Re: Public Records Request

Ms. Wood:

With this letter you will find emails and attachments produced by the Mississippi State Department of Health (MSDH) in response to your public records request originally submitted on January 4, 2022. Public records requests at MSDH are governed by Mississippi's Public Records Act (Miss. Code. Ann. § 25-61-1, et seq.) as well as any laws providing exemptions to this Act.

A chart of redactions made in the produced emails and/or their attachments is provided. Note that over 120 emails from the National Biosurveillance Integration Center (NBIC) were completely redacted in alignment with the direction of the U.S. Department of Homeland Security which oversees the NBIC.

Should you have any questions, please reach out to the following agency staff member who helped conduct the review of your documents:

David Trewolla, JD
Director, Data Governance
David.Trewolla@msdh.ms.gov

Sincerely,

DocuSigned by:

PUBLIC HEALTH AUTHORITY TO PREVENT AND CONTROL THE SPREAD OF COMMUNICABLE AND INFECTIOUS DISEASE

POSITION

The Association of State and Territorial Health Officials (ASTHO) supports the establishment of robust public health legal authorities to facilitate the timely and adequate response to communicable and infectious disease outbreaks. These legal authorities are often exercised without the need of an emergency declaration and may allow, among other things, the abatement of nuisances, investigation of the causes of disease, institution of quarantine measures, ordering individuals or groups to isolate, conducting contact tracing and case investigations, collecting data, temporarily limiting or canceling public events, temporarily restricting or closing venues, and requiring vaccination verification for certain conduct and activities (e.g., school attendance). Beyond their use in the response to the historic pandemic caused by the novel coronavirus, in the past, these powers have been routinely exercised for more commonly experienced disease outbreaks, such as mumps and measles. Additionally, other societal sectors, such as business, education, cultural, and religion often depend on public health to stop the spread of infectious disease, prevent widespread disruptions, and quell public anxiety and fear. Maintaining these state and territorial legal authorities are key to being prepared for communicable and infectious disease outbreaks both now and in the future.

Summary of Recommendations:

- Public health legal authority that facilitates a skillful response to disease outbreaks without undue delay.
- Public health authorities that are guided by data and science.
- Ensure that public health authority balances individual rights with the responsibility to protect the public's well-being.
- Support public health authority that is reasonable and aligned with disease prevention and control activities.
- Public health legal authority that is able and sufficient to respond to future disease

BACKGROUND

Establishing and using legal authority to control the spread of infectious disease dates to before the founding of the country. For example, colonial governments implemented isolation and quarantine precautions for incoming ships to prevent the introduction and spread of smallpox and other contagions.[1] These powers and activities were seen not only as a way of protecting the health of the local communities but also protective of trade and commerce.[2] As the scientific understanding of communicable and infectious disease grew, new tools such as contact tracing, disease investigation, data collection, and vaccines were added to public health's legal authority and practice. During the current pandemic public health authority has been used, with evidenced benefit, to slow the spread of the coronavirus by limiting the size of gatherings, encouraging social distancing, temporarily closing high-risk venues, and requiring the use of face coverings in certain places.[3,4,5,6,7,8,9]

Despite the successes in exercising public health authority, grave questions and negative perceptions about the role and use of public health powers in response to the pandemic and, by implication, future infectious disease outbreaks have arisen. Over the last year, the critical attitude toward the pandemic response has led to the rolling back of public health authority in several jurisdictions.[10] The reductions in public health legal authority will conceivably make it more difficult to respond to future disease outbreaks. As state and territorial policy makers

continue to address the many issues related to the current pandemic, they are encouraged to consider these potential impacts and costs.

RECOMMENDATIONS

With regards to state and territorial public health authority to prevent and control the spread of communicable and infectious disease, ASTHO recommends:

- Maintaining public health's ability to implement non-medical and medical interventions (e.g., social distancing and distribution of vaccines) swiftly and adeptly by resisting the establishment of administrative burdens that delay public health action, endangers the public and leaves our community vulnerable to infectious disease outbreaks.
- Support evidence-based laws and policies related to the identification, prevention, and control of communicable and infectious diseases.
- Ensure that public health legal authority properly and adequately balances the rights of individuals with the responsibility and obligation to protect the public's health and well-being. Law and policy that undermines and encumbers public health decision making or arbitrarily limits the scope of public health authority, can impede the ability to prevent and control the spread of disease.
- Maintain public health legal authority that is reasonable and aligned with the preventing and controlling the spread of infectious disease. For example, individuals subject to isolation or quarantine should be guaranteed the right to due process, allowed to petition a court to review the government's action, and ensured of reducing any economic, social, or emotional harm. Additionally, public health authority should be able to align with disease it is confronted and allowed to be exercised in a way to address the identifiable characteristics of the disease.
- Ensure public health legal authorities that are appropriate and necessary for the prevention and control of future communicable and infectious disease outbreaks. Other airborne, highly contagious illnesses, like measles, can be effectively contained by implementing public health measures similar to those that have been questioned during the pandemic. Furthermore, the next major public health threat may spread in other ways meaning public health authority must be able to respond to novel, unknown diseases.

APPROVAL DATES

Prevention Policy Committee Approval:
Board of Directors Approval:
Policy Expires:

ASTHO membership supported the development of this policy, which was subsequently approved by the ASTHO Board of Directors. Be advised that the statements are approved as a general framework on the issue at a point in time. Any given state or territorial health official must interpret the issue within the current context of his/her jurisdiction and therefore may not adhere to all aspects of this Policy Statement.

MS-DOH-21-1816-A-000007

Introduction

The COVID-19 pandemic continues to highlight the necessity of vaccination and the impact vaccine-preventable illnesses can have on communities. But this public health conversation and dilemma over vaccine hesitancy has been ongoing for several decades. Particularly in state legislatures, where vaccine-hesitant lawmakers can cast votes against critical vaccine policies that keep schools, families, and businesses safe.

This messaging kit takes a unique approach to the vaccine-hesitant conversation by focusing on the role of vaccines in protecting personal freedoms and economic well-being. The following guidance was developed following a series of discussions with several states to understand the biggest hurdles facing passage of vaccine legislation.

This kit includes three sections:

Messaging

This section includes a series of talking points to illustrate the role of vaccines in protecting and preserving individual freedoms and economic development. These arguments should be tailored to state-specific data, scenarios, and facts to make them applicable to your legislative audience and policy priorities.

How to Use the Messaging

The guidance in this section demonstrates how to use storytelling tactics to deploy your selected talking points, arguments, and examples. The section is divided into two scenarios: proactively telling your story when meeting with legislators and responding to a lawmaker's request or hearing on short notice.

Example Documents and Tools

This section shows the messaging and sample stories at work, in handouts, infographics, meeting notes, and more. These are intended to serve as examples that can be used to inform the design of your own state-specific messaging and tools.

Audience

The audience for this messaging is any vaccine-hesitant lawmaker holding conservative economic values with an interest in the protection of personal freedoms and liberties.

Messaging Summary

Vaccines Protect People and Businesses

- Vaccines protect individual freedoms.
- Vaccines protect businesses by reducing the spread of viruses and the need for restrictions on public activities.
- Vaccines help ensure your ability to access health care.

Families Pay the Price When Communities Don't Vaccinate

- Working families suffer when vaccine-preventable illnesses close businesses.

Vaccines Protect the Economy, Save Tax Dollars

- Vaccines save taxpayer dollars.
- When people refuse or don't have vaccines, society bears the cost.
- Vaccine-preventable outbreaks of any size can threaten the well-being of rural hospitals.

Messaging and Supporting Facts

Vaccines Protect People and Businesses

Vaccines protect individual freedoms.

Vaccines help protect your freedom to work, attend religious services, send your children to school, and travel as you see fit. An outbreak can lead to local or regional restrictions on these basic freedoms. Without vaccines, freedoms are threatened.

- **Over 110,000 restaurants** closed permanently in 2020 due to COVID-19 restrictions.[1]
- In just five months, over **160,000 businesses** closed their doors, leaving behind thousands of unemployed workers and storefront vacancies within small communities.[2]
- Schools were forced to close or severely limit classroom and extra-curricular activities during the pandemic. In April 2020, over **25 million public school students** were enrolled in schools ordered or recommended to close for in-person education[3] , putting stress on parents who still had to go to work but could not afford to pay for childcare, with those **costs increasing 47%** during the pandemic.[4]
- In response to rising COVID-19 cases, many states implemented curfews and orders to restrict activities, gatherings, and outings deemed "non-essential." [5]
- Several states enforced mandatory quarantines for travelers, required health documentation, or proof of a negative COVID-19 test. If non-compliant, fines were imposed on individuals.[6]

Vaccines protect businesses by reducing the spread of viruses and the need for restrictions on public activities.

Vaccines give employers of all sizes the ability to operate knowing their workers and patrons are protected, thus avoiding harm to the economy.

- Small businesses cannot sustain prolonged outbreaks. Vaccinations limit the impact of infections and provide confidence for merchants and their customers. During COVID-19, only 55% of small businesses projected being able to survive an extended public health crisis.[7]
- Vaccines allow workers to remain on the job. In response to the COVID-19 pandemic, 22% of small businesses considered requiring employees to be vaccinated, for the health of their businesses, workers, and customers.[7]

Vaccines help ensure your ability to access health care.

If an outbreak occurs in a community, medical facilities can become overwhelmed, limiting access to care important to you and your family.

- During the peak of the pandemic, the federal government urged hospitals and other treatment facilities to consider restricting non-emergency surgeries and procedures. [8]
- Delayed procedures likely will lead to higher health care costs for families to bear in the near future. Mortality rates may increase because of delays in important screenings, like those for breast or colorectal cancer. [9]
- Influenza can create an immense strain on health care systems, with **400,000 hospitalizations** in the 2019-2020 flu season. [10] Increased rates of flu vaccinations, coupled with other mitigation measures, resulted in just over **1,500 cases** in the first 40 weeks, reducing the burden of flu cases on communities and hospitals. [11] That's compared to about **38 million** reported symptomatic flu cases documented in the 2019-2020 flu season.

Families Pay the Price When Communities Don't Vaccinate

Working families suffer when vaccine-preventable illnesses close businesses.

If a family member becomes unemployed due to outbreak-related shutdowns, it can bankrupt a household. Families cannot afford to go unvaccinated.

- Vaccines provide job security to working families. In just the first two months of the pandemic, over **22 million** jobs were lost due to shutdowns and restrictions. [12]
- Job losses related to vaccine-preventable illnesses result in the loss of employer-provided health insurance coverage. During the pandemic, almost **15 million workers** and their dependents lost their insurance. [13] COVID-19 hospitalizations can cost between **$17,094 to $45,683**. [14]
- Treatments and hospitalizations for measles can cost a family as much as **$14,000**. [15] This cost includes lab tests and prescription drugs.

MS-DOH-21-1816-A-000012

Vaccines Protect the Economy, Save Tax Dollars

Vaccines save taxpayer dollars.

Twenty years of routine childhood immunizations have produced a net savings to taxpayers of nearly $300 billion. [16]

- The 2-Dose-Measles-Mumps-Rubella Vaccination Program alone has saved taxpayers **$3.5 billion.** [17]

When people refuse or don't have vaccines, society bears the cost.

In the first year of the pandemic, with no vaccine yet available, COVID-19 cost American taxpayers $5.9 trillion in federal relief spending [18] [19]**, in addition to $16 trillion lost due to business shutdowns, loss of productivity, declines in consumer spending, and loss of life impacts on families.** [20]

- Even before the pandemic, billions of dollars were lost each year due to vaccine-preventable infections among adults. [21]
- In 2015, unvaccinated adults cost the nation $7 billion in lost productivity, doctor visit expenses, and hospitalizations. [21]

MS-DOH-21-1816-A-000013

Vaccine-preventable outbreaks of any size can threaten the well-being of rural hospitals.

Americans depend on the success of their local hospitals. Outbreaks can test hospital finances and force them to limit services, cut staff, or even close.

- Vaccines allow rural hospitals to provide outpatient services, which are a vital source of income for rural hospitals. When these services were restricted due to the pandemic, rural hospitals lost millions of dollars, with 46% now operating in the red. [22]
- Closures of rural hospitals limit a family's health care choices. When a facility closes, an individual must travel thirty minutes or more to receive care at an alternative clinic. [22]
- Rural hospitals are integral to local economies. If one shuts down, unemployment rates can rise 1.6%, and may deter further economic development due to inaccessible health care options for prospective businesses and their employees. [23]
- In the first four months of the pandemic, U.S. hospital providers estimated a loss of $202.6 billion due to increased hospitalizations, canceled surgeries and services, the cost of personal protective equipment (PPE), and front-line worker support in the form of childcare, transportation, and screenings. [24]

MS-DOH-21-1816-A-000014

How to Use the Messaging

Why storytelling?

Stories allow you to capture the emotion needed to sway legislative support in favor of your policy proposals. **Vaccination opponents, activists and legislators alike, have successfully leveraged emotional pleas at legislative hearings, in the news media, and on social media channels to dominate the debate and win votes for short-sighted policies.** You must be able to share stories of your own to counter these narratives and promote your public health goals. Pair the messaging points created to address this select group of lawmakers with powerful stories to create a response that addresses the emotional aspects of the argument and delivers your position with impact.

Playing Offense: Telling a Story

Prepare Your Story

Adjust your messaging approach to illustrate your points through effective storytelling. Make everything you say personal.

Know Your Audience

Understand the lawmaker's background and position on vaccines.

Research any previous statements that may have been made in the news or as part of the legislative debate regarding vaccines.

Research voting histories on vaccines or other healthcare-related issues.

Use this information when identifying or choosing the best stories to highlight during your engagements on the vaccine issue.

Know Your Stories

Identify local stories to incorporate into your individual freedoms messaging.

Ask local contacts for help to identify those impacted by local vaccine-preventable outbreaks from local contacts.

Gather stories from people and businesses that align with messaging points, emphasizing those who've suffered personal and financial setbacks.

Match state-specific economic data to your gathered stories and incorporate them into your messaging points.

Customize Your Story

Don't expect a legislator to take your word for it.

Invite the people in your stories to attend your meetings. If they can join you, let them deliver the talking points.

If they cannot attend in person, consider asking your storytellers to make a short video or voice memo recording on their mobile device that you could share in your meeting.

If you want to make a series of points, ask each storyteller to focus on one of the points, that way, when the comments are presented together, each builds on, rather than repeats, the narrative.

Include the details. Explain the specifics of the illness. Talk about the impact of the illness on the family. What are the prospects for the family's recovery? **Where possible, have your storytellers ask lawmakers, in person or on video, to support vaccines.** The specifics of this call to action will depend on the details of the issue or issues in your state or territory.

Deliver Your Story

Once you've gathered your stories/storytellers, here's how to use deploy this messaging in a meeting.

Meetings With Legislators

Tell the story. Allow local examples of economic frustration and harm to demonstrate the impact vaccine hesitancy has on individual freedoms.

Support your messaging with hand-outs featuring quotes and photos of the people and places mentioned in your story.

Provide backup materials, like written statements, previous guest columns, or media statements from the people in your stories. These give your messengers credibility.

Lead your responses to questions with stories, supporting them with relevant facts that point back to your stories whenever possible.

Playing Defense: Responding on Short Notice

Prepare Your Story

The following strategies can help you assemble messaging points when preparation time is limited.

Assess the Messaging Environment

Using the preparation work done for meetings with lawmakers, prioritize the most appropriate stories for your target audience.

Predict the focus of opposing legislators and identify what stories and messaging points would be most convincing given their views on vaccines.

Review lawmakers' previous statements and past witnesses they have recruited, aligning your stories and messages to arguments that likely will be raised during the hearing, meeting, or event.

Assess Your Storytellers

Choose stories and storytellers that best illustrate the message points you believe will counter legislative opponents' arguments.

When the event is scheduled on short notice, ask if you can suggest witnesses. If allowed, offer people who've been damaged personally and economically by a vaccine-preventable outbreak, have experience speaking in public, are familiar to you, and can appear on short notice.

If a witness is unable to attend in person, ask if they could write a short statement or record a statement on a mobile device that could be used as the basis for a written or multimedia submission.

Whether your supporters testify or not, they can provide support through public comment opportunities. These invitations to submit comments, in writing or in person, are useful when responding to legislation or other policy actions. Engage all supporters, individuals and organizations, to respond to these opportunities, being mindful of deadlines associated with comment submissions.

Deliver Your Story

Consider the following strategies for using your messaging during last-minute hearings or meetings.

Prepare Your Testimony

If your messengers cannot attend the hearing or are not invited, find ways to incorporate their personal narratives into your talking points.

Focus your opening statement on as many personal stories as possible to show a direct connection to constituents.

Pair each message point to a story to create a narrative that underscores individual freedom impacts.

Telling Stories During a Hearing

Deliver your story. Use the videos or voice memos from your storytellers if allowed.

When answering questions, begin each response with a person or community hit hard by a vaccine-preventable outbreak, matching opponents' emotional arguments with the emotional impact of the existing or proposed policy.

Submit handouts and videos illustrating your testimony to the committee for inclusion in the record.

"Don't take it from me." Make the offer to connect legislators with the people referenced in your testimony.

Responding to Last-Minute Requests for Information or Meetings from Legislators

When responding to legislator requests for information, pair these documents with any handouts you've created to support your narrative.

Direct all members of your team to continue to use the same storytelling approach to ensure a coordinated and convincing voice on the issue, no matter who is responding to requests.

How to Find Stories/Witnesses

The Best Stories to Tell

Examples: A business owner that saw decreased foot traffic in a store; a family that needed to take off work to care for a sick child; an individual or family that faced high medical bills due to a vaccine-preventable illness.

Using the Media to Find Stories

Comb through media coverage of outbreaks to find quotes or other coverage about families and individuals that have been impacted.

Who Knows People with Stories to Tell?

Contact social service organizations to find people who've been impacted by a vaccine-preventable illness and are willing to share their stories. Start with pro-vaccine organizations for healthcare-related stories. Ask other agencies for help reaching individuals who've been impacted but may be interested in helping prevent future calamities for others.

Work with local public health departments where an outbreak may have taken place. Ask if there are families that would share their experiences regarding the outbreak's impact on their finances and individual freedoms.

How to Prepare and Protect Witnesses

Protecting Contact Information

Do not provide witness contact information to a legislator. Instead, facilitate meetings between legislators and your contacts. Remind witnesses to be careful about sharing contact information with journalists or others who might ask for it.

Explain the Hearing Process

If your witnesses have not previously spoken at a hearing, explain the process and provide them with a list of questions that panelists might ask them to answer. Do what you can to help witnesses feel prepared and confident.

Anticipate Social Media Feedback

Due to the overwhelming tactics of anti-vaccine supporters, prepare your witnesses for the reaction their comments will provoke, particularly on social media. Consider suggesting that they double-check their privacy settings on social media accounts. This will protect them against unwanted messages or comments. ***See the Appendix for instructions on this topic that you can share with your supporters.***

Understand Individual Comfort Level

Identify and respect the comfort level of witnesses. Some may not want to appear in person and would prefer to only submit written testimony. If they ask for help with their remarks, you can suggest areas they may want to address, but be careful not to prompt their statements in any way. The authenticity of their comments is critical to ensuring their voice makes an impact on the debate.

MS-DOH-21-1816-A-000021

Example Documents and Tools

The following documents are examples of tools, resources, and hand-outs that integrate the individual and economic freedom arguments and talking points with local stories, scenarios, and statistics. These documents use fictional data and stories to show examples of storytelling in action to teach you how to apply this approach within your particular setting.

- Graphic Presentation 1: Matching Local Stories to Emphasize Freedom and Economic Talking Points
- Graphic Presentation 2: Matching Talking Points to State-Specific Data
- Meeting Script on a 3x5 Card
- Sample Infographic Handout for Legislators
- Sample Q&A
- Sample Statements
- Examples of Emotion in Anti-Vaccine Stories

MS-DOH-21-1816-A-000022

Graphic Presentation 1: Matching Local Stories to Emphasize Freedom and Economic Talking Points

Identify families and individuals with personal stories that showcase the talking points on a local level, and pair those points with each story.

Note: All stories, names, and scenarios are fictional. Any resemblance to real individuals is coincidental.

