Peninsula, the pipeline would be trenched for a short distance west of the compressor station, then installed by horizontal directional drilling (HDD) at the shoreline and into Cook Inlet from an elevation of about 200 feet to -12 feet mean lower low water (PLP 2018-RFI 011). Groundwater is present in this area in aquifers in thick glacial and alluvial deposits, and Tertiary age (approximately 66 to 2.6 million years ago) sedimentary bedrock. Although the exact depth to groundwater is unknown at the HDD location, nearby wells drilled at similar elevations to the HDD work area encountered shallow water-bearing glacial deposits at depths between 8 and 30 feet below ground surface, as well as deeper aquifers in both glacial deposits and sedimentary bedrock units between 50 and 120 feet deep (USGS 1967; Nelson and Johnson 1981; ADNR 2018). Therefore, the HDD installed pipeline segment would likely intersect these aquifers, which are used near the project footprint by private wells (Figure 3.17-12).

Plans for control of groundwater during HDD drilling are not currently developed. Typical effects might include dewatering during drilling; pressurization of the hole, forcing drilling fluids into aquifers; and discharge of pumped groundwater (e.g., TRCA 2013). Dewatering, if required, could draw down the local water table, potentially changing local flow patterns and affecting other uses. If discharge of dewatering water is necessary, impacts to surface water, wetlands, and soils could occur if discharge water is not treated effectively, or if dissipation methods are not employed to minimize erosion. These effects are expected to be temporary, recovering days or weeks after construction, and localized in the near vicinity of the footprint, depending on drawdown extent and potential discharge location.

Summer-Only Ferry Operations Variant

The expected effects of this alternative are similar to those described under Alternative 1. The main difference between Alternative 1 and this variant relates to the need to construct concentrate and fuel storage facilities at the mine site or at the Amakdedori port site (Ausenco 2018), which would have a short-term impact on shallow groundwater during construction; and longer-term, but minor, impacts on wetlands, surface water/groundwater interactions, and groundwater recharge, which would be disturbed during construction and would continue throughout the life of the project. The local loss of these features would be reasonably restored once mining ends and the site is reclaimed.

AMERICAN OVERSIGHT

Kokhanok East Ferry Terminal Variant

The expected effects of this alternative are similar to those described under Alternative 1. The main difference between Alternative 1 and this variant is that the Kokhanok East route is approximately 15 percent shorter, which would reduce the potential shallow groundwater and water use impacts (if any) associated with road construction. It is also anticipated that fewer streams and wetlands would be impacted because the Kokhanok East route is shorter, and the primary road and spur are located along ridge tops once they separate from the proposed route in Alternative 1. Temporary shallow groundwater impacts from the construction of the Kokhanok East ferry terminal would be similar to those of the proposed Kokhanok east ferry terminal, and would only occur during construction. Borrow sites up to 125 acres may be required, which would likely impact shallow groundwater, but only during construction.

Pile-Supported Dock Variant

The expected effects of this alternative are similar to those described under Alternative 1 for the mine site, transportation corridor, and natural gas pipeline corridor. The main difference as compared to Alternative 1 relates to the pile versus earthfill supported dock. Borrow material for the proposed earthfill dock would be required, which would likely impact shallow groundwater, but only during construction.

4.17.3 Action Alternative 2 – North Road and Ferry

4.17.3.1 Mine Site

The expected effects of this alternative are similar to those described under Alternative 1 for the mine site.

4.17.3.2 Transportation Corridor

The expected effects of Alternative 2 on shallow groundwater are similar to those described under Alternative 1.

4.17.3.3 Diamond Point Port

The expected effects of Alternative 2 on shallow groundwater are similar to those described under Alternative 1 for Amakdedori port.

4.17.3.4 Natural Gas Pipeline Corridor

The expected effects of Alternative 2 on shallow groundwater along the natural gas pipeline corridor are similar to those described under Alternative 1, because the natural gas pipeline would be mostly buried in a trench along the transportation corridor roadside. This would likely locally affect shallow groundwater flow during construction; however, the trench would be equipped with a plug to reduce the alteration of the natural groundwater flow pattern and minimize erosion along the trench backfill.

Summer-Only Ferry Operations Variant

The expected effects of Action Alternative 2 on shallow groundwater for the summer-only ferry operations variant are similar to those described under Alternative 1.

AMERICAN OVERSIGHT

Pile-Supported Dock Variant

The expected effects of Action Alternative 2 on shallow groundwater are similar to those described under Alternative 1 for the pile-supported dock variant.

4.17.4 Action Alternative 3 – North Road Only

4.17.4.1 Mine Site

The expected effects of Alternative 3 on shallow groundwater at the mine site are similar to those described under Alternative 1.

4.17.4.2 Transportation Corridor

The expected effects of Alternative 3 on shallow groundwater in the transportation corridor are similar to those described under Alternative 1.

4.17.4.3 Diamond Point Port

The expected effects of Alternative 3 on shallow groundwater at the Diamond Point port are similar to those described under Alternative 1 for Amakdedori port.

4.17.4.4 Natural Gas Pipeline Corridor

The expected effects of Alternative 3 on shallow groundwater along the natural gas pipeline corridor are similar to those described under Alternative 1

Concentrate Pipeline Variant

The expected effects of Alternative 3 on shallow groundwater are similar to those described under Alternative 1, given the concentrate pipeline would be placed in the same excavation as the natural gas pipeline. The primary difference in water use between Alternative 3 and other alternatives is the loss of 1 to 2 percent of the water used to slurry the concentrate that would otherwise be available for discharge at the mine site to drainages affected by construction and water withdrawals. Reduced discharge to surface water would result in decreased groundwater recharge where there is surface water/groundwater interaction.

4.17.5 Summary of Key Issues

See Table 4.17-1 for a summary of key issues.

Table 4.17-1: Summary of Key Issues for Groundwater Hydrology Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Groundwater diversion during construction and operations	Diverted groundwater would be largely captured, treated, and discharged to the affected drainages during construction and operations to restore natural flow conditions.	Same as Alternative 1	Same as Alternative 1

AMERICAN OVERSIGHT

Table 4.17-1: Summary of Key Issues for Groundwater Hydrology Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Groundwater use during construction and operations (see Section 4.16, Surface Water Hydrology)	Groundwater use would be highest during construction and operations, and is expected to largely recover to pre-mining levels once mining ends and reclamation occurs, except for the Bulk TSF and open pit.	Same as Alternative 1	Same as Alternative 1
Open pit dewatering	Groundwater level change up to 2,200 feet below baseline condition during operations. Groundwater level change up to 50 feet below original level in post-closure. Groundwater flow direction change caused by flow towards open pit, which acts as hydraulic sink and would remain so in perpetuity. The areal extent of the cone of depression surrounding the open pit would increase as mining proceeds and the open pit becomes deeper. The estimated maximum area of the capture zone at end of mining would be about 2,470 acres. The areal extent of the cone of depression would decrease as the pit fills with groundwater to form a pit lake; however, a cone of depression would exist around the pit in perpetuity. The estimated area of the capture zone at post-closure and beyond would be about 2,350 acres.	Same as Alternative 1	Same as Alternative 1
Transportation Corridor			
Groundwater diversion during construction	Groundwater flow systems are maintained; temporary flow interruptions during construction.	Same as Alternative 1; overland route is 8% shorter, so groundwater impacts are slightly less.	Same as Alternative 1; overland route is 16% shorter, so groundwater impacts are less.

AMERICAN OVERSIGHT

Table 4.17-1: Summary of Key Issues for Groundwater Hydrology Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Groundwater use during construction and operations	Groundwater use at the construction camps would be temporary and minimal; aquifer would return to historical levels once operations end.	Same as Alternative 1	Same as Alternative 1
Port Sites			
Groundwater diversion during construction	Groundwater flow systems are maintained; temporary flow interruptions during construction.	Same as Alternative 1; Diamond Point footprint would be twice as large as Amakdedori port; temporary groundwater impacts are likely greater compared to Amakdedori.	Same as Alternative 2
Groundwater use at port during operations	Changes in groundwater quantity from water supply well would be minimal and within historical seasonal variability.	Same as Alternative 1	Same as Alternative 2
Natural Gas Pipeline			
Groundwater diversion during construction	Groundwater flow systems are maintained; temporary flow interruptions during construction.	Same as Alternative 1; 13% shorter route, so temporary groundwater impacts would be less.	Same as Alternative 1; 12% shorter route, so temporary groundwater impact is less; trench footprint may be 10% larger, slightly increasing temporary groundwater impact.
Groundwater use during construction	Groundwater use at the construction camps would be temporary and minimal; aquifer would return to historical levels once construction ends.	Same as Alternative 1	Same as Alternative 1
Concentrate Pipeline			
Groundwater diversion during construction	Not applicable	Not applicable	Buried in same trench as natural gas pipeline; trench is slightly larger than gas pipeline only installation, and may slightly increase temporary groundwater impacts; groundwater flow systems are maintained; temporary flow interruptions during construction.

AMERICAN OVERSIGHT

Table 4.17-1: Summary of Key Issues for Groundwater Hydrology Resource

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Groundwater use during operations	Not applicable	Not applicable	Concentrate pipeline would likely result in a diversion of 1 to 2% of groundwater from mine site to slurry concentrate.

4.17.6 Cumulative Effects

4.17.6.1 Alternative 1 and Variants

The geographic area considered in the cumulative effects analysis for groundwater hydrology is the near-project vicinity (i.e., within 0.5 mile to several miles) where project effects on groundwater flow patterns and use could overlap with other present and reasonably foreseeable future surface and groundwater uses. The direct and indirect effects of Alternative 1 and its variants would result in varying intensities of impacts to groundwater hydrology. Construction of the open pit requires lowering the water table in and surrounding the area of the pit to establish stable pit walls and dry working conditions. Placement of tailings in the bulk TSF in an unnamed tributary (gaging station NK 119A) to the NFK River would capture groundwater recharge and discharge and surface water flow for the foreseeable future until the tailings seepage water volumes decrease, and seepage water quality meets applicable standards for discharge.

Mine pit dewatering would cause long-term impacts to the local groundwater flow system and discharge patterns, particularly focused around the headwaters of the SFK River and UTC drainages. The most intense impacts would be experienced during the period of active mining. The plan for discharge of treated water back into the SFK and NFK rivers and UTC drainages and pit lake level recovery during closure and post-closure would serve to partly reduce impacts to shallow groundwater from these activities. However, the pit lake would remain as a hydraulic sink in perpetuity, so the local groundwater flow system around the pit would be permanently altered.

Effects on groundwater hydrology in the transportation corridor, natural gas pipeline, and port components would include small stresses on aquifers tapped by camp and port water supply wells, construction water uses, and temporary disturbances to shallow groundwater flow during road and pipeline construction. The impacted shallow groundwater aquifers are expected to return to pre-construction conditions once construction is completed, except for the port water supply wells, which would be used as long as mining occurs; and possibly used after mining ends, at least during closure.

Past and present activities that have affected groundwater hydrology in the analysis area include water supply wells in communities around Iliamna Lake, and small-scale wells or seeps associated with cabins and camps along the pipeline route, or mining exploration near the project area. Impacts associated with these activities include localized changes in groundwater flow patterns, reductions in groundwater in aquifers, and use of streams that are hydraulically connected with groundwater. These past and present actions are expected to continue throughout the project area, primarily in and around Iliamna Lake villages. Other parts of the project would be located in more remote areas, characterized as having very little development, and would not substantially draw from groundwater resources during mining operations.

AMERICAN OVERSIGHT

The implementation of Alternative 1 would impact groundwater in the project area during operations; however, these impacts are not expected to be significant beyond the boundaries of the operational mine site. Overall, the incremental contribution of Alternative 1, and impact to groundwater from the project and the past, present, and reasonably foreseeable future actions (RFFAs), would be localized high-intensity changes in the vicinity of the mine site during the life of the project, because the effects of the project on groundwater are limited to a relatively small area, and would be reduced in post-closure as the site is reclaimed and groundwater returns to pre-mining conditions in all areas except the bulk TSF and the open pit where groundwater impacts would remain.

4.17.6.2 Alternative 2 and Variants

Cumulative effects on groundwater hydrology for Alternative 2 and its variants would be similar to those discussed for Alternative 1 and its variants. Overland route of transportation corridor is 8 percent shorter, so temporary groundwater impacts during construction are likely less. The natural gas pipeline is 13 percent shorter, so temporary groundwater impacts during construction are likely less. The footprint of Diamond Point port is twice the size of Amakdedori port, so temporary groundwater impacts during construction would likely be greater under Alternative 2. Impacts of past, present, and reasonably foreseeable future actions would be similar to Alternative 1 and its variants.

4.17.6.3 Alternative 3 and Variants

Cumulative effects on groundwater hydrology for Alternative 3 and its variants would be similar to those discussed for Alternative 1 and its variants. The overland route of the transportation corridor is 16 percent shorter, so temporary groundwater impacts during construction are less. The natural gas pipeline is 12 percent shorter, so temporary groundwater impacts during construction are likely less. The footprint of Diamond Point port is twice the size of Amakdedori port, so temporary groundwater impacts during construction would be greater. Past, present, and reasonably foreseeable future actions would be similar to Alternative 1 and its variants.

AMERICAN OVERSIGHT

4.18 WATER AND SEDIMENT QUALITY

This section describes the following potential impacts of the project on surface water quality, groundwater quality, and substrate or sediment quality:

- Effects of ground disturbance and potential erosion on surface water and sediment quality.
- Effects of geochemical weathering of mined rock and tailings on the water quality of human-made waterbodies at the mine site.
- Effects of treated water discharge on water and sediment downstream of mine site facilities.
- Effects of dust deposition on water quality.
- Effects of tailings, waste rock, and contact water storage on groundwater quality and downstream resources.
- Effects of groundwater migration adjacent to the pit at closure.
- Effects of fill placement and erosion on substrate and sediment quality.
- Effects of marine construction and dredging on substrate and water quality.
- Effects on drinking water sources.

4.18.1 No Action Alternative

The geologic material at the mine site would continue to weather in place naturally. Background water and sediment quality in the mine site vicinity would not change; certain constituents would still be present in amounts exceeding regulatory levels because of natural mineralization and geochemical weathering processes. Water quality along the transportation and pipeline corridors would continue to reflect the presence of elevated levels of some constituents as described in Section 3.18, Water and Sediment Quality. Natural levels of sediment transport, deposition, and substrate modification would continue, and sediment would continue to contain certain constituents (e.g., metals) at elevated levels. No project-related geochemical processes or impacts on surface water, groundwater, or sediment quality would occur under this alternative. Consequently, under the No Action Alternative, the project would not be constructed and no new effects on water and sediment quality would occur.

4.18.2 Action Alternative 1 – Applicant's Proposed Alternative

This section describes the impacts of the project on surface water, groundwater, and substrate/sediment quality for each of the four project components. Evaluation factors considered by the US Army Corps of Engineers (USACE) in making determinations under Clean Water Act (CWA) Section 404(b)(1), Subpart C, include impacts on the following physical and chemical characteristics of the aquatic ecosystem. Impacts related to these characteristics are addressed in this and other sections of the environmental impact statement (EIS) as noted below:

- **Substrate.** Substrate includes sediment at the bottom of waterbodies as well as wetlands soils. Impacts on waterbody substrate (sediment) are summarized under "Substrate/Sediment Quality" in each of the four project component sections. Impacts on wetlands substrate are addressed in Section 4.22, Wetlands/Special Aquatic Sites.
- **Suspended Particulates/Turbidity.** Effects on turbidity and levels of suspended sediment are summarized under "Surface Water Quality" in each of the four project component sections.

AMERICAN OVERSIGHT

- **Water.** Direct effects on surface water quality and potential effects on surface water quality from migration of contaminants in groundwater are summarized under "Surface Water Quality" and "Groundwater Quality" in each of the four project component sections. Additional details are provided in Appendix K4.18.
- **Current Patterns and Water Circulation.** Impacts on currents and circulation in open waterbodies, and changes in surface water and groundwater flow patterns, are addressed in Section 4.16, Surface Water Hydrology, and Section 4.17, Hydrogeology.
- **Normal Water Fluctuations.** Impacts on stream discharge and groundwater fluctuations, and tidal effects on the project activities, are presented in Section 4.16, Surface Water Hydrology.
- **Salinity Gradients.** Effects on salinity gradients are described under "Surface Water Quality."

4.18.2.1 Mine Site

Surface Water Quality

The main objective is to manage water originating in the project area in an environmentally responsible manner while providing an adequate water supply for operations. A primary design consideration is to ensure the effective management of all contact water (process and runoff water that has come into direct contact with mining infrastructure) that would require treatment before release to the environment. This includes carefully assessing the layout of project facilities, process requirements, the area's topography, hydrometeorology, aquatic habitat and resources, and regulatory discharge requirements for managing surplus water. Water management strategies at the mine site are discussed in Section 4.16, Surface Water Hydrology. A map of the mine layout showing water storage facilities, diversion channels, collection ponds, and flowlines is provided in Figure 2-3 and Figure 4.16-1. Water balance model schematics showing estimated recycle flows between mine facilities are shown in Figure 4.16-2.

All runoff water contacting the facilities at the mine site and water pumped from the open pit would be captured to protect overall downstream water quality. Non-acid-generating quarry or waste rock would be selected and used in construction of mine site roads and embankments, utilizing techniques commonly used for grade control in open pit mines (PLP 2018-RFI 021c), such as testing for acid rock drainage (ARD) and metals at specified intervals or block sizes. The project design incorporates an analysis of water collection and management, including quantity and quality estimates, water treatment options, design of water management facilities, and strategic discharge of treated water. Implementation of the water management plan would enable the process plant to operate without additional water from off-site sources.

Effects of Ground Disturbance and Erosion. Ground disturbance during construction has the potential to lead to erosion and introduce suspended sediment and increased turbidity into waterbodies downstream of the mine site. Implementation of the water management plan during the construction phase would include the following features to minimize these effects:

- Water diversion, collection, and treatment systems would be installed to address the effects of ground disturbance and erosion on water quality during construction.
- Best management practices (BMPs) for water management and sediment control structures, including temporary settling basins and silt fences, would be installed to accommodate initial construction at the mine site.

AMERICAN OVERSIGHT

- Among the first permanent facilities to be constructed would be water management structures that would be maintained for use in adaptive management during operations. These structures would include diversion and runoff collection ditches to minimize water contact with disturbed surfaces, and sediment control measures such as settling ponds to prevent sediment from reaching downstream waterbodies.
- Stormwater runoff from facilities that do not come in direct contact with mining infrastructure would be treated for sediment and discharged under general Alaska Pollutant Discharge Elimination System (APDES) stormwater permits (Knight Piésold 2018a).

During the operations phase, implementation of the water management and sediment control plan would focus on minimizing the accumulation of contact water through diversion structures. Runoff and associated sediment control measures would be managed with BMPs and adaptive management control strategies. BMPs are described further in Section 4.14, Soils. Where water could not be diverted, it would be collected for use in the mining process or treated and discharged.

Effects of Dewatering Water Discharge in Construction. The construction phase would involve dewatering of the pit area beginning approximately 1 year before the start of operations. During construction, water collected from pit dewatering wells would be discharged to the open pit water management pond (WMP), which is expected to be in place before preproduction mining commences in Year 1. In the event that the open pit WMP is not available, water from dewatering wells would be treated prior to discharge by water treatment plant (WTP) #1 if it is in place, or by a modular WTP if WTP#1 is not in place. The modular WTP's processes for preproduction wastewater would include modules for the following processes as necessary: a temporary sedimentation pond; a sedimentation tank and/or sand separator; chemical addition and rapid mix module; a filtration module; and associated modules containing water feed/transfer pumps, chemical storage/feed systems, electricity generation, a workshop, and parts storage (PLP 2018-RFI 021b). Under either the WTP#1 scenario or the modular WTP scenario, discharge would require an APDES permit and must meet prescribed discharge limits and monitoring and reporting requirements. Following module WTP processing, water would be discharged to the South Fork Koktuli River (SFK) catchment (PLP 2018-RFI 021b).

Effects of Waste Rock/Tailings Storage and Water Management Ponds. Contact water that accumulates in on-site tailings and waste rock storage facilities and WMPs would be managed through containment and recycling/reuse so that it would not be inadvertently released to surface water downstream of these facilities until intended for treatment and discharge. Water in these containments would not be considered Waters of the State of Alaska or Waters of the US (WOUS) prior to discharge; therefore, such water would not be subject to regulation under the CWA or subject to APDES permitting requirements while retained within on-site water management facilities.

Bulk and pyritic tailings slurries from the mill would be directed to the bulk tailings storage facility (TSF) and the pyritic TSF, respectively. Potentially acid-generating (PAG) waste rock from the pit would also be stored in the pyritic TSF. Section 3.18, Geochemistry, provides a description of these materials. Precipitation and runoff water would also collect in these facilities. The bulk TSF would maintain a small operating (supernatant) pond, while the pyritic tailings would remain fully submerged in the lined pyritic TSF to minimize ARD and ML. The water over the pyritic tailings would be maintained sufficiently deep to minimize aeration of the water column, resuspension of tailings by wind-induced waves, and oxidation of the tailings. Excess water from the pyritic TSF would be pumped to the main WMP (Figure 4.16-2).

AMERICAN OVERSIGHT

The main embankment at the bulk TSF would operate as an unlined flow-through facility. Water collecting in the bulk TSF would flow through the embankment to the main embankment's seepage collection pond (SCP). From there, water would be directed either to the main WMP for use in the mill, or to the main WTP (WTP#2) for treatment and discharge. Excess surface water in the bulk TSF would be similarly managed. Water treatment byproduct sludge and reject water (water resulting from the treatment process) would be directed to the process plant and added to the pyritic TSF via the pyritic tailings slurry line. A portion of the treated water from the main WTP would be returned for use in the process plant and power plant cooling towers.

The predicted chemistry of geochemical sources contributing to the main and pyritic TSF ponds, the main SCP, and main WMP is discussed in Appendix K4.18 and shown in Table K4.18-2. Table K4.18-3 shows the predicted water quality in the ponds. Water in these ponds is predicted to contain levels of total dissolved solids (TDS), sulfate, and a number of metals in excess of water quality criteria (Table K3.18-1). These data have been used in the development of WTP processes described in Appendix K4.18.

The size of the ponds and the design criteria intended to prevent overtopping of pond water are described in Section 4.16, Surface Water Hydrology. Upset conditions that could lead to unexpected release of pond water to the environment are addressed in Section 4.27, Spill Risk.

A water surplus is anticipated during operations under normal and wetter than normal climatic conditions (Knight Piésold 2018a). Surplus water would be treated and discharged throughout the year. Section 4.16, Surface Water Hydrology, provides further details on the volume of water available for discharge compared to pre-mine flows in surrounding drainages.

Effects from Embankment Rockfill Runoff. Based on the geochemical analysis of source rock, the chemistry of runoff from rockfill in embankment dams is expected to be comparable to that of natural surface water and groundwater, with two possible exceptions (SRK 2018d):

- *Hydrothermally altered, sulfide-bearing PAG rock.* This rock would be managed separately based on PAG classification and would be used only in limited locations on the northern embankment of the pyritic TSF where runoff would be directed to the main WMP. All other dams would be constructed of non-PAG rock (PLP 2018-RFI 021c).
- *Rock containing explosive residues*. Explosives used during mining would consist of ammonium nitrate/fuel oil (ANFO) mixtures manufactured on site (PLP 2018d). This rock would be monitored until explosive residues have been leached (PLP 2018-RFI 021c).

Effects from Small Hydrocarbon Spills. The likelihood of small hydrocarbon spills from mine-related sources (e.g., mine machinery, product or waste storage facilities, or transfer operations) would be reduced through the application of BMPs, including the use of certified containers to transfer and store fuels and lubricants; secondary lined containment around bulk storage facilities; and managed storage, reuse, and/or disposal of used fuel products. Should a small spill occur, effects on the surrounding environment would be minimized by implementing controls, including automatic shutoff devices, and in-place spill response equipment and procedures (PLP 2018d). Section 4.27, Spill Risk, describes the potential for and effects of a large hydrocarbon spill.

Water Treatment during Construction. Potential effects of contact and runoff water during construction on downstream water quality would be minimized through treatment prior to discharge. Minimal water storage capacity would be available at the mine site until the completion of initial construction activities. Therefore, before completion of the bulk TSF embankments and water management structures, all contact water not meeting water quality

AMERICAN OVERSIGHT

standards would be treated in modular WTPs and released. Contact water from the following sources and activities in construction is expected to require treatment before release:

- Dewatering of the overburden aquifer above and near the pit deposit
- Water, primarily from precipitation, that accumulates in the open pit during construction
- Runoff from construction of TSF embankments.

Non-contact runoff water from excavation for site infrastructure such as the process plant, camps, power plant, or storage areas would be routed to sediment settling ponds before release. Non-contact runoff water that does not come into direct contact with mining infrastructure is considered stormwater, as defined in Code of Federal Regulations Title 40, Section 122.26(b)(13). Some or all of the stormwater discharge may require authorization from the Alaska Department of Environmental Conservation (ADEC) under the APDES Mine Site General Permit for stormwater, and would only require treatment for sediments prior to discharge into the environment.

Water Treatment during Operations. During operations, the mine site would have two WTPs: the open pit WTP (WTP#1) and the main WTP (WTP#2). Both would be constructed with multiple, independent treatment trains, which would enable ongoing water treatment during mechanical interruption of any one train. Details of the WTP systems are provided in Appendix K4.18 and summarized below.

The main WTP (WTP#2) would treat water from the main WMP, which would receive water from the bulk and pyritic TSFs and the TSF main embankment SCP. The open pit WTP (WTP#1) would treat water from the open pit WMP, which would be composed primarily of pit dewatering water. As described in Appendix K4.18, both facilities would utilize treatment plant processes commonly used in mining and other industries around the world. Key treatment steps for both WTPs would include dissolved metals oxidization, co-precipitation, clarification, ultrafiltration, and reverse osmosis (RO; Figure 2-10 and Figure 2-11). The open pit WTP would also include biological selenium removal, and the main WTP would include nanofiltration through high-pressure membranes (expected to remove selenium and other salts) and multiple-stage calcium sulfate precipitation with a lime softening process. Clarifier solids filter backwash from both WTPs would be thickened/evaporated and transferred to the pyritic TSF (HDR 2018a; PLP 2018d; PLP 2018-RFI 021d).