Matthew Perez, 48

- Restaurant owner in a college town.
- Responsible for 10 employees.
- Capacity limits reduced ability to serve customers and led to people only wanting to be seated outside, if at all.
- A small town lost a 60-year old gathering place. 10 individuals lost their jobs. Two lost health insurance for themselves and their families.

Matching talking points:

*See **Vaccines Protect Individual Freedoms** on page 5.*

Cheryl Hinks, 55

- Mother of two middle-school-aged children.
- Reduced hours and low staffing at her local hospital delayed her routine mammogram by a year.
- Diagnosed with late-stage breast cancer.
- The cost for treatment exceeded $100,000.
- Husband had to transition from full-time to part-time to help with care.

Matching talking points:

*See **Vaccines Help Ensure Your Ability to Access Health Care** on page 6.*

Alex Hinton, 39

- A former employee of Mr. Perez.
- Lost his job and health insurance for himself and family of four.
- Facing $60,000 worth of medical bills after wife and child fell ill to the vaccine-preventable illness.

Matching talking points:

*See **Working Families Suffer When Vaccine-Preventable Illnesses Close Businesses** on page 7.*

Samantha Long, 39

- Salon owner.
- Responsible for 12 employees. Tips major part of income.
- School closures canceled proms, formals, graduations, dealing a major financial blow.
- Enough cash on hand to survive closures and reduced capacity for 8 weeks. Would have been longer but had to pay for PPE, signage, and other safety precautions.
- Unable to withstand prolonged public health crisis due to decreased revenue and increased operating costs.

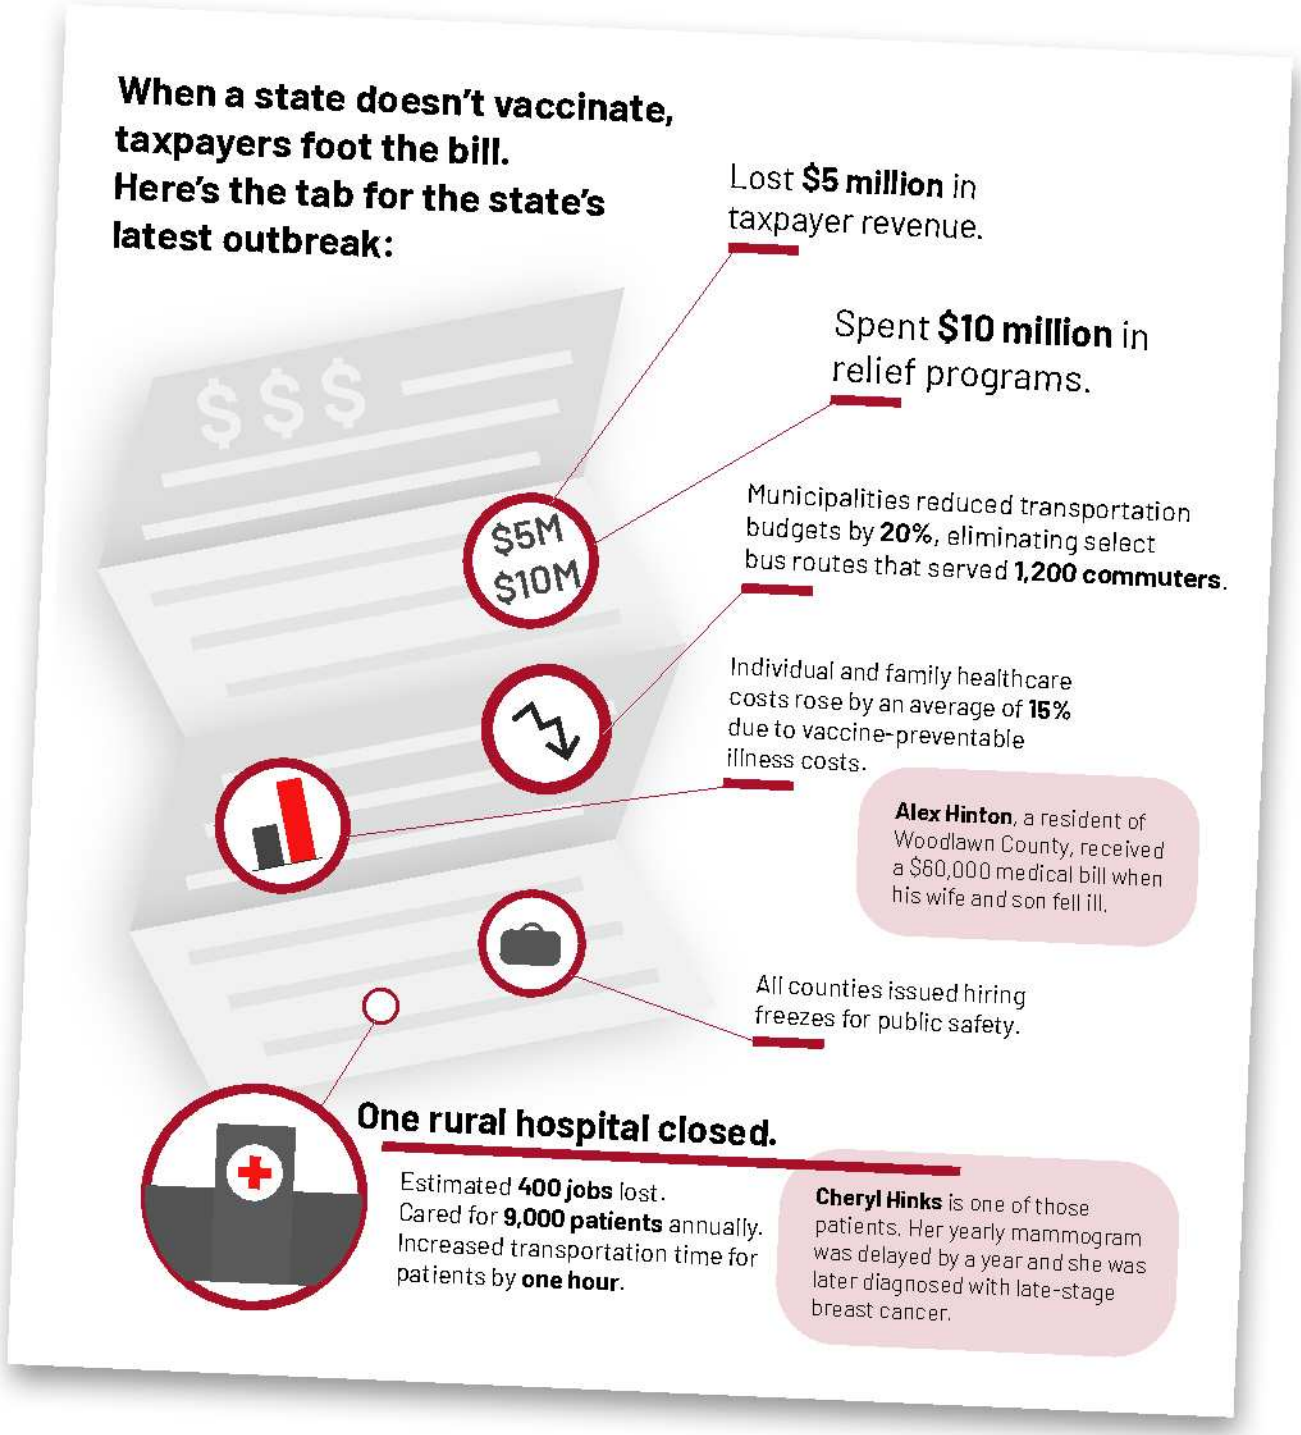
Matching talking points:

*See **Vaccines Protect Businesses by Reducing the Spread of Viruses and the Need for Restrictions on Public Activities** on page 5.*

Graphic Presentation 2: Matching Talking Points to State-Specific Data

Identify state-related facts on economic impact, unemployment, and individual freedoms, and pair this data with stories and talking points to show the state-level impact of an outbreak.

Note: The following scenarios, names, and statistics are fictional and intended to serve as an example of selecting data that supports the talking points.



MS-DOH-21-1816-A-000024

Meeting Script on a 3x5 Card

Vaxx protect individual freedoms.

- Eating and socializing at restaurants (Mr. Perez's business forced to close, 10 employees lost jobs).
- Limiting socialization hurts businesses.
- Restricting travel (out of towners for holidays/sporting events).

Vaxx protect businesses.

- Most businesses don't have the cash to survive long. (Ms. Long's salon only had 8 weeks cash on hand).
- Outbreaks decrease revenue, increase operating costs.
- During COVID only 55% of biz project surviving. Tip-reliant employees hurt the most.

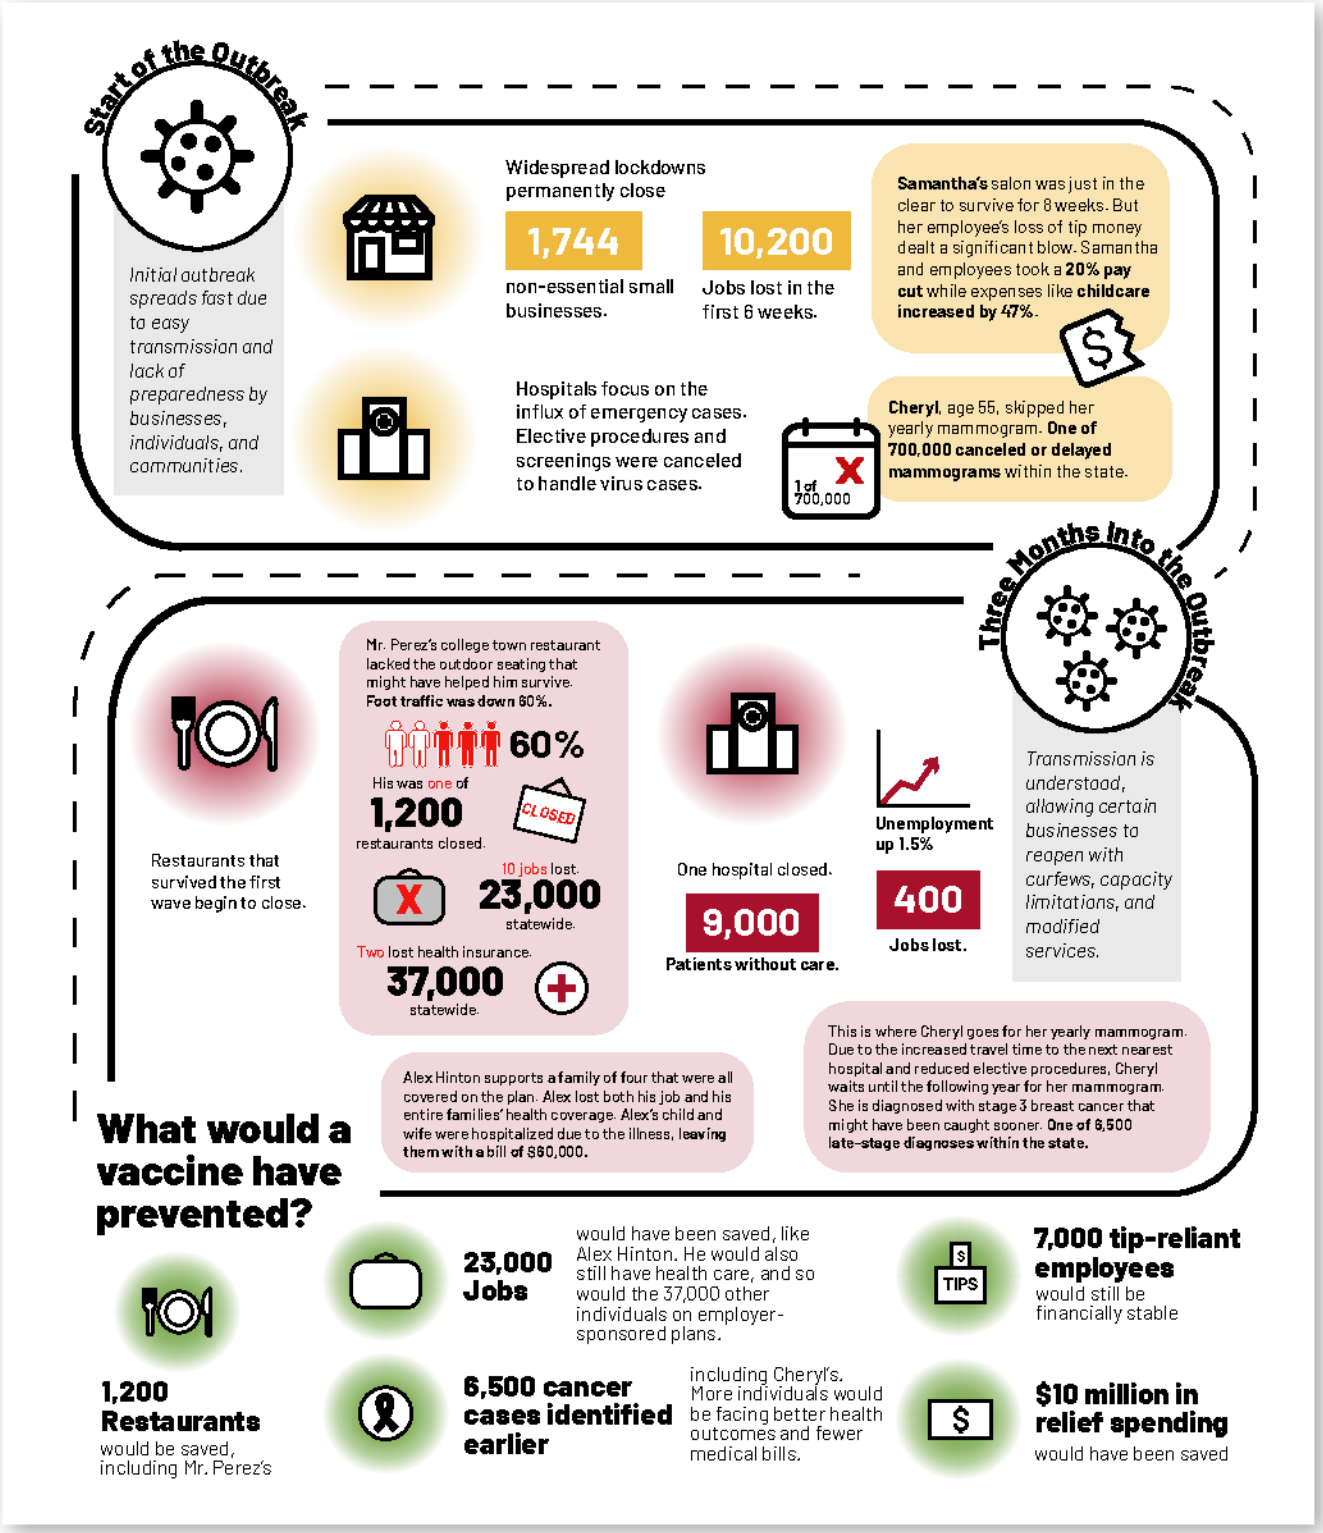
Working families suffer when vaccine-preventable illnesses close businesses.

- Mr. Perez's employees lost their jobs. Ten of the 22 million jobs lost due to COVID.
- Two managers lost health insurance, which their families depended on for coverage and care.
- Employee Alex Hinton has over $60,000 in medical bills after his wife and child fell ill.

MS-DOH-21-1816-A-000025

Sample Infographic Handout for Legislators

Organize your story into a graphic handout that visualizes state data, personal stories, and talking points. The following example illustrates this approach using fictional data.



Sample Q&A

Examples of how to combine stories with messaging to answer lawmakers' questions.

Q1. **"The government doesn't have any business in individual health decisions like vaccines. Shouldn't this be a personal choice for families?"**

A1. Vaccines safeguard many of the personal liberties that we value, like going to religious services, working, attending school, or going out for dinner. Mr. Perez's restaurant was thriving when people came together to watch sports and to visit with neighbors and friends. But when the outbreak hit hard, Mr. Perez couldn't keep his doors open and a local establishment shuttered for good. Curfews and capacity limits keep us safe amidst an outbreak, but they can make it difficult to socialize as freely as we'd like. Vaccination allows us to go out and get together safely and eliminates all precautions that could be seen as barriers to individual freedoms.

Q2. **"If there are side effects to vaccines, isn't it irresponsible of the government to encourage the public to get vaccinated? Should we really be prompting families to vaccinate their children and spouses if it could lead to catastrophic side effects?"**

A2. While the medical literature shows that vaccines are rigorously tested to ensure they are safe and effective, I think it's also important to note the indirect health benefits that we usually don't think of. For example, Mr. Hinton lost his job and his employer-sponsored health insurance due to the outbreak. His son and wife contracted the illness and their medical bills totaled over $60,000. His loss of health insurance would not have happened if he was able to keep his job. Unfortunately, that wasn't possible due to the outbreak. We also see that when these outbreaks occur and medical facilities are incredibly busy handling these cases, many patients forgo routine screenings and check-ups that can lead to a later-stage diagnosis.

A2. cont.

That means bigger health care bills and poorer health outcomes just due to delayed visits, as we saw with a local resident, Ms. Hinks, when she delayed her routine mammogram.

There are so many other health and financial factors at play should a vaccine-preventable illness take our state by storm. We're looking at the loss of jobs and health insurance, delayed doctor visits, and late- stage diagnosis of cancer. That's a huge number of health-related illnesses and significant financial stress that we can prevent with vaccines.

Q3. **"The government already spends astronomical amounts of money. These vaccination programs and requiring vaccinations will cost a lot of money, and all of that comes from taxpayers who are paying for far too much already. What's the return on investment for them?"**

A3. Let's talk about the cost of a vaccine-preventable outbreak to taxpayers as individuals and at large. From the individual standpoint, consider Ms. Cheryl Hinks. Her medical bills show the financial benefits and savings to individuals and taxpayers. Because of the recent outbreak, her medical options were limited, and her mammogram was delayed by a year. She was later diagnosed with stage 3 breast cancer. Looking at this financially, her costs for treatments are exceeding $100,000. Now if widespread vaccinations were in place, the hospital would have been able to proceed with screenings and elective procedures as normal, and her chances of catching cancer earlier would have been much higher. It would have saved her, and the thousands of other late-stage diagnosis patients, a significant amount of money in medical bills and protected their access to health care.

That's not even accounting for the medical bill savings for that vaccine-specific illness. If we look at all of the routine childhood immunizations, together they've saved taxpayers nearly $300 billion. That's a huge benefit to American taxpayers that we can't overlook.

MS-DOH-21-1816-A-000028

Q4. "Because of negative side effects and the fact that this is a highly personal, medical decision, shouldn't we leave doctors to have this conversation with patients?"

A4.

Doctors are excellent resources for this, but widespread outbreaks due to vaccine-preventable illnesses can have such a far-reaching impact. Leaving this issue to doctors isn't enough, and if we don't act on this, it can put the economic and financial safety of our state and all families at risk. Ms. Lang's salon was forced to cut back hours because of the outbreak. And since her employees rely on tips, those reduced hours hit them hard. They also had to balance reduced income with other rising costs, like childcare. So, they were going to work for less and paying more for everything else.

In addition, we saw hundreds of businesses and restaurants close. Mr. Perez' business was one of them. He was forced to lay off his 10 employees. All of this shows us that so much is in the balance. People's livelihoods and financial safety are at risk here if we don't take action to ensure families can work, travel, and congregate safely. Vaccines are more than just a medical decision. They can protect our businesses and allow employees to continue working.

MS-DOH-21-1816-A-000029

Sample Statements

Weave together talking points from the message document with the personal narratives you compile from your state.

Mr. Matthew Perez

Sample Statement #1

Mr. Chairman,

As a business owner, the sense of responsibility you have to your customers, community, and employees is enormous. Unfortunately, due to the outbreak and the precautions to stop the spread of the virus, I let a lot of those people down. As a college town restaurant, we need to be open as much as possible to serve our customers. Closing at 10 pm each night with fewer customers than normal just couldn't sustain us. We relied on a lot of out-of-state travel to see the college football games, which was all restricted to help slow the spread. Ultimately, I had to shut the doors permanently, which left my 10 very hardworking, loyal employees without a job, source of income, or health insurance. It left me with a mountain of debt. And now I too am unemployed, searching for a job in an industry that's dying due to the outbreak.

Vaccination would have allowed me to keep the place up and running. If I would have been able to operate knowing that my customers and my employees were safe, we wouldn't have needed to undergo those shutdowns. And our customers would have had the freedom to come in as they please and socialize with their friends and family. The freedom to work and gather as a community was taken away from us because of the virus. I think it's clear that vaccination would have protected my business, my employee's jobs, and a community space that so many have come to enjoy over the past several decades. Small businesses like mine could not sustain themselves throughout this outbreak. And now I'm left to pick up the pieces and try to start over.

MS-DOH-21-1816-A-000030

Ms. Cheryl Hinks

Sample Statement #2

Dear Senator Jones,

I didn't realize the number of routine things I took for granted before the outbreak hit. One of those being the yearly checkups that you do without thinking about them. Because so many people were sick, the hospital where I received my annual mammogram cut back on screenings and elective procedures. So I kept kicking that appointment down the road. Now, this hospital was always struggling, even long before the outbreak, and this outbreak maxed out their resources and forced them to close.

Being from a rural part of the state, the next closest hospital to me was an hour drive. So again, I didn't think much of it as I kept pushing my visit farther down the road given that it was even more inconvenient to get and keep an appointment. One year later, I finally was able to get my screening. And the result? Stage 3 breast cancer.

Now, over $100,000 in medical bills later, I've lost my health and financial stability. I'm one of 6,500 other people who've also received a late-stage diagnosis of cancer. Many others are like me, who were rescheduled time and time again until the inconvenience made it nearly impossible to take care of those routine visits that we had, before the outbreak, taken for granted.

On the surface, my cancer diagnosis doesn't seem to be connected to this vaccine-preventable illness. But it is, and my biggest lingering question is where my physical and financial health could be now if I were able to have that screening on time.

MS-DOH-21-1816-A-000031

Sample Statement #3

Mr. Alex Hinton

Rep. Ochoa,

I always thought about the side effects associated with getting a vaccine. But I never thought of the financial pain it could bring to me and my family until my wife and son became ill. Our income was already cut in half since I had lost my job and the associated health insurance. It was a double whammy to receive the hospital bill on top of everything else. Of course, every penny is worth the lives and health of my family, but the $60,000 bill has wiped out our savings. I worry about the credit score we've been building up over the past two years. I worry about providing for my family and supporting my children through college. I worry about what this means for our financial future in the years ahead.

No one tells you that these illnesses not only make you sick but also deliver crippling financial pain. If you fall ill, the medical bills could drain your bank account. The hospital stays, treatments, and follow-up appointments add up quickly for just one family member, let alone two. And as their health thankfully returns, the debt will linger on with us for years. We never built up our savings and financial stability with a preventable illness in mind. What this horrible experience has shown us is that vaccines are the cheapest insurance policy we have. And for families, it's an investment that cannot be understated.

Examples of Emotion in Anti-Vaccine Stories

Roll mouse over headlines for links to stories.

Opinion: I Heard Cries. Then, I Saw The Faces… My Vaccine Story

Assemblyman Jamel Holley: ' I saw the faces of the children, tightly wrapped up in warm winter clothing for long hours into the late night. Some of those children – sadly – were injured from vaccines

Gov't: Girl's Autism-Like Symptoms Linked to Vaccines: Federal Officials Say Vaccines Worsened Condition that Led to Autism Spectrum Disorder in Georgia Girl

Accepting his daughter's diagnosis was difficult, Poling tells WebMD. He says the family was in denial initially that anything was seriously wrong. "After six months of essentially our daughter being a zombie and gone, we knew this wasn't going away," he says. "This was chronic. And we had to come to grips with that."

Mandatory vaccine passports do not belong in the birthplace of freedom | Opinion

"No, these unelected bureaucrats should never be able to coerce anyone in our commonwealth to make such personal medical decisions. There is simply no justification for this overreach. You and you alone should decide."

Defending a parent's right to withhold vaccines when they want to: Mothers and fathers should have the right to refuse stringent CDC guidelines for religious or philosophical reasons

"At the age of 12 months, my son had a very serious reaction to the MMR vaccine," she states. "It was so serious that he had an immediate regression developmentally. He stopped making most sounds and suddenly couldn't even roll over on his own. It was shocking, scary, and a life-changing experience."

I watch her face as she speaks. The emotions are strong. Her sorrow is deep. "I've given thousands of babies vaccines," she continues. "And anyone who reads the label inserts knows that these substances are not without risk. But the risk is very small. I never imagined any child I inoculated would be harmed. I only saw my actions as helpful."

I nod.

"But my son was harmed, badly. It was an undeniable reaction. My son was harmed on my watch and I'm a pediatric nurse. He was harmed by a medical practice I had never questioned and this changed me. It changed our office, too. Now we all approach the topic with added nuance and depth," she explains.

UNITED STATES DISTRICT COURT
NORTHERN DISTRICT OF INDIANA
SOUTH BEND DIVISION

RYAN KLAASSEN *et al.*,

Plaintiffs,

v.

THE TRUSTEES OF INDIANA UNIVERSITY,

Defendant.

CAUSE NO. 1:21-CV-238 DRL

OPINION & ORDER

Under guiding principles of federalism, our Constitution preserves the power of the States, within constitutional limits, to adopt laws to provide for public health and safety. Twice the United States Supreme Court has upheld state authority to compel reasonable vaccinations. The States don't have arbitrary power, but they have discretion to act reasonably in protecting the public's health.

Students at Indiana University have a significant liberty protected by the Constitution—refusing unwanted medical treatment based on bodily autonomy. The Fourteenth Amendment says no state may "deprive any person of life, liberty, or property, without due process of law." U.S. Const. amend. XIV § 1. Given this due process protection of liberty, longstanding constitutional law prevents a public university—an arm of the State—from mandating a vaccine for its students unless it has rationally pursued a legitimate interest in public health for its campus community.

This case presents that question: whether Indiana University has acted constitutionally in mandating the COVID-19 vaccine for its students, as announced on

May 21, 2021. Albeit, and this should not be overlooked, this case does so only in the context of a preliminary injunction motion, not for a final decision on the merits.

Indiana University's policy has real implications. Students may be deprived of attending the university without being vaccinated or qualifying for an exemption. Still they have real options—taking the vaccine, applying for a religious exemption, applying for a medical exemption, applying for a medical deferral, taking a semester off, or attending another university or online. The policy applies for the fall 2021 semester only.

Eight students sued Indiana University because of its vaccination mandate and because of the extra requirements of masking, testing, and social distancing that apply to those who receive an exemption. They ask the court to enter a preliminary injunction—an extraordinary remedy that requires a strong showing that they will likely succeed on the merits of their claims, that they will sustain irreparable harm, and that the balance of harms and the public interest favor such a remedy.

The court now denies their motion. The Constitution and longstanding precedent should endure. Recognizing the students' significant liberty to refuse unwanted medical treatment, the Fourteenth Amendment permits Indiana University to pursue a reasonable and due process of vaccination in the legitimate interest of public health for its students, faculty, and staff. Today, on this preliminary record, the university has done so for its campus communities. The students haven't established a likelihood of success on the merits of their Fourteenth Amendment claim or the many requirements that must precede the extraordinary remedy of a preliminary injunction.

MS-DOH-21-1816-A-000038

FACTS

A. *Parties*.

Indiana University is a world-renowned public research university, with seven campuses, two regional centers, and three medical centers across the State of Indiana, providing education to over 90,000 undergraduate and graduate students and employment for over 40,000 employees [Ex. 116 ¶ 4]. The university, with its flagship campus in Bloomington, Indiana home to over 40,000 students, continually ranks as one of the top 100 universities in the country, and one of the top 150 universities in the world.

The eight students here have varied backgrounds. Jaime Carini (age 39) is a graduate student pursuing two doctorates in music, with but her examinations and dissertation to complete [Ex. 121 at 10, 19-20, 23]. She has received an exemption from the university's vaccination requirement already [*id.* 57-58].

Ashlee Morris (age 26) is an incoming first year law student at the McKinney School of Law who has worked hard for six years to get there to pursue her J.D. [Ex. 123 at 10, 66-67]. She too has received a religious exemption from the university's vaccination requirement [*id.* 44]. She testifies that she will not attend the law school if she must wear a mask or undergo surveillance testing [*id.* 66-67].

Seth Crowder (age unknown) is pursuing his MBA at the Kelley School of Business [Ex. 124 at 13]. He too has received a religious exemption from the university's vaccination requirement already [*id.* 9, 20-21]. He has not decided if he will return to school if he must wear a mask or undergo surveillance testing this fall semester [*id.* 42].

Macey Policka (age 22) is a senior at Indiana University studying English (medieval studies) [Ex. 125 at 8-9]. She also has received a religious exemption from the university's vaccination requirement [*id.* 22]. She plans to return to Indiana University regardless of the outcome of this case [*id.* 36-37]

Ryan Klaassen (age 19) is an incoming sophomore at Indiana University studying biochemistry [Ex. 120 at 5, 15-17]. He has received a religious exemption to the university's vaccination requirement [*id.* 33]. He says he hasn't decided if he will return to Indiana University if the injunction is not granted. [*id.* 41-43].

Daniel Baumgartner (age 18) is an incoming freshman at Indiana University who plans to study business [Ex. 122 at 8, 12-13]. He has received a religious exemption to the university's vaccination requirement [*id.* 8]. He has not decided if he will go to Indiana University this fall if he must wear a mask or undergo surveillance testing [*id.* 41].

Margaret Roth (age unknown) is an incoming freshman at Indiana University and has already registered for classes [Ex. 126 at 9, 20]. She has a religious objection to the vaccine but has not requested an exemption, though she would qualify, because she prefers not to wear a mask or undergo testing [*id.* 45-47]. She says she will most likely not attend Indiana University if the injunction isn't granted [*id.* 9].

Natalie Sperazza (age unknown) is an incoming sophomore who will be taking five classes this fall [Ex. 127 at 11]. She has not applied for an exemption and believes she wouldn't qualify [*id.* 15-16]. She says she will not attend Indiana University this fall if the policy remains in place [*id.* 42]. She appears to be the only student without an exemption or basis for an exemption.

B. *COVID-19.*

COVID-19 is an infectious disease caused by the novel coronavirus. It primarily spreads through respiratory droplets, viral particles suspended in the air, and touching mucosal membranes with contaminated hands [Ex. 115 ¶ 6].[1] The initial presentation of an infection ranges from no symptoms at all (asymptomatic) to severe illness and death; and even after recovery, various long-term health problems may linger [*id.* ¶ 8].[2]

Individuals with longstanding systemic health inequities or preexisting or immunocompromising conditions, and elderly individuals prove at greater risk of severe illness or hospitalization following an infection [*id.* ¶ 9].[3] Children and young adults are less likely to experience serious illness or death from infection [Ex. 115 ¶ 10; Ex. 117 ¶ 21]. Though data from the Centers for Disease Control and Prevention (CDC) suggest that more young adults are becoming infected with the virus than other age groups [Ex. 115 ¶ 16],[4] these individuals are less likely to require hospitalization or die [*id.* ¶ 10].[5]

[4] Of the total reported cases, those reported from the 18-29 age group account for 22.5 percent of all infections—the highest proportion of any age group—despite accounting for only 16.4 percent of the United States population. *See* CDC, *Demographic Trends of COVID-19 Cases and Deaths in the U.S. Reported to CDC,* https://covid.cdc.gov/covid-data-tracker/#demographics (last visited July 18, 2021).

[5] *See also* CDC, *Risk for COVID-19 Infection, Hospitalization and Death by Age (Updated June 24, 2021)*, https://www.cdc.gov/coronavirus/2019-ncov/covid-data/investigations-discovery/hospitalization-death-by-age.html (last visited July 18, 2021) (individuals aged 30-49 twice as likely to be hospitalized, individuals 50-64 four times as likely to be hospitalized, individuals aged 30-39 four times as likely to die, individuals 40-49 ten times as likely to die, individuals 50-64 thirty-five times as likely to die). The most

Worldwide COVID-19 has infected almost 189 million people and caused 4 million deaths, with these numbers still changing daily.[6] In the United States, the novel coronavirus has infected over 33.5 million citizens, losing to death over 600,000 [Ex. 115 ¶ 15]. Since March 6, 2020, Indiana has had over 750,000 confirmed COVID-19 cases and over 13,000 deaths [*id.* ¶ 14]. The COVID winter of 2020-2021 was particularly rough, until vaccines became options first in December 2020 and then in the early months of 2021.

As vaccination now increases, data gathered by the CDC point toward the waning of new COVID infections across the country—down from a peak of 312,325 new cases reported on January 8, 2021, with a seven-day average positive test rate of 13.85 percent, to 39,719 new cases reported on July 16, 2021, with a seven-day average positive test rate of 5.01 percent.[7] The rate of new cases today is akin, if not greater, to the rate of new cases reported during the peak of the pandemic's first wave in the spring 2020, through the relative rate of positive tests thankfully remains much lower.[8]

Our nation has come a long way since the darker days of 2020 that tested many people, though some uncertainty persists even now in this 2021 summer. The current

---

recent CDC figures suggest that only 0.04 percent of cases from this age group result in death, and this group represents only 0.5 percent of all COVID deaths. CDC, *Demographic Trends of COVID-19 Cases and Deaths in the U.S. Reported to CDC*, https://covid.cdc.gov/covid-data-tracker/#demographics (last visited July 18, 2021) (6,174,415 individuals aged 18-29 contracted the virus, and 2,732 individuals died).

[6] *See* CDC, *Global Cumulative Cases of COVID-19 Reported* (July 18, 2021), https://covid.cdc.gov/covid-data-tracker/#global-counts-rates (citing World Health Organization (WHO), *WHO Coronavirus (COVID-19) Dashboard* (July 16, 2021), https://covid19.who.int/).

[7] CDC, *COVID Data Tracker*, https://covid.cdc.gov/covid-data-tracker/#trends_dailytrendscases (last visited July 18, 2021).

[8] *Id.* (35,080 new cases reported on April 9, 2020, with a seven-day average positive test rate of 20.43 percent).

seven-day moving averages of new COVID-19 cases has increased by 69.3 percent in the past week alone; the positive test rate has increased by 40.7 percent; and new hospital admissions have increased by 35.8 percent.[9] Recalling the bell curves we all have become accustomed to seeing, the trend still proves sharply down from the worse days of COVID-19, but virulent and highly transmissible variants of this coronavirus present new challenges [Ex. 115 ¶ 36]. As of July 3, 2021, the CDC estimates that 57.6 percent of new cases come from the Delta variant.[10] New COVID-19 cases often originate in unvaccinated individuals [Ex. 115 ¶ 38-39].

In Indiana, 561 new cases were reported on July 15, 2021; and the most recent data suggest a seven-day average positive test rate of 4.3 percent for unique individuals from July 3, 2021 to July 9, 2021, lower than the national average.[11] Of all positive cases, 18.4 percent, the highest proportion of all age populations, comes from young adults aged 20-29.[11] In Indiana, approximately 67.3 percent of all cases came from the Delta variant.[12] Our country and our state have vastly improved, but challenges remain.

C. *Indiana University Board of Trustees.*

The Indiana General Assembly endows the Indiana University Board of Trustees with the responsibility to fulfill its powers and duties under the law. Ind. Code § 21-27-

[9] CDC, *COVID Data Tracker Weekly Review* (July 16, 2021) https://www.cdc.gov/coronavirus/2019-ncov/covid-data/covidview/index.html.

[10] *Id.*; *see also* CDC, *COVID Data Tracker*, https://covid.cdc.gov/covid-data-tracker/#variant-proportions (last visited July 18, 2021).

[11] Indiana State Department of Health, *COVID Dashboard*, https://www.coronavirus.in.gov/2393.htm (last visited July 18, 2021).

[12] Indiana State Department of Health, *COVID Dashboard*, https://www.coronavirus.in.gov/2393.htm (last visited July 18, 2021).

2-1. The Trustees may pass all bylaws necessary to put into effect its powers. Ind. Code. § 21-27-4-3. The Trustees may set conditions and standards for admission that are in the "best interests of the state and the state educational institution." Ind. Code § 21-40-3-1(b).

Among these powers, the Trustees may govern "the conduct of the state educational institution's students, faculty, and employees, wherever the conduct might occur, to prevent unlawful or objectionable acts that . . . violate the reasonable rules and standards of the [university] designed to protect the academic community from . . . a serious threat to person or property of the academic community." Ind. Code § 21-39-2-3(b). The university remains answerable to the legislature, particularly its funding.

D. *State Law on Vaccines*.

Indiana requires all public university students to be vaccinated for diphtheria, tetanus, measles, mumps, rubella, and meningococcal disease before attending school. Ind. Code § 21-40-5-2. All but one of these vaccinations have been required since 1993. Outside these state-mandated vaccines, Indiana University has had a policy for managing infectious and communicable diseases since at least 2015 designed to take "reasonable measures to ensure the safety of members of the university community during global and local infectious disease events" [Ex. 229]. Students must report vaccination status, save for religious and medical exemptions, including any "contraindication to a vaccine" [*id.*]. This reporting occurs according to state law and recommendations from the CDC's Advisory Committee on Immunization Practices. *See* Ind. Code. § 21-40-5-2.

Since this pandemic's advent, many states have considered bills that would prohibit either vaccine "mandates" or vaccine "passports." For instance, just last week

the State of Ohio passed a law banning public vaccine mandates. *See* 2021 Bill Text OH H.B. 244, Sec. 3792.04(B)(1) (signed July 14, 2021). Other states have more reservedly passed laws that would prohibit just having to show proof of COVID-19 vaccination—hence the term COVID-19 passport. Indiana's General Assembly recently enacted law that prohibits a vaccine passport, not a vaccine requirement.[13] Ind. Code § 16-39-11-5.

E. *Vaccine Guidance for Institutions of Higher Education*.

Governmental agencies and collegiate associations have with one chorus promoted vaccination to address the COVID-19 pandemic, though they typically have remained silent on whether universities should mandate a vaccine. Today more than 500 colleges and universities have mandated vaccination, though many are private institutions of higher learning, not public universities.[14]

The CDC recommends that institutions of higher learning (IHEs) "can return to full capacity in-person learning, without requiring or recommending masking or physical distancing" only when "all students, faculty, and staff are fully vaccinated prior to the start of the semester."[15] The Indiana State Department of Health aligns with the CDC.[16]

---

[13] This statute applies to "the state or a local unit." Ind. Code § 16-39-11-5(a). The students withdrew their claim under this law because the statute omits a private right of action, leaving enforcement to the Indiana State Department of Health. *See, e.g.*, Ind. Code § 16-19-3-18. For sake of clarity, the court never reaches the point whether this anti-passport law applies to a public university or not.

[14] *See* Andy Thomason & Brian O'Leary, *Here's a List of Colleges That Will Require Students or Employees to Be Vaccinated Against Covid-19*, The Chronicle of Higher Education (July 15, 2021), https://www.chronicle.com/blogs/live-coronavirus-updates/heres-a-list-of-colleges-that-will-require-students-to-be-vaccinated-against-covid-19?cid2=gen_login_refresh ("The Chronicle has so far identified 583 such campuses.").

[15] CDC, *Guidance for Institutions of Higher Education (IHEs)* (June 4, 2021), https://www.cdc.gov/coronavirus/2019-ncov/community/colleges-universities/considerations.html.

[16] ISDH, *Public Resources: Back to School Resources (Universities)* (July 18, 2021), https://www.coronavirus.in.gov/2400.htm.

Likewise citing the CDC, the United States Department of Education has said "IHEs where everyone is fully vaccinated can return to full capacity in-person learning without requiring or recommending masking, physical distancing, or screening testing."[17] The American College Health Association has recommended that institutions require COVID-19 vaccinations for all on-campus students for the fall semester.[18]

F. *Indiana University's Vaccine Mandate.*

Acting under state authority, *see* Ind. Code § 21-38-3-4, and with the vision of promoting public health and restoring the educational and social environment of the university's campuses, President Michael McRobbie created a university restart committee during the spring of 2021 to make recommendations to the Board of Trustees for the fall semester [Ex. 104 at 5; Ex. 116 ¶ 22]. The restart committee's charge was to advise and recommend requirements necessary to resume "normal face-to-face" operations [Ex. 116 ¶ 22].