Based on an independent review of the WTP source terms and processes (Appendix K4.18; AECOM 2018i), discharge water from both WTPs is currently expected to meet ADEC criteria. There is some concern, however, that salt and selenium could build up over time in the pyritic TSF, which has the potential to lead to increased TDS concentrations that would require treatment in the main WTP (AECOM 2018i). This may require further investigation as design progresses and/or long-term adaptive management strategies (Chapter 5).

Treated water from the WTPs would be used to supply process needs, and the remainder would be discharged to the environment downstream of the mine site. All WTP#1 treated water and most WTP#2 treated water would be discharged, and a small portion of the WTP#2 treated water would be used for process and power plant needs. Water discharge points would be located in the North Fork Koktuli River (NFK), SFK, and Upper Talarik Creek (UTC) drainages (Figure 4.16-1). Water from both treatment plants would be strategically discharged in a manner that would optimize downstream aquatic habitat, based on modeling and monitoring during discharge (PLP 2018d).

ADEC regulates wastewater discharges from hard-rock mining facilities through various permits:

AMERICAN OVERSIGHT

- APDES Individual Permit for point source discharge into WOUS
- Integrated Waste Management Permit for solid waste disposal and wastewater discharge not into WOUS
- APDES Multi-sector General Permit for stormwater discharge
- Domestic Wastewater Discharge Permit.

State of Alaska regulations require that the condition of these permits ensure compliance with state water quality standards that are based on the use classification for the waterbody receiving discharge, and on the state's antidegradation policy. Some waterbodies may also have site-specific water quality criterion. For constituents that exceed criteria in background surface water and groundwater (Section 3.18.1, Appendix K3.18), there are currently no plans to incorporate site-specific background levels of constituents into discharge limits (ADEC 2018-RFI 064a).

Effects of Discharge Water Temperature. Modeling of temperature impacts using documented baseline temperatures and flow data, and predicted WTP discharge temperature and flow rates, indicates the magnitude of expected effects on temperature (PLP 2018-RFI 047). Because the modeled temperature effects are based on a limited set of measured water temperatures and flow scenarios collected at specific locations, the calculated discharge impacts reflect those conditions and locations. The calculated temperature effects provide a reasonable estimate of typical temperature effects from operational WTP discharges, summarized as follows:

- Temperature changes in the NFK watershed approximately 0.5 mile downstream of the WTP discharge point would be expected to be in the range of about -0.2 to +0.3°C (average of about +1.2°C) in summer months, and from about +1.7 to +3.6°C (average of about +2.8°C) in winter months.
- Temperature changes in the SFK watershed approximately 1 mile downstream of the WTP discharge point at the outfall of Frying Pan Lake would be expected to be in the range of about -1 to +1°C (average of about -0.15°C) in summer months.
- Temperature changes in the UTC watershed approximately 3 miles downstream of the WTP discharge point would be expected to be in the range of about 0 to +0.3°C (average of about 0.12°C) in summer months, and from about +0.3 to +0.7°C (average of about +0.54°C) in winter months.

Effects of Treated Water Discharge on Spatial Trends. Discharge of treated water from WTPs during operations would also have an effect on water conditions other than temperature within receiving waters (e.g., dissolved oxygen levels, turbidity, nutrient levels). As with temperature, these effects would be expected to be spatially limited to the area at and immediately downstream of discharge points, and would be managed by the planned strategic discharge of treated water between the three planned discharge points (PLP 2018d). Changes in water condition that occur at each discharge point would also be expected to be diluted through natural flow over a relatively short distance, and to return to background or near-background conditions. The effect of discharges on natural stream conditions would vary by location and seasonally, depending on background flow and other variable factors (e.g., fluctuations in water clarity, nutrient levels or dissolved oxygen content). Additionally, installing engineered discharge chambers at discharge points would reduce effects on certain water conditions such as turbidity and dissolved oxygen by baffling the discharge and allowing for more equilibration of water condition at the discharge point (Knight Piésold 2018f). The overall effect on nutrient levels would be expected to be minimal, given the nutrient-rich natural condition of streams in the area (PLP 2018d).

AMERICAN OVERSIGHT

Effects from Deposition of Fugitive Dust. Fugitive dust from various mine site sources with elevated levels of certain metals would be deposited on soils surrounding the mine site and would have the potential to run off into downgradient waterbodies or be deposited directly on waterbodies. Section 4.14, Soils, presents the incremental concentrations of metals that would be expected in the top inch of soil at the end of operations. Appendix K4.18 provides the methodology used to calculate the incremental increase in surface water and Table K4.18-12 shows the results. The results indicate a small expected increase in the concentration of metals in surface water as a result of dust deposition, ranging from 0.1 to 0.7 percent, which would not result in exceedances of the most stringent water quality criteria (Table K3.18-1). PLP is developing a fugitive dust control plan (FDCP) for mitigation and control of fugitive dust and wind erosion related to project activities. The anticipated plan would utilize BMPs and best available control technology (BACT) (PLP 2018-RFI 071a). Dust suppression water would be used at the mine site and along the transportation corridor as described below (PLP 2018-RFI 021c).

Effects from Dust Suppression Water. During operations, dust suppression at the mine site would use untreated contact water from the open pit WMP. This water source would be applied only to areas of the mine site where runoff is collected and treated. Outside of these areas, dust suppression would use non-contact water from other unaffected water sources outside of the mine site footprint (PLP 2018-RFI 021c).

Effects during Closure/Post-Closure. Water management and treatment during closure and post-closure is expected to minimize effects on water quality during both the physical closure of the site and associated reclamation activities, as well as during long-term post-closure and associated maintenance and monitoring activities.

Once mining ceases, partial dewatering would be maintained to allow the PAG waste rock to be moved from the pyritic TSF to the open pit, and to maintain pit wall stability until the PAG waste rock buttresses the potentially unstable lower walls of the open pit (see Section 4.15, Geohazards, and Appendix K4.15). The pyritic tailings would then be re-slurried using water in the pyritic tails and the tailings pumped to the open pit for subaqueous disposal. The water level in the open pit would be maintained to allow controlled placement and management of the PAG waste rock in dry areas of the pit, while keeping a water cover over the submerged pyritic tailings. Backhauling of the PAG waste rock would end approximately 14 years into closure and the transfer of pyritic tailings would end about 15 years into closure. Dewatering of the open pit would cease at the end of closure Phase 1 once the transfer of these materials is complete. PAG waste rock would be submerged within 2 years of placement as the water level in the pit rises (PLP 2018-RFI 092). Once dewatering ceases, groundwater behind the pit walls would begin to rise to create a pit lake. The open pit would then be allowed to fill with surface water runoff and groundwater, but would be kept at a maximum management level so that groundwater would continue to flow into the open pit from all directions, and it would remain as a hydraulic sink.

Surface runoff from reclaimed areas would be collected and either treated in the WTPs or directed to the open pit lake. Free water on the surface of the bulk TSF would be pumped to the main WMP through approximately year 15 post-closure, then to the open pit through approximately year 50 post-closure. The bulk TSF would be graded and revegetated to direct surface runoff toward the closure spillway at approximately year 10 post-closure. Seepage water from the embankment seepage collection systems would be collected and either treated in the WTPs or directed to the pit lake until determined to be suitable for discharge, anticipated after approximately year 50 post-closure.

AMERICAN OVERSIGHT

Surface runoff into the pit lake could cause metals to leach from the pit walls. In addition, contaminated groundwater would flow into the pit as described below under "Groundwater Quality." As a result, water quality in the pit lake would be expected to be acidic, with elevated concentrations of TDS, sulfate, and some metals (antimony, arsenic, cadmium, copper, lead, manganese, mercury, molybdenum, nickel, selenium, and zinc) exceeding water quality standards as a result of the oxidation of sulfide minerals in the pit walls and the natural concentrations of metals found in the mineralized rock. Appendix K4.18 describes pit lake water quality modeling further and Tables K4.18-5 through K4.18-8 summarize predicted lake water quality for the four closure phases. Once the level of the pit lake has risen to about 890 feet above mean sea level, anticipated to occur at approximately year 20 post-closure, water would be pumped from the pit to maintain the lake level at the maximum management level, treated as required at WTP#3 (redesigned for post-closure from WTP#1), and discharged to the environment downstream of the mine site in Frying Pan Lake in the SFK drainage.

Water treatment during closure/post-closure would use the operations WTPs #1 and #2 as needed, with WTP#1 upstream of Frying Pan Lake reconfigured and redesignated WTP#3. Treated water would be discharged within the NFK, SFK, and UTC drainages at the locations shown on Figure 4.16-1 (Knight Piésold 2018d). Water quality would be monitored and the treatment process would be adjusted as needed. Table K4.18-5 provides an estimate of treated discharge water quality from the pit lake. The reclamation and closure plan and financial assurance mechanisms required by the State of Alaska would include financial provisions for operating water treatment facilities and conducting ongoing monitoring indefinitely in the post-closure period.

Summary of Mine Site Effects on Surface Water Quality. Process-related (contact) water would not be considered WOUS or subject to APDES permitting while such water is retained in on-site water management facilities and recycled/reused on site. Contact water collected in mine facilities (e.g., bulk TSF, pyritic TSF) is not expected to meet Alaska water quality criteria for discharge (Alaska Administrative Code Title 18, Section 70, ADEC 2018) and would not be released directly to the environment without prior treatment to meet specific discharge requirements. WTP processes are expected to be effective in treating water to meet discharge criteria, although concerns regarding potential long-term increased TDS levels may require further investigation as design progresses and/or adaptive management strategies are implemented during operations (Chapter 5). The discharge limits described in this section and Appendices K3.18 and K4.18 would become part of an APDES permit, which would have monitoring requirements to ensure that discharged water meets applicable water quality criteria. The geographic extent of impacts on surface water chemical quality attributable to contact water would be limited to areas used for on-site storage of contact water before treatment. Temperature effects ranging from about -1 to 3.6°C would occur up to 0.5 to 3 miles downstream of the mine site.

Groundwater Quality

Section 3.17, Hydrogeology, and Section 3.18, Water and Sediment Quality address the affected environment with respect to groundwater flow and quality, respectively. With an effective water management and treatment program, impacts on groundwater quality would be limited to discrete portions of the project area. The principal mechanisms responsible for potential effects on groundwater quality at the mine site are summarized below.

Effects from TSF Seepage. Groundwater that could be affected by vertical seepage from the unlined bulk TSF would flow north down the NFK west drainage and be captured by the main embankment SCP. Groundwater modeling estimates that the bulk TSF would contribute about 0.2 cfs of seepage to the underlying groundwater system during and at the end of mining. The

AMERICAN OVERSIGHT

seepage rate would decrease over time after closure as the tailings consolidate and porewaters are squeezed out. The main embankment of the bulk TSF would be designed to promote seepage to the SCP, thereby minimizing the volume of water contained within the tailings impoundment and promoting embankment stability (Section 4.15). Hydraulic containment of seepage flow from the bulk TSF would be achieved and maintained using a series of control measures (Appendix K4.15, Table K4.15-1) (PLP 2018d; PLP 2018, RFI 006, 006a, 008f; Knight Piésold 2018a):

- North-flowing underdrains beneath the bulk TSF.
- Tailings beaches that would promote a north-sloping phreatic surface in the bulk tails.
- Upstream liners, low-permeability core zones, and grout cutoff walls at the south embankment of the bulk TSF and the main, south, and east embankments of the SCP.
- Seepage pump-back wells downgradient of the three SCPs.

Groundwater modeling suggests that a sump or pumping wells with an operating elevation of 1,250 ft at the main SCP and a grout curtain with an effective hydraulic conductivity of $1x10^{-5}$ cm/s would be effective in capturing seepage (Piteau 2018). Containment of affected groundwater would be monitored using wells to assess groundwater levels and quality (Knight Piésold 2018a). The predicted concentration of constituents in groundwater beneath the bulk TSF and between the TSF and the main SCP would be similar to those listed in Table K4.18-2 and Table K4.18-3 for the main SCP. Several metals, TDS, and sulfate in the main SCP are predicted to exceed baseline concentrations and regulatory criteria at the end of mining and the end of closure Phase 3, and thus would require continued treatment at WTP#3 in post-closure (Knight Piésold 2018d).

Groundwater beneath the pyritic TSF is less likely to be impacted because this facility would be fully lined. The potential for liner damage (e.g., from ice or placement of waste rock) leading to leakage of tailings porewater was evaluated in the EIS-Phase Failure Modes Effects Analysis (FMEA), and the likelihood of occurrence was considered to be low to moderate (AECOM 2018l). Potential leakage through the liner would be diluted by unimpacted groundwater flowing northward down the NFK east drainage, and would be intercepted by the main WMP and its downgradient seepage pumpback wells.

Based on the proposed seepage collection systems, the TSFs are not expected to result in impacts on downgradient groundwater quality outside of the mine site. The vertical extent of impacts is expected to be limited to shallow groundwater in overburden deposits and the bedrock contact zone between the TSFs and seepage collection facilities (Figure 4.16-1 and Section 4.17, Hydrogeology). However, impacts on local groundwater within the mine site could be sufficient to exceed water quality regulatory criteria, and those effects could persist through the life of the mine and well into post-closure Phase 4. Should monitoring at seepage collection systems in post-closure indicate that water quality meets approved criteria for discharge without treatment, direct discharge would occur. If monitoring were to find that groundwater quality is not improving during the post-closure period, additional remedies would be implemented to capture and/or treat impacted groundwater. It is anticipated that groundwater locally impacted by limited seepage from the TSFs would meet regulatory discharge criteria at approximately year 50 post closure (Knight Piésold 2018d).

Effects from WMP Leakage. Table K4.18-3 shows the predicted concentration of mine-related constituents in water in the main and open pit WMPs. Water in these ponds is anticipated to contain TDS, sulfate, and a number of metals at levels exceeding discharge water quality criteria. Pond water leaking through the pond liners would be intersected by underdrain systems

AMERICAN OVERSIGHT

included in the design of those facilities, and subsequently pumped back to the respective WMP (PLP 2018-RFI 019a); however, some water could bypass the underdrain system and seep into underlying shallow groundwater. In the case of the open pit WMP, all underlying shallow groundwater would be completely within the capture zone of the dewatered open pit during operations and post-closure; hence, any impacted groundwater would be recycled through the dewatering and treatment process, or contained in the pit lake.

In the case of the main WMP, the estimated maximum leakage rate through the liner of 1 liter per second (Piteau 2018) would yield a daily leakage rate of nearly 23,000 gallons. Without intervention, water not captured by the underdrain system would be expected to mix with shallow groundwater and discharge into the NFK watershed. To prevent this, a line of monitoring/pumpback wells would be installed along the north side and at the northwest corner of the main WMP. Should monitoring of these wells show impacts from liner leakage, the wells would be used to intercept and recycle shallow groundwater back to the main WMP. Based on the current mine plan, it is possible that gaps exist along the main WMP embankment that would allow potentially affected groundwater to flow through areas where wells are limited (e.g., along the southwest side of the embankment, Figure 4.16-1). As discussed in the EIS-Phase Failure Modes Effects Analysis (FMEA), the final location and spacing of pump-back wells would be determined based on additional hydrogeologic investigation as design progresses to minimize the likelihood of this occurrence. Because the main WMP would be removed at the end of mining during post-closure Phase 2 (Knight Piésold 2018 Closure WMP), this potential effect would not occur during subsequent post-closure periods (Piteau 2018).

Effects from Pit Overburden Stockpile Seepage. Seepage from pit overburden materials that would be excavated and stockpiled could affect surface water or groundwater quality. Potential effects would be limited by segregating mineralized overburden from non-mineralized overburden, and stockpiling mineralized materials that exhibit a high potential for leaching in the pyritic TSF. Prior to excavation, overburden materials would be characterized by drilling and sampling, thereby allowing materials to be segregated visually during excavation. This technique is common in open pit mining for grade control (PLP 2018-RFI 021c). As a secondary control to address placement of potential PAG material in the non-mineralized overburden stockpile, multiple lines of monitoring wells would be installed downgradient from the stockpile and monitored for exceedances of applicable water quality standards. If exceedances were observed, the wells would be converted to pumping wells to intercept and redirect impacted water to the open pit WMP for treatment and permitted discharge (PLP 2018-RFI 021c).

Effects on Seeps. The likelihood that impacted groundwater would discharge at previously recognized seeps at the mine site is small, considering that most overburden with seeps overlying the open pit would be removed and that seeps present in the footprints of the TSFs and mine facilities would be covered. Impacted groundwater is expected to be captured by the seepage collection systems or contained within the open pit cone of depression and would not be expected to surface as seeps within the mine site. However, should seeps occur downgradient of mine facilities, surface water runoff controls would be used to capture and route it to the appropriate collection ponds for treatment and subsequent discharge. Monitoring would also be conducted to recognize new seeps that may form, measure their water quality, and ensure that the seepage is captured and routed to the appropriate seepage control pond, or if water quality is satisfactory, discharged to the environment.

Dust Leaching to Groundwater. Fugitive dust deposited on soils surrounding the mine site has the potential to leach into groundwater. Section 4.14, Soils, presents the baseline and incremental concentrations of metals in soil at the end of operations. These results are compared to ADEC migration-to-groundwater levels to estimate the magnitude of this effect on groundwater. Table K4.18-13 presents the metals concentrations in soil after dust deposition,

AMERICAN OVERSIGHT

as well as ADEC comparative action levels for the migration to groundwater criteria for soils. The predicted percent increase in metals concentration attributable to dust deposition was less than 0.8 percent for all metals with the exception of antimony, which is predicted to increase in concentration by approximately 3 percent. Modeling and calculations of dust deposition do not indicate that any new exceedances of the ADEC levels would result from the dust effects. Arsenic was the only metal that would be expected to exceed these criteria; however, that exceedance would result from baseline soil conditions, and dust deposition would be expected to increase arsenic concentrations in soil by only about 0.6 percent.

Effects from Pit Lake in Closure. Surface water in the pit would continue to be pumped out during the first 15 years of closure while pyritic tailings and PAG waste rock are being placed in it. Pumping of groundwater may initially be maintained in a localized area of the open pit at the end of mining to facilitate safe placement of the waste while maintaining pit wall stability in the lower portion of the pit where faults are present (Section 4.15, Geohazards) (PLP 2018-RFI 023a). Pumping of water from the pit during early closure, and cessation of most groundwater pumping while waste is being placed, is expected to result in the groundwater level adjacent to the pit rising faster than the pit lake level rise, such that contact water in the pit is not likely to extend beyond the pit walls except in the localized area of temporary wall stability depressurization. Hydraulic containment would be maintained during all closure phases because overall flow gradients would be toward the pit lake radially from all directions, thereby limiting the extent of migration and capturing any pit-contaminated groundwater (PLP 2018-RFI 019d).

All pit dewatering would cease once placement of the PAG waste rock and pyritic tailings is complete to allow the pit lake to rise and cover the waste. Inputs of contaminated water into the pit lake from the waste and walls are predicted to exceed regulatory limits for water quality for a number of constituents, including TDS, sulfate, and metals (Table K4.18-5 through Table K4.18-8).

After lake level rise, groundwater gradients toward the pit would be maintained by managing the pit lake level through pumping and treating the lake water in perpetuity. With the pit water level maintained at the maximum management level of 890 ft msl, groundwater flow is expected to be directed radially toward the pit from all directions. The pit water would be retained in the pit and would not contribute (flow out) to affect the quality of groundwater outside of the radius of influence of the pit. Modeling indicates that the open pit hydraulic capture zone would extend 1,000 ft or more from the crest of the pit in post-closure (Piteau 2018). Section 4.17 and Appendix K4.17 provide additional information on the analysis of groundwater flow in closure.

Groundwater monitoring would be conducted at selected wells surrounding the pit lake to confirm that groundwater flow is toward the pit and that impacted groundwater is not migrating outside of the pit. Should the monitoring find that groundwater does not flow toward the pit or that groundwater quality outside the pit is degraded during the post-closure period, the maximum management level (890 ft msl) currently proposed would be reconsidered, and the pit lake level would be lowered to maintain hydraulic containment. Modeling of post-closure pit water quality indicates that the open pit water would need to be treated in perpetuity (Knight Piésold 2018d).

[Placeholder: Additional information on pit lake modeling, lake stratification, and its effects on water quality was received November 1, 2018 (PLP 2018-RFI 021c). This information will be reviewed and incorporated as appropriate in the DEIS.]

Effects on Drinking Water Wells. Groundwater is abundant in the project area and would be used as a source of potable water. The proposed water supply wells would be sited on a groundwater high located upgradient, and on the north (opposite) side of, the NFK east and

AMERICAN OVERSIGHT

north drainages that contain seepage collection systems for the pyritic TSF and main WMP (Figure 4.16-1). Thus, groundwater that could be potentially affected by mine site facilities would not be expected to affect drinking water sources used by on-site workers.

Effects on Wetlands. Disruption, in-filling, and removal of wetlands could influence groundwater recharge and discharge patterns, which could affect groundwater quality in the vicinity of the mine site. Currently, although sulfides appear to be naturally oxidizing in the deposit area, the groundwater is not acidic (see Section 3.18, Water and Sediment Quality). Reducing conditions are prevalent, partly because of deposition of organic carbon from wetlands and infiltration of organic carbon during spring thaw. The redox state of the overburden may change during mine operations as the water table is lowered and previously saturated soils and sediments are exposed to oxygen. This change in redox conditions could release metals to groundwater as oxidation occurs, and possibly precipitate reduced metals within sediment pores. Concentrations of metals in shallow groundwater may also increase because of the disruption of wetlands and increased sedimentation, resulting in an increase in suspended particulates with adsorbed metals.

Summary of Effects on Mine Site Groundwater Quality. Impacts on groundwater quality from mine site activities under Alternative 1 would likely be limited to effects on local groundwater in the near vicinity of mine facilities, within the footprint of the mine site. These impacts would be such that groundwater would not meet regulatory criteria at certain discrete locations within the mine site (e.g., shallow groundwater beneath the bulk TSF and groundwater in the open pit as the lake level rises). Groundwater entering the pit where it would mix with pit lake water would be pumped and treated in perpetuity to maintain the open pit as a hydraulic sink. Groundwater quality beneath the NFK west and NFK east drainages would likely be impacted during operations, but would be expected to improve in the decades after mine closure. Monitoring would be conducted after the end of mining, during the closure and post-closure periods, to determine whether groundwater quality in these localized areas improves after mining ceases. If monitoring shows that groundwater quality is not improving during the post-closure period, additional remedies would be implemented to capture and/or treat the impacted groundwater as needed.

Substrate/Sediment Quality

This section describes impacts on waterbody substrates. Impacts on wetlands substrates are addressed in Section 4.22, Wetlands.

Effects of Fill Placement on Physical Substrate. Placement of fill for construction of TSFs, WMPs, stockpiles, seepage and sediment ponds, and other facilities at the mine site would bury substrate in a number of streams and ponds. Section 4.22 lists the acreages of fill placement in both waterbodies and wetlands.

Placement of fill would also cause changes in sediment supply to streams downgradient. At mine site locations where streams would be filled, such as at the bulk TSF and associated seepage and sediment ponds, the downstream sediment supply to the NFK River would be cut off, depleting the natural supply of sediment to downstream gravels and potentially affecting aquatic habitats (see Section 4.24, Fish Values). A decrease in water flow from fill placement would also lower the natural level of coarse sediment transport, potentially allowing more fine particles to accumulate within the streambed.

Summer-Only Ferry Operations Variant. Potential operational scenarios under the summer-only ferry operations variant would affect substrate because of the increased operational footprint at the mine site (Ausenco Engineering 2018). Ore concentrates and additional diesel fuel would be stockpiled at the mine site, requiring additional container and fuel storage areas

AMERICAN OVERSIGHT

that would total approximately 38 acres. These storage areas would be constructed partially or wholly on wetland areas, thereby directly affecting substrate.

Effects of Erosion on Physical Substrate. Sediment release from erosion during construction and operations would be minimized through the use of BMPs (described above under "Surface Water Quality"). Sediment control measures applied during construction would include the use of temporary settling basins and silt fences. Sediment control measures during operations through closure would include a number of diversion channels that would direct surface runoff away from project facilities, and sediment ponds that would allow material to settle out of the water column, thus inhibiting downstream sediment transport. Surface runoff and seepage from stockpiles would be captured by drainage ditches and routed into sedimentation ponds to allow settling before water is released downstream. If these systems were designed properly to allow for adequate capacity and BMPs were followed, sediment releases and impacts on downstream substrate would be minimal. However, the potential exists for erosion during periods of high precipitation and runoff to overwhelm the BMPs, resulting in an influx of fine sediment and increased turbidity into gravel-dominated streambeds. In this event, suspended fine particles could settle and fill in interstitial spaces among the gravel, potentially affecting the streambed's ecosystem (see Section 4.24, Fish Values).

Construction of the mine site facilities would block some streamflow, reducing natural erosion during high-precipitation events; however, increased streamflow where WTP effluent is discharged could increase the sediment eroded and transported downstream that is then redeposited, thus modifying substrate both upstream and downstream. Current designs for WTP discharge indicate that each outfall pipeline would be equipped with a discharge chamber to mitigate the potential for erosion at discharge points. Discharge chambers would be buried at sufficient depth for thermal insulation against freezing. Each outfall pipeline would be designed first to drain into the discharge chambers to reduce the energy of water outflow, then to release the water into the drainage (Knight Piésold 2018f).

Impacts on Sediment Quality during Construction and Operations. Mining and exposing rock to chemical and physical weathering and erosion may increase the natural (pre-mine) rates of these processes and release constituents into surrounding surface water and substrate. Therefore, the evaluation of impacts on sediment quality depends largely on water quality and the other direct sedimentation impacts described above (e.g., erosion, dust). The chemical quality of sediment in some sections of streams at the mine site would be altered by fill placement, sediment accumulation upstream of embankments, and migration of contact water to downstream collection facilities. For example, contact water from the flow-through bulk TSF main embankment could introduce contaminants into native sediment between the TSF and the downstream SCP. Chemical components in water (such as metals and sulfate) could be absorbed by sediment or adsorbed onto sediment surfaces. Conversely, sediment could retain chemical constituents and slowly release them into water.

With containment and implementation of BMPs, impacts on sediment quality from surface disturbances would be limited to localized areas of the project footprint. Adverse effects on sediment quality downstream of treated WTP discharge points are not expected because the water would be treated before discharge and the potentially affected sediment would be contained by seepage and sediment ponds upstream of the discharge points. Likewise, although sediment in fully lined or contained facilities such as the pyritic TSF, WMPs, and pit lake would contain acid and metals from the mining process, these would not affect native sediment in downstream waterbodies.

Impacts on Sediment Quality from Fugitive Dust. Fugitive dust from various mine site sources and activities has the potential to affect concentrations of metals in sediment. Appendix

AMERICAN OVERSIGHT

K4.18 provides the methodology used to calculate the predicted incremental increase in metals concentrations in sediment, and Table K4.18-11 shows the results. Increases in the metals concentration in sediment due to dust deposition are anticipated to be minimal. Total increases in the concentrations are predicted to be less than 1 percent for all metals except antimony, which would be expected to increase by about 3 percent. Dust deposition would not be expected to result in any exceedances of the most stringent sediment quality criteria (Table K3.18-1).

Effects on Sediment Quality during Closure. During closure and reclamation, soil and sediment beneath the facilities slated for removal (such as the pyritic TSF and WMPs) would be tested for contaminants, and any impacted materials exceeding applicable regulatory levels would be either treated or removed and placed in the open pit (Knight Piésold 2018b). Surface runoff and groundwater that may be hydraulically connected to on-site sediment would be monitored downstream of the TSFs and WMPs at selected locations during post-closure to verify that potentially contaminated sediment is not affecting downstream water quality.

It is possible that contaminants may be held within sediment between the reclaimed pyritic TSF and WMP footprints that are tested at closure. Sediment can retain chemical constituents and release them into overlying water slowly, for decades or longer. Contaminants can be flushed out of coarse sediments such as gravels relatively quickly; by contrast, fine sediments like silts, muds, and clays found in some of the glacial lake deposits at the mine site can retain contaminants in porewater, and can store them for long periods of time because of their higher surface area. Even in areas where downstream water quality is monitored; contaminants held in sediment may continue to be slowly released into waterbodies over the long term, potentially beyond the point that monitoring points would be closed where water meets the discharge criteria. Thus, low-intensity sediment contamination in between the removed facilities could persist at the mine site for decades in post-closure potentially contributing to water quality impacts over time. To address this potential impact, Chapter 5, Mitigation, provides a recommendation for additional testing of sediment quality between facility footprints at closure.

4.18.2.2 Transportation Corridor

Surface Water Quality

Road Corridor. Impacts on surface water quality along the road corridor could result from erosion at construction sites and stream crossings. Erosion and sedimentation would be managed by implementing BMPs as described in Section 4.14, Soils.

Based on a field review of geology at material sites, PAG material has not been identified at any site along the transportation corridor, and the rock types present are not typical of PAG rock. Rock types would be investigated further during site evaluation before construction. If PAG material is identified, it would not be used for construction, and the material site would be relocated to an alternate location with non-PAG rock (PLP 2018-RFI 035).

The potential for small amounts of vehicle- or ferry-related pollutants to affect streams along the transportation corridor is discussed below under "Substrate/Sediment Quality." Section 4.27, Spill Risk, discusses the potential for containers containing concentrate to affect water quality.

Ferry Construction and Operations. Impacts on surface water quality could result if ferry-induced suspended sediment in Iliamna Lake near the terminals were to exceed background levels (Table K3.18-12). However, because the ferry would approach the dock perpendicularly at low power and the propeller base plane would be 4 ft above the keel, the potential for propeller-induced erosion of the lakebed would be limited (PLP 2018-RFI 013). In the unlikely event that fine bottom sediments were resuspended by ferry operations, it is

AMERICAN OVERSIGHT

expected that TSS concentrations would be expected to return to background levels within a short distance (less than 100 ft) from the ferry.

Stormwater runoff at the ferry terminals would be a potential source of impacts on surface water quality. Releases from ferry terminal facilities (e.g., generators, maintenance shops, or parking areas), if they occurred, would have the potential to affect surface water quality through stormwater runoff. The risk and impact of releases at the ferry terminals would be reduced through implementation of engineering controls (e.g., secondary containment, planned material management, and the presence of spill response equipment). In addition, stormwater treatment systems would be in place at both ferry terminal locations to capture potential contaminants (PLP 2018-RFI 093).

Groundwater Quality

Road construction and ferry operations are not expected to have a measurable effect on groundwater quality. It is possible that a localized increase in turbidity at stream crossings could occur in an exchange with shallow groundwater, but the effects of such an increase on the groundwater's chemical composition are likely to be imperceptible.

Substrate/Sediment Quality

Erosion Effects. Project-induced erosion and increased sedimentation on waterbody substrates is possible during construction activities such as vegetation removal, excavation, and grading. Withdrawal of water from permitted waterbodies during construction and operations also has the potential to disturb fine sediment on streambeds and lakebeds. These effects are expected to be of low intensity with the implementation of BMPs such as dust control and erosion and sedimentation control measures, and compliance with permit stipulations for water extraction methods. Effects during road construction would likely be limited to the close vicinity of stream crossing areas within the construction right-of-way. The potential for erosion and sedimentation is expected to be seasonal (reduced in winter by frozen conditions), and to continue for the life of the unpaved roads, which would be permanent, as they would be needed to support water treatment at the mine site in post-closure.

Should BMPs be inadequate or overwhelmed by high-precipitation events, eroded soils and sediments could be transported by water and wind, potentially causing sedimentation into nearby waterbodies. Section 2.24, Fish Values, describe effects on fish habitat and aquatic resources. Streams intersecting the transportation corridor vary in grain size and substrate composition, with some crossings composed mainly of sand, silt, and organic material and others having a higher concentration of gravel, cobbles, and boulders (Section 3.18, Water and Sediment Quality) (PLP 2018-RFI 036). The Gibraltar river bridge crossing location is largely dominated by gravel and cobbles. Stream crossings in areas where substrate is predominantly fine-grained would likely be subject to greater erosional effects and impacts on substrate than those with predominantly coarser substrates.

Placement of Fill Material. Road construction would include the placement of fill onto waterbody substrates at stream crossings, lakes, and ponds along the transportation corridor. Gravel fill would be placed at certain bridge abutments and at the ends of culverts larger than 3 ft in diameter to protect the bridge structures and substrate from erosion. Fill would also be placed inside larger culverts requiring fish passage to simulate streambed material for aquatic habitat. The areas and lengths of streams affected are quantified in Table 4.22-3 and shown in Figure 3.22-3 and Figure 3.22-4. The direct effect of fill placement would be to permanently bury existing sediment, as the road would remain during post-closure. Fill placement at the ferry landings would extend about 100–150 ft onto the nearshore lake sediment and would

AMERICAN OVERSIGHT

remain in place at closure. Potential indirect effects under CWA Section 404(b)(1) include temporary localized sediment suspension and redeposition downstream during construction.

Sediment Contamination. Small amounts of vehicle- or ferry-related pollutants such as fuel, oil, and lubricants would be used during the normal course of operations. These pollutants could be released onto the roadbed and run off to stream or pond substrates, or could be released into Iliamna Lake and incorporated into lakebed substrate. These potential impacts related to sediment contamination would likely be of low intensity, and would extend throughout the life of the mine and into post-closure. Section 4.27, Spill Risk, addresses impacts from potential major spills along the transportation corridor.

Summer-Only Ferry Operations Variant. Under the summer-only ferry operations variant, activities at the ferry terminals would be reduced for approximately 6 months per year, during the winter (Ausenco Engineering 2018). As a result, roadway use would also be greatly reduced, particularly on the south side of Iliamna Lake. During the period of no use, the potential for impacts on substrate and sediment quality would also be reduced because of the lower activity levels. However, the potential for impacts would not be eliminated entirely because limited quantities of fuel, lubricants, or other potential contaminants would still be stored at local ferry terminal facilities, and because some roadway use would still be expected. During the periods of ferry operation, the intensity of activity would approximately double to account for the reduced length of the operational season. Overall, the effect of this variant on substrate would be essentially the same as the effect of Alternative 1.

4.18.2.3 Amakdedori Port

Surface Water Quality

Surface Water Runoff and Treatment. Amakdedori port would be the shoreline hub for shipping, receiving, and storage of concentrate containers, fuel, reagents, and other freight for the project. The outside of concentrate containers would be vacuumed or spray-washed at the port site (PLP 2018-RFI 45). A container barrier wall built around the fuel tanks and a perimeter containment curb constructed around the terminal would prevent surface water runoff from these facilities and activities from reaching off-site surface water.

The WTP at Amakdedori port would treat surface runoff from the port facilities, which could potentially contain constituents from the above sources. Runoff water from the port facilities would likely have some similarities to mine contact water in terms of solids, but would not be expected to have the same levels of TDS given the lack of material processing. The treatment process would include dissolved metal oxidation using potassium permanganate, followed by co-precipitation with ferric chloride. Water from the co-precipitated solids would flow into flocculators/clarifiers to separate out the solids. The clarified water would then be treated with sodium hydrogen sulfide, sodium hydroxide, and ferrous sulfate to further co-precipitate the remaining metals under reducing conditions. The solids removed would be thickened and disposed of appropriately. The treated water would be suitable for discharge, with a discharge point in marine waters at the end of the dock structure. A potable WTP and a sewage treatment plant would also be located at the port site.

Dust Impacts on Marine Water Quality. Deposition of dust from concentrate handling at the offshore lightering locations would have minimal potential to result in impacts on water quality in Cook Inlet. Such impacts would be mitigated, and possibly eliminated, by implementing BMPs to prevent the dust from entering the water. The containers would be inverted and opened deep into the cargo hold of the ships below potential crosswinds, and concentrate would not be released until the fall of the material is less than 10 ft and the discharge elevation is 20 ft or

AMERICAN OVERSIGHT

more below the hatch. The concentrate is expected to still be moist from processing, but a water fog system could be installed to minimize dust if required (PLP 2018c; PLP 2018-RFI 45). Section 4.27, Spill Risk, addresses impacts on water quality under potential upset conditions.

Impacts on Salinity Gradients. Salinity gradients that might occur naturally at the locations of freshwater discharges into the port areas would assimilate quickly into adjacent marine waters due to natural mixing by wind-driven currents and waves, and thus would not likely be affected by port operations.

Suspended Particulates/Turbidity from Causeway Fill. Increased concentrations of suspended sediment and redeposition would occur in Kamishak Bay during the placement of fill material for causeway construction and the installation of sheet pile for the wharf structure. Such conditions could persist for up to several days after the completion of construction. The duration and extent of the increase in suspended sediment concentrations would depend on the amount of fine sediment in the fill material and disturbed seafloor material, as well as weather conditions (i.e., tides and wind-driven currents and waves would disperse suspended sediment even as it settles to the seabed). Fill material would consist of either blasted granitic bedrock trucked along the road from the closest material site, MS-A08, or imported by barge from existing commercial sources (PLP 2018-RFI 005; PLP 2018-RFI 035) such as the granite quarry at Diamond Point (ADNR 2014). The seafloor material consists of silty fine sand with gravel and a fines content of about 14 to 19 percent. The incremental increase in project-induced suspended sediment and redeposition is expected to be small compared to the naturally moderate to high load of suspended sediment and the sediment migration that occurs in Cook Inlet (Section 3.18, Water and Sediment Quality).

Pile-Supported Dock Variant. Compared to the causeway alternative, this dock variant would essentially be transparent to water movements in the port area; that is, a pile-supported dock would not be capable of deflecting alongshore currents away from the shore in the same manner as a solid-fill causeway. Except for very localized wake effects in the immediate vicinity of each pile, which would be limited to a few pile diameters' distance from each pile (on the lee side), no alteration of water movements or sedimentation processes would occur. Vibrations caused by pile driving during construction could affect sediment substrate; however, these effects would be limited to the actual pile driving period, and would not be expected to cause a substantial change in the character of the surrounding substrate.

Groundwater Quality

Impacts on groundwater quality at the port site are expected to be limited. No excavation or placement of fill would occur at depths that intersect the water table. Using groundwater for drinking water supplies at the port would not adversely affect groundwater quality. A single groundwater well is planned for the port site for potable water supply (location to be identified during detailed design). The well would be sited on uplands far enough from shore to mitigate the risk of potential saltwater intrusion, and water would be piped to the port site from the wellhead (PLP 2018-RFI 022a).

Substrate/Sediment Quality

Effects on Freshwater Substrate. Sediment in Amakdedori Creek on the southwest side of the terminal and in ponds to the north has the potential to be affected by erosion and overland runoff, especially during construction. BMPs would be in place to avoid or minimize these effects. The port terminal would be built at an elevation of 35 ft, about 15 ft above the floodplain of Amakdedori Creek. As described above, runoff from the terminal would be contained and treated, minimizing the potential for contaminants to reach Amakdedori Creek. Section 4.14,

AMERICAN OVERSIGHT

Soils, and Section 4.16, Surface Water Hydrology, provide further descriptions of BMPs and potential flooding effects, respectively.

Summer-Only Ferry Operations Variant. The summer-only ferry operations variant would have an increased operational footprint at the port site, which could cause increased effects on substrate (Ausenco Engineering 2018). The additional concentrate storage under this variant would require placement of fill along the east bank of Amakdedori Creek (PLP 2018-RFI 065). Section 4.22, Wetlands, provides the acreage of wetland substrate coverage under this variant.

Effects on Marine Substrate. The causeway would be approximately 1,200 feet long with an average base width of 250 feet, and the wharf would extend another 700 feet with a width of 120 feet (PLP 2018-RFI093); the footprint on the floor of Kamishak Bay would be approximately 9 acres. Placement of fill and riprap on top of the seabed during causeway construction and installation of sheet pile for wharf construction would result in the burial of substrate beneath the footprint, disturbance of seafloor sediment during fill placement and sheet pile driving, and settling of suspended solids away from the footprint as described above under "Surface Water Quality." Dredging of offshore sediment would not be required at the Amakdedori port site. Section 4.24, Fish Values, discusses impacts on the primarily soft sediment habitat types in this area.

Low levels of marine vessel-related pollutants such as fuel, oil, and lubricants may be released into Kamishak Bay and Cook Inlet waters and become incorporated into seafloor sediment. Strong currents, shallow water, and high tidal exchange in Cook Inlet, however, create an ongoing flushing of seawater in the inlet. Marine vessel activity in Upper Cook Inlet does not appear to have contributed to measurable sediment contamination (USACE 2013). Potential contaminants from marine vessels accessing Amakdedori port would be diluted and flushed into the North Pacific Ocean, and are expected to contribute a negligible amount of contamination to existing low background levels (Section 3.18, Water and Sediment Quality). Section 4.27, Spill Risk, discusses impacts from upset conditions.

4.18.2.4 Natural Gas Pipeline Corridor

Surface Water Quality

Impacts on surface water quality within the natural gas pipeline corridor would be associated with installation of the pipeline at water crossings and the use of local water sources for hydrostatic testing. Impacts at material sites and stream crossings would be the same as those described above for the transportation corridor.

Surface water quality at pipeline stream crossings is expected to be within water quality standards for turbidity during construction. Natural turbidity measurements at stream crossings along the transportation corridor were mostly below the instrument's minimum detection level of 7–11 nephelometric turbidity units (NTU) during 2018 field studies (Section 3.18, Water and Sediment Quality) (PLP 2018-RFI 036). ADEC water quality standards specify that turbidity levels may not exceed 5 NTU above these conditions (when the natural turbidity level is 50 NTU or less). Isolated occurrences of impacts above this standard could occur (e.g., during high-precipitation periods along summer construction segments), but are expected to be reduced within a short time frame because of planned redundancies in BMPs, erosion and sediment control measures, and reclamation/cleanup crew functions.

The extent of potential impacts from hydrostatic testing for pipeline pressure testing would be limited because the water volumes required would be small compared to the volumes of potential sources from rivers and small lakes along the route. Impacts on surface water quality

AMERICAN OVERSIGHT

would likely be imperceptible. Discharges of hydrostatic test water would meet the requirements of the applicable APDES general permit.

Groundwater Quality

Trenching Effects. The pipeline trench would likely intersect shallow groundwater intermittently along the overland portion of the route, causing potential impacts on groundwater quality similar to those of the transportation corridor. There could be local alterations to shallow groundwater flow patterns (Section 4.17, Hydrogelology) and small changes in the composition of groundwater that would likely not exceed applicable regulatory criteria. The extent of groundwater impacts would be limited to particular areas, primarily in the vicinity of river and stream crossings.

Horizontal Directional Drilling Effects on Drinking Water Wells. Horizontal Directional Drilling (HDD) operations would be required only for the natural gas pipeline at the Kenai shore approach near Anchor Point. Impacts of HDD operations on groundwater and potential drinking water sources would be expected to be minimal and localized relative to baseline groundwater supply wells (Section 3.18, Water and Sediment Quality). Dewatering would not be required for HDD operations, precluding the risk of changes in local groundwater flow patterns (Section 4.17, Hydrogeology). Drilling fluid would likely be composed of bentonite and water. The potential risk exists for drilling fluids, injected under pressure, to propagate away from the borehole and escape into the local aquifer (PLP 2018-RFI 051). Drilling fluid returns would be closely monitored during operations to ensure no excessive fluid loss. Drilling fluid returns would be treated via a separation system, and the cleaned fluid would be reinjected into the borehole for use during drilling, or stored in tanks at the surface for later disposal off site (PLP 2018-RFI 051).

Substrate/Sediment Quality

Potential impacts on waterbody substrate from erosion and sedimentation, fill placement, and contamination would be similar to those described above for the transportation corridor. No waterbody substrates would be crossed by the pipeline segment east of Cook Inlet. West of Cook Inlet, trench excavation and placement of cover material at stream crossings would be within the acreages documented for the road fill prism in Table 4.22-3. BMPs would be in place to control runoff and erosion during trenching, backfilling, and other ground-disturbing activities; therefore, impacts would be avoided or minimized.

Placement of fill at pipeline landfalls in Cook Inlet and Iliamna Lake would entail trenching into the existing bottom sediment and covering the pipeline with at least 3 ft of fill to a water depth of 12 ft (PLP 2018-RFI 013). Section 4.16, Surface Water Hydrology, addresses the potential for sediment suspension, plume transport, and redeposition to occur during construction in the marine environment.

4.18.3 Action Alternative 2 – North Road and Ferry

4.18.3.1 Mine Site

Buttressed Downstream Bulk TSF Main Embankment. Due to similar seepage design and downstream capture under Alternatives 1 and 2, the downstream dam alternative for the bulk TSF main embankment would likely have the same impacts on surface water and groundwater quality as centerline construction. However, construction of the downstream dam alternatives would require a 45–60 percent increase in fill because of the larger embankment footprint (PLP 2018-RFI 075). This would result in a corresponding increase in impacts on substrate in the

AMERICAN OVERSIGHT

NFK west drainage through permanent burial by fill, and greater potential for erosion and redeposition impacts (described under Alternative 1).

4.18.3.2 Transportation Corridor

Mine Site to Eagle Bay, and Pile Bay to Diamond Point Roads. Water and substrate impacts associated with the mine site to Eagle Bay and Pile Bay to Diamond Point roads would be similar to the road plus pipeline impacts for the north-road-only alternative. Including pipeline construction, these roads would result in the same number of stream crossings as the north-road-only route, and about 20 percent more stream crossings than the Alternative 1 (PLP 2018-RFI 086).

Eagle Bay to Pile Bay Ferry. Ferry operations from Eagle Bay to Pile Bay would have similar impacts on water and substrate quality as ferry operations in Alternative 1.

Summer-Only Ferry Operations Variant. Although the summer-only ferry operations variant would reduce water quality impacts on the lake during the 6-month winter season, ferry operations and activity would be increased during the 6 months of ferry operations and would require the use of either a vessel twice as large or two ferry vessels. Placement of additional fill at the mine site and the port site would be required to support additional storage areas for concentrate and diesel (PLP 2018-RFI 065), resulting in corresponding increases in burial of existing lake substrate and in suspended solids and turbidity during fill placement. Additional concentrate storage at the port site under this variant would also require an increase in fill placement along the west side of Iliamna Bay near Williamsport (see Section 4.22, Wetlands, for the acreage of wetland and waterbody substrate coverage under this variant). The likelihood of small spills and contaminated runoff would increase because of the extra container and fuel storage under this variant, although this is expected to be mitigated by water treatment of runoff as described under Alternative 1 (major spills from extra container and fuel storage are addressed in Section 4.27, Spill Risk).

4.18.3.3 Diamond Point Port

Terminal Runoff and Lightering Locations. Impacts from surface water runoff and treatment at the terminal, and from dust at the lightering locations, would be the same as described for Alternative 1.

Groundwater Quality at Dredge Disposal Area. Because of the differences in the approaches to the proposed dock facilities between Amakdedori port and Diamond Point port, dredging of marine substrate at the Diamond Point location would be required to achieve a 20-foot water depth. This dredging would generate approximately 650,000 cubic yards of material, of which a minimum of 50 percent would be used in dock construction. The remaining dredge spoils would be transported and disposed of onshore in a bermed facility located west and upland of the dock site, about 200 feet from the shoreline (PLP 2018-RFI 063). Most interstitial water (e.g., water contained in the dredged sediment) would be expected to drain back into Cook Inlet during placement of the dredged material onto a barge prior to transport; however, some limited amount of water would remain in the dredge spoils and would be placed in the upland disposal site with the solids. The saline water placed in the bermed containment would be expected to seep into underlying soils, and would mix with any shallow groundwater present. The overall area of the potential groundwater impact would be somewhat limited by the proximity of the disposal site to the shoreline.

Impacts on Salinity Gradients. Salinity gradients that might occur naturally at the locations of freshwater discharges into the port area would assimilate quickly into adjacent marine waters

AMERICAN OVERSIGHT

due to natural mixing by wind-driven currents and waves, and thus would not likely be affected by port operations.

Proposed Earthen Fill Dock: Suspended Particulates/Turbidity and Substrate Effects. Construction of dock facilities at Diamond Point would have a higher direct impact on marine substrate than construction under Alternative 1, as the footprint of these structures would cover roughly 90 more acres of seabed with fill than the Amakdedori port structures (PLP 2018-RFI 072). Placement of the fill causeway and wharf structure would contribute suspended sediment to the water column, leading to temporary turbidity and redeposition in the vicinity of construction. These effects are expected to be greater than those of the Alternative 1 causeway construction because of the greater amount of fill placement, and because the finer seabed material in Iliamna Bay is expected to travel farther before settling. This would cause an increase in the extent of turbidity effects and redeposition compared to Alternative 1, and an increase compared to the pile-supported dock variant under this alternative.

Some dredging of shallow offshore sediments would be required for construction of a marine vessel channel at the Diamond Point port. Initial dredging and maintenance dredging over two decades of production at the mine would cover an area of approximately 60 acres. These activities would temporarily increase suspended solids in the water column, which would be redeposited on marine substrate, effects that would not occur under Alternative 1. The extent of these effects could range from localized to beyond the mouth of Iliamna Bay, depending on tides and wave conditions.

Pile-Supported Dock Variant: Suspended Particulates/Turbidity and Substrate Effects. Construction of a pile-supported dock at Diamond Point would result in less of a direct impact on substrate than a fill causeway, as the piles would be driven through vibratory and hammer methods and would require no fill (PLP 2018-RFI 072). Effects would be slightly greater than the effects of constructing a pile-supported dock under Alternative 1; however, as the footprint of the piles would be about twice as large as the dock footprint under Alternative 1. Temporary and limited contributions of suspended sediment would be expected to occur during construction of the pile structure.

4.18.3.4 Natural Gas Pipeline Corridor

Impacts on water and sediment quality would be the same as described under Alternative 1 for the portion of the pipeline that would begin on the Kenai Peninsula and cross Cook Inlet to Kamishak Bay. Impacts would be the same as described for the transportation corridor under Alternative 3 for the portion from Diamond Point to the mine site.

Ursus Cove to Diamond Point

Construction along the pipeline corridor through Ursus Cove to Diamond Point could have incremental effects on substrate and water quality. Constructing this segment of pipeline would result in approximately three additional stream crossings, with associated impacts on surface and groundwater quality similar to those described for other sections of the natural gas pipeline corridor. In addition, the pipeline trench has the potential to intersect shallow groundwater in Ursus Cove.

4.18.4 Action Alternative 3 – North Road Only

Under Alternative 3, impacts on the pipeline corridor would be the same as those described for Alternative 2. The following section describes impacts for the mine site, transportation corridor, and port that would be different under Alternative 3.

AMERICAN OVERSIGHT

4.18.4.1 Mine Site

Under Alternative 3, impacts on the mine site would be the same as for other alternatives, with minor differences in effects under the concentrate pipeline variant. Impacts of this variant are described below.

Concentrate Pipeline Variant. The concentrate pipeline from the mine to the port under this variant would require an electric pump station at the mine site, which would require a small increase in fill placement over stream substrate in a NFK east tributary (PLP 2018-RFI 066). This variant would also reduce the amount of WTP water released at discharge locations at the mine site by approximately 1 to 2 percent (PLP 2018-RFI 066). This could result in slight reductions in temperature effects, impacts on substrate, and turbidity or erosional effects at the locations of treated water discharges. Inclusion of the concentrate pipeline would result in a slight increase in the potential for minor spills at the mine site. Section 4.27 examines major spill scenarios.