Indiana University's Executive Vice President for University Clinical Affairs and the School of Medicine's Dean spearheaded the restart committee [*id.* ¶ 23]. It included fifteen members with expertise in public health, epidemiology, virology, data modeling and monitoring, risk mitigation, health equity, health sciences, and law [*id.*; Ex. 300 at 4-

[17] U.S. Dept. of Educ., *ED COVID-19 Handbook, Volume 3: Strategies for Safe Operation and Addressing the Impact of COVID-19 on Higher Education Students, Faculty, and Staff* 9 (June 2021), https://www2.ed.gov/documents/coronavirus/reopening-3.pdf.

[18] Am. College Health Ass'n, *American College Health Association Recommends COVID-19 Vaccination Requirements for All On-Campus College Students in Fall 2021* (April 29, 2021), https://www.acha.org/ACHA/About/ACHA_News/ACHA_Recommends_COVID-19_Vaccination_Requirements_for_Fall_2021.aspx.

5]. The committee consisted of seven MDs, some with additional degrees in public health or other PhDs, and others with graduate degrees in public health, risk mitigation, law, and ethics [Ex. 300 at 5].

The restart committee met regularly to review the university's campus population and experiences from the 2020-2021 year, as well as "guidelines from the CDC, IU Health, the ISDH, the Indiana Governor's Office, and the Central Indiana Corporate Partnership, among others," "scientific literature and data, including COVID-19 case and hospitalization rates for Indiana," and "input from other Indiana and out-of-state IHEs" [Ex. 116 ¶¶ 24-26]. The data considered by the restart committee were vast [Exs. 302-317, PowerPoint presentations from December 8, 2020 to April 6, 2021); *see also* Ex. 301 ¶ 2].

Four MDs from this committee presented near-weekly from December 2020 to June 2021 to Indiana University's Executive Academic Leadership Council, including the President and Executive Vice Presidents as part of the medical response team's ongoing COVID-19 evaluation efforts [Ex. 301 ¶ 4]. The Board of Trustees adopted the restart committee's recommendations for the 2021 fall semester [Ex. 116 ¶ 29].

The aim was short and strategic—vaccinate everyone, subject to certain exemptions [*id.* ¶ 31; Exs. 101, 300]. Initially, the policy required all students, faculty, and staff to submit proof of vaccination before returning to campus, but the university revised this requirement after Indiana passed its anti-passport law [Ex. 101]. The policy today requires all students, faculty, and staff to be fully vaccinated, which the university defines as being two weeks post the second dose of the Pfizer and Moderna vaccines, or two weeks post the single dose of the Johnson & Johnson vaccine, before returning to campus

between August 1 to August 15 for the fall 2021 semester [Ex. 118 at 3, 5; *see also* Exs. 102-104].

The choice of foregoing vaccination is not inconsequential. If not vaccinated, students are not permitted on campus, their emails and university accounts are suspended, and their access cards are deactivated [Ex. 118 at 7]. Although it seems from argument that the university will not create an informant culture, it reserves the right to pursue disciplinary action should a student deceive the process. Faculty and staff who refuse vaccination face termination. The faculty councils from Indiana University—Bloomington and Indiana University-Purdue University Indianapolis and the staff council from Indiana University—Bloomington, have endorsed the policy, as has the graduate and professional student government [Ex. 116 ¶ 45-60].

The university's COVID-19 vaccine policy has exemptions. A student may request an exemption for religious reasons; provide proof from a physician of an allergy to the vaccine or one of its component parts (a medical exemption); provide proof from a physician of active pregnancy or breastfeeding, receiving a hematopoietic or solid organ transplant, receiving treatment with Rituximab within the past 3-6 months, or COVID-specific monoclonal antibodies[19] in the past 90 days (a medical deferral) [Ex. 210 at 3]. Students who are enrolled in an online program, with no on-campus component, don't need to receive the vaccine [*id.*].

[19] Monoclonal antibody therapy involves the injection of laboratory-made proteins that mimic the immune system's ability to fight off various pathogens. FDA, *Coronavirus (COVID-19) Update: FDA Revokes Emergency Use Authorization for Monoclonal Antibody Bamlanivimab* (April 16, 2021), https://www.fda.gov/news-events/press-announcements/coronavirus-covid-19-update-fda-revokes-emergency-use-authorization-monoclonal-antibody-bamlanivimab.

For those who receive exemption from vaccination, the policy imposes additional safety requirements. These requirements apply to six of the eight students here who have received exemptions and potentially a seventh who qualifies for an exemption. Such students must participate in more frequent mitigation testing, quarantine if exposed to someone who has tested positive for COVID-19, wear a mask in public spaces, and return to their permanent address or quarantine if there is a serious outbreak of COVID-19 [Ex. 118 at 6].

G. *Experts.*

The parties have tendered declarations, supplemental declarations, and testimony from several experts, leaving to the court the task of deciding what weight to give to their opinions. Among the more than 100 exhibits admitted for this preliminary injunction motion, the experts and other materials refer to numerous medical studies and industry guidance on the risks of COVID-19 and the risks of the vaccines—where the parties in part have drawn the battle lines. The court has endeavored to be studious in reviewing at times a daunting record on this emergent timetable.

MS-DOH-21-1816-A-000049

The university offers Dr. Cole Beeler, MD,[20] and Dr. Aaron Carroll, MD, MS,[21] and the students tender Dr. Peter McCullough, MD, MPH.[22] All have credentials and opinions that exceed restatement here. Much of that treatment occurs later in this opinion as the court makes additional findings of fact and discusses its legal analysis. Though points of agreement occur at times, these experts largely disagree about the urgency of vaccination, particularly for often younger university students, the effects from natural COVID-19 infection, and the risks of the three emergency use approved vaccinations.

For the students, Dr. McCullough says the risks of COVID-19 to college age students in 2021 proves significantly lower than in 2020 because of the rapidly declining infection rate, increasing likelihood of herd immunity in Indiana, low risk of serious complications or death from COVID-19 in college-aged students, low risk of asymptomatic spread, and other posited COVID-19 treatments [Ex. 117 ¶ 73; *see also* Exs. 221-22, 233-34, 240-41, 246-47, 251]. He views a mandate as unwise and a violation of the medical ethics principle of autonomy translated to the university setting [Ex. 117 ¶ 73]. He opines that the risks associated with the COVID-19 vaccines "are not minor or

[20] Dr. Beeler is an assistant professor of clinical medicine at Indiana University Medical School. He earned his BS and MD from Indiana University and is board certified in infectious disease and internal medicine [Ex. 115 ¶ 1-5; Ex. 128 at 5, 7-11, 13-17, 21-22, 31, 147-150].

[21] Dr. Carroll is the chief health officer for Indiana University and associate dean for research mentoring at Indiana University Medical School who holds various professorial positions. He earned his BA from Amherst College, his MD from the University of Pennsylvania, and his MS from the University of Washington. He is board certified in preventative medicine-clinical informatics, pediatrics, and by the National Board of Medical Examiners [Ex. 116 ¶ 1-6; Ex. 206 at 7-8].

[22] Dr. McCullough is a professor of medicine at Texas A & M University School of Medicine and practices medicine at various Texas hospitals. He received his BA from Baylor University, MD from University of Texas Southwestern Medical School, and his MPH in epidemiology from the University of Michigan. He is board certified in internal medicine and cardiovascular disease [Ex. 117 ¶ 1-12].

unserious and can include hospitalization and death," however "unpredictable" and "impossible to calculate" [*id.*]. His opening declaration largely isn't stated to any reasonable degree of medical certainty [*id.*; *but cf.* Ex. 222 at 11].

For the university, Dr. Beeler says the COVID-19 vaccine mandate facilitates a "safe and reliable way to assure lack of spread of COVID" within the university's campus communities and "prevents morbidity and mortality" [Ex. 115 ¶ 87; *see also* Ex. 319]. He appreciates that, though COVID-19 often will not pose "disproportionate bad outcomes" in the university's constituency, "any bad outcome from COVID is potentially avoidable with the vaccines where the benefit dwarfs the potential rare risks," and risks that "may not be causally linked" [Ex. 115 ¶ 87]. He recalls that "the vaccines used for COVID are based on technology that has been developed over decades and have repeatedly been shown to be safe when given to millions of patients" [*id.*]. He calls the vaccines "known science" applied to a "novel pathogen" with often "uncertain and threatening immediate and long-term consequences to [the university's] students, faculty, staff, and communities at large" [*id.*]. He says the risk of asymptomatic hosts puts others at risk [*id.*]. In support, Dr. Carroll marshals relevant industry, governmental, and university guidance and the relevant scrutiny the restart committee gave to it [Exs. 116, 301]. Dr. Beeler states his opinions to a reasonable degree of medical or professional certainty [Ex. 115 at 25; Ex. 319 at 8].

H. *Emergency Use Authorization of Vaccines.*

COVID-19 caught the world unaware. Initially, there were no vaccines or treatments, and testing was expensive and difficult to secure. Four days after the United

States Department of Health and Human Services (HHS) declared a public health emergency, it issued a second declaration allowing the United States Food and Drug Administration (FDA) to grant emergency use authorizations (EUAs) for medical devices and interventions to combat the pandemic. 85 Fed. Reg. 7316, 7316-7317; 85 Fed. Reg. 18250, 18250-18251.

Despite creating an expedited pathway to distribute new medical products during emergencies, products that receive EUA approval still must adhere to specified safety, efficacy, and manufacturing criteria, and HHS must ensure medical providers and individuals are informed of the product's EUA status, the "significant known and potential benefits and risks of such use, and of the extent to which such benefits and risks are unknown;" and for individuals, of the option to refuse and the consequences of such a decision. 21 U.S.C. § 360bbb-3(e)(1)(A)(ii)(I)-(III). An EUA generally allows a manufacturer to apply for EUA approval using interim clinical trial data, and the data need only demonstrate the product "may be effective" and that the known and potential benefits outweigh the known and potential risks.[23] The statute anticipates the FDA will impose additional obligations beyond those enumerated. 21 U.S.C. § 360bbb-3(e)(1)(B).

There have been six significant public health emergencies for which the FDA has authorized EUAs: anthrax, swine flu (H1N1), MERS (Middle East respiratory syndrome

[23] 21 U.S.C. § 360bbb-3(c)(2)(A); FDA, *Emergency Use Authorization for Vaccines Explained*, https://www.fda.gov/vaccines-blood-biologics/vaccines/emergency-use-authorization-vaccines-explained (last visited July 13, 2021).

coronavirus), Ebola, Zika, and now COVID-19.[24] During these events, EUAs were issued for diagnostic tests (swine flu, MERS, Ebola, Zika, and COVID-19), off-label use of previously approved and use of unapproved pharmaceuticals (anthrax, swine flu, and COVID-19), novel vaccines (anthrax and COVID-19), and medical devices (swine flu and COVID-19).[24] FDA authorization for EUA vaccinations began in 2005 during the anthrax scare, particularly for use in the armed forces. *See* 70 Fed. Reg. 5452, 5453 (Feb. 2, 2005).[25] Later in 2009, based on a CDC request, the FDA issued the first EUA that was geared towards civilians, including infants, for Tamiflu, an antiviral otherwise approved for use in adults. 74 Fed. Reg. 56644 (Nov. 2, 2009).[26]

Not all EUAs are created equally. Because of the widespread use of a COVID-19 vaccine, the FDA informed manufacturers that it expected the same level of endpoint efficacy data as required for full approval, enough safety data to justify by clear and compelling evidence the vaccine's safety, and confirmation of the technical procedures and verification steps necessary to support full approval.[27] In short, and as described in more detail below in this opinion's analysis, the FDA promulgated guidance that

---

[24] FDA, *Emergency Use Authorization – Archived Information*, https://www.fda.gov/emergency-preparedness-and-response/mcm-legal-regulatory-and-policy-framework/emergency-use-authorization-archived-information#H1N1 (last visited July 16, 2021).

[25] *See also* Stuart L. Nightingale *et al.*, *Emergency Use Authorization (EUA) to Enable Use of Needed Products in Civilian and Military Emergencies, United States*, 13(7) Emerging Infectious Diseases 1047 (July 2007), https://wwwnc.cdc.gov/eid/article/13/7/06-1188_article.

[27] FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* (May 2021), https://www.fda.gov/regulatory-information/search-fda-guidance-documents/emergency-use-authorization-vaccines-prevent-covid.

enhanced the basis on which any COVID-19 vaccine would meet EUA approval. In setting these more stringent standards, the FDA invited EUA applications only for vaccines positioned well to receive full approval.[28]

I. *COVID-19 Vaccines*.

In the United States, three vaccines rushed to the front: two using mRNA technology and one using a viral vector [Ex. 115 ¶ 23-26]. Johnson & Johnson's vaccine is a viral vector vaccine (implementing technology since the 1970s) that uses a modified version of a virus to teach the immune system to respond [Ex. 115 ¶ 87].[29] Pfizer and Moderna's vaccines use mRNA, a novel type of vaccine, but one based on decades of research using easily accessible materials found already in many laboratories [*id.*].[30]

[28] The industry guidance has since been superseded twice, once in February 2021 and once in May 2021. FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* (May 2021). Pfizer, Moderna, and Johnson & Johnson's applications were submitted in accordance with the October 2020 enhanced guidance, *see* FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Pfizer-BioNTech)* (2020) https://www.fda.gov/media/144416/download; (application submitted November 20, 2020); FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Moderna)* (2020) https://www.fda.gov/media/144673/download (application submitted November 30, 2020); FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Janssen)* (2021) https://www.fda.gov/media/146338/download (application submitted February 4, 2021).

[29] *See* CDC, *Understanding Viral Vector COVID-19 Vaccines*, https://www.cdc.gov/coronavirus/2019-ncov/vaccines/different-vaccines/viralvector.html (last visited July 16, 2021).

[30] *See* CDC, *Understanding mRNA COVID-19 Vaccines*, https://www.cdc.gov/coronavirus/2019-ncov/vaccines/different-vaccines/mrna.html (last visited July 16, 2021).

Having quickly adapted the existing technology, Moderna started testing the vaccine in humans in March 2020.[31] Pfizer began clinical trials in late April 2020.[32]

By the time Pfizer applied for an EUA on November 20, 2020, their application included safety, immunogenicity, and efficacy data from over 40,000 study participants in ongoing phase I, II, and III, randomized, placebo-controlled, observer-blind, clinical trials conducted in the U.S., Argentina, Brazil, Germany, South Africa, and Turkey.[33] A team of representatives from across the FDA, including experts in clinical review, toxicology, biostatistics, products, production facilities, pharmacovigilance, data integrity, bioresearch monitoring, and labeling reviewed the data submitted by Pfizer, and independently assessed the risks and benefits of the vaccine.[34] The agency granted the EUA on December 11, 2020, noting that Pfizer "met the FDA's expectations as conveyed in [the agency's] June and October guidance documents."[35]

pharmacovigilance, data integrity, bioresearch monitoring, and labeling, reviewed the data submitted by Johnson & Johnson, and independently assessed the risks and benefits of the vaccine.[42] The FDA granted the EUA on February 27, 2021, noting that "the vaccine meets the FDA's expectations for safety and effectiveness appropriate for authorization of a vaccine for emergency use."[43]

With these vaccines, an emerging light appeared at the end of the tunnel. As of July 17, 2021, 337,239,448 doses of vaccine have been administered, and 161 million Americans, or 48.5 percent of the total population, is fully vaccinated.[44] Of adults over the age of eighteen, 59.4 percent are fully vaccinated.[44] In Indiana, 5,749,173 doses have been administered, and 2,888,239 Hoosiers, or 49.6 percent of those over the age of twelve, are fully vaccinated.[45] Of ages 18-24, who account for 9.2 percent of the U.S. population, 11,720,847, or 42.2 percent, are fully vaccinated.[46] In Indiana, 164,098 individuals aged 20-24, or 34.7 percent, are fully vaccinated.[47]

J. *Risks of Vaccines*.

Though the vaccines show remarkable effectiveness against infection and severe cases of COVID-19, and "have undergone and will continue to undergo the most intensive safety monitoring in U.S. history," they are not without risks, heretofore rare for serious risks [Ex. 115 ¶ 33].[48] Many recipients experience mild local and systemic reactions, including fever, headache, muscle pain, chills, and tiredness.[48] In very rare cases, more serious side effects seem to emerge such as allergic reactions or blood clots with low platelets [Ex. 115 ¶ 66; Ex. 117 ¶ 38].[48] For young men specifically, experts are studying a temporal correlation between vaccines and myocarditis, an inflammation of the heart muscle, or pericarditis, inflammation of tissue around the heart [Ex 117 ¶ 37].[49] However, the risk of myocarditis appears to be exceptionally small [Ex. 115 ¶ 67].[50]

The medical community closely tracks adverse events from the vaccine in a national database called VAERS, or the Vaccine Adverse Event Reporting System.[51] This database is used to track adverse events temporally related to all vaccine administration, including for the COVID-19 vaccines, but it is not a definitive or final resource to

[51] HHS, *VAERS*, https://vaers.hhs.gov/.

conclusively prove contraindications.[52] "While very important in monitoring vaccine safety, VAERS reports alone cannot be used to determine if a vaccine caused or contributed to an adverse event or illness."[53] Nevertheless, the FDA considers VAERS data when assessing whether to make changes to any approval or to apply any additional warnings to vaccines.[54] Based on this surveillance, reports of anaphylaxis appears to be rare, blood clotting concerns are rare but higher in women under the age of 50, myocarditis is rare but more common in young people, and reports of death are rare.[55]

The FDA has issued revisions to the patient and provider fact sheets about the risk of myocarditis and pericarditis acknowledging data about this risk.[56] Furthermore, the FDA and CDC recommended a pause on the use of Johnson & Johnson's vaccine in light of reports of clotting in young women (a pause subsequently lifted).[57] Recent changes last week occurred because of reported neurological impacts of the Johnson & Johnson

vaccine, based on VAERS data.[58] These refinements indicate that the ongoing safety of these vaccines are rigorously monitored by agency professionals.

K. *Herd Immunity.*

Much has been said of herd immunity at the national and state levels. The university too wants to achieve herd immunity. Herd immunity occurs when a virus cannot spread because so many of the individuals it encounters are protected against infection [Ex. 117 ¶ 14-17; Ex. 115 ¶ 43-44].[59] The students say we are there [Ex. 117 ¶ 14-17]. The university disagrees [Ex. 116 ¶ 43]. As more infectious variants emerge, some suggest the percent immunized must also increase to reach herd immunity [Ex. 115 ¶ 19-22].[60] Like many aspects of the pandemic, the point at which society is able to conclude enough people have protection from the virus is still undetermined.

The character of immunity is also uncertain. As COVID-19 is a new disease, and the vaccines are even newer, the long-term efficacy of immunity derived from vaccination and infection is not proven [Ex. 117 ¶ 68-72; Ex. 115 ¶ 70].[61] Immune responses appear to exist for at least several months following a COVID-19 infection [Ex. 117 ¶ 68-72; Ex. 319

¶ 1].[61] Dr. Beeler explains a recent study that suggests that vaccination after COVID-19 exposure secures more protection than just antibodies from prior contraction of the virus—in terms of duration and strength against the prevailing variants [Ex. 128 at 82].[62]

The parties disagree over the relative risk of college students spreading the virus to the community, with the students contending the risk is very low [*see* Ex. 117 ¶ 29-31], and the university contending the risk is real [*see* Ex. 115 ¶ 51-52]. There is no consensus on this issue, and some research has not been peer-reviewed.[63] Nevertheless, peer-reviewed research suggests that outbreaks on college campuses pose a risk of spreading to neighboring communities.[64] Data suggest that as of May 26, 2021, 260,000 infections have been linked to universities and colleges in 2021, including 3,062 reported cases across the Indiana University system—though this data appears limited to students, faculty members, staff members, and other college workers, and thus does not provide insight on greater community spread [*see* Ex. 115 ¶ 52].[65] Universities are unique

A Data-Driven Modeling Study*, Computer Methods in Biomechanics & Biomedical Eng'g, https://doi.org/10.1080/10255842.2020.1869221 (Jan. 13, 2021) (Stanford researchers looked at county spikes following outbreaks at 30 universities and concluded that outbreaks at 17 campuses translated directly into respective community spikes).

[65] N.Y. Times, *Tracking Coronavirus Cases at U.S. Colleges and Universities (May 26, 2021)*, https://www.nytimes.com/interactive/2021/us/college-covid-tracker.html (last visited July 13, 2021). The New York Times appears to be the most comprehensive database for tracking COVID-19 cases across U.S. colleges and universities, collecting and compiling data from individual universities, local health

environments, with students, faculty, and staff often in close contact, particularly given the number that call Indiana University home.

L. *The Student's Objections.*

The eight plaintiffs in this case, all students of Indiana University, don't want the vaccine. Six of the eight have received exemptions already. One would qualify if she applied. The other appears not to qualify for an exemption.

Ryan Klaassen is concerned that the vaccine is too new to be safe [Ex. 120 at 18]. He objects to the masking and testing requirements because of their unreasonableness and the potential for discrimination [*id.* 36]. He complied with the university's mask policy during his freshman year, including wearing a mask in most places, and has undergone many COVID-19 tests [*id.* 27].

Jaime Carini has up to seven more years to finish her joint dissertation after she finishes her exams [Ex. 121 at 23]. Her physician provided a letter saying she should not take the vaccine, though the letter has not been presented to the university or to the court [Ex. 121 at 52-53]. She applied for a religious exemption and received one [*id.* 57]. She did not apply for a medical exemption [Ex. 100 ¶ 187 (never applied for one); Ex. 121 at 60]. Despite wearing a mask in public spaces when required and previously taking several COVID-19 tests, she objects to the mask policy because it makes it difficult for her to breathe, she gets bad acne from the mask, and she struggles deadlifting with a mask [Ex.

departments, counties, states, and through open record requests at universities who would not otherwise provide data.

121 at 44, 47-51]. She also doesn't like surrendering her biological information for testing [*id.* 55]. In total, she views the university's policy as a cultural harm [*id.* 55-56].

Daniel Baumgartner says he has a deeply held religious objection to wearing a mask and being tested. He wore a mask while attending religious services, in school, and at stores in the past [Ex. 122 at 8, 18-20]. He previously contracted COVID-19 and says he has "natural" COVID antibodies, though for how long he doesn't know [*id.* 21-22].

Ashlee Morris believes she previously contracted COVID-19 [Ex. 123 at 27-28]. She has been tested before and acknowledges that she did not suffer any lasting harm from the test [*id.* 35]. She wore a mask to work, on a plane, and when she went to a casino, but not to stores even if signs were posted [*id.* 35-37]. She testifies she has a religious objection to wearing a mask and being tested [*id.* 45-48]. She admits that she has never experienced discrimination because she did not wear a mask [*id.* 56].

Seth Crowder has a deeply held religious objection to wearing a mask and being tested [Ex. 124 at 29-30]. He has worn a mask once or twice a week since March 2020, including to stores and restaurants [*id.* 22].

Macey Policka objects generally to the extra requirements of masks and tests because of the minimal risk to those in her age group, also stating that vegans and pescatarians are less likely to experience serious illness [Ex. 125 at 28]. She lived on the Bloomington campus for the 2020 school year, complied with the university's masking policy, and underwent weekly mitigation testing from which she states she did not suffer any harm [*id.* 14-18]. She has never experienced judgment or alienation due to wearing a

mask at the university but is concerned about having to wear a mask while pursuing her theatre degree [*id.* 25, 42].

Margaret Roth objects to the mask and testing requirements because she thinks masks are silly and she claims nasal swabs cause cancer [Ex. 126 at 12, 29, 35-36]. She has worn a mask while at school, shopping, and working [*id.* 31-33]. She has a religious objection to the vaccine but did not file for an exemption because she doesn't want to be subject to testing or wear a mask [*id.* 45-47].

Natalie Sperazza complied with the university testing and masking requirement during the 2020 school year [Ex. 127 at 30-32]. She has been tested for COVID-19 many times, including while working at Amazon, where she would occasionally go to get tested just to have a break [*id.* 25-26, 30].

M. *Procedure.*

The students filed a preliminary injunction motion. The court expedited briefing and discovery. The court held oral argument on July 13, 2021, after receiving the record the day before. The parties stipulated to the admissibility of all exhibits. The parties stipulated not to present additional testimony at the preliminary injunction hearing because it would duplicate what they had presented already.

Further evidentiary hearing is generally required for a preliminary injunction motion when there are "genuine issues of material fact" and either side "intends to introduce evidence [at the hearing] that if believed will so weaken [the other's] case as to affect the judge's decision on whether to issue the injunction." *Ty, Inc. v. GMA Accessories, Inc.*, 132 F.3d 1167, 1171 (7th Cir. 1997). That said, such a hearing isn't necessary when the

evidence would essentially duplicate the declarations, depositions, and other documents the parties have already submitted. *See Goodman v. Ill. Dep't of Fin. & Pro. Regul.*, 430 F.3d 432, 439 (7th Cir. 2005) (summarizing *Ty, Inc.*, 132 F.3d at 1171); *Ty, Inc.*, 132 F.3d at 1171. No additional hearing was necessary here. The court has considered over a hundred written exhibits, including sworn depositions and declarations, and heard three hours of argument. This motion is ripe for immediate ruling.

STANDING

Before considering the preliminary injunction motion, the court must ensure its jurisdiction. *See Common Cause Ind. v. Lawson*, 937 F.3d 944, 949 (7th Cir. 2019); *Simic v. City of Chicago*, 851 F.3d 734, 738 (7th Cir. 2017). The United States Constitution confines the federal judiciary's power to "Cases" and "Controversies." U.S. Const. Art. III § 2. For a case or controversy to exist, a plaintiff must have standing—an injury, fairly traceable to the defendant's conduct, that the court's decision will likely redress. *Uzuegbunam v. Preczewski*, 141 S. Ct. 792, 797 (2021); *Spokeo, Inc. v. Robins*, 136 S. Ct. 1540, 1547 (2016).

Indiana University raises the issue of standing. Of the eight students here, six have received an exemption under the university's policy and one (Margaret Roth) qualifies so long as she pursues it. This leaves one student (Natalie Sperazza) who yet faces an unexemptible choice this semester: either she gets vaccinated or she cannot attend Indiana University this fall. She doesn't qualify for an exemption. At minimum, she has standing—an injury fairly traced to Indiana University's decision to mandate the vaccine and one the court can redress. *See Uzuegbunam*, 141 S. Ct. at 797; *Taylor v. McCament*, 875 F.3d 849, 853 (7th Cir. 2017).

The court has subject matter jurisdiction under Article III so long as one plaintiff has standing. *See Horne v. Flores*, 557 U.S. 433, 446 (2009); *Massachusetts v. E.P.A.*, 549 U.S. 497, 518 (2007). Even when the standing of others may prove doubtful, *see*, *e.g.*, *Chi. Joe's Tea Room, LLC v. Vill. of Broadview*, 894 F.3d 807, 813 (7th Cir. 2018), the court's jurisdiction remains intact so long as one plaintiff has demonstrated standing to assert her rights, *Horne*, 557 U.S. at 446. The court thus may proceed to this preliminary injunction motion without addressing the standing of the other students. *See id.*

That said, the court remains mindful (and the reader should too) that it cannot issue a mere advisory opinion. Article III's "case or controversy" requirement prohibits "advisory opinions that do not affect the rights of the parties before the court." *Matlin v. Spin Master Corp.*, 979 F.3d 1177, 1181 (7th Cir. 2020) (citation omitted). The court isn't a law office established for legal advice—the federal judiciary decides cases, not hypothetical outcomes. If the court's decision doesn't affect a litigant's rights, "the aggrieved party [is] unable to illustrate the redressability component of standing, rendering any judicial decision in the case an impermissible advisory opinion." *United States v. Brixen*, 908 F.3d 276, 280 (7th Cir. 2018). In short, the court won't decide today issues that would not redress the injuries these particular students allege.

PRELIMINARY INJUNCTION STANDARD

A preliminary injunction is a "very far-reaching power, never to be indulged [] except in a case clearly demanding it." *Cassell v. Snyders*, 990 F.3d 539, 544 (7th Cir. 2021) (quoting *Orr v. Shicker*, 953 F.3d 490, 501 (7th Cir. 2020)). To obtain an injunction, the students "must make a threshold showing that: (1) absent preliminary injunctive relief,

[they] will suffer irreparable harm in the interim prior to a final resolution; (2) there is no adequate remedy at law; and (3) [they have] a reasonable likelihood of success on the merits." *Tully v. Okeson*, 977 F.3d 608, 612-13 (7th Cir. 2020) (quoting *Turnell v. CentiMark Corp.*, 796 F.3d 656, 662 (7th Cir. 2015)); *see also Winter v. Nat. Resources Defense Council, Inc.*, 555 U.S. 7, 20 (2008). If they make these threshold showings, the court "consider[s] the balance of harms between the parties and the effect of granting or denying a preliminary injunction on the public interest." *Tully*, 977 F.3d at 613 (quotation omitted).

ANALYSIS

A. *These Students Aren't Likely to Succeed on the Merits.*

No case to date has decided the constitutionality of whether a public university, such as Indiana University, may mandate that its students receive a COVID-19 vaccine.[66] Given the unique constitutional nature of this case, the court assesses the students' likelihood of success first, ever mindful that this determination proves preliminary only.

The students must show a likelihood of success on the merits. This is their burden. This showing must be "strong," which "normally includes a demonstration of how the applicant proposes to prove the key elements of [the] case." *Tully*, 977 F.3d at 613 (quoting *Ill. Republican Party v. Pritzker*, 973 F.3d 760, 762-63 (7th Cir. 2020)). Though an "applicant need not show that [she] definitely will win the case," a "mere possibility of success is not enough." *Pritzker*, 973 F.3d at 762-63.

[66] A district court recently upheld a COVID-19 vaccine mandate, albeit by a private employer (hospital). *See Bridges v. Houston Methodist Hosp.*, 2021 U.S. Dist. LEXIS 110382, 7-8 (S.D. Tex. June 12, 2021).

1. *The Fourteenth Amendment.*

The students pursue a Fourteenth Amendment claim. The Bill of Rights—the first ten amendments to the United States Constitution—originally applied only to the federal government. *See McDonald v. City of Chicago*, 561 U.S. 742, 754 (2010). Individual states weren't obligated to respect its protections against citizens. *See Livingston's Lessee v. Moore*, 32 U.S. 469, 551-52 (1833); *see also McDonald*, 561 U.S. at 754 (citing *Moore*, 32 U.S. at 551-52). This changed with the Fourteenth Amendment in 1868.

The Fourteenth Amendment "furnishe[d] an additional guaranty against any encroachment by the States upon the fundamental rights [that] belong to every citizen as a member of society." *United States v. Cruikshank*, 92 U.S. 542, 554 (1875); *accord United States v. Morrison*, 529 U.S. 598, 622 (2000); *see also* 42 U.S.C. § 1983; *Albright v. Oliver*, 510 U.S. 266, 271 (1994); *Power v. Summers*, 226 F.3d 815, 819 (7th Cir. 2000). For today's dispute, the Fourteenth Amendment says no "State [may] deprive any person of life, liberty, or property, without due process of law." U.S. Const. amend. XIV § 1. This due process clause applies to the States and protects, absent a deprivation with due process, certain rights to life, liberty, and property. Indiana University is a state actor, *Medlock v. Trustees of Ind. Univ.*, 738 F.3d 867, 871 (7th Cir. 2013), so the Fourteenth Amendment also applies to it.

As interpreted, the Fourteenth Amendment has both substantive and procedural dimensions. *See Cleveland Bd. of Educ. v. Loudermill*, 470 U.S. 532, 541 (1985). This case concerns substantive due process—"a substantive limitation on the power of government to legislate." *Durigan v. Sanitary Dist. No. 4*, 5 F. Appx. 492, 494 (7th Cir. 2001); *see Campos*

v. Cook Cnty., 932 F.3d 972, 975 (7th Cir. 2019). The Fourteenth Amendment protects a person's substantive rights in life, liberty, and property. U.S. Const. amend. XIV § 1. Certain rights or liberties have been deemed "fundamental," so they receive greater protection. *See Washington v. Glucksberg*, 521 U.S. 702, 720-21 (1997).

Bearing that in mind, the court initially approaches this case in a two-fold manner. First, the law requires a "careful description" of the asserted right or liberty. *See id.* at 721; *see*, *e.g.*, *Doe v. City of Lafayette*, 377 F.3d 757, 768 (7th Cir. 2004). Second, the court must determine whether the so-defined right or liberty is fundamental under the Constitution. *See Glucksberg*, 521 U.S. at 721; *Doe*, 377 F.3d at 768. The Fourteenth Amendment's due process clause specially protects fundamental rights and liberties—those that objectively are "deeply rooted in this Nation's history and tradition" and so "implicit in the concept of ordered liberty" that "neither liberty nor justice would exist if they were sacrificed." *Glucksberg*, 521 U.S. at 721 (citations omitted); *accord Khan v. Bland*, 630 F.3d 519, 535 (7th Cir. 2010). These guideposts direct and restrain due process decisionmaking. *Glucksberg*, 521 U.S. at 721.

Many rights explicitly secured in the Bill of Rights are considered fundamental, having been gradually incorporated as substantive guarantees under the Fourteenth Amendment. These fundamental rights include, as examples, freedom of speech, *Gitlow v. New York*, 268 U.S. 652 (1925); freedom of the press, *Near v. Minnesota*, 283 U.S. 697 (1931); the right against cruel and unusual punishment, *Robinson v. California*, 370 U.S. 660 (1962); and the right to keep and bear arms, *McDonald*, 561 U.S. at 742. There are others.

Fundamental rights aren't limited to those specifically enumerated in the Bill of Rights. Beginning with *Griswold v. Connecticut*, 381 U.S. 479, 483 (1965), the Supreme Court recognized a right to privacy within the "penumbra" of other constitutional protections and called it fundamental. This right to privacy has included the right for both married and unmarried couples to purchase contraceptives, *see Griswold*, 381 U.S. at 484-86; *Eisenstadt v. Baird*, 405 U.S. 438, 454-55 (1972), to abortion, *see Roe v. Wade*, 410 U.S. 113, 153 (1973), to sexual privacy, *Lawrence v. Texas*, 539 U.S. 558, 578 (2003), and to marital privacy, *Obergefell v. Hodges*, 576 U.S. 644, 664-65 (2015). As these cases illustrate, privacy rights largely have been confined to "to sexual and reproductive rights, such as the right to use contraceptives or have an abortion or engage in homosexual acts." *Wolfe v. Schaefer*, 619 F.3d 782, 784 (7th Cir. 2010).

The students and university disagree on the constitutional analysis. Declaring a right or liberty fundamental has important implications. Modern constitutional jurisprudence employs a different analysis when a person's fundamental right is at stake. If the government infringes on a fundamental right, the court often applies strict scrutiny. *Glucksberg*, 521 U.S. at 721. In such circumstances, the Fourteenth Amendment "forbids the government to infringe . . . fundamental liberty interests *at all*, no matter what process is provided, unless the infringement is narrowly tailored to serve a compelling state interest." *Id.* (quoting *Reno v. Flores*, 507 U.S. 292, 302 (1993)); *see*, *e.g.*, *Siefert v. Alexander*, 608 F.3d 974, 981 (7th Cir. 2010); *Ent. Software Ass'n v. Blagojevich*, 469 F.3d 641, 646 (7th Cir. 2006). This is the most rigorous form of constitutional scrutiny of government action.

Whereas infringements on other rights or liberties, though still constitutionally scrutinized, must meet what courts call rational basis review. *Glucksberg*, 521 U.S. at 722, *Sweeney v. Pence*, 767 F.3d 654, 668 (7th Cir. 2014). The law normally applies this standard to Fourteenth Amendment challenges to infringed liberties, if not fundamental or based on a suspect classification. *Roman Catholic Diocese of Brooklyn v. Cuomo*, 141 S. Ct. 63, 70 (2020) (Gorsuch, J., concurring); *see, e.g.*, *Glucksberg*, 521 U.S. at 721. It is less stringent than strict scrutiny. Under rational basis review, "legislation is presumed to be valid and will be sustained if the classification drawn by the statute is rationally related to a legitimate state interest." *City of Cleburne v. Cleburne Living Ctr.*, 473 U.S. 432, 440 (1985). The students argue for strict scrutiny, and the university argues for rational basis review.

2. *The Constitution in a Public Health Crisis.*

We live in the era of the COVID-19 virus—worldwide seeing to nearly 189 million cases and 4 million deaths, with these numbers changing daily. The United States hasn't been immune. Our citizens have recovered or struggled to recover from over 33 million cases of this novel coronavirus when over 606,000 tragically have passed.[67] A public health crisis of this magnitude begs the question: how should the law respond to state action that infringes on the People's liberties during such times?

To be sure, the Constitution isn't put on the shelf. Indeed, in times of crisis, perhaps constitutional adherence proves the very anchor we all need against irrational and overweening government intrusion that would otherwise scuttle the ship. As the

[67] CDC, *Trends in Number of COVID-19 Cases and Deaths in the US Reported to CDC, by State/Territory* (July 16, 2021), https://covid.cdc.gov/covid-data-tracker/#trends_dailytrendscases.

arbiters of the Constitution's checks and balances, *see Marbury v. Madison*, 5 U.S. 137, 176-78 (1803); *accord Morrison*, 529 U.S. at 616, the courts play an important role in ensuring that the government doesn't simply declare a never-ending public emergency and expand its powers *ad libitum* to the People's detriment.

Under our country's federalist system, state and federal governments share regulatory authority over public health matters. States traditionally exercise most authority under their inherent police power—and reasonably so when public health may flux and evolve by locale. States thus have the power, within constitutional limits, to pass laws that "provide for the public health, safety, and morals[.]" *Barnes v. Glen Theatre*, 501 U.S. 560, 569 (1991); *accord Glucksberg*, 521 U.S. at 729-31; *Zucht v. King*, 260 U.S. 174, 176-77 (1922), *Jacobson v. Commonwealth of Massachusetts*, 197 U.S. 11, 24-25 (1905).

To answer the question today, the court travels back in time to 1905: a time before the modern tiers of constitutional analysis (strict scrutiny and rational basis) and one rampaged by the smallpox epidemic. In that year, the United States Supreme Court issued a leading decision in answer to this question.

In *Jacobson*, 197 U.S. at 12, Massachusetts passed a law that allowed a city, if "necessary for the public health or safety," to enforce vaccination of its citizens. If a person refused, he could be fined $5.00 (about $140.00 today). *Id.*; *Cuomo*, 141 S. Ct. at 70 (Gorsuch, J., concurring). The law allowed an exception for children who had physician-signed certificates saying they weren't fit for vaccination, but no such exemption existed for adults. *Jacobson*, 197 U.S. at 12.

The City of Cambridge, relying on this statute and acting through its board of health, ordered its citizens vaccinated for smallpox. *Id.* at 12-13. Smallpox was devastating, claiming almost 300 million lives in the 20th century before being eradicated.[68] In the early 1900s, and closer to the time that Massachusetts wrestled with the disease, there were 1,596 cases of smallpox in Boston, with 270 deaths, in a city with a population close to 561,000.[69] Massachusetts, particularly Boston, was an epicenter of one of two major smallpox outbreaks. Opponents of vaccination questioned its safety and efficacy; though generally safe, it could cause ulceration, lobar pneumonia, cellulitis, parotitis, sepsis, and tetanus, to name a few conditions.[70] Side effects ostensibly posed a greater problem than mild smallpox.[71] The smallpox vaccine wasn't risk-free in the early 1900s. That said, vaccinations had been used for some considerable time—begun by state-supported facilities in England in 1808 and mandated by many other countries throughout the 1800s before the Massachusetts mandate in 1902. *Id.* at 31, n.1. This all transpired before the FDA came into being.

Henning Jacobson refused the vaccine in Massachusetts. After a trial, a jury found him guilty of refusing the vaccine. The court sentenced him to jail until he paid the $5.00

criminal fine. On appeal, he argued that the Massachusetts law authorizing the vaccine mandate violated his Fourteenth Amendment rights. *Id.* at 13.

The United States Supreme Court rejected his challenge. A state's police power "must be held to embrace, at least, such reasonable regulations established directly by legislative enactment as will protect the public health and the public safety." *Id.* at 25. This power included the "authority of a state to enact quarantine laws and health laws of every description;" and such power extended to "all laws that relate to matters completely within its territory and which do not by their necessary operation affect the people of other states." *Id.* The Constitution gave Massachusetts broad deference: a court should only intervene "if a statute purporting to have been enacted to protect the public health, the public morals, or the public safety, has no real or substantial relation to those objects, or is beyond all question, a plain, palpable invasion of rights secured by the fundamental law." *Id.* at 31.