4.18.4.2 Transportation Corridor

Alternative 3 would increase the project footprint but would eliminate surface water quality impacts associated with the ferry crossing of Iliamna Lake. The northern access all-road route would result in an increase of about 20 percent in the number of stream crossings relative to Alternative 1, with a corresponding increase in substrate impacts (described under Alternative 1).

Concentrate Pipeline Variant. Inclusion of a concentrate pipeline under this alternative would result in slightly greater impacts on water and substrate/sediment quality than the all-road route alternative without the concentrate pipeline. The concentrate pipeline would be buried during road construction, and the road corridor would be widened by less than 10 percent to accommodate the pipeline, which could result in a marginal increase in turbidity effects on water quality and fill placement over substrate. An electric pump station would be required along the transportation corridor under this variant (PLP 2018-RFI 066), resulting in a small increase in the footprint in an upland area that is unlikely to affect water quality or substrate. Inclusion and operation of the concentrate pipeline would also result in an increased potential for impacts on substrate and surface water quality due to potential minor spills/leaks, although the likelihood of occurrence would be low with the use of a leak-detection system (major spill scenarios for concentrate are discussed in Section 4.27, Spill Risk). Because only the molybdenum concentrate (2.5 percent of the total concentrate production) would be trucked from the mine site to the port, a large reduction in road traffic would be anticipated, thereby reducing some potential impacts from dust, erosion, and runoff.

Concentrate Return Water Pipeline Option. Under this option, the return water pipeline would be buried in the same trench as the slurry and natural gas pipeline, requiring the trench to be widened by a few feet and resulting in an increased footprint of the transportation corridor (PLP 2018-RFI 066). Thus, the return water pipeline would result in a minimal increase in the same water quality and substrate/sediment quality effects as described above. There would be an increase in the likelihood of minor spills of contact water in this pipeline affecting water and sediment quality, that would not exist under the other options.

4.18.4.3 Diamond Point Port

Concentrate Storage and Bulk Handling. Concentrate would be dewatered at the port site and the dewatered concentrate would be stored in a large building until the loading of concentrate onto bulk carriers for transport. The storage building would result in a slight increase in the footprint at the port site beyond that of Alternative 2, with a corresponding slight

AMERICAN OVERSIGHT

increase in substrate burial at the small tributary to Cottonwood Bay (Chapter 2, Alternatives, Figure 2-64). Bulk handling of the concentrate would utilize controls to reduce dust emissions, such as covered conveyors that are used at Red Dog Mine dock facilities (PLP 2018-RFI 066).

The water removed from the concentrate would be treated in a WTP to meet marine water quality standards and discharged through an outfall pipeline and diffuser to the marine environment. Treatment would consist of adding chemicals for pH adjustment and metals precipitation, followed by use of clarifiers for solids removal and additional metals precipitation with sodium hydrogen sulfide and filtration. Solids and/or brine captured in the clarification and filtration steps would be trucked to the mine site or barged to an off-site disposal facility (PLP 2018-RFI 066).

Concentrate Pipeline Variant. The concentrate pipeline option utilizing a return water pipeline would result in no additional project footprint at Diamond Point, and would preclude the need for the discharge of treated water at the Cook Inlet terminus. This pipeline concentrate variant would eliminate the need for a dewatering WTP at the port, instead requiring a return water pump station of appropriate capacity (PLP 2018-RFI 066). This option would result in a negligible change in the footprint at the port site and likely no changes in impacts on substrate compared to Alternative 2 or Alternative 3 without the return water pipeline.

4.18.5 Impacts Summary Table

Table 4.18-1 summarizes general anticipated impacts on surface water, groundwater, and substrate/sediment quality from construction, operations, and closure of the mine site and associated development and activities.

Table 4.18-1: Summary of Key Issues for Water and Sediment Quality

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Mine Site			
Mine Site Construction	**Surface Water**: Ground disturbance and fill placement could result in increased turbidity in local waterbodies and streams, to be mitigated through BMPs. **Groundwater**: Metals concentrations in shallow groundwater may increase as a result of the disruption of wetlands and fill placement. **Substrate**: Ground disturbance and fill placement would result in substrate burial[1] and increased erosion and sedimentation if BMPs are inadequate, and would reduce natural levels of coarse sediment transport to downstream substrates.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1. *Downstream Bulk TSF Variant*: A 45% to 60% increase in fill required; increased substrate burial[1] and ground disturbance potential for increased erosion and surface water turbidity.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1. *Concentrate pipeline variant:* Small increase in substrate burial in NFK-east tributary.[1]

AMERICAN OVERSIGHT

Table 4.18-1: Summary of Key Issues for Water and Sediment Quality

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Tailings and Contact Water Storage (TSFs and WMPs)	**Surface Water**: Pond water quality in TSFs and WMPs would exceed water quality standards, but would be contained within the mine site footprint and treated prior to discharge to the environment. Runoff of contact water from the TSF and WMP embankments would be monitored and diverted to WMPs or WTPs for treatment as necessary. **Groundwater**: Local impacts on shallow groundwater quality in the NFK west, east, and north drainages are likely from vertical seepage through the bulk TSF, or leakage through the pyritic TSF or WMP liners. This would result in localized exceedances of water quality standards within the mine site footprint, which would be captured and treated prior to discharge to the environment. No mine site effects on drinking water wells are expected. **Substrate**: Burial from fill placement in the NFK west, east, and north drainages.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1. *Downstream Bulk TSF Variant:* Increase in substrate burial as described above.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.
Fugitive Dust Effects	**Surface Water**: Metals concentrations in surface water predicted to increase by 0.1% to 0.7% as a result of fugitive dust deposition, although no exceedances of water quality standards are expected. **Groundwater**: No leaching to groundwater above ADEC migration-to-groundwater levels, except for arsenic, which exceeds in baseline and with a predicted 0.6% dust-related increase. **Substrate**: Metals concentrations in sediment would increase by 0.1% to 3%, but no exceedances of SQGs.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.

AMERICAN OVERSIGHT

Table 4.18-1: Summary of Key Issues for Water and Sediment Quality

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Treated Water Discharge	**Surface Water:** WTPs would effectively treat metals and other constituents in WMPs and TSF pond water to meet discharge criteria; the potential exists for an increase in TDS during operations, requiring adaptive management of WTP processes. Temperature changes in the range of -1°C to +3.6°C are predicted in the NFK, SFK, and UTC drainages about 0.5 mile to 3 miles downstream of WTP discharges. **Groundwater:** WTPs would effectively treat dewatering water from open pit and potential groundwater contamination from TSFs captured in seepage collection systems. **Substrate:** Potential erosion effects from WTP effluent would be minimal with discharge chambers to dissipate outflow energy.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.	**Surface Water**: Impacts similar to those of Alternative 1. *Concentrate pipeline variant*: Estimated decreased discharge volume by 1% to 2% could result in marginal changes in temperature effects. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.
Mine Site Closure	**Surface Water**: Impacted sediment between the locations of TSFs and SCPs/WMPs locations could continue to release contaminants into surface water over time. Pit lake water quality would exceed water quality standards, but would be pumped to maintain operational levels and treated prior to being discharged to the environment. **Groundwater**: Local groundwater quality in the immediate vicinity of the pit and downstream of TSFs may exceed water quality standards, but would be contained by overall gradient toward pit lake or SCP capture, and treated to meet discharge criteria. **Substrate**: Potentially contaminated sediment between TSFs and SCPs/WMPs would be monitored after closure and remediated if necessary.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1. *Downstream Bulk TSF Variant:* Increased substrate burial beneath the bulk TSF would be permanent.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1.

AMERICAN OVERSIGHT

Table 4.18-1: Summary of Key Issues for Water and Sediment Quality

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Transportation Corridor			
Road Construction and Operations	**Surface Water**: Localized increase in turbidity at approximately 100 stream crossings. Impacts are expected to be short term and mitigated through BMPs. **Groundwater**: Impacts anticipated to be negligible. **Substrate**: Potential erosion and sedimentation at stream crossings to be mitigated through BMPs. Placement of fill at bridge and culverts would bury existing substrate.[1]	**Surface Water**: Localized increased turbidity at 20% more stream crossings than under Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Potential increase in substrate impacts[1] with additional stream crossings.	**Surface Water**: Impacts similar to those of Alternative 2. *Concentrate pipeline variant*: Marginal increase in turbidity due to wider road corridor. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 2. *Concentrate pipeline variant:* Marginal increase in substrate[1] due to wider road corridor.
Ferry Construction and Operations	**Surface Water**: Potential for ferry-induced increase in nearshore TSS/turbidity; expected to return to background levels within a short distance (less than 100 ft) from ferry. *Summer-Only Ferry Operations Variant:* Reduced TSS/turbidity impacts in winter and increased impacts in summer; overall same as Alternative 1. **Groundwater**: No impacts anticipated. **Substrate**: Fill placement at the ferry would extend 100–150 ft onto the nearshore lake substrate. *Summer-Only Ferry Operations Variant:* Increased fill placement on lake substrate at terminals.[1]	**Surface Water**: Impacts similar to those of Alternative 1. Ferry terminal locations changed to Eagle Bay and Pile Bay. *Summer-Only Ferry Operations Variant:* Impacts similar to those of Alternative 1. **Groundwater**: No impacts anticipated. **Substrate**: Impacts similar to those of Alternative 1. Ferry terminal locations changed to Eagle Bay and Pile Bay. *Summer-Only Ferry Operations Variant:* Impacts similar to those of Alternative 1.	**Surface Water:** No impacts on lake water quality anticipated (no ferry). **Groundwater**: No impacts anticipated. **Surface Water:** No impacts on lake substrate (no ferry terminals).

AMERICAN OVERSIGHT

Table 4.18-1: Summary of Key Issues for Water and Sediment Quality

Impact Causing Project Component	Alternative 1 and Variants	Alternative 2 and Variants	Alternative 3 and Variants
Port Site			
Causeway Fill/ Construction	**Surface Water**: Placement of fill would result in a localized increase in TSS/turbidity in Kamishak Bay for the duration of construction. *Pile-Supported Dock Variant*: Lower TSS/turbidity impacts due to reduced area of disturbance.[1] **Groundwater**: No impacts anticipated. **Substrate**: Placement of fill and causeway construction would result in disturbance of seafloor sediment and burial of substrate beneath the causeway footprint.[1] *Pile-Supported Dock Variant*: Less burial of marine substrate.[1]	**Surface Water**: Greater extent of TSS/turbidity increase due to finer grained sediment and dredging activities; extent would range from the close vicinity of the dock to the mouth of Iliamna Bay, depending on tides and waves. *Pile-Supported Dock Variant*: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1; stockpile of dredged material may have local impacts on shallow groundwater quality. **Substrate**: Area of direct impact on substrate would increase[1] due to a larger causeway and access route. *Pile-Supported Dock Variant*: Impacts similar to those of Alternative 1.	**Surface Water**: Impacts similar to those of Alternative 1. **Groundwater**: Impacts similar to those of Alternative 1. **Substrate**: Impacts similar to those of Alternative 1. *Concentrate Pipeline Variant:* The WTP would effectively treat dewatering water to meet discharge limits prior to marine environment.
Natural Gas Pipeline			
Construction Effects	**Surface Water**: Impacts similar to those for the transportation corridor under Alternative 1. **Groundwater**: Impacts west of Cook Inlet similar to those for the transportation corridor under Alternative 1. The risk of HDD drilling fluid affecting drinking water supply wells on Kenai Peninsula is expected to be localized and minimized through pressure monitoring during drilling; drilling fluid and cuttings would be disposed of offsite. **Substrate**: Impacts similar to those for the transportation corridor under Alternative 1.	**Surface Water**: Impacts similar to those for the transportation corridor under Alternative 2 (road and ferry). **Groundwater**: Impacts west of Cook Inlet similar to those for the transportation corridor under Alternative 2. Impacts east of Cook Inlet same as those for Alternative 1. **Substrate**: Impacts similar to those for the transportation corridor under Alternative 2 (road and ferry).	**Surface Water**: Impacts similar to those for the transportation corridor under Alternative 3 (road construction). **Groundwater**: Impacts west of Cook Inlet similar to those for the transportation corridor under Alternative 3. Impacts east of Cook Inlet same as those for Alternative 1. **Substrate**: Impacts similar to those for the transportation corridor under Alternative 3 (road construction).

Notes:
1. Acreages of waterbody substrate burial provided in Section 4.22, Wetlands.

AMERICAN OVERSIGHT

4.18.6 Cumulative Effects

Past, present, and reasonably foreseeable future actions (RFFAs) within the cumulative impact study area have the potential to contribute cumulatively to impacts on surface water, groundwater, or substrate quality. Section 4.1 details the past, present, and RFFAs considered for evaluation. The limited number of past and present actions considered is not expected to result in lingering effects that would be anticipated to have a timing nexus with the project, and these actions are therefore not considered further as potential contributors to cumulative impacts.

Several RFFAs detailed in Section 4.1 are considered to have no potential for cumulative impacts on surface water, groundwater, or substrate quality in the study area. These include non-industrialized point source activities that are unlikely to result in any appreciable impact beyond a temporary basis (e.g., subsistence, tourism, recreation, hunting and fishing). Other RFFAs removed from further consideration include those sufficiently distant from the study area to eliminate infrastructure co-use by other parties (e.g., Donlin, Copper Joe), or those RFFAs that may occur in the marine environment of Cook Inlet (e.g., lease sales or proposed natural gas pipeline crossings or shoreside facilities). In the marine environment, impacts related to the Pebble project are isolated to the area around the proposed port sites; there is unlikely to be a significant contribution to or by other projects occurring in marine waters in the Cook Inlet region.

RFFAs that could contribute cumulatively to surface water quality or freshwater substrate impacts, and that are therefore considered in this analysis, are limited to those activities that would occur within the Nushagak River or Kvichak River drainages, or in other waterbodies intersected by the transportation corridor in the Cook Inlet drainage. RFFAs that could contribute cumulatively to impacts on groundwater quality are even more limited, consisting only of activities in the mine site area, or immediately within or adjacent to the transportation corridor.

The following specific RFFAs were carried forward in this analysis based on their potential to contribute cumulatively to impacts on surface water, groundwater, or substrate quality in the study area:

- Pebble Project buildout—development of 55 percent of resource over a 78-year period.
- Exploration activities at Pebble South, Big Chunk South, Big Chunk North, Fog Lake, and Groundhog prospects.
- Shotgun prospect exploration and development.
- Diamond Point rock quarry.

The most important potential future actions in this analysis are those that are likely to contribute to impacts on surface water, groundwater, or substrate quality and are regionally common to the project. Because development at remote locations can be financially prohibitive, RFFAs near the project that could potentially minimize costs through co-use of project infrastructure are also considered important to this analysis.

The Pebble Project buildout and commercialization of the Shotgun prospect are the only mineral deposit RFFAs considered for exploration and development. All other mineral deposit RFFAs are considered for exploration only. The Pebble project buildout is the most notable RFFA, and would result in additional development not included under Alternative 1:

- Increased pit footprint
- Increased TSF and waste rock storage capacity
- Additional processing infrastructure

AMERICAN OVERSIGHT

- Construction of a new port site with diesel fuel and concentrate pipeline(s) extending to the mine site.

The estimated area of disturbance would be greater than under Alternatives 1 and 2 combined, based on infrastructure buildout at the mine site. The buildout would correspond to an increase in the magnitude and local extent of ground disturbance impacts and fill placement on substrate, with a duration increase of up to 98 years. The potential for impacts on surface water, groundwater, and substrate would increase, and would be greater than the combined impacts of Alternatives 1 and 2. Additional design features to capture and treat impacted water and waste streams would be necessary to manage mine site impacts. Also, adding a diesel fuel line would increase the likelihood of hydrocarbon spills along the pipeline and at pipeline terminals, potentially contributing to the cumulative impact of spills.

Development of the Shotgun prospect, while potentially contributing cumulatively to regional impacts on surface water quality within the Nushagak River watershed, would not physically overlap with the Pebble project area. The cumulative impact in the common areas of the lower Nushagak River watershed would be expected to be minimal if the design features applied to the Pebble project were to achieve the anticipated water discharge controls. No cumulative effect on groundwater quality would be expected, given the geographical separation of activities.

Some limited RFFAs associated with mineral exploration activities (e.g., Pebble South, Big Chunk North, Big Chunk South, Fog Lake, and Groundhog) could have some limited impacts on surface water and substrate quality in common watersheds to the Pebble project (e.g., drill pads, camps); however, they would be seasonally sporadic, temporary, and localized based on their remoteness. The potential could also exist for greater impacts on surface water and substrate through co-use of transportation infrastructure with the Pebble project.

The footprint of the Diamond Point rock quarry partially coincides with the Diamond Point port's footprint under Alternatives 2 and 3. Cumulative impacts would be limited to a potential increase in localized impacts on surface water and substrate quality from commonly shared project footprints with the quarry site under Alternatives 2 and 3.

Overall, the magnitude of cumulative impacts on surface water, groundwater, and substrate quality from RFFAs in general would be expected to be minimal, with the exception of activities from the Pebble project buildout RFFA. Cumulative effects would increase within the mine site footprint when expanded to include buildout development and increased fill placement.

3.24.1 Action Alternative 1 – Applicant's Proposed Action

3.24.1.1 Aquatic Habitat

Mine Site

The mine site would be located in the Koktuli River and Upper Talarik Creek (UTC) watersheds.

The 36-mile North Fork Koktuli (NFK) and 40-mile South Fork Koktuli (SFK) rivers join to form the Koktuli River (KR), which flows 39 miles downstream into the Mulchatna River. The Mulchatna River continues 44 miles before joining the Nushagak River, which then flows another 109 miles into Bristol Bay. UTC flows for approximately 39 miles into Iliamna Lake, which drains into the Kvichak River, which flows 50 miles downstream into Bristol Bay. The two forks of the KR and the UTC subbasins encompass approximately 355 square miles, representing approximately 0.9 percent of the 39,184-square-mile Bristol Bay watershed. The general characteristics and features of the NFK, SFK, and UTC drainage basins are described in Section 3.16, Surface Water.

North Fork Koktuli River

The majority of the mine site facilities would be within the NFK watershed, including the most of the tailings storage facility (TSF), pyritic TSF, water management ponds (main and open pit), mill site/camp, and water treatment plant #2 discharge location – north (Figure 3.24-1). The NFK River watershed extends northeast from the confluence with the SFK River to Groundhog Mountain, approximately 7 miles northeast of the mine site (Figure 3.24-1). The NFK drains 64.7 miles of currently documented anadromous stream channels, with a total basin area of about 113 square miles, which represents 0.3 percent of Bristol Bay's 39,184-square-mile watershed area. Approximately 23 percent of the NFK basin area and 15 miles of mainstem channel are upstream of the mine site footprint. The Alaska Department of Fish and Game (ADF&G) Anadromous Waters Catalog (AWC) (ADF&G 2018) lists 12 anadromous fish-bearing tributaries entering the NFK, including Tributary 1.19, which would contain the majority of the mine site footprint.

Mainstem base flows in the NFK at the mine site (just above the Tributary 1.19 confluence) were typically 15 to 20 cubic feet per second (cfs) in winter, and 40 cfs in summer, with Tributary 1.19 contributing another 4 to 5 cfs and 20 cfs in winter and summer, respectively.

Throughout most of its length, the mainstem NFK is a low-gradient (mostly 0.1 to 0.8 percent), unconfined, meandering, single-thread channel bordered by shrub and dwarf shrub riparian species dominated by willows (R2 et al. 2011). Habitat typing, as listed in Table 3.24-1, shows that the mainstem NFK below the mine site is dominated by riffle habitat with few mainstem pools. Upstream of the mine site, the NFK contains equal proportions of riffle and run/glide habitats, with increasing frequency of beaver-formed pools. The upper 10 miles of the NFK flow through a region with small (less than 3 acres) shallow lakes, dominated by Big Wiggly Lake (Figure 3.24-1).

Beaver ponds and other off-channel habitats are widely distributed throughout most of the NFK (Table 3.24-1). Off-channel habitats, which include side channels, percolation channels, alcoves, isolated ponds, riverine wetlands, and beaver ponds, are hydrologically connected to the NFK via surface flows or groundwater upwelling (for groundwater assessment, see

AMERICAN OVERSIGHT

Schlumberger 2011). See Section 3.22, Wetlands, for a description of riverine wetlands in the analysis area.

Instream cover for fish rearing is relatively scarce in the mainstem NFK due to the absence of large riparian trees and associated woody debris; but cobble substrates, undercut banks, and overhanging vegetation provide some refugia (R2 et al. 2011). Small woody debris and increased depths associated with beaver dams provide cover in many off-channel locations. Substrate is dominated by gravel with low amounts of fine sediments (less than 10 percent) in reaches below the mine site. The prevalence of non-embedded gravel substrates and dominance of riffle and run/glide habitats provides spawning habitat for salmonids. A summary of anadromous and resident fish habitat for the NFK, SFK, and UT is provided in Table 3.24-1. In contrast to the lower river, substrate in the mainstem above the mine site contained higher amounts of sand and silt.

Chinook salmon spawning habitat occurs throughout the lower 20 miles of the NFK below the mine site, and extends into the upper NFK adjacent to Big Wiggly Lake. The majority of spawning habitat occurs in the first 10 miles of the NFK approximately 20 miles downstream from the mine site (R2 et al. 2011). Juvenile Chinook rearing habitat occurs throughout most of the NFK mainstem (Table 3.24-2), as well as several NFK tributaries, including Tributary 1.40, 5 miles above the SFK confluence; Tributary 1.17 below Black Lake; Tributary 1.19 and its primary sub-tributary at the mine site; and Tributary 1.24, which flows through Big Wiggly Lake. Juvenile Chinook were most commonly observed in riffles and other mainstem habitats, but were also found to occupy low-velocity off-channel habitats.

Coho salmon spawning and rearing habitat is widely distributed in the NFK basin (Table 3.24-2). Preferred coho spawning habitat appears to be in the 10 miles of mainstem immediately downstream of the mine site based on field observations (R2 et al. 2011).

Sockeye salmon spawning habitat primarily occurs in the lower 10 miles of the NFK, but the run extends upstream to the vicinity of Big Wiggly Lake (R2 et al. 2011). Although some spawning habitat has been documented in the upper NFK basin, most juvenile rearing habitat occurs downstream of the mine site based on field observations.

Fixed hydrologic station data and multiple surveys from 2004 to 2008 show that the mainstem NFK remains perennial during base flow levels at all fish-bearing study sites (R2 et al. 2011). The NFK's seasonal hydrograph shows periods of maximum flows during spring snowmelt and late summer/fall rain events, with low flows during mid-summer, and minimum base flows in winter/early spring (Knight Piésold et al. 2011). Mean monthly base flows in the lower reach of the NFK averaged 60 to 90 cfs during winter months (January-March), 700 cfs during spring snowmelt (May), 200 cfs during summer base flow (July), and 350 to 450 cfs during fall rains (September-October). All three tributaries (i.e., NFK, SFK, and UTC) display sequences of losing and gaining reaches due to groundwater percolation and emergence, respectively (Schlumberger 2011, 2015).

Groundwater studies indicate that surface waters percolating into the NFK groundwater remain in the NFK subbasin, and do not transfer to either the SFK or UTC subbasins. Emerging groundwater is important to aquatic species due to its cooling effect on mainstem flows during summer, its warming effect during winter, and its direct relationship with spawning site selection for several salmonid species. Areas of groundwater upwelling are most evident in the mainstem NFK downstream of the mine site, in a reach 15 to 20 miles upstream of its confluence with the SFK. Seasonal hydrographs for several reaches of the mainstem NFK are presented in Section 3.16, Surface Hydrology.

[2] Other off-channel habitats include beaver pond outlets, alcoves, isolated ponds, side channels, and percolation channels

Source: R2 et al. 2011

The observed water temperatures in the NFK ranged from a low of 0.3 to a maximum of 21.9 degrees Celsius (°C) (R2 et al. 2011). Water temperatures in the NFK downstream of the mine site generally remain cool during the summer and cold during winter months, with mean daily temperatures typically between 10°C and 15°C during July and August. However, maximum summer water temperatures did exceed the Alaska Department of Environmental Conservation (ADEC) 15° C criteria for aquatic life and fish life-stages (ADEC 2009) at some locations in the upper basin. For a more detailed description of surface and groundwater baseline conditions, see Section 3.16, Surface Water; Section 3.17, Hydrogeology; and Section 3.18, Water and Sediment Quality.

Tributary 1.19 and Sub-tributaries

Tributary 1.19 and sub-tributaries to the NFK would contain the majority of the mine site footprint. A summary of the aquatic habitat in Tributary 1.19 is provided below.

Tributary 1.19 is incised coarse gravel, cobble, and boulder bed stream flowing through moraine and colluvial deposits with heavily vegetated banks, and a slope of 2 to 3 percent that drains

AMERICAN OVERSIGHT

approximately 8 square miles. It is a first-order stream characterized by flashy runoffs during snowmelt and rainstorm events due to higher precipitation, steep catchment in the surrounding uplands, full exposure to incoming storms, and lack of surface flow losses to groundwater in the lower reaches. Channel habitat features are dominated by short rapids/riffle reaches and irregularly spaced scour pools. Documented anadromous fish habitat use includes rearing habitat for Chinook salmon (*Oncorhynchus tshawytscha*), and rearing and spawning for coho salmon (O. kisutch). Resident fish species include Arctic grayling (*Thymallus arcticus*), Dolly Varden (*Salvelinus malma*), rainbow trout (O. mykiss) and slimy sculpin (*Cottus cognatus*).

Stream 1.19b is an incised, coarse gravel and cobble bed stream flowing through glacial drift deposits with heavily vegetated banks, and a slope of 1 percent that drains approximately 4 square miles. The channel goes dry during winter and summer low-flow periods due to the small drainage area, steep terrain, and lack of ponds or other storage features. The stream also loses groundwater to the upper mainstem of the NFK, which contributes to dry channel conditions during low-flow periods. Coho salmon have been documented using this stream as rearing habitat.

South Fork Koktuli River

The SFK River extends approximately 40 miles upstream from the confluence with the NFK to the headwaters, including over 60 miles of documented anadromous stream habitat and a 107-square-mile drainage area, representing 0.3 percent of the Bristol Bay watershed (Figure 3.24-1). Approximately 18 percent of the mine site footprint occurs in the headwaters of the SFK basin, including the mine pit, overburden stockpile, pit water management and treatment facilities, and miscellaneous facilities (Figure 3.24-2). These mine site components would occupy approximately 1.9 square miles of the upper watershed, or 1.8 percent of the SFK basin area. The mine pit and associated sediment pond embankment are expected to capture or block approximately 1.4 miles of stream channel known to support resident fish habitat.

Like the NFK, the SFK is a low-gradient (0.03 to 0.6 percent), riffle- and shrub-dominated meandering stream with an abundance of off-channel habitat (R2 et al. 2011), especially in the lower 20 miles downstream of the mine site where the floodplain broadens (Table 3.24-1). Stream gradient increases in the uppermost 1.5 miles, just downstream and into the footprint of the mine pit. Small, shallow lakes are common adjacent to the mainstem channel in the upper 10 miles of the watershed. The low-gradient and gravel-dominated substrate of the mainstem SFK below the mine site provides spawning and rearing habitat for resident and anadromous salmonids. Gravel quality is suitable for spawning and egg incubation, although the proportion of fines in the mainstem substrate is somewhat higher than in the NFK and UTC basins. The lack of large riparian tree species along the SFK mainstem yields little large, woody debris cover; but undercut banks, overhanging vegetation, instream cobbles, and beaver-related small, woody debris is available as cover for rearing fish.

Streamflow patterns in the SFK reflect those in the NFK, with two base-flow periods (summer post-snowmelt and winter) and two high-flow periods (spring snowmelt and fall rain events). Unlike the NFK, the mainstem SFK has a 10-mile intermittent reach from 2 miles below Frying Pan Lake to SFK Tributary 1.19 (R2 et al. 2011). This reach has been observed dry during summer and/or winter low-flow periods from 2004 to 2008 (Knight Piésold et al. 2011). Loss of surface flow in this reach is due to thick, permeable glacial deposits and an average transfer of 22 cfs from the SFK basin into the UTC basin via groundwater exchange. Groundwater remaining in the SFK basin re-emerges at the downstream end of the dry reach 20 miles above the NFK confluence (Knight Piésold et al. 2011).

AMERICAN OVERSIGHT

Chinook salmon spawning habitat has been documented from the SFK/NFK confluence upstream to Frying Pan Lake (Table 3.24-2), although more recent sampling indicated preferred spawning habitat occurs in the lower 20 miles of the SFK (R2 et al. 2011). As noted above, the mainstem SFK from SFK Tributary 1.19 to the Frying Pan Lake outlet routinely dries up during base-flow periods; consequently, that reach is not considered quality habitat. Chinook habitat does not extend into the upper SFK basin above Frying Pan Lake or in the footprint of the mine site. However, rearing habitat occurs throughout the mainstem below Frying Pan Lake, and in the lower 4 miles of SFK Tributary 1.19, which drains the southern side of Kaskanak Mountain.

Coho spawning habitat in the mainstem SFK extends almost up to the outlet of Frying Pan Lake, although spawning habitat is limited in the middle intermittent reach. Most spawning habitat was observed via aerial surveys in the lower 20 miles of the mainstem, and in two tributaries: SFK 1.13 and SFK 1.19 (R2 et al. 2011). Juvenile coho rearing habitat occurs throughout the SFK basin, including the mainstem, tributaries, and headwaters upstream of Frying Pan Lake. Juvenile coho in the SFK routinely use off-channel habitats, including beaver ponds, side channels, and alcoves. Juvenile coho overwintering habitat has been documented in the reaches SFK-A and SFK-B (Figure 3.24-3).

Sockeye salmon spawning habitat is limited to lower reaches SFK-A, SFK-B and SFK-C, and rearing habitat occurs throughout the SFK (Figure 3.24-3).

Chum spawning habitat is limited to the lower 20 miles of the river, downstream of the seasonally dry channel (Table 3.24-2). Adult chum salmon appear to target areas of rising groundwater during redd site selection; consequently, the highest densities of chum salmon redds occurred in the reach immediately downstream of the dry channel, where accretion of groundwater is most evident (R2 et al. 2011). Rainbow trout habitat occurs in several reaches of the SFK, including upstream of Frying Pan Lake and tributaries, but densities of this species were lower than for other resident salmonids (R2 et al. 2011).

Water temperature in the SFK ranged from an observed low of 0.7°C to a maximum of 24.4°C. Similar to the NFK, water temperatures tended to be warmer in the upper watershed, where lakes are prevalent; and cooler in the lower reaches due to emerging groundwater (R2 et al. 2011). Average daily temperatures during July and August were typically 13°C to 16°C in the upper half of the SFK mainstem, but only 8°C to 12°C below the intermittent reach. Maximum summer water temperatures exceeded the ADEC 15° C criteria for aquatic life and fish life-stages (ADEC 2009) at several water quality stations in the upper SFK.

Upper Talarik Creek

UTC flows south about 39 miles from its headwaters on the eastern edge of the mine site downstream into Iliamna Lake near the town of Iliamna (Figure 3.24-1). The UTC watershed is approximately 135 square miles, representing 0.3 percent of the entire Bristol Bay watershed area. Mine site facilities in the UTC basin would be limited to the mine access road and a water treatment discharge pipe, or less than 0.5 percent of mine site footprint (Figure 3.24-2). However, the eastern edge of the mine pit is at the SFK and UTC watershed boundary; consequently, the mine pit (primarily through pit dewatering) and associated roads and facilities could affect aquatic habitat in the UTC. Stream channel gradient is steeper in the UTC, compared to the NFK and SFK, at less than 1 percent to 2 percent (R2 et al. 2011). Aquatic habitat in the UTC varies from riffle-dominated to run/glide-dominated reaches with relatively few mainstem pools (Table 3.24-1). The upper reach and much of the lower reach of the UTC possess relatively wide floodplain with associated off-channel habitat, but the middle reach is more confined and largely restricted to a single channel. Unlike the NFK and SFK, this middle reach of the UTC is forested, which contributes large, woody debris into the stream channel;

AMERICAN OVERSIGHT

whereas shrub and dwarf shrub species (including willows [*Salix* spp.]) dominate the upper and lower reaches of the UTC. In addition to large, woody debris, undercut banks, overhanging vegetation, and small woody debris associated with beaver dams also provide instream and overhead cover. The UTC mainstem contains an abundance of gravel substrate relatively free of fine sediments, providing spawning habitat.

Chinook salmon spawning and rearing habitat is interspersed throughout the entire length of the 39-mile mainstem UTC; however, Chinook spawning habitat in UTC tributaries is limited to a very short reach of UTC Tributary 1.41, and in UTC Tributary 1.19, which receives groundwater flow from the SFK. Juvenile Chinook rearing habitat was observed in mainstem habitat features such as run/glide, pool, and riffles in reaches UT-C through UT-E; juvenile Chinook overwintering habitat has been documented in reaches UT-C, UT-D, and UT-E of the UTC (Figure 3.24-4).

Coho salmon spawning habitat extends almost the entire length of the mainstem UTC and into several tributaries (UTC tributaries 1.60, 1.35, 1.31, and 1.41). The distribution of juvenile coho was similar to that for spawning, with the addition of several minor tributaries. Densities of juvenile coho were generally similar in mainstem and off-channel habitat; and maximum densities were observed in UTC Tributary 1.41, which drains the western side of the upper basin immediately proximal to the mine pit. Coho were observed in November, and again the following April, in reaches UT-D through UT-F, suggesting these reaches may provide overwintering habitat (Figure 3.24-4).

Sockeye spawning habitat has been documented in most of the mainstem UTC up to the headwaters bordering the mine site, and also encompassed several tributaries, including 1.60, 1.90, 1.35, 1.39, and 1.41 (Table 3.24-2). Although the spawning habitat is widespread in the UTC, preferred spawning habitat occurs in reaches UTC-A (R2 et al 2011); and in Tributary 1.60, where up to 43 percent of the UTC sockeye run spawned in 2008 (Figure 3.24-4). Sockeye rearing habitat is also widespread in the UTC basin, although field observations indicate habitat is somewhat limited in the mainstem and tributaries, likely due to the early emigration of juveniles into Iliamna Lake. Rainbow trout use multiple habitats, including riffle, glides, pools, and beaver ponds throughout all reaches of the UT.

The annual hydrograph for the UTC shows the two high-flow and two base-flow periods, similar to the NFK and SFK (Knight Piésold et al. 2011). An exception is UTC Tributary 1.19, which receives groundwater accretion from the SFK. Mean monthly streamflows in this tributary were consistently 20 to 30 cfs throughout the year. The groundwater inflow from Tributary 1.19 also reduced water temperatures in the lower mainstem UTC, which generally remained below 10°C. Measured water temperatures in the UTC ranged from a low of 2.5°C to a maximum of 18.8°C. Although summer water temperatures did sometimes exceed the ADEC 15° C criteria for aquatic life and fish life-stages (ADEC 2009), summer water temperatures in the UTC were generally 3°C to 5°C cooler than comparable temperatures in the NFK and SFK, due in part to the abundance of groundwater emergence and the relative lack of inflow from warm, shallow lakes.

UT	Coho salmon	61	63	3
UT	Sockeye salmon	47	31	1
UT	Chum salmon	28	0	2
UT	Pink salmon	-	-	4
UT	Rainbow trout[4]	-	-	42

[1] Includes mileage from mainstem and tributary reaches outside of the mine site analysis area or within the transportation analysis area

[2] Includes AWC (ADF&G 2018) listing as "spawning" or "rearing"; lakes not included

[3] Additional waters listed as species "present," but not specified by life stage

[4] Stream mileage based on highest reported rainbow trout observation in AWC (ADF&G 2018) (life-stages not specified)

Transportation and Natural Gas Pipeline Corridors

The analysis area where effects would occur from road and pipeline construction and operations is defined in Figure 3.24-5. The corridor, including access roads, would cross a total of which 44 rivers and streams documented to support fish. Due to the wide geographic area and numerous waterbody crossings, it is reasonable to assume additional fish habitat occurs than is currently documented. [NOTE: Fish distribution data is pending review of 2018 field data and will be included in the DEIS].

Table 3.24-3 summarizes the length of stream channels occupied by Pacific salmon and rainbow trout of the transportation and natural gas pipeline corridor. Table 3.24-4 lists anadromous streams that would be crossed by the access roads from the mine site to Amakdedori port. A total of seven anadromous streams would be crossed by the transportation corridor.

AMERICAN OVERSIGHT

Table 3.24-3: Estimated Mileage of Habitat for Pacific Salmon and Rainbow Trout within Streams Crossed by the Transportation and Natural Gas Pipeline Corridor[1]

Transportation Corridor	Species	Spawning (mi)[2]	Rearing (mi)[2]	Present (mi)[3]
South Access Road	Chinook salmon	0	0	0
South Access Road	Coho salmon	2	4	13
South Access Road	Sockeye salmon	41	0	2
South Access Road	Chum salmon	8	0	0
South Access Road	Pink salmon	2	-	0

[1] Mileages associated with the north access road and UTC are shown in Table 3.24-2

[2] Includes AWC (ADF&G 2018) listing as "spawning" or "rearing"; lakes not included

[3] Additional waters listed as species "present," but not specified by life stage

North Access Road

The north access road, including the Iliamna spur road, would cross 32 waterbodies. Of these, nine are documented fish bearing streams, five of which are anadromous fish habitat (Figure 3.24-5). The road would cross the major drainages of UTC and the Newhalen River. As noted in Table 3.24-3 and described above, the UTC and tributaries support spawning, rearing, and migratory habitat for all five species of Pacific salmon and resident fish species. The Newhalen River provides important migratory fish habitat for sockeye and Chinook salmon migrating between Iliamna Lake and Lake Clark. Chinook salmon spawning habitat has been documented 0.75 mile downstream from the proposed Newhalen River crossing. Tributaries of the Newhalen River upstream of the crossing provide spawning and rearing habitat for both resident and anadromous species. Arctic char are also known to inhabit the Newhalen River between Sixmile Lake and Iliamna Lake.

Table 3.24-4. Anadromous Waters Crossed by Access Roads and Pipeline along the Transportation and Natural Gas Pipeline Corridor

Tributary [1]	AWC Code	R.M. [2]	Feature	Species/Life-stage [3]

AMERICAN OVERSIGHT

Iliamna Lake

Iliamna Lake is a large, oligotrophic lake with a surface area of 1,012 square miles. Iliamna Lake and its numerous tributaries provide spawning and rearing habitat for all five species of Pacific salmon and resident salmonid species, including Dolly Varden and rainbow trout. Major tributaries associated with the project area include the Newhalen River, UTC, and the Gibraltar River. The western half of Iliamna Lake is wide, with linear margins and few islands; whereas the eastern half (particularly the far northeastern end) has a contorted shoreline with an abundance of bays, islands, and rocky shoals. The majority of tributaries, including those supporting anadromous species, enter Iliamna Lake on the northern shoreline and surrounding the eastern basin, including Kokhanok Bay; tributaries are relatively uncommon on the western shoreline.

Juveniles and adults of all five salmon species use the lake habitat as a migration corridor between Bristol Bay and Iliamna Lake, via the Kvichak River. Of the anadromous salmonids, sockeye are the most common species in Iliamna Lake, where they are known to use shoreline habitat for spawning (EPA 2014), particularly in the northeastern portion of the lake (Figure 3.24-5). Juveniles also immigrate to the lake from spawning tributaries to use lacustrine rearing habitats, particularly in the eastern half of the lake. Iliamna Lake is also heavily used by adfluvial rainbow trout, which use both littoral and limnetic lake habitats for summer foraging (SEBD 2015; Minard et al. 1992).

The lake margin in the vicinity of the north ferry terminal is gently sloped and dominated by fine sediments, whereas margin habitat at the south ferry terminal is steeper and rocky. Physical characteristics of Iliamna Lake are described in Section 3.16, Surface Water Hydrology.

South Access Road

The south access Road would cross 65 waterbodies. Thirty-three are documented fish-bearing streams, two of which are anadromous fish habitat (Figure 3.24-3). The south access road would extend from the south ferry terminal on the southern shore of Iliamna Lake to Amakdedori port, and includes eight material sites (Figure 3.24-5). The road would cross two anadromous streams, per AWC (Table 3.24-3). The first would be a multi-span bridge over the Gibraltar River approximately 1.2 miles upstream of where it flows into Iliamna Lake. The Gibraltar River and Gibraltar Lake drainage and tributaries provide spawning and rearing habitat for sockeye, coho, chum, arctic char, whitefish, and other resident species, including Dolly Varden and lake trout. The second anadromous crossing would be a bridge over a tributary that meets Amakdedori Creek approximately 2.5 miles above the Cook Inlet. No stream crossings would occur on the 1.4-mile spur road that connects the south access road to the town of Kokhanok.

Kokhanok East Ferry Terminal Variant

[Note: Section will be updated for the Draft EIS].

Cook Inlet Portion of Natural Gas Pipeline Corridor

Cook Inlet is in southcentral Alaska, and extends approximately 180 miles from the Gulf of Alaska to Anchorage. The natural areas of Cook Inlet most likely to be affected by the project are the Lower Cook Inlet central zone and Kamishak Bay (NMFS 1977). The lower central zone is defined as the region north of the Barren Islands between Kamishak and Kachemak bays, and south of a line from Anchor Point to Chinitna Bay. This zone is an area dominated by tidal circulation, with mostly poorly sorted sands as bottom sediments (NMFS 1977). Approximately half of the 95-mile pipeline route would traverse depths of 200 feet or more, with a substrate largely composed of sand, shells, and pebbles.

AMERICAN OVERSIGHT

Amakdedori Port

The Amakdedori port would be in the central portion of Kamishak Bay, which is a relatively shallow, rocky bay with low-energy tidal circulation (NMFS 1977). The southward net transport of water from upper Cook Inlet along the western shore carries heavy loads of suspended matter into Kamishak Bay. This transportation of water also results in the movement of drift ice, which forms in the shallow tidal flats of upper Cook Inlet, into Kamishak Bay. The drift ice thoroughly scours extensive stretches of the intertidal zone, resulting in relatively poor development of eelgrass beds (NMFS 1977). According to the ShoreZone tool from NOAA-Fisheries (2018), the nearest eelgrass to the Amakdedori port location is in a small cove about 4.4 miles south.

The coastal habitat in the immediate area of Amakdedori port is classified as exposed mobile or partially mobile sediment, or rock and sediment; the environmental sensitivity index is defined as mixed sand and gravel beaches, and the coastal class is sand and gravel flat fan and/or narrow sand and gravel beach (NOAA 2018).

3.24.1.2 Resident and Anadromous Fishes

This section describes fish species that have the potential to occur in the EIS analysis area. Fish life history characteristics are available through the ADF&G fish webpages (ADF&G 2018h). For a description of Bristol Bay and Cook Inlet commercial fisheries, refer to Section 3.6, Commercial and Recreational Fisheries.

Mine Site

North Fork Koktuli River

Chinook salmon, coho salmon, sockeye salmon, and chum salmon have been documented in the NFK watershed (ADF&G 2018). Pink salmon (*Oncorhynchus gorbuscha*) are documented in the mainstem Koktuli River and the UTC, but do not occur in the NFK. Other species found in the NFK watershed include rainbow trout, Dolly Varden, Arctic grayling, lamprey (*Lampetra* spp.), including species such as brook lamprey (*P. planeri*), threespine stickleback (*Gasterosteus aculeatus*), ninespine stickleback (*Pungitius pungitius*), sculpins (including species such as slimy and coast range sculpin [*Cottus aleuticus*]), northern pike (*Esox lucius*), and whitefish (various species, including round whitefish [*Prosopium cylindraceum*], humpback whitefish [*Coregonus pidschian*], and least cisco [*Coregonus sardinella*]). The approximate stream mileage listed in the AWC (ADF&G 2018) for anadromous species and rainbow trout in the NFK by life-stage is given in Table 3.24-5. The relative distribution and abundance of anadromous and resident salmonid species, based on AWC data (ADF&G 2018) and 2004-2008 EBD (R2 et al. 2011), are shown on Figure 3.24-2.

Adult Chinook salmon have been documented entering the NFK as early as July 12, with peak documented spawner counts occurring between July 23 and August 4. Juvenile Chinook salmon are present year-round in the project area, consisting of three age classes, young-of-the-year (0+), yearlings (1+), and 2+. Surveys have shown highest abundance of summer and overwintering juvenile Chinook in the mainstem, 30 miles downstream of the NFK Tributary 1.19 and the mine site.

Adult sockeye have been documented entering the NFK as early as July 5, with peak documented spawner counts occurring in a 1-week window between July 27 and August 4. Juvenile sockeye salmon were observed in April, July, and August; and based on length, frequency distributions were young-of-the year fish. Juvenile densities were low throughout the NFK, suggesting typical downstream migration to lake-rearing habitat soon after emergence.

AMERICAN OVERSIGHT

Adult coho salmon have been documented entering the NFK as early as August 15, with peak documented spawner counts occurring between September 5 and September 28. Juvenile coho salmon are present year-round in the project area, consisting of four age classes: young-of-the-year (0+), yearlings (1+), 2+, and 3+ age, with the preponderance young–of-the-year overwintering and outmigrating as 1+ fish. Juvenile coho were the most common Pacific salmon inhabiting the NFK basin, where they used most of the mainstem and nearly all of the surveyed tributaries, including the upper headwaters.

Adult chum salmon have been documented entering the NFK as early as July 5, with peak documented spawner counts occurring between July 12 and July 20. In addition to Pacific salmon, rainbow trout were observed at several locations in the mainstem NFK downstream of the mine site, as well as in NFK Tributary 1.19, but their relative abundance was low compared to most other salmonids (R2 et al. 2011). Other resident fish are distributed in low abundance in the lower reaches of the NFK, with Dolly Varden and slimy sculpin being distributed throughout the drainage.

AMERICAN OVERSIGHT

South Fork Koktuli River

Chinook, coho, sockeye, and chum salmon have been documented in the SFK watershed (ADF&G 2018). Pink salmon have not been documented in the SFK. Other fish species documented in the SFK watershed include rainbow trout, Dolly Varden, arctic grayling, lamprey, threespine and ninespine stickleback, sculpin (may include slimy and/or coastrange sculpin), northern pike, whitefish (round whitefish, humpback whitefish, and/or least cisco), and burbot. Arctic char have also been documented in the SFK; however, fish surveys did not encounter this species (R2 et al. 2011). Overall, the SFK supports more fish species than either the NFK or UTC. The approximate stream mileage listed in the AWC (ADF&G 2018) for anadromous species and rainbow trout in the SFK by life-stage is given in Table 3.24-5. The relative distribution and abundance of anadromous and resident salmonid species, based on AWC (ADFG 2018) and EBD data (R2 et al. 2011), are shown on Figure 3.24-3.

The mine pit and associated sediment pond embankment would be expected to capture or block approximately 1.4 miles of stream channel known to support resident fish (arctic grayling, sculpin, and stickleback) in the upper SFK watershed. No anadromous fish were documented in this reach during sampling in 1991, 2004, or 2008, although coho juveniles were observed in the mainstem SFK immediately downstream of the southern edge of the open pit and associated service road in a 2008 survey (ADF&G 2018).

Adult Chinook salmon have been documented entering the SFK as early as July 5, with peak documented spawner counts occurring between July 20 and August 1. Juvenile Chinook salmon are present year-round in the project area, consisting of 3 age classes: young-of-the-year (0+), yearlings (1+), and 2+. Densities of juvenile Chinook were higher in the mainstem SFK than in off-channel habitats, similar to the distribution seen in the NFK. Adult sockeye have been documented entering the SFK as early as July 5, with peak documented spawner counts occurring between July 23 and August 3. Densities of adult sockeye salmon were highest in the lower 20 miles of the mainstem SFK, as was noted for both Chinook and coho salmon (R2 et al. 2011). Juvenile sockeye salmon were observed in April, July, and August; based on length frequency distributions, two age classes are indicated: young-of-the year, and 1+ age fish. Juvenile densities were low throughout the SFK, suggesting typical downstream migration to lake rearing habitat soon after emergence. Adult coho salmon have been documented entering the SFK as early as August 15, with peak documented spawner counts occurring between September 5 and September 28. Coho salmon are more abundant and widely distributed in the SFK than are the other species of Pacific salmon (Table 3.24-2). Juvenile coho salmon are present year-round in the project area, consisting of 4 age classes: young-of-the-year (0+), yearlings (1+), 2+, and 3+ age, with the preponderance young–of-the-year overwintering and outmigrating as 1+ fish. The known upper limit of juvenile coho above Frying Pan Lake extends to the immediate region of the proposed mine pit; however, juvenile densities are highest in the most downstream reaches. Juvenile coho were observed in the lower reaches of the SFK during overwintering surveys.

Adult chum salmon have been documented entering the NFK as early as July 5, with peak documented spawner counts occurring between July 11 and July 26. Juvenile chum salmon were only observed in the vicinity of high redd densities, likely due to the abbreviated rearing periodicity of this species.

Ten resident fish species, including burbot and lamprey species, are found in low abundance throughout the SFK, with Dolly Varden and Arctic grayling considered the most widely distributed (R2 et al. 2011).

AMERICAN OVERSIGHT

Upper Talarik Creek

In addition to the four species of Pacific salmon found in the NFK and SFK, the UTC also contains an intermittent run of pink salmon in the lower reaches. The UTC is also known as important habitat for large, adfluvial rainbow trout. Other resident species found in the UTC include Dolly Varden, Arctic grayling, whitefish (may include round whitefish, humpback whitefish, and/or least cisco), sculpin (may include slimy and/or coastrange sculpin) and two species of stickleback (i.e., threespine and ninespine). Arctic char have been documented in the UTC; however, no Arctic char were observed in environmental baseline studies (R2 et al. 2011). The approximate stream mileage listed in the AWC (ADF&G 2018) for anadromous species and rainbow trout in the UTC by life-stage is given in Table 3.24-2. The relative distribution and abundance of anadromous and resident fish species, based on AWC data (ADF&G 2018) and EBD surveys (R2 et al. 2011), are shown on Figure 3.24-4.

Pink salmon have been documented in the lower 4 miles of the UTC, where more than 300 adult pink salmon were observed in 2006, but only 5 in 2007, and zero in 2004-2005 and 2008-2009 (SEBD 2018). It is uncertain if the migrants represented a native run, or if they were strays from other watersheds. No juvenile pink salmon were observed during fish sampling surveys, which is not unexpected, given that particular species' rapid seaward emigration as newly emerged fry.

Adult sockeye salmon were the most abundant salmonid in the UTC basin, which drains directly into Iliamna Lake, a major spawning and rearing area for sockeyes. Abundance of sockeye salmon in the UTC exceeded abundance in both the SFK and the NFK basins combined (R2 et al. 2011). Chum salmon occur in the mainstem UTC up to Tributary 1.35, about 25 miles above the UTC mouth (Table 3.24-2) (ADF&G 2018). Chum salmon were the least-abundant salmonid species in the UTC basin (R2 et al. 2011), with most observations of adult fish made during aerial surveys; terrestrial surveys documented very few juveniles, likely due to this species' early seaward migration.

The distribution of juvenile Chinook in the UTC is similar to the distribution of spawning, although juveniles have been observed higher in the headwater reaches, and also are known to inhabit additional tributaries, including UTC 1.35 and a west-side tributary immediately adjacent to the mine pit (R2 et al. 2011). Chinook are also presumed to use the lower reaches of the UTC's largest tributary—First Creek or UTC 1.60—which flows into UTC 4 miles above Iliamna Lake.