Of note, *Jacobson* upheld only the constitutionality of the state statute, *id.* at 39 ("We now decide only that the statute covers the present case, and that nothing clearly appears that would justify this court in holding it to be unconstitutional and inoperative in its application to the plaintiff in error."); and phrased its holding in terms of a reasonable regulation established "directly by legislative enactment," *id.* at 25, but the case contemplated the action of local state bodies when vested legislatively with the power to act to safeguard public health and safety, *see*, *e.g.*, *id.* at 25, 38. A State's power, "whether exercised directly by the legislature, or by a local body acting under its authority, may be exerted in such circumstances," and only "regulations so arbitrary and oppressive in

particular cases [would] justify the interference of the courts to prevent wrong and oppression." *Id.* at 38.

The students want *Jacobson* confined to its time, whereas the university believes it applies with full force. In the years since, the high court has leaned on *Jacobson* to uphold government measures intended for the public welfare under effectively rational basis review, finding the measures reasonably advancing a legitimate state interest. For example, *Zucht*, 260 U.S. at 175-77, relied on *Jacobson* to uphold a city ordinance excluding from its public schools children not having a certificate of vaccination, holding that it was within the state's police powers reasonably to so act. According to *Zucht*, *Jacobson* settled the state's power "to provide for compulsory vaccination" and, "consistently with the federal Constitution, delegate to a municipality authority to determine under what conditions health regulations shall become operative." *Id.* at 176. This was not authorization of "arbitrary power," but only that broad discretion required for the protection of the public health." *Id.* at 177. In doing so, "state and federal legislatures [enjoy] wide discretion to pass legislation in areas where there is medical and scientific uncertainty." *Gonzales v. Carhart*, 550 U.S. 124, 163 (2007) (citing *Jacobson*, 197 U.S. at 30-31).

Based on this power, states and their authorized arms have historically adopted vaccination mandates. For instance, all fifty states and the District of Columbia have laws

requiring students to receive certain vaccines before they may attend school.[72] Many align their vaccine requirements with CDC's immunization recommendations, and all laws provide exemptions for medical reasons and nearly all religious exemptions.[72] Adult vaccination mandates often have been limited to the private employment sector,[73] though not always. For instance, the State of Indiana requires all public university students to receive vaccinations for diphtheria, tetanus, measles, mumps, rubella, and meningococcal disease, save for religious and medical exemptions. *See* Ind. Code § 21-40-5-2.

Similarly, but outside the vaccination context, *Hamilton v. Regents of the University of California*, 293 U.S. 245, 264 (1934), relied on *Jacobson* to uphold a state university's decision to compel military training for its students (five years before World War II). Certain minors (not adults) were required to take a course in military science and tactics, part of training prescribed by the country's war department at the time. The students objected on religious grounds through the Fourteenth Amendment—"no more than an assertion that the due process clause of the Fourteenth Amendment as a safeguard of 'liberty' confers the right to be students in the State University free from obligation to take military training as one of the conditions of attendance." *Id.* at 262. *Hamilton* held this view "untenable," recognizing the government's duty to the people to maintain

[72] Nat'l Conf. of State Legislatures, *States with Religious and Philosophical Exemptions from School Immunization Requirements* (April 30, 2021), https://www.ncsl.org/research/health/school-immunization-exemption-state-laws.aspx.

[73] Michael J. Vernick, Molly E. Whitman & McKenzie F. Miller, *The Mandate Maze*, Inside Higher Ed (May 25, 2021), https://www.insidehighered.com/views/2021/05/25/advice-legal-issues-related-vaccine-mandates-opinion.

peace and order and every citizen's "reciprocal duty, according to his capacity, to support and defend government against all enemies." *Id.* at 262-63. Justice Cardozo eloquently concurred: "The right of private judgment has never yet been so exalted above the powers and the compulsion of the agencies of government. One who is a martyr to a principle—which may turn out in the end to be a delusion or an error—does not prove by his martyrdom that he has kept within the law." *Id.* at 268.

Repose the thought whether we face just such a common enemy today in COVID-19. In this century, other than the Supreme Court's reliance on *Jacobson* in 2007, *see Gonzales*, 550 U.S. at 163, courts have returned again to its guidance during the COVID-19 pandemic. Just last year, this circuit endorsed *Jacobson*. *See Pritzker*, 973 F.3d at 763 ("The district court appropriately looked to *Jacobson* for guidance, and so do we."). The circuit held that "*Jacobson* t[ook] off the table any general challenge" to an executive order that subjected religious gatherings to recommended limits on gatherings, rather than mandatory ones. *Id.* at 763-64. The Illinois governor implemented "an order designed to address a serious public-health crisis," and *Jacobson* afforded broad deference "[a]t least at this stage of the pandemic." *Id.*

That decision was almost ten months ago—in terms of the law very recent, but in terms of this ever-evolving health crisis before the proverbial rinderpest. We are no longer at the same stage of the COVID-19 pandemic; indeed, some—like the students—argue that the pandemic is effectively over. And since this circuit's *Pritzker* decision, more cases bearing on the subject of public health in the COVID-19 pandemic have arrived.

One such decision—and one heavily briefed by the parties—is *Roman Catholic Diocese of Brooklyn v. Cuomo*, 141 S. Ct. 63 (2020). In *Cuomo*, the State of New York adopted capacity restrictions on religious institutions that treated them less favorably than so-called "essential" businesses, *id.* at 66, including liquor and hardware stores, *id.* at 69 (Gorsuch, J., concurring). *Cuomo* applied strict scrutiny because the law targeted religious practice contrary to the First Amendment, as incorporated against the states by the Fourteenth Amendment, and enjoined the limitations, saying they were not narrowly tailored to fulfill the state's compelling interest in controlling the spread of COVID-19. *Id.* at 67 (majority opinion).

Cuomo enhanced the law's focus under the First Amendment. *See Cassell*, 990 F.3d at 543 (citing *Cuomo* for the proposition that "[i]ntervening authority from the Supreme Court offers plaintiffs a greater prospect for success on the merits of their First Amendment claim than either the district court or we had expected"). So this begs another question: to what extent has *Cuomo*—if any—impacted the broad deference the court would seemingly afford a state during a pandemic under *Jacobson* to act in the interest of public health? *Cuomo*'s majority opinion never referenced *Jacobson*.

The students read *Cuomo* as implicitly overruling *Jacobson*, or at least as abrogating it. Though the Supreme Court may overrule a case without explicitly saying so, *see Levine v. Heffernan*, 864 F.2d 457, 461 (7th Cir. 1988), this is a tall task. Before a federal court concludes that the Supreme Court has implicitly overruled a prior decision, it must be "certain or almost certain that the decision or doctrine would be rejected by the higher court if a case presenting the issue came before it." *Olson v. Paine, Webber, Jackson & Curtis,*

Inc., 806 F.2d 731, 741 (7th Cir. 1986). This high bar is rarely met. *Id.* It isn't met here. *Cuomo* and *Jacobson* involved entirely different modes of analysis, entirely different rights, and entirely different kinds of restriction. *See Cuomo*, 141 S. Ct. at 70 (Gorusch, J., concurring) (saying the same). "*Jacobson* applied what would become the traditional legal test associated with the right at issue"—exactly what *Cuomo* did. *Id.* The cases walk hand-in-hand.

This history isn't all rosy. Unsuccessful thus far, the students turn to *Buck v. Bell*, 274 U.S. 200 (1927). In a rather infamous case, an eight-member majority, save for one dissenting justice, upheld the involuntary sterilization of a woman based on a Virginia law that rested on faulty science and public support for "eugenics"—the repulsive notion that the human race could be improved by controlling reproduction from those with developmental challenges, mental illness, or criminal histories. Citing *Jacobson* for the principle that "compulsory vaccination is broad enough to cover cutting the Fallopian tubes," and offering the chilling justification that "[t]hree generations of imbeciles are enough," the majority upheld the law against a Fourteenth Amendment challenge. *Id.* at 207. This case isn't *Buck*; and one over-extension of *Jacobson* merely counsels once more that the Constitution cannot be cut loose even now, in a pandemic's seeming twilight. *Cuomo*, 141 S. Ct. at 68.

Jacobson was written before the modern tiers of constitutional scrutiny, so a legitimate question is the extent to which *Jacobson* applies with full force today. This is a topic of some debate. *See, e.g.*, *id.* at 70 (Gorsuch, J., concurring) ("*Jacobson* didn't seek to depart from normal legal rules during a pandemic, and it supplies no precedent for doing

so."); *Calvary Chapel Dayton Valley v. Sisolak*, 140 S. Ct. 2603, 2608 (2020) (Alito, J., dissenting) ("it is a mistake to take language in *Jacobson* as the last word on what the constitution allows public officials to do during the COVID-19 pandemic"); *Big Tyme Inv., LLC v. Edwards*, 985 F.3d 456, 470-71 and n.3 (5th Cir. 2021) (Willett, J., concurring) ("I am not the first to express doubts about *Jacobson*"); *S. Bay United Pentecostal Church v. Newsom*, 959 F.3d 938, 943 n.2 (9th Cir. 2020) (Collins, J., dissenting) ("I am unable to agree with the Fifth Circuit's conclusion that *Jacobson* instructs that all constitutional rights may be reasonably restricted to combat a public health emergency.") (quotations omitted), *cert. denied*, 140 S. Ct. 1613 (2020). No Supreme Court opinion has overruled or abrogated *Jacobson*.

Considering the modern tiers of constitutional scrutiny, the court reads *Jacobson* and *Cuomo* harmoniously, appreciating their respective spheres. Though *Jacobson* was decided before tiers of scrutiny, it effectively endorsed—as a considered precursor—rational basis review of a government's mandate during a health crisis. *See Jacobson*, 197 U.S. at 31; *see also Cuomo*, 141 S. Ct. at 70 (Gorusch, J., concurring). In its words, if a law purporting to be enacted to protect public health "has no real or substantial relation to [that legitimate aim]" or if the law proves "a plain, palpable invasion of rights secured by the fundamental law," the court's job is to give effect to the Constitution. *Jacobson*, 197 U.S. at 31. Should the court have this melding of history and modernity wrong in faithfully adhering to the Fourteenth Amendment's plain original meaning of "life" and "liberty," comfort should come in knowing that *Jacobson*, whether rational basis review by any other name, leads to the same result today.

This view remains consistent with the right at stake in *Jacobson*: though a true "liberty" proved at stake—the right to refuse a vaccine during a smallpox epidemic—this interest in bodily autonomy, though protected by the Constitution, wasn't fundamental under the Constitution to require greater scrutiny than rational basis review. *See Sweeney*, 767 F.3d at 668 (rational basis review for infringements on non-fundamental rights). At the same time, *Jacobson* didn't hold that the government's authority in a pandemic balloons for it do whatever it wants in the name of public safety.

Jacobson instead counseled that federal courts should require a rational relation to a legitimate interest in public health. *See Jacobson*, 197 U.S. at 31; *Cuomo*, 141 S. Ct. at 70 (Gorsuch, J., concurring). That *Cuomo* imposed heightened scrutiny of the government's interference with the free exercise of religion—a fundamental right under the First Amendment—was presciently contemplated a century beforehand by *Jacobson*: a court should intervene if a state imposes a regulation that is "beyond all question, a plain, palpable invasion of rights secured by the *fundamental* law." *Jacobson*, 197 U.S. at 31 (emphasis added). Because *Cuomo* involved a fundamental right, a "right[] secured by the fundamental law" under today's jurisprudence, the court intervened. *See Cuomo*, 141 S. Ct. at 67; *see also Glucksberg*, 521 U.S. at 721 (Fourteenth Amendment forbids the government to infringe "fundamental" liberty interests at all, unless it has narrowly tailored its law to serve a compelling state interest). The Constitution's original meaning should be so enduring.

The university seems to argue that *Jacobson* gave even more deference than rational basis review during a public health crisis, but not fairly so; and, even then, *Jacobson* cannot

be taken once more too far. *See, e.g.*, *Big Tyme*, 985 F.3d at 467; *ARJN #3 v. Cooper*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 22286, 19 (M.D. Tenn. Feb. 5, 2021); *Let Them Play MN v. Walz*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 23485, 15 (D. Minn. Feb. 8, 2021); *Culinary Studios, Inc. v. Newsom*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 23775, 38-39 (E.D. Cal. Feb. 8, 2021); *Oakes v. Collier Cnty.*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 15174, 4 n.4 (M.D. Fla. Jan. 27, 2021); *M. Rae, Inc. v. Wolf*, __ F. Supp.3d __, 2020 U.S Dist. LEXIS 241961, 16 n.25 (M.D. Pa. Dec. 23, 2020); *Denver Bible Church v. Azar*, 494 F. Supp.3d 816, 829 (D. Colo. 2020); *AJE Enterprise LLC v. Justice*, 2020 U.S. Dist. LEXIS 222186, 12 (N.D. W. Va. Oct. 7, 2020).

Jacobson doesn't justify blind deference to the government when it acts in the name of public health or in a pandemic. For instance, the decision left the door open for people with legitimate medical concerns to challenge the vaccine mandate. *See Jacobson*, 197 U.S. at 38-39. And the deference owed to the States during a pandemic or public health crisis under *Jacobson* doesn't extend indefinitely. *See Pritzker*, 973 F.3d at 763.

> [A]t the outset of an emergency, it may be appropriate for courts to tolerate very blunt rules. . . . [B]ut a public health emergency does not give . . . public officials *carte blanche* to disregard the Constitution for as long as the medical problem persists. As more medical and scientific evidence becomes available, and as States have time to craft policies in light of that evidence, courts should expect policies that more carefully account for constitutional rights.

Calvary Chapel, 140 S. Ct. at 2605 (Alito, J., dissenting); *accord Cassell*, 458 F. Supp.3d at 993-94 ("courts must remain vigilant, mindful that government claims of emergency have served in the past as excuses to curtail constitutional freedoms.").

In short, the Constitution doesn't permit the government to declare a never-ending public emergency and expand its powers arbitrarily. *See Belcher v. Norton*, 497 F.3d 742, 753 (7th Cir. 2007) ("substantive due process . . . affords protection of the individual against arbitrary action of government"). Instead, as our country and communities progress through a pandemic, the government must continually update its practices in light of the most recent medical and scientific developments. And a law or policy should be written with a mindset that medicine and science, and the circumstances that they create, will evolve, and so must the law or policy evolve or be revisited in amendment.

In sum, the law today recognizes *Jacobson* as a precursor to rational basis review. This is consistent with statements of many justices who continue to acknowledge *Jacobson* as good law, albeit with constitutional restraint.[74] Government action that infringes on the liberty interest here, as in *Jacobson*, is subject to rational basis review. *See Sweeney*, 767 F.3d at 668.

[74] *See, e.g., Democratic Nat'l Comm. v. Wisconsin State Legislature*, 141 S. Ct. 28, 43 (2020) (Kagan, J., dissenting). ("To be sure, deference is usually due to a legislature's decisions about how best to manage the COVID pandemic.") (citing *South Bay*, 140 S. Ct. at 1613-14) (Roberts, C.J., concurring in denial of an injunction seeking to prevent a COVID-19 executive order); *South Bay*, 140 S. Ct. at 1613 (Roberts, C.J., concurring); *Calvary Chapel*, 140 S. Ct. at 2608 (Alito, J., dissenting) ("Language in *Jacobson* must be read in context"); *id.* at 2614 (Kavanaugh, J., dissenting); *Cuomo*, 141 S. Ct. at 71 (Gorsuch, J., concurring); *Cuomo*, 141 S. Ct. at 79 (Sotomayor, J., dissenting) (courts "play a deadly game in second guessing the expert judgment of health officials about the environments in which a contagious virus, now infecting a million Americans each week, spreads most easily"); *Glucksberg*, 521 U.S. at 742 (Stevens, J., concurring) ("As Justice Brennan pointed out in his *Cruzan* dissent, we have upheld legislation imposing punishment on persons refusing to be vaccinated . . . . In most cases, the individual's constitutionally protected interest in his or her own physical autonomy, including the right to refuse unwanted medical treatment, will give way to the State's interest in preserving human life.").

3. *Defining the Right & Constitutional Analysis.*

The students assert a right to refuse the vaccine, saying the mandate infringes on their bodily autonomy and medical privacy. Indiana University throws a challenge flag here. To it, these students are merely saying they have a right to refuse a vaccine *so that* they may attend college. The university says the right being infringed then isn't the right to refuse a vaccine, but the right to attend college. Indeed, if they choose to forego college at Indiana University, there is no vaccine requirement. To the university, the students aren't being forced to take the vaccination against their will; they can go to college elsewhere or forego college altogether. If this case were merely that, merely the right to attend university, this state action wouldn't trample on their rights. There is no fundamental or constitutional right to a college education, *see, e.g.*, *Charleston v. Bd. of Trustees*, 741 F.3d 769, 774 (7th Cir. 2013); *Bissessur v. Ind. Univ. Bd. of Trustees*, 581 F.3d 599, 601 (7th Cir. 2009); *Williams v. Wendler*, 530 F.3d 584, 589 (7th Cir. 2008), much less one at a particular institution.

But that's not what this case concerns, and that's not the liberty at stake. The "unconstitutional conditions doctrine" forbids the university from pulling the rug out from under the students in a roundabout way. Under this doctrine, argued by the students as "coercion," "the government may not deny a benefit to a person because he exercises a constitutional right." *Koontz v. St. Johns River Water Mgmt. Dist.*, 570 U.S. 595, 604 (2013) (citations omitted); *Regan v. Taxation with Representation of Wash.*, 461 U.S. 540, 545 (1983). This doctrine protects constitutional rights "by preventing the government from coercing people into giving them up." *Koontz*, 570 U.S. at 604. It "aims to prevent

the government from achieving indirectly what the Constitution prevents it from achieving directly." *Planned Parenthood of Ind. v. Comm'r*, 699 F.3d 962, 986 (7th Cir. 2012). The students say this state actor is denying a benefit—a public university education—because they are exercising a constitutional right to refuse a vaccine.

The first step in an unconstitutional condition claim "is to identify the nature and scope of the constitutional right arguably imperiled by the denial of a public benefit." *Id.* Here, the Fourteenth Amendment "liberty" at stake is a college student's right to refuse a vaccine, today at this stage of the pandemic [Tr. 26, 30-31]. The Supreme Court has assumed (using its word) and strongly suggested that individuals have a constitutional right to refuse unwanted medical treatment, *see, e.g., Cruzan v. Director, Missouri Dept. of Health* 497 U.S. 261, 279 (1990); *Glucksberg*, 521 U.S. at 720. *Cruzan* held that a competent individual had a constitutional right to refuse unwanted lifesaving hydration and nutrition; and *Glucksberg* recognized that an individual had a liberty interest in refusing unwanted lifesaving medical treatment, though not any fundamental right to assisted suicide. *See Cruzan*, 497 U.S. at 279; *Glucksberg*, 521 U.S. at 728.

But in these, and in other cases, this liberty interest has remained confined either by duly enacted and constitutional state laws or the state's legitimate interests that it had rationally pursued in regulation. *See also Washington v. Harper*, 494 U.S. 210, 221-22 (1990) (prisoner has a "significant liberty interest in avoiding the unwanted administration of antipsychotics drugs under the Due Process Clause . . . [but] no greater right than that recognized under state law"); *Vitek v. Jones*, 445 U.S. 480, 492 (1980) ("Compelled treatment in the form of mandatory behavior modification programs . . . was a proper

factor to be weighed by the District Court. . . . Were an ordinary citizen to be subjected involuntarily to these consequences, it is undeniable that protected liberty interests would be unconstitutionally infringed absent compliance with the procedures required by the Due Process Clause."); *Ingraham v. Wright*, 430 U.S. 651, 673, 683 (1977) ("Among the historic liberties so protected was a right to be free from, and to obtain judicial relief for, unjustified intrusions on personal security. . . . The Eighth Amendment's prohibition against cruel and unusual punishment is inapplicable to school paddlings, and the Fourteenth Amendment's requirement of procedural due process is satisfied by Florida's preservation of common-law constraints and remedies.")

The rights recognized (or assumed) in these cases weren't "simply deduced from abstract concepts of personal autonomy." *Glucksberg*, 521 U.S. at 725. They were rooted in longstanding common law rules or legal traditions consistent with this Nation's history. *See id.* The students, quite skillfully represented in this emergency setting, offer no preliminary record of such historic rules, laws, or traditions that would facilitate the court's announcement, now in mere days from receiving this case, that a right to refuse a vaccine is anything more than a significant liberty under the Fourteenth Amendment.

The dearth of this record isn't a passing point. Indeed, both *Cruzan* and *Glucksberg* were limited to an individual's choice related to the refusal of lifesaving subsistence or medical treatment—with no ramifications to the physical health of others. Vaccines address a collective enemy, not just an individual one. Indeed, "the elimination of communicable diseases through vaccination [is] one of the greatest achievements of public health in the 20th century," *Bruesewitz v. Wyeth LLC*, 562 U.S. 223, 226 (2011) (Scalia,

J.) (citation and quotations omitted), and it continues to be so now in this century. A vaccine is implemented as a matter of public health, and historically hasn't been constitutionally deterred from state mandate. *See, e.g.*, *Zucht*, 260 U.S. at 176-77; *Jacobson*, 197 U.S. at 30-31.

In the backdrop of the Fourteenth Amendment's ratification in 1868, for instance, England had already passed its first compulsory vaccination act for smallpox in 1853 (and so had many countries). *See Jacobson*, 197 U.S. at 31, n.1. Science wasn't absolute or infallible at that time—nor is it today. But the "possibility that the belief may be wrong, and that science may yet show it to be wrong, is not conclusive; for the legislature has the right to pass laws which, according to the common belief of the people, are adapted to prevent the spread of contagious diseases." *Id.* at 35. Appreciating the relative risks of vaccines, they nonetheless "are effective in preventing outbreaks of disease only if a large percentage of the population is vaccinated." *Wyeth*, 562 U.S. at 227.

Added comfort comes from the consistent use of rational basis review to assess mandatory vaccination measures. *See, e.g.*, *Prince v. Massachusetts*, 321 U.S. 158, 166-67 (1944) (parent "cannot claim freedom from compulsory vaccination for the child more than for himself on religious grounds" and "[t]he right to practice religion freely does not include liberty to expose the community or the child to communicable disease or the latter to ill health or death"); *Zucht*, 260 U.S. at 176-77; *Jacobson*, 197 U.S. at 30-31; *Phillips v. City of New York*, 775 F.3d 538, 542-43 (2d Cir. 2015); *Workman v. Mingo Cnty. Bd. of Educ.*, 419 F. Appx. 348, 355-56 (4th Cir. 2011); *W.D. v. Rockland Cnty.*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 33515, 74 (S.D.N.Y. Feb. 22, 2021); *Doe v. Zucker*, __ F. Supp.3d __, 2021 U.S.

Dist. LEXIS 28937, 111 (N.D.N.Y. Feb. 17, 2021); *Connecticut Citizens Defense League, Inc. v. Lamont*, 465 F. Supp.3d 56, 72 (D. Conn. 2020); *Middleton v. Pan*, 2016 U.S. Dist. LEXIS 197627, 20 (C.D. Cal. Dec. 15, 2016); *George v. Kankakee Cmty. Coll.*, 2014 U.S. Dist. LEXIS 161379, 8-9 (C.D. Ill. Oct. 27, 2014), *recommendation adopted*, 2014 U.S. Dist. LEXIS 160737, 1-2; *Boone v. Boozman*, 217 F. Supp.2d 938, 954 (E.D. Ark. 2002).

Given over a century's worth of rulings saying there is no greater right to refuse a vaccination than what the Constitution recognizes as a significant liberty, the court declines the students' invitation to extend substantive due process to recognize more than what already and historically exists. *See Glucksberg*, 521 U.S. at 721; *Harper*, 494 U.S. at 221-22; *Prince*, 321 U.S. at 166-67; *Zucht*, 260 U.S. at 176-77; *Jacobson*, 197 U.S. at 30-31.

Quite separately from this, the Constitution never provides a fundamental right to a collegiate education. Nor does it secure as a fundamental liberty a student's right to attend a public university no matter his or her vaccinated status. The court isn't saying a student doesn't have the right to choose. Of course every individual does—subject to the state's reasonable measures designed to pursue legitimate ends of disease control or eradication.

The students argue that the university's vaccine mandate doesn't provide for informed consent. "The notion of bodily integrity has been embodied in the requirement that informed consent is generally required for medical treatment." *Cruzan*, 497 U.S. at 269. Informed consent "entails an opportunity to evaluate knowledgeably the options available and the risks attendant upon each." *Canterbury v. Spence*, 464 F.2d 772, 780 (D.C. Cir. 1972). The students acknowledge that, for medical products under an EUA like the

three COVID-19 vaccines, HHS must establish conditions to facilitate informed consent. *See* 21 U.S.C. § 360bbb-3(e)(1)(A)(ii). HHS must ensure that individuals taking the vaccine are informed "that the Secretary has authorized the emergency use of the product," "of the significant known and potential benefits and risks of such use, and of the extent to which such benefits and risks are unknown," and "of the option to accept or refuse administration of the product, of the consequences, if any, of refusing administration of the product, and of the alternatives to the product that are available and of their benefits and risks." *Id.*

The students admit that the informed consent requirement under the EUA statute only applies to medical providers. The university isn't directly administering the vaccine to its students; instead, it is requiring students to obtain the vaccine from a medical provider and to attest that they have been vaccinated, save for certain exemptions. The students will be informed of the risks and benefits of the vaccine and of the option to accept or refuse the vaccine by their medical providers. *See id.* The university isn't forcing the students to undergo injections. The situation here is a far cry from past blunders in medical ethics like the Tuskegee Study.[75]

The university is presenting the students with a difficult choice—get the vaccine or else apply for an exemption or deferral, transfer to a different school, or forego school for the semester or altogether. But this hard choice doesn't amount to coercion. The

[75] *See* CDC, *The U.S. Public Health Service Syphilis Study at Tuskegee* (as part of a study on the history of untreated syphilis, "researchers did not collect informed consent from participants and they did not offer treatment, even after it was widely available"), https://www.cdc.gov/tuskegee/index.html (last visited July 16, 2021).

students taking the vaccine are choosing it among other options, and before the shot reaches their arms, they are made aware of the risks and the option to refuse.

One last point before moving on. As a final push, the students argue that the vaccination requirement violates their free exercise of religion. The First Amendment says "Congress shall make no law . . . prohibiting the free exercise" of religion. U.S. Const. amend. I. The Supreme Court has declared this right to exercise religion as fundamental and subject to strict scrutiny. *See Cantwell v. Connecticut*, 310 U.S. 296, 303 (1940). But the Constitution also permits general regulations that incidentally burden religious practices: the "right of free exercise does not relieve an individual of the obligation to comply with a valid and neutral law of general applicability on the ground that the law proscribes (or prescribes) conduct that his religion prescribes (or proscribes)." *Employment Division v. Smith*, 494 U.S. 872, 879 (1992) (quotations omitted). Neutral and generally applicable regulations need only be supported by a rational basis. *Ill. Bible Colleges Ass'n v. Anderson*, 870 F.3d 631, 639 (7th Cir. 2017).

The vaccine mandate is a neutral rule of general applicability. It applies to all students, whether religious or not. It doesn't discriminate among religions. Indeed, the university has chosen to *enable* the practice of religion by providing a religious exemption to this vaccination requirement—one that the university, on this record, has freely granted to students if they request it, no questions asked. This is consistent with the Constitution. *See Nikolao v. Lyon*, 875 F.3d 310, 316 (6th Cir. 2017) (religious plaintiff had no constitutional right to an exemption from mandatory vaccination law for public school students, though state provided one); *Phillips*, 775 F.3d at 543 (state "could

constitutionally require that all children be vaccinated in order to attend public school. . . . [but the State went] beyond what the Constitution requires by allowing an exemption for parents with genuine and sincere religious beliefs"); *see also Workman*, 419 F. Appx. at 356; *Whitlow v. California*, 203 F. Supp.3d 1079, 1084 (S.D. Cal. 2016); *Boone*, 217 F. Supp.2d at 954. Indiana University adopted a religious exemption, despite a religious-neutral vaccine mandate, which the law views as a matter of grace. Indeed, six of the eight students here applied for just such a religious exemption and obtained one.

In short, based on this analysis, all roads effectively lead to rational basis review: *Jacobson* as a precursor to or stand-alone iteration of it, the modern tiers of constitutional scrutiny, the unconstitutional conditions doctrine, and the First Amendment as applied through the Fourteenth Amendment to this state actor. And to this road once traveled the court now turns.

4. *On This Preliminary Record, Non-Exempt Students Haven't Shown a Likelihood of Success on their Claim that Indiana University Lacks a Rational Basis for Its Vaccine Mandate.*

Determining that the students have a liberty interest under the Fourteenth Amendment's due process clause doesn't end the analysis. *See Cruzan*, 497 U.S. at 278. To decide whether the students' constitutional rights have been violated, or more appropriately whether they are likely to succeed on such a claim, the court must balance their liberty against the relevant state interests in accord with the Constitution. *See id.* Two students aren't exempt from the COVID-19 vaccine mandate: Natalie Sperazza and Margaret Roth. They assert a right to refuse the vaccine, saying the mandate infringes on their bodily autonomy and medical privacy.

"Stemming the spread of COVID-19 is unquestionably a compelling interest." *Cuomo*, 141 S. Ct. at 67 (majority opinion). According to the federal government and the State of Indiana, a state of emergency persists related to COVID-19, all the while restrictions are being scaled back gradually. Recognizing today's status of this pandemic, neither health professionals, government representatives, nor this court may say public health *vis-à-vis* COVID-19 has waned from being a legitimate state interest. Improved it undoubtedly has—today seems a world altogether different from last year—but public health remains a legitimate interest of the state to pursue. Indiana University too has a legitimate interest in promoting the health of its campus communities—students, and not least the faculty and staff who come daily in contact with them.

The students argue that the pandemic is basically over, but this goes against current proclamations from the Secretary of Health and Human Services, the Indiana State Department of Health, Governor Eric Holcomb, and the CDC, all then supported for institutions of higher learning by the U.S. Department of Education and the American College Health Association.[76] In Indiana (and nationally), the trend line remains sharply down (since winter) in terms of both new cases and deaths, though the recent snapshot of seven-day lookbacks proves nearly triple what it was just when this case commenced.

[76] *See, e.g.*, U.S. Dep't of Educ., *ED COVID-19 Handbook, Volume 3: Strategies for Safe Operation and Addressing the Impact of COVID-19 on Higher Education Students, Faculty, and Staff* 9 (June 2021), available at [Ex. 116 at 7], https://www2.ed.gov/documents/coronavirus/reopening-3.pdf ("COVID-19 vaccination is the leading prevention strategy [institutions of higher learning] can use to return to normal operations."); Am. College Health Ass'n, *ACHA Guidelines: American College Health Association Recommends COVID-19 Vaccination Requirements for All On-Campus College Students in Fall 2021* (Apr. 29, 2021), https://www.acha.org/ACHA/About/ACHA_News/ACHA_Recommends_COVID-19_Vaccination_Requirements_for_Fall_2021.aspx. Though it appears many public universities, including those in the State of Indiana, are ACHA members, Indiana University is not. The guidance is nonetheless pertinent here.

It isn't unreasonable to believe that, absent concerted vaccination, the fall and winter months will prove more arduous than these summer months for the university [Ex. 129 at 32]. Vastly improved, yes; out of the woods we aren't, not on this preliminary record.

The students argue that the bell curve that depicts ongoing cases and deaths from this pandemic's outset mirrors the CDC's continuum of pandemic phases that directs more conservative measures, not more draconian ones [*see*, *e.g.*, Exs. 212, 222, 230-231]. The students call this pandemic in the "deceleration" or "preparation" intervals—terms of art that define its waning stages. Deceleration occurs when state or local health officials rescind community mitigation measures because no new cases are occurring or are occurring infrequently; and preparation occurs when the pandemic is declared ended because evidence indicates that the disease is transitioning to seasonal patterns of transmission [Ex. 231]. The overall trend line may well support a seeming deceleration [*cf.* Exs. 222, 319]; but Indiana University insisting on vaccinations for its campus communities is rationally related to ensuring the public health of students, faculty, and staff this fall. Even under the university's pandemic and infectious disease action levels [Ex. 212], the university must continue to consult CDC and Indiana State Department of Health standards; and those today favor vaccination.

Let's not forget why we are here at this more promising stage of the pandemic, July 18, 2021. Antibody resistance developed naturally from prior cases has been a contributor to be sure; but, materially, improvement has come because of vaccinations—nationally over 161 million complete (over 337 million doses) and statewide nearly 3 million complete (and over 5.7 million doses). The vaccination campaign has markedly

curbed the pandemic. In fact, certain age-stratified, agent-based modeling of COVID-19 has concluded that another 279,000 deaths and nearly 1.25 million more hospitalizations would have occurred by the end of June 2021 but for the vaccines.[77] Stemming illness, hospitalizations, or deaths at the university level hardly proves irrational.

It isn't a foregone conclusion that this is overkill. This pandemic continues to evolve, and medicine and science with it. Science is a process in search of fact. One such moving target is the Delta variant (B.1.617.2). A mere four days ago Indiana reported 612 COVID cases—the highest count in more than six weeks (since May 27, 2021)—that health officials attributed largely to the Delta variant and the unvaccinated population. Though this daily case count is much lower than at the pandemic's height, the CDC, Indiana's State Department of Health, and epidemiologists have identified the Delta variant of particular lingering concern.[78] The CDC labeled Delta a "variant of concern" in mid-June.[79] Current science shows it more virulent and transmissible. A peer-reviewed study from scientists (issued July 8, 2021) found that the Delta variant has mutations that allow it to evade certain natural antibodies, with vaccination proving the best protection [Ex.

[77] *See* Alison Galvani *et al.*, *Deaths and Hospitalizations Averted by Rapid U.S. Vaccination Rollout* (Commonwealth Fund, July 2021), https://doi.org/10.26099/wm2j-mz32.

[78] *See* Shari Rudavsky, *Delta Variant on the Rise in Indiana, State Health Officials Say*, IndyStar (July 9, 2021, 12:58 PM), https://www.indystar.com/story/news/health/2021/07/09/covid-delta-variant-rise-indiana-state-health-officials-say/7908502002/ ("Not only is the Delta variant more readily transmitted from person to person, there's some indication it may cause more severe disease, said Indiana State Health Commissioner Dr. Kris Box.").

[79] *See See* CDC, *SARS-CoV-2 Variant Classifications and Definitions* (July 13, 2021), https://www.cdc.gov/coronavirus/2019-ncov/variants/variant-info.html.

319].[80] Reports of surges of Delta cases among the 12-29 age group have occurred.[81] For now, Indiana University has reasonably concluded that the safety and public health of its campus communities can be augmented by the vaccines [*id.*]. *See Gonzales*, 550 U.S. at 163 (citing *Jacobson*, 197 U.S. at 30-31) (the law gives "wide discretion to pass legislation in areas where there is medical and scientific uncertainty").

Indiana University reasonably believes the vaccine promotes the safety of not only its students, but that of its entire community. This wasn't (and still isn't) a decision taken lightly. It wasn't a decision reached overnight. It wasn't a decision taken by some fly-by-night committee undetached from the current science, the current progress of the fight

A recent United Kingdom study, albeit still abstracted, concluded that most Delta infections in a younger group (age 5-49) occurred in the unvaccinated population. *See* Steven Riley *et al.*, *REACT-1 Round 12 Report: Resurgence of SARS-CoV-2 Infections in England Associated with Increased Frequency of the Delta Variant*, medRxiv (June 21, 2021) (not peer-reviewed pre-print), https://www.medrxiv.org/content/10.1101/2021.06.17.21259103v1.

against the pandemic, or experience and training in relevant fields of study. The restart committee was led by Indiana University's Executive Vice President for University Clinical Affairs and the School of Medicine's Dean. The committee consisted of seven MDs, some with additional degrees in public health or other PhDs, and others with graduate degrees in public health, risk mitigation, law, and ethics [Ex. 300 at 5]. Of its 15 members, two were deans of public health and others were experts in public health, epidemiology, virology, and other relevant areas of the health sciences, including health equity [Ex. 116 ¶ 23]. The committee met regularly and considered a wide variety of sources and information [*id.* ¶ 24].

A mere sampling of presentations from committee meetings from December 8, 2020 to April 6, 2021 [Exs. 302-317] shows the committee focused on COVID-19 evolution; EUA data; reactogenicity data; communications with the Indiana State Department of Health; CDC guidelines and updates; university-wide surveillance testing and data; data trends based on vaccinated and unvaccinated individuals; on-campus and off-campus transmission events; morbidity and mortality figures; efficacy of mitigation efforts on and off campus; international, national, state, county, and school vaccine uptake data; vaccine efficacy against variants; vaccine risk data; vaccine hesitancy surveys and campus opinion polling; and policies and requirements of other universities across the country [*see also* Ex. 301 ¶ 2]. In addition, four MDs from this committee presented near-weekly from December 2020 to June 2021 to Indiana University's Executive Academic Leadership Council, including the President and Executive Vice Presidents as part of the medical response team's ongoing COVID-19 evaluation efforts [*Id.* ¶ 5]. The process ultimately

filtered through the judgment of the Board of Trustees. This was a deliberative decision based on a wealth of scientific, medical, empirical, and industry-wide data.

For the impact of this vaccine mandate, the students focus only on the student body; and that is certainly an important part of the analysis here. The students argue that the fatality rate for healthy individuals age 20-49 is far less than older individuals [*see*, *e.g.*, Ex. 117 at 21-24; Ex. 243]. Dr. McCullough calls the mortality rate 0.15 percent [Ex. 241 ¶ 3]. He testifies that 16 deaths of young adults (aged 18-29) occurred in 2020, but none thus far in 2021 [Ex. 117 ¶ 34]. The students point out that the university's student body had one death last year [*id.* ¶ 25]. Indiana University reasonably views a 0.15 percent death rate as unacceptable for its communities, particularly given the safe preventative measure of a vaccine [Ex. 319 ¶ 4]. At approximately 90,000 students, that rate would risk 135 student lives, not accounting for other mitigation efforts to the better or those with immunocompromising conditions to the worse. The university's student population is not a homogenous group of just young healthy adults [*id.*].

In addition, the student's position overlooks the larger Indiana University community. Dr. McCullough, in fairness, takes a wider snapshot yet, pointing to a longitudinal serosurvey (blood sampling) of community residents near Pennsylvania State University suggesting that students' return in August 2020 had limited transmissible effect on the local community [Ex. 117 ¶ 29-30].[82] But Indiana University's perspective was more intimate. The university analyzed the number of individuals

[82] *See* Callum R. K. Arnold *et al.*, *SARS-CoV-2 Seroprevalence in a University Community: A Longitudinal Study of the Impact of Student Return to Campus on Infection Risk Among Community Members*, medRxiv (Feb. 14, 2021) (non-peer reviewed pre-print), https://pubmed.ncbi.nlm.nih.gov/33619497/.

within its campus population known to have increased risk factors for COVID-19 and determined that over 8,500 faculty and staff remained at increased risk of complications if they contracted the disease [Ex. 116 ¶ 26], with the ongoing risk of asymptomatic spread that vaccines help address [Ex. 129 at 53-54]. Faculty and staff at Indiana University who have daily contact with students represent an even broader demographic than just the student body, and this policy was intended to protect them too. The court credits Dr. Carroll and Dr. Beeler over Dr. McCullough on this point given their firsthand knowledge of Indiana University's specific circumstances.

The university's policy has broad support within its community. As of June 25, 2021, over 42,000 students had received the vaccine; and that number has no doubt grown [Ex. 116 ¶ 46]. Two university faculty councils—elected representative bodies interested in the quality of learning and student life—issued statements in support [*id.* ¶ 47]. The staff council at Indiana University's main campus in Bloomington likewise endorsed the policy [*id.* ¶ 49]. The graduate and professional student government also issued a resolution supporting the policy [*id.* ¶ 50]. Eight students have filed this lawsuit, and perhaps others await this ruling to decide. Under the circumstances, on this preliminary record, the law respects the right of this university community to self-govern reasonably.