Adult Chinook salmon have been documented entering the UT as early as July 6, with peak documented spawner counts occurring between July 31 and August 8. Juvenile Chinook salmon are present year-round in the project area, consisting of three age classes: young-of-the-year, (0+), yearlings (1+), and 2+. Adult sockeye have been documented entering the UT as early as July 5, with peak documented spawner counts occurring between July 17 and August 3. Juvenile sockeye salmon were observed in April, July, and August; and based on length frequency, distributions indicate two age classes: young-of-the year, and 1+ age fish. Juvenile densities were low throughout the UT, suggesting typical downstream migration to lake-rearing habitat soon after emergence.

Adult coho salmon have been documented entering the UT as early as August 8, with peak documented spawner counts occurring between September 2 and September 5. Juvenile coho salmon are present year-round in the project area, consisting of four age classes: young-of-the-year (0+), yearlings (1+), 2+, and 3+ age, with the preponderance young–of-the-year overwintering and outmigrating as 1+ fish. Juvenile coho were observed in the upper reaches of the UT during overwintering surveys.

AMERICAN OVERSIGHT

Adult chum salmon have been documented entering the NFK as early as July 15, with peak documented spawner counts occurring between July 31 and August 3. Low numbers of juvenile have been observed in the UT, consistent with the species life history of abbreviated river residence time after emergence.

Dolly Varden, slimy sculpin, and Arctic grayling are the only resident fishes documented in the headwater reaches near the mine site during baseline field surveys. Unlike the NFK and the SFK, rainbow trout were relatively common and widely distributed in the UTC basin, although only juveniles were observed in the headwater reaches near the mine site. Overall, densities of rainbow trout in surveyed reaches were low compared to most of the Pacific salmon species (R2 et al. 2011). Non-migratory stream-resident rainbow trout are thought to occur in all three tributaries, but UTC also supports an adfluvial population of large trout that migrate between UTC, Iliamna Lake, and other lake tributaries. This species was targeted in a radio telemetry study in 2007 and 2008, where 97 adult trout were captured and tagged in UTC; 70 fish were subsequently tracked throughout the western half of Iliamna Lake and many of the lake's western tributaries through spring of 2009 (SEBD Chapter 15 2018). UTC-tagged trout visited 10 tributaries to western Iliamna Lake, with most detections in UTC, Lower Talarik Creek, Pete Andrews Creek, the Newhalen River, and the Kvichak River. Migration patterns included spring immigration into tributaries (presumably for spawning), summer foraging throughout the western half of Iliamna Lake or in several tributaries, followed by fall immigration and overwintering in the lower mainstem reaches or outlet lagoon habitats of the five tributaries listed above (Minard et al. 1992). Only 12 to 13 percent of tagged trout returned to UTC for spring spawning or summer foraging, suggesting that some of the tagged fish were transients from other natal tributaries. Relatively few tag detections in Iliamna Lake occurred east of the line between Gibraltar Creek and the Newhalen River; however, a large proportion of detections occurred in offshore areas of western Iliamna Lake, suggesting a pelagic migratory pattern.

Transportation and Natural Gas Pipeline Corridors

North Access Road

Anadromous fish distributed in the UTC basin include Chinook, coho, sockeye, and pink salmon. Resident salmonid species found in the UTC include Dolly Varden, Arctic grayling, rainbow trout, and whitefish (may include round whitefish, humpback whitefish, and/or least cisco). Resident non-salmonid fishes observed during sampling in the 1990s and 2004-2008 were sculpin (may include slimy and/or coastrange sculpin) and two species of stickleback (threespine and ninespine). The AWC (ADF&G 2018) also lists arctic char in the UTC; however, sampling conducted in the 1990s and in 2004-2008 did not encounter this species (R2 et al. 2011).

As noted in Table 3.24-2, the north access road would cross channels tributary to the UTC that support rearing and/or spawning by coho salmon, and the mainstem UTC at the bridge location is listed for spawning and rearing for Chinook, coho, and sockeye salmon, as well as spawning by chum and pink salmon. The proposed crossing at First Creek (UTC 1.60) has coho-spawning life-stage in the immediate vicinity of the crossing, but there is also sockeye spawning and coho rearing downstream, and Chinook are listed as present. Sockeye spawning is the only life-stage specified at the proposed Newhalen River bridge crossing, but the AWC lists unspecified life-stages for Chinook and coho as present at that location. Arctic char are also known to inhabit the Newhalen River between Sixmile Lake and Iliamna Lake. The Newhalen River serves as an important link between Iliamna Lake and Lake Clark, which supports large populations of sockeye salmon. Resident fish identified at that location include Arctic grayling, humpback and round whitefish, longnose sucker, rainbow trout, and slimy sculpin (Frissel 2014).

AMERICAN OVERSIGHT

Iliamna Lake

Eleven fish species have been reported from Iliamna Lake, including all five anadromous Pacific salmon (Chinook salmon, coho salmon, chum salmon, pink salmon, and sockeye salmon) and Arctic char, five non-anadromous salmonids (adfluvial populations of rainbow trout, Dolly Varden, lake trout, Arctic grayling, and humpback and/or round whitefish), and several resident species (e.g., northern pike, slimy sculpin, ninespine stickleback). With some exceptions, annual aerial surveys of spawning salmon areas have been conducted since 1920 by ADF&G (Morstad 2003), which have detected shoreline spawning in most areas of Iliamna Lake, with heaviest spawning along island and bay habitats in the eastern lake basin. Input of marine-derived nutrients from carcasses of spawned-out salmon (particularly sockeye) is an important factor in the productivity of Iliamna Lake and its primary spawning tributaries (EPA 2014). The migration of juvenile sockeye leaving Iliamna Lake in late May and early June after lake ice-melt has been estimated at over 200 million fish over a 3-week period. The most common subsistence fishery is for sockeye salmon; but targeted fisheries also include Arctic grayling and whitefish (Holen and Lemons 2012). See Section 3.9, Subsistence, for more information on subsistence use.

Rainbow trout are widely distributed in the Iliamna Lake basin. Seventy of 97 radio-tagged adult trout were tracked throughout the western half of Iliamna Lake and many of the lake's western tributaries through spring of 2009 (SEBD 2018). UTC-tagged trout migrated from 10 tributaries to western Iliamna Lake, with most detections in UTC, Lower Talarik Creek, Pete Andrews Creek, the Newhalen River, and the Kvichak River. Migration patterns included spring immigration into tributaries (presumably for spawning), summer foraging throughout the western half of Iliamna Lake or in several tributaries, followed by fall immigration and overwintering in the lower mainstem reaches or outlet lagoon habitats of the five tributaries listed above (Minard et al. 1992). Relatively few tag detections in Iliamna Lake occurred east of the line between Gibraltar Creek and the Newhalen River; however, a large proportion of detections occurred in offshore areas of western Iliamna Lake, suggesting a pelagic migratory pattern.

South Access Road

Four anadromous species/life-stages are listed in the AWC (ADF&G 2018) for the lower Gibraltar River (Table 3.24-3): coho present, chum spawning, sockeye spawning, and Arctic char present. Whitefish are also distributed throughout the lower Gibraltar River. The Amakdedori Creek tributary is an anadromous stream listed for coho spawning and sockeye spawning life-stages at the proposed crossing location, and chum spawning is listed downstream of the location. Dolly Varden; slimy sculpin are also present in this tributary. Resident fish species also inhabit 32 other stream channels that would be crossed by the south access road.

Kokhanok East Ferry Terminal Variant

[Note: Section will be updated for the Draft EIS].

Cook Inlet Portion of Natural Gas Pipeline Corridor

All 5 species of Pacific salmon, Pacific herring (*Clupea pallasii*) and pond smelt (*Hypomesus olidus*) are found in the Cook Inlet management area (ADF&G 2018h). The Cook Inlet area also supports several important groundfish species, including sablefish (*Anoplopoma fimbria*), Pacific cod (*Gadus macrocephalus*), walleye pollock (*G. chalcogrammus*), lingcod (*Ophiodon elongatus*), and pelagic shelf rockfish species (*Sebastes spp.*). Other fish species includes sculpins, skates (*Rajidae*), sharks, commander squid (*Berryteuthis magister*), giant Pacific octopus (*Enteroctopus dofleini*), shortspine thornyhead (*Sebastolobus alascanus*), and

AMERICAN OVERSIGHT

numerous other rockfish species (Rumble et al. 2016). Flatfish species known to occur in the Cook Inlet and/or Kamishak Bay include flathead sole (*Hippoglossoides elassodon*), rock sole (*Lepidopsetta bilineata*), arrowtooth flounder (*Atheresthes stomas*), and Pacific halibut (*H. stenolepis*), the latter of which are highly valued in both commercial and recreational fisheries.

Robards et al. (1999) conducted beach seines and mid-water trawls in nearshore habitats of lower Cook Inlet, and found a diverse near-shore fish community of at least 52 species. Spatial differences in species diversity and abundance were observed in Cook Inlet, likely due to local oceanographic conditions and sediment inflow. The study also found significant changes in fish community abundance and diversity between 1976 and 1996, apparently related to large-scale climate changes in the North Pacific.

Clams are abundant along many Cook Inlet beaches. Stocks of razor clams (*Siliqua patula*) are concentrated in the Polly Creek area on the western side of Cook Inlet, and along the eastern side from Anchor Point to Kasilof River. Other clam species include littleneck (*Protothaca staminea*) and butter clams (*Saxidomus giganteus*), which are prolific in Kachemak Bay (Szarzi et al. 2007). Several species of crab are found in the Cook Inlet area, including Tanner (*Chionoecetes bairdi* and *C. opilio*), red king (*Paralithodes camtschaticus*), golden king (*Lithodes aequispinus*), and Dungeness crabs (*Metacarcinus magister* or *Cancer magister*) (ADF&G 2002b). Several species of shrimp are also found in Cook Inlet, including pink (*Pandalus borealis*), sidestripes (*P. dispar*), humpy shrimp (*P. goniurus*), coonstripe shrimp (*P. hypsinotus*), and spot shrimp (*P. platyceros*) (ADF&G 2002b). Other shellfish species include octopus, green urchin, sea cucumber, and scallops. The predominant octopus species in Cook Inlet is the giant Pacific octopus (*Enteroctopus dofleini*).

Amakdedori Port

Sockeye are abundant in several tributaries to Kamishak Bay, including the Kamishak River and in Mikfik and Chenik lakes, and in Amakdedori Creek near the proposed port site. Amakdedori Creek had average annual sockeye salmon runs of 1,200 fish between 1970 and 1980, which increased to 2,700 fish annually from 1981 to 2010 (Hollowell et al. 2016). The estimated escapement of pink salmon in Amakdedori Creek in 2015, measured by aerial survey using area under the curve estimation, was 25,945 fish. Other basins supporting strong runs of pink salmon in Kamishak Bay include the Bruin Bay River, Sunday Creek, and Browns Peak Creek. Principal chum salmon streams entering Kamishak Bay include the Kamishak and Little Kamishak rivers and Cottonwood Creek. Pacific herring may be harvested in the Kamishak Bay district when biomass allows, although this fishery was closed for the 14th consecutive year as of 2015 (Hollowell et al. 2016).

3.24.1.3 Aquatic Invertebrates

Mine Site

Macroinvertebrates and periphyton (freshwater organisms attached to or clinging to plants and other objects projecting above the bottom sediments) community assemblages are an important component of the aquatic food web for salmonids, and effective indicators of habitat and water quality (Barbour et al. 1999). Due to their mobility, long life cycle, and sensitivity to environmental conditions, macroinvertebrates have been frequently used for long-term monitoring, and have demonstrated their sensitivity to changes in ecological conditions (EPA 2002). Macroinvertebrate biological assessment indices have been developed for Cook Inlet Basin Ecoregion streams (Rinella and Bogan 2007), which established important macroinvertebrate community response to disturbance intensity in the region. Metrics such as

AMERICAN OVERSIGHT

number of taxa, percent EPT genera, and Shannon's Diversity Index (SDI) were found to decrease at sites with increased disturbance intensity, while other metrics such as percent dominant taxa increased with disturbance intensity (Rinella and Bogan 2007).

The Koktuli River watershed supports a rich and diverse macroinvertebrate community (Bogan et al. 2012). Sampling of wadeable streams of the Kvichak and Nushagak watersheds in the Bristol Bay region of Alaska, including the Koktuli and Upper Talarik Creek watersheds, found mean site richness to be similar across four subwatersheds (ranging between 23 and 30 taxa), with Chironomidae family members the most common across all sites (Bogan et al. 2012).

Freshwater macroinvertebrate and periphyton surveys were conducted between 2004 and 2008 in the project area to characterize species diversity, abundance, density, and community structure. Study locations included the NFK River, SFK River, Kaskanak Creek, UTC, Chulitna River, Frying Pan Lake, and Big Wiggly Lake. Study locations correspond with monitoring sites for water quality, hydrology, and fisheries (Figure 3.24-2).

The methodological details for the 2004 to 2008 study period can be found in Chapter 15, Chapter 40, and Appendix F of the Pebble Project EBDs (R2 et al. 2011). The resulting inventories serve as a basis for assessing potential project impacts.

Macroinvertebrates

A total of 132 primary macroinvertebrate samples and duplicates at a minimum frequency of 10 percent were collected from the monitoring sites established in the project area. Macroinvertebrate metrics, as described in the Alaska Stream Condition Index (ASCI) protocol (Major and Barbour 2001), were calculated from macroinvertebrate data collected using the ASCI method and the Surber method (R2 et al. 2011). These metrics are indicators of habitat change (Major and Barbour 2001), and include taxa richness, percent Ephemeroptera, Plecoptera, and Trichoptera genera (together referred to as "EPT genera") taxa; percent Chironomidae family taxa (Chironomidae is within order Diptera); percent other Diptera order taxa; percent dominant taxon; and Community Tolerance Index (CTI).

The overall results for both the Surber method and the ASCI method indicate that Diptera, including the Chironomidae family, is the dominant taxon in the mine site project area; and Ephemeroptera is the majority taxa of EPT. Macroinvertebrate populations with a high proportion of Chironomidae family members in the population can indicate a more stressful aquatic habitat in general (Barbour et al. 1999). The aquatic conditions at the mine site include high numbers of Chironomidae family, which is considered typical for this area (Oswood et al. 1995).

These observations are consistent with aquatic-habitat surveys, which indicate that the analysis locations in the mine site area are composed mainly of riffle/cobble stream habitats with few to no human-caused effects. Measurements of habitat parameters at each location were found to be within ranges considered good to optimal for aquatic habitat (Major and Barbour 2001). Analysis of water quality results indicated good to optimal parameter levels for diverse macroinvertebrate communities, as is generally the case.

CTI reflects aquatic habitat quality, and is based on the relative tolerance of macroinvertebrate taxa to stressful conditions. CTI scores in 2004, 2005, and 2007 ranged from 3.9 through 6.1, 4.9 through 6.0, and 4.5 through 6.6, respectively (possible range of values zero through ten).

Periphyton

A total of 115 periphyton samples and additional duplicate samples were collected at a frequency of approximately 10 percent. The 2004 data indicated relatively uniform taxa richness

AMERICAN OVERSIGHT

across all seasons. Periphyton metrics were based on the taxa identifications. Taxa richness at all sample locations ranged from 12 to 19. The percent dominant taxon at all sample locations ranged from 21 to 72 percent. The percent dominant taxon in periphyton samples at times totaled more than 50 percent. This result is generally considered a negative indicator for stream health (Wehr and Sheath 2003). However, the stream reaches sampled are considered representative of unimpaired conditions and occur in a region of minimal human effect. Measurements of water-quality parameters consistently fell within ranges considered good to optimal for aquatic habitat health. These results exhibit the natural variability in these environments.

In 2005 and 2007, periphyton samples were analyzed for chlorophyll-a to quantify productivity. In 2005, average chlorophyll-a concentrations ranged from 2.1 milligrams per square meter (mg/m^2) to 17.0 mg/m^2, with variability among the samples. In 2007, average chlorophyll-a concentrations ranged from 2.3 mg/m^2 to 30.2 mg/m^2. No consistent temporal trends were observed in the chlorophyll data between 2005 and 2007, nor was there a trend found between macroinvertebrate taxa richness or percent EPT and chlorophyll-a concentrations. However, Chironomidae often made up a high percentage of the taxa composition; and in many cases, was the dominant taxon, encompassing more than 50 percent of the sample. Some Chironomidae genera feed on periphyton, or prey on taxa that consume periphyton. In 2005, percent Chironomidae was found to be highly correlated with chlorophyll-a concentrations ($R^2 = 0.7908$), but this trend was not as evident in 2007 ($R^2 = 0.1157$).

The survey results show that sample locations were composed largely of riffle/cobble habitat. Riffle/cobble is the preferred habitat of EPT taxa. The sampling results for the mine site indicate low-percent EPT, high-percent Chironomidae, and high-percent dominant taxon, conditions which have been associated with poor stream health in other Alaska-based studies (ADF&G 2007). No statistically significant relationship was found between most water quality results and the macroinvertebrate metrics data. However, taxa richness in ASCI samples was negatively correlated with temperature.

Transportation and Natural Gas Pipeline Corridors

Locations for macroinvertebrate and periphyton studies were selected to characterize conditions in the project area. Sampling was conducted at two sites: Y Valley Creek, and an unnamed creek site (see Figure 3.24-6). Because a relatively small portion of the transportation corridor would be in Cook Inlet drainages, only two locations were established for macroinvertebrate and periphyton sampling. Sample locations in the project area were selected based on undisturbed habitat with few to no human-caused effects. The methodological details for the 2004 to 2008 study period can be found in Chapter 15, Chapter 40, and Appendix F of the Pebble Project EBDs (R2 et al. 2011).

Macroinvertebrate taxa richness was higher in the ASCI samples than in the Surber and the drift samples; and community assemblages were largely driven by Diptera taxa, and in most cases, Chironomidae. Of the Diptera taxa, the Orihocladiinae subfamily (within the Chironomidae family) tended to make up a large percentage of the samples. Of the EPT taxa, the Heptageniidae, Baetidae, Chloroperlidae, and Brachycentridae families were well represented in the Surber samples. The presence of these sensitive species is indicative of the comparatively optimal conditions at the site for macroinvertebrate colonization (Merritt and Cummins 1996).

A range of macroinvertebrate habitats was sampled using the ASCI method, while only riffle/cobble habitat was sampled using Surber samplers. Taxa richness was greater in ASCI samples (15 to 16 taxa) than compared with Surber and drift samples (five and seven taxa, respectively). The difference in taxa richness indicates that most of the macroinvertebrate taxa

AMERICAN OVERSIGHT

diversity is to be found in habitats other than riffle/cobble habitat. Macroinvertebrate studies in other regions have documented variability in taxa richness among samples (DePauw et al. 2006). However, there are insufficient data from this study area to statistically define trends or relationships with respect to particular sampling method variable, or timing of sampling.

An assessment of parameters related to habitat quality indicates optimal conditions at the unnamed creek and Y Valley Creek locations during all sampling events. Standard water quality parameter results were in the optimum range for aquatic life (Hem 1985). Dissolved oxygen levels at the unnamed creek were slightly supersaturated, indicative of cool stream temperatures and swift water conditions at the location. The locations sampled in this study were in an undisturbed area with few to no human-caused effects.

Periphyton metrics for the 2004 data were based on the taxa identifications. Taxa richness was greater for Y Valley Creek than for the unnamed creek (17 and 8 taxa, respectively). The percent dominant taxon was much higher for the unnamed creek than for Y Valley Creek (79 percent and 35 percent, respectively). The percent dominant taxon in periphyton samples at times totaled more than 50 percent. This result is generally considered a negative indicator for stream health (Wehr and Sheath 2003). However, the stream reaches sampled are considered representative of unimpaired conditions, pristine, and in a region of minimal human effect. Measurements of water-quality parameters consistently fell within ranges considered good to optimal for aquatic habitat health. These results exhibit the natural variability in these environments.

In 2004, one periphyton sample was collected from each of the two sampling locations, and then analyzed for diatom taxa composition. Results of this analysis indicate 19 diatom genera were present in the project area. In 2005, 10 periphyton samples were collected at one location (Y Valley Creek) and analyzed for chlorophyll-a to quantify productivity. In 2005, average chlorophyll concentrations were 2.4 mg/m^2. Diatom analysis signified a diverse set of taxa present. Average chlorophyll-a concentrations for Y Valley Creek were in the normal range, compared to other studies in Alaska.

Cook Inlet Portion of Natural Gas Pipeline Corridor

Coastal assessment studies in lower Cook Inlet have shown the area supports a healthy benthic community with balanced populations of species. Species abundance, richness, and diversity indexes are similar to undisturbed habitats and estuaries (Saupe et al. 2005). Investigations of the entire Cook Inlet area have found the lower Cook Inlet to be exposed to fewer contaminants than other locations in Alaska (Saupe et al 2005). Overall, Shannon-Weaver Diversity (H') for benthic communities (Saupe et al. 2005) ranged from 0.91 to 5.64. Polychaete worms have been found to be the most dominant taxonomic group in benthic communities.

Macroinvertebrates such as crabs, butter clams, little neck clams, shrimp, and octopus are commercially harvested in lower Cook Inlet. Cook Inlet supports a large numbers of razor clams and a popular sport fishery on the western side of Cook Inlet. The eastern side of Cook Inlet has been closed to clamming since 2015, due to low population levels.

Amakdedori Port

Available information is included above in the Cook Inlet Portion of Natural Gas Pipeline section.

AMERICAN OVERSIGHT

Figure 3.24-6: Cook Inlet Aquatic Invertebrates Sampling Sites

AMERICAN OVERSIGHT

3.24.1.4 Fish Tissue Trace Element Analysis

Overall, data collected during the 2004-2008 period indicate that the concentrations of trace elements in fish tissue are generally low, and reflective of the natural conditions of the mine site area drainages. Some trace elements were detected at elevated concentrations. However, these concentrations are attributed to natural conditions and are documented as existing or baseline conditions.

Fish samples collected between 2004 and 2008 included 345 whole body, 236 muscle, and 87 liver samples. These samples were collected from the waterbodies (NFK, SFK, and UTC) and several lakes in the mine site area, and represented several species of fish, including northern pike, Dolly Varden, Arctic grayling, coho and Chinook salmon, and whitefish. Most of the 14 target trace elements were detected in the samples, including methylmercury. Copper and zinc were present at the highest concentrations across different waterbodies. A wide variability of elemental concentrations was apparent over time and among waterbodies, fish species, and tissue types.

Differences in tissue copper concentrations appeared to reflect the differences in the underlying geology of the drainages. For example, whole-body copper concentrations in coho and Chinook salmon were higher in SFK than in the other two rivers; Copper-rich bedrock in the headwaters of SFK may explain this observation, because the underlying geology contributes significantly to the elemental concentration in the surface water and sediment substrates, and aquatic organisms and the fish uptake of trace elements occur via these environmental media and the food chain. Elemental concentrations were typically higher in liver than in muscle; substantially for some elements (e.g., zinc).

Overall, the existing baseline data on fish tissue elemental concentrations represent the baseline or existing conditions that are reflective of the natural variabilities in the mine site area that arise due to various factors, such as biogeochemical differences among the major drainages, species- and element-specific differences in uptake, and accumulation of different trace elements by different fish species.

For a detailed report on fish tissue trace metals analysis, refer to EBD Chapter 10, Section 10.3

Alternatives 1 and 2 Summer Only Ferry Operations Variant

The summer only ferry options variant is described in Chapter 2, Alternatives. Aquatic habitat and fish distribution would be the same for this variant as described in Alternative 1.

Alternative 1 Kokhanok East Ferry Terminal Variant

[NOTE: AQUATIC HABITAT AND FISH DISTRIBUTION FOR THIS VARIANT WILL BE UPDATED FOR THE DRAFT EIS.]

The proposed Kokhanok East route crosses eight streams, one of which is classified as anadromous. This stream has been documented to support spawning and rearing habitat for sockeye salmon and arctic char. The shoreline of the proposed ferry terminal location is generally rocky and deepens rapidly, suggesting that it is unlikely to be preferred spawning habitat (RFI 078).

Alternative 1 and 2 Pile Supported Dock Variant

The pile supported dock variant is described in Chapter 2, Alternatives. Aquatic habitat and fish distribution would be the same for this variant as described in Alternative 1.

AMERICAN OVERSIGHT

3.24.2 Action Alternative 2 – North Road and Ferry

Mine Site

The affected environment as described under Alternative 1 is applicable to Alternative 2.

3.24.2.1 Aquatic Habitat

Transportation Corridor and Natural Gas Pipeline Corridor

The transportation corridor includes the mine site road, two spur roads to ferry terminals on Iliamna Lake, and the natural gas pipeline corridor from the mine site to Diamond Point. The transportation corridor under Alternative 2 would crosses 116 waterbodies, including 23 anadromous fish streams and 28 resident fish streams. The natural gas pipeline from Eagle Bay Creek to Ursus Cove would cross 89 total drainages, including 37 fish streams, of which 13 are anadromous.

The affected environment as described under Alternative 1 for the Cook Inlet portion of the natural gas pipeline is applicable to Alternative 2.

Access Corridor – Mine Site to Ferry Terminal

The access corridor follows the Alternative 1 route from the mine site to 1 mile south of the bridge crossing the mainstem UTC (Figure 3.24-6). Along this route, the road and pipeline would cross 21 stream channels, 8 of which are listed in the AWC as anadromous streams (Table 3.24-6), with another 6 channels inhabited by resident fish species, and 12 channels believed to be fishless (see Appendix K3.24) As noted above, the Newhalen River provides a migratory connection between Iliamna Lake and Lake Clark for large numbers of adult and juvenile sockeye salmon.

Table 3.24-6. Anadromous waters crossed by access roads along the Alternate 2 Transportation and Natural Gas Pipeline Corridor[1]

Tributary [2]	AWC Code	R.M. [3]	Feature	Species/Life-stage [4]
UTC 1.36, 1.34, and mainstem	See Table 3.24-2 for details			
n/a (tributary to Newhalen River)	324-10-10150-2207-3027-4011	1.9	culvert	COp
n/a (tributary to Newhalen River)	324-10-10150-2207-3027-4011-5005	0.6	culvert	COr
Newhalen River	324-10-10150-2207	15.5	bridge	Kp, Ss, COp
n/a (tributary to Eagle Bay)	324-10-10150-2235	5.8	culvert	Ss, ACp

Iliamna River	324-10-10150-2402	4.1	bridge	CHp, COp, Kp, Pp, Ss
Browns Peak Creek	248-10-10040		n/a	COr
Un-named	248-20-10030		n/a	CHp

1 Channels that would be crossed by the Alternative 2 natural gas pipeline are shown in Table 3.24-3

2 Tributary name from EBD 2011, if available

3 R.M. = river miles at crossing above mouth or confluence of tributary (approx.)

4 Species/Life-stage at crossing (from AWC). Species: K=Chinook, S=sockeye, CO=coho, CH=chum, P=pink; AC=arctic char; Life-stage: s=spawning, r=rearing, p=present (life-stage not specified)

AMERICAN OVERSIGHT

Iliamna Lake

This alternative includes a ferry terminal site at Eagle Bay, approximately 20 miles east of the terminal for Alternative 1, with the other ferry terminal site in Pile Bay (Figure 3.24-6). The ferry route would pass to the south of the Triangle, Flat, and Porcupine Island clusters. Although the islands contain extensive littoral shoal habitat, the ferry route would remain well offshore, where depths range from 200 to over 900 feet. Physical characteristics of Iliamna Lake are described above in this section. Annual aerial surveys of spawning sockeye salmon in littoral habitats along Iliamna Lake have been conducted by ADF&G since 1920 (Morstad 2003). Spawning surveys have shown heavy use of the northeastern arm of Iliamna Lake, with highest densities associated with the main island archipelagos, Pedro Bay, and the Newhalen shoreline. Lower densities of spawning have been observed near Eagle Bay or along the southern shore of Pile Bay, which possesses minimal littoral habitat. Consequently, the midwater route of the ferry would not intersect known sockeye spawning habitat, except at the ferry terminal site in Eagle Bay. However, Pile Bay serves as a migration route for upstream migrant salmon (and trout) to the Iliamna River, Pile River, and several other anadromous tributaries, as well as an outmigration pathway for ocean-bound juvenile salmon.

Access Corridor – Ferry Terminal to Port

The Pile Bay ferry terminal site would connect to the existing Williamsport-Pile Bay Road via a short spur road. Realignments and improvements would be made to the existing road. From the town of Williamsport, a new spur road would extend south to the Diamond Point port site. No stream crossings are associated with the Pile Bay spur road, and a single crossing of a channel with resident fish species is associated with the Diamond Point spur road. The existing Williamsport-Pile Bay Road between the two spur roads contains 12 stream crossings, including a bridge over the anadromous Iliamna River (Table 3.24-6). Three other bridges and two culverts cross resident fish streams, with six culverts crossing fishless streams.

Diamond Point Port

The proposed port site at Diamond Point is at the intersection of Iliamna and Cottonwood Bays. Both bays are relatively shallow (mostly less than 40 feet in depth), with sand and pebble substrates interspersed by rocky reefs and extensive mud-dominated intertidal flats at the heads of each bay. Scattered eelgrass is present along the shoreline between Diamond Point and Williamsport, as well as west of the point in Cottonwood Bay. More extensive reefs and eelgrass beds are found in the larger Iniskin Bay to the north of Iliamna Bay.

3.24.2.2 Resident and Anadromous Fish

Transportation Corridor and Natural Gas Pipeline Corridor

[NOTE: Fish data for this section is pending review of 2018 field data and will be included in the DEIS].

The affected environment as described under Alternative 1 for the Cook Inlet portion of the natural gas pipeline is applicable to Alternative 2.

Access Corridor – Mine Site to Ferry Terminal

The eight anadromous streams that would be crossed by this portion of the access corridor have been documented to contain Chinook, coho, sockeye salmon, and Arctic char. Resident species include slimy sculpin, rainbow trout, Dolly Varden, longnose suckers (*Catostomus catostomus*), and ninespine stickleback.

AMERICAN OVERSIGHT

Iliamna Lake

See above sections for general information on fish resources in Iliamna Lake. The ferry route for this alternative traverses the eastern basin of Iliamna Lake, including the vicinity of Eagle Bay and Eagle Islands, as well as the full length of Pile Bay.

Access Corridor – Ferry Terminal to Port

This portion of the access corridor would cross the Iliamna River approximately 4 miles above its mouth. The Iliamna River supports all five species of Pacific salmon, including important spawning habitat for sockeye salmon.

Diamond Point

Marine fish and invertebrates were sampled in the Iniskin-Iliamna Bay Estuary (IIE) by beach seining, otter trawling, and gill or trammel netting in two different time periods (2004-2008, and 2010-2012) to establish baseline conditions and temporal variations in species composition and abundance in the marine habitat (Pentec Environmental and Hart Crowser 2005). Additional sampling occurred in 2012 outside of the IIE, in the adjacent Cottonwood Bay, and immediately south in Rocky and Ursus coves for preliminary characterizations of the fish community. The use of multiple sampling gears provided a better coverage of several habitat types, potential spawning area, nursery areas, species distribution, and use within and outside of embayment in marine and estuarine environments.

Beach seine capture data from the IIE indicate that in the nearshore sandy/cobble habitats, 41 fish species were collected; however, not all species were captured at all stations and months. Overall, Pacific herring, juvenile pink salmon, juvenile chum salmon, Dolly Varden, surf smelt (*Hypomesus pretiosus*), and Pacific sand lance (*Ammodytes hexapterus*) were the most common species captured in beach seines. The fishes captured in otter trawl represented fauna of open water and deeper waters than represented by seine. Some 28 species were captured, dominated by snake prickleback (*Lumpenus sagitta*), yellowfin sole (*Limanda aspera*), starry flounder (*Platichthys stellatus*), Pacific herring, and walleye pollock. In gill nets, Pacific herring (multiple-year classes) dominated the catch, followed by Dolly Varden in both sampling periods. Trammel nets mostly captured spiny dogfish (*Squalus acanthias*), starry flounder, Pacific halibut, and whitespotted greenling (*Hexagrammos stelleri*).

The capture of young Pacific herring and salmonids suggests that these species use these areas for rearing. The Pacific herring supported a strong commercial fishery (for roe) until 1998; it was closed for fishing in 1999 due to low abundance. However, biomass of Pacific herring has not improved to historical level (ADF&G 2009). Young salmonids also use the bays for rearing, as do the adults for migration into nearby tributaries. Adult salmonids provide commercial, subsistence, and recreational fishery. Seining in three tidal lagoons in Iliamna and Cottonwood Bays indicated that threespine stickleback was the most abundant species, followed by juvenile chum salmon and pink salmon.

3.24.2.3 Aquatic Invertebrates

Locations for macroinvertebrate and periphyton sampling were selected to characterize diversity, abundance, and density in freshwater habitats in the transportation and natural gas pipeline corridor study area. The sampling locations are representative of streams in the Bristol Bay drainage. The study area for macroinvertebrates and periphyton consists of three stream-sampling sites. These sites consisted of unnamed streams that were named Bear Den Creek, Red Creek, and Ursa 100B for reporting purposes. The transportation corridor study area extends eastward beyond the Bristol Bay drainages into the Cook Inlet drainages. Section 15.4

AMERICAN OVERSIGHT

in Chapter 15 (EBD) describes the macroinvertebrate and periphyton studies in the Bristol Bay drainages study area.

Aquatic habitat surveys indicate that the sample sites consisted largely of riffle/cobble habitat, which is the highest-quality habitat for EPT taxa. At sites sampled in 2005, the proportion of riffle/cobble habitat in each stream reach ranged from 70 to 85 percent.

A range of macroinvertebrate and periphyton sample-collection methods was employed during the field sampling. Slightly more taxa per site were collected using the ASCI method in 2004 than in 2005, indicating possible inter-annual variability. The number of taxa collected in 2005 from riffle/cobble areas by Surber sampler was generally less than the in ASCI samples, which were collected in more diverse habitats. Macroinvertebrate studies in other regions have documented variability in taxa richness among samples (DePauw et al. 2006). However, there are insufficient data from this study area to statistically define trends or relationships with respect to particular sampling method variable, or timing of sampling.

There were 235 macroinvertebrate taxa, including 64 Chironomidae taxa, identified in the Bristol Bay drainages study area (which includes both the mine and the transportation corridor study areas). Three of the non-Chironomidae macroinvertebrate taxa and three of the Chironomidae taxa were identified only in transportation corridor study area samples. The differences in numbers of taxa collected between the two sampling years is attributed to changes in the sampling program.

Dipteran taxa were not dominant at sampling sites in the transportation corridor study area. In 2005, Diptera composed a higher percentage than EPT in ASCI samples from all the sites, while EPT taxa composed a higher percentage than Diptera in Surber samples from all the sites. This may indicate that there were more Dipteran taxa in the varied habitats sampled using ASCI methods. Periphyton taxa richness and chlorophyll-a concentrations were both higher at Bear Den Creek than at the other two sites.

In 2005, Diptera comprised a higher percentage than EPT in ASCI samples from all the sites, while EPT taxa comprised a higher percentage than Diptera in Surber samples from all the sites.

Measurements of water-quality and habitat-quality parameters at each site fall within ranges considered good to optimal for aquatic and riparian habitat (Major and Barbour 2001). The concentration of dissolved oxygen (DO) was consistently high at all sites, and supersaturation (DO higher than 100 percent) was found at some sites. Water temperature ranged from 5.5°C to 13.2°C, and was much lower in 2005 than in 2004, except at Ursa I00B. No statistical analyses were performed on water quality and macroinvertebrate metric data because of limited data, and no trends were noted.

3.24.3 Action Alternative 3 – North Road Only

Mine Site

The affected environment as described under Alternative 1 is applicable to Alternative 3.

3.24.3.1 Aquatic Habitat

Transportation and Natural Gas Pipeline Corridors

The access route would include an 82.3-mile-long north road corridor and natural gas pipeline that would skirt the eastern edge of Iliamna Lake, thereby avoiding a crossing of Iliamna Lake (Figure 3.24-5). The natural gas pipeline would be buried adjacent to the road alignment to

AMERICAN OVERSIGHT

Diamond Point, then would follow the route into Cook Inlet to the Kenai Peninsula, as described above.

The affected environment as described under Alternative 1 for the Cook Inlet portion of the natural gas pipeline is applicable to Alternative 3.

Along this corridor, there are numerous watersheds ranging in size from large rivers to very small seasonally flowing channels containing anadromous and resident fish species. As part of the environmental baseline documentation, multiple sites were surveyed along the Alternative 3 transportation and natural gas pipeline corridor from 2004 to 2008 for fish and aquatic habit. Primary survey sites were directly on or near the representative road and pipeline alignment. In addition, support survey sites were upstream or downstream of the primary sites or on nearby tributaries. There were 61 primary survey sites and 44 support sites surveyed during this period. The survey sites were grouped into the watershed groups: Upper Talarik, Newhalen, Isolated watersheds, Roadhouse/Northeast Bay/Eagle Bay, Youngs/Chekok/Canyon, Knutson Bay/Pedro Bay, Pile Bay/Lonesome Bay, and Iliamna River; and Williams Creek. All groups except the Williams Creek group are in the Bristol Bay drainage. Overall, this alternative would involve 118 stream crossings, with 23 listed as anadromous waters (Table 3.24-7), 28 containing resident fish species only, and 67 small channels designated as fishless (K3.24). Nine of the anadromous streams that would be crossed by the Alternative 3 transportation and natural gas pipeline corridor are listed in Table 3.24-6.

Table 3.24-7. Anadromous Waters Crossed by Access Road and Pipeline Along the Alternate 3 Transportation and Natural Gas Pipeline Corridor[1]

Tributary [2]	AWC Code	R.M. [3]	Feature	Species/Life-stage [4]
n/a (tributary to Eagle Bay Creek)	324-10-10150-2239-3005	2.4	bridge	Ss, ACp
n/a (tributary to Chekok Bay)	324-10-10150-2261	5.6	bridge	COp, Ss, ACp
n/a (tributary to Chekok Bay)	324-10-10150-2261-3006	1.0	bridge	COp, Ss, ACp

Chekok Creek	324-10-10150-2267	3.3	bridge	COp, Ss, ACp
Knutson Creek	324-10-10150-2301	1.6	bridge	Ss, ACp
n/a (tributary to Lonesome Bay)	324-10-10150-2333	0.9	bridge	Ss
Pile River	324-10-10150-2341	1.6	bridge	Ss, ACp
Long Lake outlet	324-10-10150-2343	1.8	bridge	Kp, Sp
n/a (3 crossings)	324-10-10150-2343-3006	0.4, 0.7, 0.9	Culvert, bridge, culvert	Sp

1 Not including 9 anadromous streams that would be crossed by this alternative listed in Table 3.24-2. Note this alternative would cross Eagle Bay Creek approximately 4 miles above its mouth.

2 Tributary name from EBD 2011, if available

3 R.M. = river miles at crossing above mouth or confluence of tributary (approx.)

4 Species/Life-stage at crossing (from AWC). Species: K=Chinook, S=sockeye, CO=coho, CH=chum, P=pink; AC=Arctic char; Life-stage: s=spawning, r=rearing, p=present (life-stage not specified)

The Isolated Watershed Group includes two watersheds that drain the southwestern flanks of Roadhouse Mountain; however, these isolated watersheds did not appear to have any surface

AMERICAN OVERSIGHT

connection to the Newhalen River or Iliamna Lake. The Roadhouse/Northeast Bay/Eagle Bay Watershed Group includes three watersheds that drain into Iliamna Lake: Roadhouse Creek, an unnamed Tributary to Eagle Bay, and Eagle Bay Creek. The Youngs/Chekok/Canyon Watershed Group includes three watersheds that drain into the northern edge of Iliamna Lake: Youngs Creek, Chekok Creek, and Canyon Creek. The Knutson Bay/Pedro Bay Watershed Group consists of Knutson Creek and eleven unnamed tributaries that drain the western and southern sides of Knutson Mountain into Pedro Bay. The Pile Bay/Lonesome Bay Watershed Group includes the Pile River and two unnamed tributaries that flow into Lonesome Bay. The Iliamna River Watershed Group originates on the western side of the Chigmit Mountains and flows southwest into Pile Bay. Williams Creek is the only stream associated with the northern access corridor that drains into Cook Inlet.

Diamond Point Port

The affected environment as described under Alternative 2 is applicable to Alternative 3.

3.24.3.2 Resident and Anadromous Fish

Transportation Natural Gas Pipeline Corridors

As described above, the transportation and natural gas pipeline corridors would cross several rivers, lakes, streams and lake outlets within several different watersheds. Most of these watersheds drain into Iliamna Lake with the exception of the Isolated Watershed Group where precipitation, evaporation and groundwater exchange appear to be the dominant hydrologic process.

See Table 3.24-2 for a description of fish species found in the UTC and Newhalen watershed groups.

Isolated Watershed Group. No fish were found in these survey sites during the October 2007 sampling.

Roadhouse/Northeast Bay/Eagle Bay Watershed Group. Four fish species were documented at the primary survey sites: slimy sculpin, Dolly Varden, rainbow trout, and ninespine stickleback. Coho salmon, sockeye salmon, and Arctic char are also known to occur in this watershed group.

Youngs/Chekok/Canyon Watershed Group. Sockeye salmon, rainbow trout, Dolly Varden, and slimy sculpin were found at sites in this watershed group. Other fish known in this group include coho salmon and Arctic char.

Knutson Bay/Pedro Bay Watershed Group. Sockeye salmon, Dolly Varden, and slimy sculpin were documented at sites in this watershed group, but Arctic char are also known to be present in this watershed.

Pile Bay/Lonesome Bay Watershed Group. Slimy sculpin and threespine stickleback were documented in primary and support survey sites. Although no salmon were observed during the fish surveys, sockeye salmon and Arctic char are known to be present.

Iliamna River Watershed Group. Sockeye salmon, Dolly Varden, and slimy sculpin were observed in this watershed group. Approximately 3,000 adult sockeye salmon were observed at two support survey sites in August 2004.

Williams Creek Watershed. Williams Creek, which drains into the Cook Inlet at Williamsport, contained Dolly Varden when sampled in 2004.

AMERICAN OVERSIGHT

Diamond Point Port

See description of fish resources at Diamond Point under Alternative 2.

3.24.3.3 Aquatic Invertebrates

Epibiota

Epibiota surveys were conducted in intertidal zones representing a wide range of habitats (Figure 3.24-6). Diverse intertidal habitat types provide feeding areas for numerous pelagic fish (which live in the open ocean) and demersal fish (which live close to the ocean floor), and invertebrates in lower Cook Inlet. In the rocky intertidal habitats, the distribution of vegetation and invertebrates is determined by elevation, substrate, season, and exposure to physical stressors, such as waves, sun, and ice scour. Diversity of both plants and animals among the rocky stations tend to increase with declining wave exposure and salinity and increasing sediment load. Ice is another major stressor of the biologic communities, because winter ice can severely reduce or completely remove sessile epibiota (immobile organisms that live on the surface of other organisms) each winter.

Baseline sampling results indicated several trends in the data. Fewer species of algae less tolerant of saline and variable light (i.e., more estuarine) conditions were present; and areas with high wave exposure had the greatest potential for high macroalgal diversity due to the high levels of disturbance and greatest exposure to a larger recruiting stock, particularly at Cook Inlet waters.

Subtidal sampling for epifauna had limited visibility and detected relative sparse epifaunal abundance. Kelp was prevalent closest to shore. Rocky substrate dominated most diver transects; therefore, invertebrate fauna was dominated by mobile organisms. Common attached invertebrates included sponges, hydroids, sea anemones, the rock jingle, and bryozoans. Common mobile invertebrates included snails, chitons, nudibranchs, crabs, and sea stars. Few demersal fish were observed. Bottom-oriented fish like whitespotted greenling, starry flounder, and other flatfishes were common.

Infauna

Intertidal infauna (animals that live in ocean floor sediments) studies were conducted at multiple intertidal stations between 2004 and 2008 (Figure 3.24-6).

Intertidal infauna study results indicate that all animals identified at the genus level are abundant in marine assemblages elsewhere in Alaska (Blanchard et al. 2003). Between 2004 and 2008, differences in abundance, biomass, and diversity were found in the infauna sampling results. These differences reflect small-scale spatial and temporal occurrences and illustrate the constantly shifting baseline conditions in the intertidal infauna assemblage.

Intertidal studies found that the average number of infaunal taxa observed ranged from 1.6 to 8.0 in 2004, and ranged from 1.6 to 14.2 in 2008.

Subtidal study results indicate stability in subtidal ecology through time. The variability of the results of subtidal faunal measures was considerable, but is comparable to the results of studies of similar marine assemblages elsewhere (Feder et al. 2005). Communities are dominated by a few taxa with high abundance, and there is a moderately diverse assemblage of taxa within sites.

Subtidal infauna was, overall, more abundant and more diverse than intertidal infauna. Greater stability and lower stress in subtidal environments lead to more abundance and diversity.

AMERICAN OVERSIGHT

Intertidal environments experience increased wave action, large temperature and salinity shifts, and seasonal ice-gouging, which exert more stressful influences not experienced in subtidal habitats. Despite the physical stresses, some areas of the intertidal environment exhibited substantial biomass of large infauna that far exceeded the subtidal biomass. In addition, the infauna at subtidal stations exhibited a higher degree of within-station similarity than did the infauna at intertidal stations—a reflection of the greater diversity of intertidal substrates; again, likely a consequence of the harsher nature of the intertidal environment.

Subtidal studies found that coarse substrates dominated the area, and the biota therefore reflected this habitat type. Attached and burrowing animals, rather than burrowing infauna, dominated the diverse transects. The average abundance of all taxa observed ranged from 2,210 to 5,150 per square meter. Biomass ranged from 25.9 to 298 grams per square meter. The number of taxa observed ranged from 26 to 40 among sites sampled.

Alternative 3 Concentrate Pipeline Variant

The concentrate pipeline variant is described in Chapter 2, Alternatives. Aquatic habitat and fish distribution would be the same as described under Alternative 3- Transportation Corridor.

3.24.3.4 Alternatives Fish Stream Summary Table

A comparison of number of stream crossings, fish streams, anadromous streams, and resident fish is given in Table 3.24-8.

Table 3.24-8: Fish Stream Summary Table

Alternative	Stream Crossings	Fish Streams	Anadromous*	Resident**
Alternative 1 North Access Corridor	32	11	6	5
Alternative 1 South Access Corridor	65	33	2	31
Alternative 2 Road Sections	21	14	8	6
Alternative 2 Pipeline Sections	118	51	23	28
Alternative 3 Road and Pipeline Sections	116	51	23	28

*Data from AWC catalog

** Resident fish stream data from EBD, RFI 85 2018 fish survey [will be updated for DEIS]

3.24.3.5 Climate Change

There are likely to be hydrological impacts associated with projected changes in temperature, precipitation, and evapotranspiration in the Bristol Bay watershed, including changes in the magnitude and timing of streamflow that are likely to affect salmon habitat and populations. Changes in hydrology are likely to affect existing habitat via changes in water volume and velocity along with channel forms, which may lead to declines in habitat availability for spawning and rearing salmon populations.

AMERICAN OVERSIGHT

Both hydrology and water temperature of freshwater systems affect critical life stages of salmonid species. These hydrological changes are likely to have different effects on salmon populations depending on the amount of time they spend rearing in freshwater habitats, their life stage, and their ability to adapt to changes in environmental conditions.

Populations of Pacific salmon species are likely to adapt to changes in temperature, precipitation, and hydrology in different ways; the geographic location of populations is likely to affect their ability to adapt to these changes. The genetic and life history diversity within and among the Bristol Bay Pacific salmon populations will likely be crucial for maintaining the resiliency of the regions salmon stocks under a future environment characterized by climate change and increased anthropogenic stressors (Hilborn et al. 2003, Schindler et al. 2010, Rogers and Schindler 2011).

AMERICAN OVERSIGHT

4.24 FISH VALUES

The Environmental Impact Statement (EIS) analysis area includes watersheds and downgradient aquatic habitats affected by project components from headwater streams to marine waters. Potential direct and indirect impacts to fish and aquatic habitat and aquatic invertebrates include:

- Physical loss of stream, lake, and marine habitat
- Blockage of stream channels preventing fish or other aquatic species passage
- Aquatic habitat effects due to instream flow reductions from mine water withdrawal or capture and redirection of groundwater
- Sedimentation of aquatic habitat due to surface erosion of mine roads, stockpiles, or other activities
- Erosion from vegetation removal; shoreline erosion associated with ship or ferry wakes; benthos disturbance/mortality from docks and pipelines
- Changes in instream water quality such as temperature, turbidity, pH, dissolved oxygen, and metal or chemical contaminants
- Injury or mortality of fish or other aquatic species.

Permit compliance requirements, including standard and special terms and conditions, best management practices (BMPs), and environmental monitoring would be established by regulatory agencies and landowners with permitting authority. These requirements would be implemented as part of construction management and facility operations to avoid, minimize, and control risks to fish and aquatic habitat in the project area.

4.24.1 No Action Alternative

Under the No Action Alternative, the Pebble Project would not be constructed, and no new impacts to aquatic resources would occur.

4.24.2 Action Alternative 1

4.24.2.1 Habitat Loss

Mine Site

North Fork Koktuli

As described in Section 3.1, Introduction to Affected Environment, approximately 82 percent of the 10.7-square-mile (mi^2) mine site footprint would occur in the North Fork Koktuli (NFK) River basin (Figure 4.24-1). Tributary 1.19 would be blocked to anadromous and resident fish by the tailings storage facility (TSF) sedimentation pond and dam immediately above the tributary's confluence with the NFK. This anadromous tributary and its sub-tributaries provide 6.2 miles of spawning and rearing habitat for coho salmon, 2.9 miles of rearing habitat for Chinook salmon, and 12.7 miles of spawning and rearing habitat for resident fish species, including rainbow trout, Dolly Varden, Arctic grayling, and sculpin (Table 4.24-1). This direct loss of habitat would occur during project construction, and would be permanent, although a sub-tributary of Tributary 1.19 would remain free–flowing, and may provide habitat for resident species.

AMERICAN OVERSIGHT

Table 4.24-1: Miles of Stream Channel Impacted Due to Fill, Excavation, Inundation, or Blockage to Upstream Migrant Fishes and Resident Fishes

Tributary	Channel Function	Miles
NFK Tributary 1.19	Chinook Salmon Rearing	2.9
	Coho Salmon Rearing	6.2
	Coho Salmon Spawning	3.9
	Resident Salmonid Presence	12.1
	Resident Non-Salmonid Presence	12.7
	Fishless	8.1
SFK Mainstem	Resident Non-Salmonid Presence	0.5
	Fishless	1.0
Tributaries to upper SFK	Resident Non-Salmonid Presence	0.8
	Fishless	2.2

When compared to the total mileage of currently documented anadromous waters in the three tributaries associated with the mine site (i.e., the NFK, South Fork Koktuli River [SFK], and the Upper Talarik Creek [UTC]), the loss of Tributary 1.19 habitat represents 4 percent and 3 percent of spawning and rearing habitat for coho salmon, respectively; and 3 percent of Chinook salmon rearing habitat. In the context of the entire Bristol Bay drainage, with its 9,816 miles of currently documented anadromous waters, the loss of Tributary 1.19 represents a 0.002 percent reduction in miles of anadromous stream habitat, or a 0.03 percent decrease in accessible drainage area.

Documented anadromous waters only represent waters where salmon have been observed, and are not considered representative of all anadromous waters in the Bristol Bay drainage. The total estimated mileage of anadromous waters in Bristol Bay drainage is likely much higher than currently documented. The mine site area is one of the few areas in the Bristol Bay drainage where numerous small channels and tributaries have been surveyed for salmon.

Within the mine site footprint, approximately 2.3 miles of Tributary 1.19 mainstem and sub-tributary stream channels would remain free-flowing. This habitat would not be accessible to anadromous fish due to blockage by downstream dams, but may continue to provide spawning and rearing habitat for resident species. In addition to the remaining free-flowing channels, approximately 1.4 miles of stream channel would be converted to reservoir habitat.

Approximately 276 acres of riparian wetland would be directly and permanently impacted by the mine site footprint; predominately in the NFK watershed. These impacts would include reduced surface water infiltration, retention, and groundwater flow; increased surface water runoff; and reduced water quality functions. Surface water BMPs would be implemented during construction, operations, and closure; and changes in riparian wetlands would likely not be detectable downstream from the mine site.

South Fork Koktuli River

The open pit and related mine facilities are expected to directly and permanently impact approximately 2.0 miles of fish habitat in the upper mainstem SFK and a headwater tributary (Table 4.24-1). The affected stream channels are not classified as anadromous, but provide habitat for populations of resident fish, including sculpin, Arctic grayling, and stickleback

AMERICAN OVERSIGHT

(Buell 1991). The extent of these impacts would be limited to waters in the footprint of the mine site footprint.

Upper Talarik Creek

The open mine pit and perimeter road are expected to extend to the western edge of the UTC drainage; the only mine site components that would occur in the UTC drainage are the transportation corridor road, the buried natural gas pipeline, and the eastern water treatment plant discharge pipe and facility (Figure 4.24-1). No aquatic habitat would be directly lost in the UTC due to mine construction, operations, or closure.

Transportation Corridor

Road/Pipeline

The road and pipeline would cross nine anadromous and 35 resident fish streams. Bridge and culvert crossings would be designed and installed in accordance with established Alaska Department of Transportation & Public Facilities (ADOT&PF) and Alaska Department of Fish and Game (ADF&G) standards to provide fish passage for all life stages resulting in minimal loss of aquatic habitat, except for the permanent loss of streambed habitat within the footprint of bridge piers on the Newhalen and Gibraltar rivers. Single-span bridge crossings would be designed to maintain a riparian buffer between the bridge abutments and the active channel. The road/pipeline footprint and associated crossing structures would impact approximately 13.5 acres of riparian vegetation, and interrupt floodplain connectivity in certain locations. The impact to riparian vegetation would be permanent for the life of the project. BMPs such as road fill drain culverts may be considered during design and permitting to maintain floodplain connectivity and to maintain riparian habitat function.

Ferry Terminal/Iliamna Lake Pipeline

Docking facilities for the ice-breaking ferry at the north and south ferry terminals are expected to include rock and gravel ramps extending approximately 40 feet into Iliamna Lake. Consequently, there would be permanent, direct impacts due to loss of approximately 1 acre of benthic habitat under the ramp footprints.

Horizontal directional drilling (HDD) and trenching from lay barges would be used to install the pipeline segments from the lakeshore into waters deep enough to avoid navigational hazards. There would be temporary impacts to near-shore benthic habitats during construction, and permanent impacts to benthic habitat beneath the footprint of the pipeline in deeper waters.

Amakdedori Port

Amakdedori port would be a gravel causeway with a footprint of 14 acres. Placement of gravel in the nearshore environment would have permanent impacts on marine benthos habitat.

Natural Gas Pipeline

The construction phase would include installation of a 104-mile-long, 12-inch diameter gas pipeline on the floor of Cook Inlet from between the Kenai Peninsula and Amakdedori port. HDD would be used to install the pipeline segments from the shoreline into waters deep enough to avoid navigational hazards. These activities may involve displacement of some substrate material along with the associated organisms. There would be a permanent, direct loss of benthic habitat beneath the pipeline footprint on the bottom of Cook Inlet. Habitat alteration would be limited over time, and would not have quantifiable effects to populations of fish and shellfish.

AMERICAN OVERSIGHT

4.24.2.2 Fish Displacement, Injury, and Mortality

Mine Site

North Fork Koktuli and South Fork Koktuli

Direct displacement, injury, and mortality of fish would occur during project construction in the NFK and SFK. Timing (May 15 to July 15) of construction in anadromous fish streams according to the ADF&G Fish Habitat Permit would minimize impacts to out-migrating juveniles and avoid the presence of spawning adults. Fish capture and relocation would be implemented according to ADF&G Aquatic Resource Permit (ARP) requirements to reduce impacts to resident fish. Stipulations contained in the ARP would determine timing, capture methods, and relocation protocols. Regardless of the scope of the capture and relocation effort, some fish would be displaced and experience injury or mortality. The extent or scope of these impacts would likely be limited to waters in the vicinity of the mine site footprint, and may not be measurable or detectable downstream from the affected stream channel.

Upper Talarik

No fish displacement or mortality would be expected in the UTC due to mine construction, operations, or closure.

Transportation Corridor

Bridge, Culvert, and Natural Gas Pipeline Installation

Direct and localized mortality of fish from construction activities at stream crossings and the ferry terminals may occur, although with limited impact. Temporary water diversions or dewatering of stream reaches during construction could result in direct mortality due to fish stranding and desiccation. Fish entrainment or impingement at screens during pumping may also result in direct mortality or injury.

As stated above, timing and capture/relocation would be conducted according to established ADF&G practices and permit conditions to reduce impacts. Water pump intake screens used for dewatering and water withdrawal would be designed, constructed, and certified according to ADF&G standards to prevent fish impingement to reduce impacts.

Iliamna Lake Pipeline

The construction phase would include installation of an 18-mile-long gas pipeline on the floor of Iliamna Lake between the north and south ferry terminals. HDD and extended-reach backhoes would be used to install the pipeline segments from the lakeshore into waters deep enough to avoid navigational hazards. These activities may involve displacement of some substrate material along with the associated organisms. There would be permanent, direct mortality of benthic organisms beneath the pipeline footprint on the bottom of Iliamna Lake.

Sockeye salmon are known to use shoreline habitat for spawning, and therefore could be potentially affected; however, documented spawning areas are more than 0.5 mile from the ferry terminals and primary entry points of the pipeline into the lake (EPA 2014).

Ferry Terminals

Docking facilities for the ice-breaking ferry at the north and south ferry terminals are expected to include rock and gravel ramps extending approximately 40 feet into Iliamna Lake. There would be permanent, direct mortality to benthic organisms within the approximately 1-acre total ramp footprints.

AMERICAN OVERSIGHT

Ferry Operations

Propeller Entrainment or Injury

Direct impacts of propeller-induced injury or mortality to anadromous or resident fishes by motorboat propellers are not frequently assessed, and are limited to a few studies (Holland 1986; Killgore et al. 2011; Whitfield and Becker 2014). These primarily involved non-salmonid species; the paucity of field studies has been largely due to physical constraints imposed by sampling behind towboats (Killgore et al. 2011). A review of these publications indicated a number of biotic factors may affect fish strike rates by ferry propellers at Iliamna Lake, including:

- Life history traits of a species (pelagic versus nest or redd builders)
- Coincidence in timing of emigration and migration /movement of specific life stages with the path of a moving ferry
- Distribution of fish size/ species in the water column relative to ferry draft
- Spawning behavior
- Fish avoidance behavioral responses to ferry noise/turbulence
- Number, speed, and configuration of propeller blades (horizontal versus vertical)
- Fish size.

Table 3.24-2 in Chapter 3 shows the estimated seasonal presence and activity of life stages of common species that may be exposed to ferry/boat transiting between the north and south ferry terminals. Documented sockeye lake spawning is concentrated towards the northeastern portion of the lake (see Section 3.24, Fish Values); likely due to numerous islands and abundant sheltered habitats. As discussed below under wake stranding, the ferry terminals are on exposed, high-energy beaches with no documented beach spawning habitat in the immediate vicinity; therefore, ferry operations impacting adult sockeyes is unlikely. Juvenile sockeye have the highest potential to interact with the ferry operations due to their relative abundance and wide distribution throughout the Iliamna Lake system.

The potential exists for chronic, direct adverse interaction of ferry propeller blades and various life stages of migratory and non-migratory fish species throughout the 20-year operations phase of the project. The ferry has the potential to entrain fish into the turbulent zone created by propeller blades, although benthic species or midwater species larger than 10 millimeters are less susceptible to entrainment, and are expected to detect and avoid propeller-related impacts. Although unlikely, propeller strikes or shear forces could result in fish injury or mortality. Impacts are expected to be at the individual level.

Wake Impacts

Analysis of juvenile salmon stranding data from the lower Columbia River by Pearson et al. (2006) identified the following factors in affecting stranding:

- Fish availability in the shallow nearshore zone along the beach
- Nearshore ship-wake properties and wave run-up characteristics (wave height and period), as well as direction and extent of wave draw-down and run-up on the beach
- River elevation (river stage and tidal height)
- Beach characteristics (slope, distance to navigation channel).

Pearson et al. (2006) also noted that fish stranding occurred primarily during nighttime vessel passages, and no stranding occurred at the same locations during daytime passages. A radio telemetry study by Otter Tail (2010) on the Kuskokwim River reported no evidence of stranding

AMERICAN OVERSIGHT

of seaward-emigrating salmon when the prevailing wake height was less than 1.5 inches along the gravel bars surveyed; however, these fish did not occupy confined segments of the river.

The ferry terminal locations are relatively exposed, short beaches unprotected from wave energy. Numerous small storm berms are present on the beach faces, indicative of changing seasonal water levels. In contrast to studies conducted on rivers, stranding of fry from ferry wakes is not expected to be a detectable source of mortality in Iliamna Lake due to the perpendicular route of travel in relation to the shoreline. The Iliamna Lake ferry is expected to produce a 4-inch wake at its 6-knot approach speed; however, the wake would dissipate within 30 feet of the hull. Consequently, any impacts on juvenile and adult fish due to boat wake would be extremely limited in scale—both spatially and temporally.

Amakdedori Port

Short-term effects on both migratory and non-migratory marine fish species may occur during construction of the port. Fish are susceptible to injury and mortality from sound waves generated by pile-driving during construction of the proposed dock (Caltrans 2015). Mortality from sheet-pile installation is possible, but unlikely, due to the fish moving into existing available habitat in Cook Inlet.

Propeller Entrainment or Injury

Various propeller-driven tugs and other ships would be accessing Amakdedori port to transport equipment and personnel during project construction, operations, and closure. The impacts are similar to the above description of the Iliamna Lake ferry operations. This disturbance is expected to be chronic, but infrequent in duration, and localized in geographic extent.

Wake Impacts

During mine operations, marine barges or lightering vessels are expected to make up to 33 trips per year between the port and the offshore anchored bulk carriers. The barge's low transit speeds (5 to 7 knots), minimal draft (3 to 8 feet), distance from shoreline to jetty mooring locations (approximately 1,500 feet), and the presence of naturally occurring waves in Kamishak Bay, are all expected to limit wake-induced impacts on fish.

Natural Gas Pipeline

There would be permanent, direct mortality of benthic organisms beneath the pipeline footprint on the bottom of Cook Inlet during pipeline installation. The effect is expected to be of short duration and local to construction activities.

4.24.2.3 Stream Flow

Mine Site

Operation of the mine site is expected to result in an overall net reduction in available water for release into downstream channels. Reductions of instream flows in the mainstem and select tributary reaches of the NFK, SFK, and the UTC, due to filling of stream channels by the TSF or other stockpiles, excavation of channels and capture of groundwater at the mine pit, or the retention of surface runoff from mine facilities, would result in direct and long-term impacts to aquatic habitat and fish species. Streamflow reductions would begin during project construction, and would continue through operations and post-closure.

AMERICAN OVERSIGHT

During project construction and operations, a network of seepage and sedimentation ponds would collect runoff and seepage from stockpiles, the mine pit, and other mine components (e.g., roads, embankments, and construction sites). Runoff and seepage water would be routed into the mill for ore processing and reuse, or routed to one of two water treatment plants for use in dust control or power plant cooling. Water would also be treated and released into stream channels at three locations: 1) NFK Tributary 1.19 immediately upstream of the NFK confluence; 2) the SFK at its confluence with Frying Pan Lake; and 3) a tributary to the UTC approximately 2 miles below its headwaters (Figure 4.24-1). The water would be treated before discharge in compliance with water quality standards to protect aquatic life, as specified in an Alaska Pollutant Discharge Elimination System (APDES) permit. Treated water would be discharged to groundwater via buried infiltration chambers designed to provide energy dissipation, erosion control, and freeze protection.

Reduction in streamflows could directly impact the quantity and quality of instream habitat for upstream migration of adult salmonids, spawning, and egg incubation, and rearing habitat for juvenile fish. Reductions in flows could also directly impact available habitat for benthic macroinvertebrate (BMI) production, which is critical for fish growth and survival. The magnitude and extent of impact would vary among the three principal tributaries, according to the degree of surface water and groundwater capture, the location of impacts in the basin, the proximity and size of downstream tributaries, and the magnitude of flow augmentation at the water release facilities.

Fish Habitat Changes Associated with Stream Flow

Downstream of the project footprint, habitat changes—as measured by weighted usable area—vary by species and life stage; drainage basin and reach; and for wet, average, and dry years (R2 Consultants 2018). Treated water releases from mine site facilities would be optimized to benefit priority species and life stages for each month and stream.

In general, most species would have larger-percentage reductions in usable spawning habitat in reaches just below the mine site than further downstream during project operations and post-closure. The percentage reductions in habitat would generally decrease in a downstream direction until reaching the confluence of the NFK and the SFK (with a few exceptions). Rainbow trout, chum, sockeye, Dolly Varden, and Arctic grayling would have habitat decreases only in the headwater tributaries. Chinook and coho spawning habitat would decrease throughout the NFK and SFK drainages. Once the mainstem Koktuli is reached, flow changes would not be detectable. Therefore, the downstream extent of habitat impacts associated with flow reductions would be downstream of the confluence of the NFK and the SFK, and upstream of the mainstem Koktuli River confluence with the Swan River (the end of the model domain).

AMERICAN OVERSIGHT

Table 4.24-2: Priority species and life stages used to determine habitat flow needs in the Mine Site Area

Month	Priority Species/Life Stages		
	SFK	NFK	UTC

Nov			
Dec	Chinook Juvenile Rearing	Chinook Juvenile Rearing	Coho Juvenile Rearing

Spawning Habitat

Throughout the mine site area in average precipitation years, Chinook and coho spawning habitat would be reduced; while chum, sockeye, rainbow, Dolly Varden, and Arctic grayling spawning habitat generally would be increased (Table 4.24.3). In wet years, the decreases in habitat would be lower, and the increases greater; in dry years, the habitat decreases would be greater and the increases would be lower. Post-closure, flow reductions would be lower than during mining, resulting in smaller reductions and increases in habitat.

Table 4.24-3 Average precipitation year spawning habitat for all streams and species in the mine site area pre-mine, during operations, and post-closure

	Habitat Available			Change in Available Habitat			
	Pre-Mine	During Operations	Post Closure	During Operations		Post Closure	
Species	(acres)	(acres)	(acres)	(acres)	(% diff)	(acres)	(% diff)
Chinook	*82.54*	*79.51*	*81.14*	*-3.02*	*-3.7%*	*-1.40*	*-1.7%*
Coho	*105.56*	*102.87*	*104.21*	*-2.69*	*-2.6%*	*-1.34*	*-1.3%*
Chum	*180.10*	*181.07*	*180.84*	*0.97*	*0.5%*	*0.74*	*0.4%*
Sockeye	*133.00*	*133.73*	*133.65*	*0.73*	*0.5%*	*0.65*	*0.5%*
Rainbow	*98.46*	*101.40*	*100.01*	*2.94*	*3.0%*	*1.55*	*1.6%*
Dolly Varden	*203.58*	*204.02*	*203.90*	*0.44*	*0.2%*	*0.32*	*0.2%*
Arctic Grayling	*132.24*	*135.59*	*133.10*	*3.34*	*2.5%*	*0.86*	*0.7%*

AMERICAN OVERSIGHT

North Fork Koktuli

The trends in habitat change modeled in the entire mine area are shown in the changes in NFK spawning habitat. In average precipitation years during mine operations, salmonid habitat availability would decrease by 2.01 acres (8.1 percent) for spawning Chinook, and 1.86 acres (5.5 percent) for coho, while it would increase by 2.12 acres (5.8 percent) for spawning rainbow trout, 1.42 acres (4.4 percent) for sockeye, and 1.95 acres (5.5 percent) for Arctic grayling. Post-closure, habitat changes are predicted to be reduced to a 2.7 percent loss in Chinook, and 2.1 percent loss for coho. Habitat gains for the other species follow the same trend.

South Fork Koktuli

The trends in habitat change modeled indicate there would be a reduction in sockeye spawning habitat in the SFK. In average precipitation years, salmonid habitat availability would decrease by 1.02 acres (2.8 percent) for spawning Chinook, 0.82 acre (2.4 percent) for coho, and 0.69 acre (1.3 percent) for sockeye. Habitat would increase by 0.80 acre (2.4 percent) for spawning rainbow trout, and 1.18 acres (2.6 percent) for Arctic grayling. Habitat changes for Dolly Varden and chum salmon are less than 1 percent.

Upper Talarik Creek

Due to low-magnitude flow changes in the UTC basin, spawning habitat changes for all species would be less than 1 percent during both mining operations, and post-closure.

Juvenile Habitat

Juvenile salmonid habitat would be affected by the reduced flows associated with both mining and post-closure operations. In general, Chinook and rainbow trout juvenile habitat would be reduced, while sockeye juveniles (and the other salmonid species, to a lesser extent) would generally benefit from reduced flows associated with the mining operations. Sockeye juvenile habitat increases would generally be associated with the SFK-C reach, where habitat would be increased by 0.76 acre (44 percent) during mining operations; while rainbow habitat losses would be greatest in SFK-190, where habitat would decrease by 0.15 acre (13.3 percent) during operations.

Changes in habitat for juveniles would be reach-specific. The changes in habitat availability would be less associated with upstream or downstream reach locations, and more dependent on reach-specific habitat features. For example, beginning at the mine site in the NFK drainage, moving downstream in average years, juvenile coho habitat would alternate between increases and decreases in habitat in each reach (NKF-190, NFK-C, NFK-B, NFK-A).

Table 4.24-4 Average precipitation year juvenile habitat for all streams and species in the mine site area pre-mine, during operations, and post-closure

	Habitat Available			Change in Habitat Available			
	Pre-Mine	During Operations	Post Closure	During Operations		Post Closure	
Species	(acres)	(acres)	(acres)	(acres)	(% diff)	(acres)	(% diff)
Chinook	*57.44*	*57.40*	*57.23*	*-0.05*	*-0.1%*	*-0.22*	*-0.4%*
Coho	*55.47*	*55.58*	*55.43*	*0.11*	*0.2%*	*-0.03*	*-0.1%*
Chum	--	--	--	--	--	--	--

AMERICAN OVERSIGHT

Table 4.24-4 Average precipitation year juvenile habitat for all streams and species in the mine site area pre-mine, during operations, and post-closure

	Habitat Available			Change in Habitat Available			
	Pre-Mine	During Operations	Post Closure	During Operations		Post Closure	
Sockeye	*41.11*	*41.85*	*41.20*	*0.75*	*1.8%*	*0.09*	*0.2%*
Rainbow	*56.01*	*55.70*	*55.59*	*-0.31*	*-0.6%*	*-0.42*	*-0.8%*
Dolly Varden	*62.97*	*63.25*	*63.06*	*0.27*	*0.4%*	*0.09*	*0.1%*
Arctic Grayling	*101.06*	*101.91*	*101.39*	*0.85*	*0.8%*	*0.33*	*0.3%*

North Fork Koktuli

In average precipitation years, juvenile salmonid habitat availability would increase for all species by between 0.03 acre, or 0.2 percent (sockeye) and 0.96 acre or 2.9 percent (Arctic grayling), except for a decrease in rainbow trout habitat of 0.02 acre (0.2 percent). Post-closure, habitat changes would be reduced to less than 1 percent for all species. As mentioned above, the habitat changes would vary based on reach-specific conditions, with the largest percentage of changes occurring in small tributary NFK-190. However, in a downstream direction, reaches would alternate between habitat gains and losses for several species.

South Fork Koktuli

In average precipitation years, juvenile salmonid habitat availability would decrease for all species by between 0.07 acre, or 0.2 percent (Arctic grayling), and 0.31 acre, or 1.5 percent (rainbow trout), except for an increase in sockeye juvenile habitat of 0.73 acre (7.1 percent). Post-closure, habitat changes would be less than 1 percent for all species, except for a decrease in rainbow trout habitat of 0.27 acre (1.3 percent), and an increase in sockeye habitat of 0.14 acre (1.3 percent). The largest changes in habitat in the SFK area are associated with rainbow trout habitat, which increased in the SFK-C reach.

Upper Talarik Creek

Due to low-magnitude flow changes in the UTC basin, juvenile habitat changes for all species would be less than 1 percent during both mining operations and post-closure.

Transportation Corridor

Road Construction

Except temporarily during construction, potential impacts on stream flows are not expected to occur at bridge and culvert crossings. All work in fish-bearing streams would be subject to design considerations, restoration requirements, and timing windows, as specified by ADF&G Title 16 Fish Habitat Permits (AS 16.05.841-871). In accordance with ADF&G criteria, bridge and culvert construction activities in anadromous waters would occur from May 15 to June 15, to avoid impacts to migrating salmon. Infrequent barriers to fish passage could occur at stream crossings using culverts due to temporary blockage. The impact is expected to be localized and temporary. Routine inspection and maintenance of culverts, bridges, and roads would be regularly conducted in compliance with right-of-way (ROW) and ADF&G permit conditions, to ensure that culvert-related erosion, wash-out, or debris blockage do not result in permanent

AMERICAN OVERSIGHT

impacts to fish passage or downstream habitat. More stringent monitoring and maintenance standards may be required by ROW lease stipulations from respective land owners.

Water withdrawals would occur at lakes, ponds, and streams along the road corridor, according to ADNR and ADF&G permit conditions for dust control and hydrostatic testing during the summer construction seasons; and would not be expected to impact overwintering fish or habitat. Withdrawals from fish-bearing waters would use pump screens certified by ADF&G to prevent fish impingement. Disposal methods for hydrostatic test water would be developed in accordance with APDES General Permit AKG320000 for energy dissipation and sediment control. No chemicals would be added to the hydrostatic test waters.

Natural Gas Pipeline

The final configuration of the natural gas pipeline would generally be within the prism of the access road. Stream crossings would be open cut or HDD at culvert crossings, and attached to bridges at major river crossings. This configuration would reduce the risk of ponding, interception of surface water flows, and sedimentation, as related to the pipeline ditch.

Potential impacts to groundwater and surface water during pipeline construction would likely involve interception of shallow groundwater and surface water during trenching activities, which would be captured and locally flow along the trench backfill. Impacts could extend beyond the life of the project, because the pipeline would be abandoned in place. Ditch plugs are typically installed to intercept shallow groundwater flows. Typical BMPs for surface water management could include maintaining natural surface water patterns; crowning of ditch backfill to allow for settlement to original ground level; contouring of surrounding terrain; construction of settlement infiltration basins; and prompt revegetation of riparian and wetlands and a robust monitoring and maintenance program. Ditch dewatering and hydrotest water would be discharged to approved sites as per Alaska Department of Environmental Conservation (ADEC) requirements. All work in fish-bearing streams would be subject to design considerations, restoration requirements, and timing windows, as specified by ADF&G Title 16 Fish Habitat Permits (AS 16.05.841-871).

4.24.2.4 Stream Productivity

Mine Site

The loss of connection between Tributary 1.19 and the mainstem NFK due to stockpile embankments and pond dams could result in permanent, direct effects on the quantity of spawning habitat by interrupting gravel transport into the mainstem NFK. Geomorphic studies conducted as part of the environmental baseline effort concluded that most instream gravel is recruited from local streambank erosion, rather than transported from upstream reaches, EBD Chapter 3, Geology and Mineralization); however, a source like Tributary 1.19 would also be expected to contribute gravel into mainstem reaches. Two other sizeable tributaries (NFK Tributaries 1.17 and 1.12) meet the mainstem NFK within 5 miles below the mine site, so the effects of reduced gravel recruitment would likely be limited in area. Spawning surveys conducted from 2004 to 2008 indicated the heaviest spawning by coho and chum salmon was concentrated in the mainstem NFK in the 9-mile reach immediately below the mine site and Tributary 1.19. In contrast, Chinook and sockeye salmon spawning areas were concentrated in the mainstem NFK 10 to 20 miles downstream of the mine site, where potential impacts of upstream gravel interruptions are less likely.

Baseline concentrations of dissolved organic carbon in the surface waters in the project area ranged from 1 milligram per liter (mg/L) to 2 mg/L; concentrations of nitrate+nitrite ranged from 0.1 to 0.3 mg/L; and mean concentrations of total phosphorous ranged from 0.02 to 0.04 mg/L,

AMERICAN OVERSIGHT

indicative of oligotrophic nutrient status in the aquatic ecosystem. This is consistent with the characteristics of headwater stream orders 1, 2, and 3; with existing riparian vegetation providing low inputs of organic matter. The lack of a mature deciduous overstory likely contributes to the oligotrophic conditions, and is unique to headwater streams in the project area; specifically, the NFK and SFK. The extent or scope of the loss of riparian productivity would likely be limited to waters in the vicinity of the mine site footprint, and may not be measurable or detectible downstream from the affected stream channel.

The importance of marine-derived nutrients in Bristol Bay watershed lakes from returning salmon is well documented, as noted in Chapter 3, Affected Environment. As shown in the baseline data above, marine-derived nutrients does not appear to have a measureable influence on the nutrient availability in the Koktuli or uppermost reaches of the Upper Talarik watersheds in the project area. This may be due to the comparatively small numbers of spawning fish, high flushing flows in the fall after spawning has occurred and the lack of large woody debris for carcass retention. The extent or scope of these impacts would likely be limited to waters in the vicinity of the mine site footprint, and may not be measurable or detectible downstream from the affected stream channel.