To that point, no one has argued that Indiana University's policy is *ultra vires*. Indiana's General Assembly endowed the university's Board of Trustees to act in the "best interests of the state and the state educational institution," Ind. Code § 21-40-3-1(b), including the power "to prevent unlawful or objectionable acts that . . . violate the reasonable rules and standards of the [university] designed to protect the academic

community from . . . conduct presenting a serious threat to person or property of the academic community," Ind. Code § 21-39-2-3(b). The university remains answerable to the legislature, particularly its coffers.

The Indiana General Assembly has prohibited a vaccine passport in this state, but not a vaccine requirement. *See* Ind. Code § 16-39-11-5. Still, in assessing the reasonableness of vaccination mandates, the law considers underlying legislative authority. *See Zucht*, 260 U.S. at 175; *Jacobson*, 197 U.S. at 12-13; *see also Washington*, 494 U.S. at 221-22 (recognizing liberty interest under both state's policy and due process clause, but "no greater right than that recognized under state law"). On this preliminary record, Indiana University faces still an "objectionable" and "serious threat" to the "academic community" that its vaccination policy seeks reasonably to address for campus health. *See Zimmerman v. Bd. of Trustees of Ball State Univ.*, 940 F. Supp.2d 875, 890-91 (S.D. Ind. 2013) (defining "objectionable"). This is consistent with the Fourteenth Amendment.

Focusing on just mortality risk from COVID-19 leaves out much of the debate. Dr. McCullough and Dr. Beeler (with Dr. Carroll), for instance, offer competing views on the risks of the novel coronavirus and the risks of the vaccines [Exs. 115-117, 222, 319].[83] This is precisely the debate of medical professionals that state policymakers, including

[83] The experts at times debate relatively modest side effects from vaccines after natural infection (*e.g.*, fever or fatigue), but these are self-limited and not dangerous [Ex. 319 ¶ 6], so the court addresses them no more here. Even Dr. McCullough admits that other longstanding vaccines, including those mandated by state law, have common side effects, such as a risk of a fever [Ex. 117 ¶ 56].

authorized arms of the state, are best suited to resolve in setting policy for constituents, including here for the students at Indiana University.

Without vaccination, college-aged students remain at risk for serious long-term complication from COVID-19, including prolonged debilitating symptoms that interfere with normal life such as myocarditis, reduced aerobic capacity, and brain damage [Ex. 319 ¶ 5].[84] Long COVID remains a studied phenomenon. With Indiana reporting that individuals aged 20-29 have had more positive cases than any other age demographic [Ex. 115 ¶ 14], and with more than 260,000 cases linked to American college and universities since January 1, 2021 [*id.* ¶ 17], this proves still a legitimate risk.[85] Focusing only on mortality disregards the serious compromise to the quality of life that face some students who contract the virus [*see also id.* ¶ 10-11].

The students say the risks of the vaccine, especially at this stage and to their age group, outweigh any benefits a vaccine might confer. These argued risks include

---

[84] *See* Mark W. Tenforde *et al.*, *Symptom Duration and Risk Factors for Delayed Return to Usual Health Among Outpatients with COVID-19 in a Multistate Health Care Systems Network — United States, March–June 2020*, 69:30 Morbidity and Mortality Weekly Report 993, 997-98 (July 24, 2020), https://www.cdc.gov/mmwr/volumes/69/wr/mm6930e1.htm?s_cid=mm6930e1_w ("Nonhospitalized COVID-19 illness can result in prolonged illness and persistent symptoms, even in young adults and persons with no or few chronic underlying medical conditions."); Giovanni Andrea Gerardo Crameri *et al.*, *Reduced Maximal Aerobic Capacity after COVID-19 in Young Adult Recruits, Switzerland, May 2020*, 25(36) Euro. [85] The New York Times has tracked coronavirus cases at American college and universities, though its numbers have not been seemingly updated since May 26, 2021. *See* The New York Times, *Tracking Coronavirus Cases at U.S. Colleges and Universities*, https://www.nytimes.com/interactive/2021/us/college-covid-tracker.html (last visited July 18, 2021).

myocarditis, clotting, death, and others [Ex. 117 ¶ 48-49]. Some of these concerns are easier to assuage based on current science than others—and the court isn't the final arbiter of an evolving science, only of the law. The court must base today's decision on the snapshot of this preliminary record alone. It answers the question only whether the students have made a strong showing that Indiana University failed to act reasonably in achieving campus health to warrant the extraordinary remedy of a preliminary injunction.

That said, Dr. Beeler concludes that with millions of people getting the vaccine, experts "have [a] much tighter lens than we normally would for any other vaccine in history to identify some of those extremely rare concerns" [Ex. 128 at 80], and that younger people have a "higher probability" of facing issues with COVID-19 infection than after vaccination [*id.* 78]. All vaccine manufacturers conducted Phase 3 trials for EUA that never revealed the risks the students have presented [*id.* 79].

Since then, reports have shown the risk of myocarditis (heart inflammation), while present and something worthy of continued investigation, to be seemingly rare—one study suggesting the risk is about eight in one million and the other study suggesting the risk is about twenty in one million.[86] This issue has garnered increasing attention. The FDA reported CDC data (through May 31, 2021) of 475 cases of myocarditis (heart inflammation) and pericarditis (inflammation of membrane around heart) in vaccinated

[86] *See* Han W. Kim *et al.*, *Patients with Acute Myocarditis Following mRNA COVID-19 Vaccination*, JAMA Cardiol (June 29, 2021), https://jamanetwork.com/journals/jamacardiology/fullarticle/2781602; Israeli Ministry of Health, *Surveillance of Myocarditis (Inflammation of the Heart Muscle) Cases Between December 2020 and May 2021* (Feb. 6, 2021), https://www.gov.il/en/departments/news/01062021-03.

individuals age 30 and younger [Ex. 117 ¶ 49].[87] This data came from the Vaccine Adverse Event Reporting System (VAERS)—anecdotal data that, while important to analyze, requires further investigation before drawing conclusions. *See*, *e.g.*, *Rider v. Sandoz Pharm. Corp.*, 295 F.3d 1194, 1199 (11th Cir. 2002) ("case reports alone ordinarily cannot prove causation"); *Glastetter v. Novartis Pharms. Corp.*, 252 F.3d 986, 989-90 (8th Cir. 2001) ("causal attribution based on case studies must be regarded with caution").[88] Still, on June 24, 2021, a CDC safety panel reported a "likely association" in young adults from mRNA COVID-19 vaccines and myocarditis and pericarditis, though it emphasized that it remained rare and typically mild, with the benefits of the vaccine still outweighing the risks [Ex. 117 ¶ 51].[89] This assessment of heart inflammation's rarity and the overarching benefits of the vaccines has a bench of current medical support on this record,[90] again

Rosner *et al.*, *Myocarditis Temporally Associated with COVID-19 Vaccination*, Circulation (June 16, 2021) (manuscript only), https://www.ahajournals.org/doi/10.1161/CIRCULATIONAHA.121.055891 ("[N]o data are available specific to vaccine-associated myocarditis. The clinical course of vaccine-associated myocarditis-like illness appears favorable, with resolution of symptoms in all patients. Given the potential morbidity of COVID-19 infection even in younger adults, the risk-benefit decision for vaccination remains highly favorable."); Mayme Marshall *et al.*, *Symptomatic Acute Myocarditis in Seven Adolescents Following Pfizer-BioNTech COVID-19 Vaccination*, 148(1) Pediatrics (July 2021) (peer-reviewed case report) https://pediatrics.aappublications.org/content/early/2021/06/04/peds.2021-052478 ("This report summarizes a series of US cases of myocarditis and myopericarditis following the Pfizer-BioNTech COVID-19 mRNA vaccine in adolescent males . . . . At present, there is no definite causal relationship between these

giving Indiana University a rational connection between its mandate and its aim of campus health. This proves no less true when contracting COVID-19 (without the vaccine) already presents a risk of myocarditis [Ex. 319 ¶ 5]. No one should blithely dismiss the call for further investigation, but the students' case isn't strong today.

The students argue the temporal association of these risks, but just because the rooster crows doesn't mean he caused the sun to rise. A close review of Dr. McCullough's testimony reveals a true failing. Even he, the students' own tendered expert, a credentialed and board-certified physician in internal medicine and cardiovascular disease, stops short of declaring a causative link between any vaccine and myocarditis. He uses soft and inconsequential language, calling his suspicion "possible" and "unpredictable" [Ex. 117 ¶ 48, 73], not probable or causative to a reasonable degree of medical certainty. *See Harris v. Owens-Corning Fiberglas Corp.*, 102 F.3d 1429, 1433 (7th Cir. 1996) ("mere possibility of . . . causation is not enough"). He says he has examined college-age patients with myocarditis after a vaccine injection [Ex. 117 ¶ 59], but once again never testifies that one was caused by the other. *See Ervin v. Johnson & Johnson, Inc.*, 492 F.3d 901, 904–05 (7th Cir. 2007) ("mere existence of a temporal relationship between taking a medication and the onset of symptoms does not show a sufficient causal relationship").

cases and vaccine administration. . . . The benefits of vaccination significantly exceed possible risks."); Elisabeth Albert *et al.*, *Myocarditis Following COVID-19 Vaccination*, 16(8) Radiology Case Reports 2142, 2144 (May 2021) (case report) https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8130498/ (University of Massachusetts researchers found "small risk" of myocarditis, and concluded that "there is a significantly higher risk of cardiac involvement from COVID-19 infection compared to COVID-19 vaccination" such that "vaccination should remain the cornerstone for population immunity").

With ever evolving COVID-19 science, more will be known tomorrow, next month, and next year; but a courtroom is no place for guesswork today, even if well-inspired. *See Daubert v. Merrell Dow Pharms., Inc.*, 509 U.S. 579, 590 (1993); *Rosen v. Ciba-Geigy Corp.*, 78 F.3d 316, 319 (7th Cir. 1996); *Constructora Mi Casita v. NIBCO, Inc.*, 448 F. Supp.3d 965, 970-71 (N.D. Ind. 2020). Dr. Beeler testifies that "there is no proof of causation between the vaccination and myocarditis" [Ex. 115 ¶ 69]. The court gives Dr. McCullough's testimony little weight on this record.[91] These statements are made with considered humility. The court isn't deciding causation today to be sure. At the same time, the students haven't marshaled strong evidence that would call into legitimate question the reasonableness of the university's actions, or to meet their burden of an extraordinary remedy of a preliminary injunction.

The students return to VAERS to discuss the risk of death from the vaccines. Dr. McCullough says VAERS reported 6,136 deaths after vaccines as of June 18, 2021 [Ex. 117 ¶ 45]. He says VAERS received more adult death reports from COVID-19 vaccines than all other vaccines combined [*id.*]. The students offer an interim abstract from clinically

[91] For additional examples, Dr. McCullough cites one article that "*speculate[s]* that adverse reaction against the COVID-19 vaccine was responsible for the development of myocarditis *due to its temporal relationship*." Tommaso D'Angelo *et al.*, *Myocarditis after SARS-CoV-2 Vaccination: A Vaccine-induced Reaction?*, Can. J. Cardio. (June 9, 2021), https://www.ncbi.nlm.nih.gov/pmc/articles/PMC8187737/ (last visited July 17, 2021) (emphases added). Even then, the authors say "substantial evidences other than temporal aspects still need to be provided to demonstrate the causality[.]" *Id.* Dr. McCullough also cites a Reuters article concerning an Israeli study, rather than the study itself, when the Reuters article appears to overstate the study. For instance, the article refers to 275 cases, but those cases included both COVID-19 exposures and vaccinations. Only 148 cases occurred after vaccination. Even so, the study's authors conclude merely that there is "*some probability for a possible link* between the second vaccine dose and the onset of myocarditis among young men aged 16 to 30," not a probable link. Israeli Ministry of Health, *Surveillance of Myocarditis (Inflammation of the Heart Muscle) Cases Between December 2020 and May 2021* (Feb. 6, 2021), https://www.gov.il/en/departments/news/01062021-03 (emphasis added).

trained reviewers that considered the VAERS data as of April 2021, who grouped the reports as those where the vaccine was most likely not a factor, where it may have been, and where it was the most likely factor [Ex. 254].[92] Of the 250 deaths reported at the time, the reviewers concluded that 13 deaths were most likely caused by vaccines, noting that these individuals had strong reactions soon after vaccination and died the same day or during the next couple days [*id.*], though again temporal anecdotes like these aren't as telling. *See Ervin*, 492 F.3d at 904–05. They warrant further investigation to be sure; but in close review this interim abstract offers no scientific or medical basis for drawing its conclusion. Indeed, when the court asked counsel at oral argument what the basis was for it, he too could offer no explanation [Tr. 34-37]. And more to the point, Dr. McCullough again stops short of testifying that any one reported death in VAERS was caused by a vaccine, despite this interim abstract [Ex. 117 at 21-26]. The students thus haven't presented evidence today demonstrating Indiana University's decision was irrational in pursuing its goal of campus health.

The CDC has explored this issue as well and seems to have marshaled data, at this time, that any risk of death is rarer than the risk of death from a young adult COVID-19 infection. According to the CDC, 25,038,458 individuals aged 18-29 have been given their first dose of the vaccine as of July 18, 2021, with VAERS reporting a total of 68 deaths, or

[92] *See* Scott McLachlan *et al.*, *Analysis of COVID-19 Vaccine Death Reports from the Vaccine Adverse Events Reporting System (VAERS) Database* (June 2021) (not peer-reviewed pre-print), https://www.researchgate.net/publication/352837543_Analysis_of_COVID-19_vaccine_death_reports_from_the_Vaccine_Adverse_Events_Reporting_System_VAERS_Database_Interim_Results_and_Analysis. Dr. Beeler calls this a "reliable study looking at an unreliable system" based on passive reports unvalidated by studies and unconfirmed data [Ex. 128 at 124-25].

approximately 0.00027 percent, if in fact any are related.[93] Alternatively, of the 6,174,415 cases of COVID-19 in this age group, 2,732 died, or approximately a 0.04 percent.[94] In balancing the risks,[95] Indiana University wasn't irrational in favoring the route that promoted greater safety for its students.

The experts disagree over the relative risk of asymptomatic transmission (and indeed over many scientific conclusions), with the students contending that transmission from asymptomatic infections is "trivial and inconsequential" [Ex. 117 ¶ 26-27],[96] and the university pointing to its own experience and national trends indicating that asymptomatic transmission is "certainly still very possible" [Ex. 115 ¶ 52].[97] As with any

new pathogen, scientific understandings of the character and risks of transmission are ever evolving, but a review of the balance of the current peer-reviewed research and other literature presented by the parties suggest that asymptomatic transmission, while less prevalent than symptomatic transmission, routinely occurs. Naturally, this conclusion may change as scientists continue to study the virus and population transmission events.

Other risks exist or may become known. For instance, the FDA warns of the potential for blood clots, reported the most in females ages 18-49, but calls this risk "remote."[32] Just four days ago, the FDA added a warning to its fact sheet for the Janssen COVID-19 vaccine that Guillain-Barré syndrome (a neurological disorder in which the body's immune system damages nerve cells and causes muscle weakness and sometimes paralysis) has occurred in some people who have received the vaccine. The FDA calls this risk "very low."[98] In contrast, Dr. Beeler testifies that brain damage proves a risk from COVID-19 without a vaccine [Ex. 319 ¶ 5], as do several neurological diagnoses, particularly for those hospitalized by a COVID-19 infection.[99] The risks aren't all one-

[99] *See, e.g.*, Maxime Taquet *et al.*, *6-Month Neurological and Psychiatric Outcomes in 236,379 Survivors of COVID-19: A Retrospective Cohort Study Using Electronic Health Records*, 8 Lancet Psychiatry 416-27 (published online April 6, 2021), https://www.thelancet.com/journals/lanpsy/article/PIIS2215-0366(21)00084-5/fulltext (though calling for more data, concluding that the "severity of COVID-19 had a clear effect on subsequent neurological diagnoses"). In fairness, this same study said whether COVID-19 was associated with Guillain-Barré syndrome "remains unclear."

sided, but the wealth of data and studies on which Indiana University has relied makes the likelihood that the students will prevail on their claim here quite low.

Don't forget that vaccines generally aren't without medical risks. In 1993, the Indiana General Assembly required that all public university students receive vaccinations for five conditions, *see* Ind. Code § 20-12-71-11, which it later amended in 2007 to add one more, *see* Ind. Code § 21-40-5-2. Today that required list covers diphtheria, tetanus, measles, mumps, rubella, and meningococcal disease. Early diphtheria vaccines began in the 1920s, with more recent vaccines being developed in the 2000s. Tetanus vaccines were introduced in the late 1940s. The first measles vaccine was developed in 1963, with the MMR vaccine licensed for use in 1971. The MMRV vaccine (which protects against measles, mumps, rubella, and varicella) was licensed in 2005 per the CDC. The first meningitis vaccine was licensed in 1974 in the United States, but more modern vaccines were licensed in 2005, 2012, and then 2015. Risks of these vaccines are varied, including more minor issues of fever or headache to more serious concerns of seizure or death, though frequently low risks.

To be sure, EUA of the COVID-19 vaccines occurred on a tighter timetable and has existed only since December 2020 and February 2021. The students thus voice concerns about the experimental nature of the vaccines, though their counsel assures that their suit will persist even if the FDA grants the vaccine manufacturers full approval. Not all EUAs are equal, and the one required for COVID-19 vaccines was more robust than usual.

For an EUA to issue, the U.S. Department of Health and Human Services (HHS) must first conclude that the biological threat identified in the emergency declaration "can

cause a serious or life-threatening disease or condition[.]" 21 U.S.C. § 360bbb-3(c)(1). Additionally HHS must conclude, "based on the totality of scientific evidence available to the Secretary, including data from adequate and well-controlled clinical trials, if available, it is reasonable to believe" the new product is effective in diagnosing, treating, or preventing the disease and "the known and potential benefits of the product . . . outweigh the known and potential risks of the product, taking into consideration the material threat posed" by the public health emergency. 21 U.S.C. § 360bbb-3(c)(2). Further, there must be "no adequate, approved, and available alternative to the product" and the product must comport with "other criteria as the Secretary may by regulation prescribe." 21 U.S.C. § 360bbb-3(c)(3)-(4).

In addition to these criteria, HHS must ensure medical providers are informed of the product's EUA status, the "significant known and potential benefits and risks of the . . . product, and of the extent to which such benefits and risks are unknown," and the availability, risks, and benefits of alternative products. 21 U.S.C. § 360bbb-3(e)(1)(A)(i)(I)-(III). HHS must ensure that individuals who receive the product are informed of the product's EUA status, the "significant known and potential benefits and risks of such use, and of the extent to which such benefits and risks are unknown," and "of the option to accept or refuse administration of the product, of the consequences, if any, of refusing administration of the product, and of the alternatives to the product that are available and of their benefits and risks." 21 U.S.C. § 360bbb-3(e)(1)(A)(ii)(I)-(III). For these reasons, those who go to get these vaccines receive fact sheets from the FDA.

The impetus behind issuing an EUA, as opposed to going through the process for full FDA approval, comes from the urgency required. The standard process for vaccine approval requires a manufacturer to demonstrate compliance with statutory, regulatory, and agency standards. *See* 42 U.S.C. § 262(j); 21 U.S.C. § 355(b)(1)(A); 21 C.F.R. §§ 601.2(a), 600.3(n), (p). Among other things, a manufacturer must conduct various studies, including clinical trials, to prove that the vaccine is safe for use and is effective. 21 U.S.C. § 355(b)(1)(A)(i); 21 C.F.R. § 600.3(s). These trials must be complete before an application can be submitted; indeed for COVID-19, the FDA requires manufacturers to collect and include any data from severe adverse events for six months after the trials conclude.[100] Though this process is designed to ensure safe vaccines for public use, it can take an average of ten years to go from a mere idea to an approved vaccine.[101] This can occur more quickly too; indeed, just two days ago, the FDA granted priority review of one vaccine, reportedly meaning that full approval from the FDA could come as soon as early next year.[102]

On the other hand, as opposed to waiting until clinical trials conclude, an EUA allows a manufacturer to apply using interim clinical trial data, and the data need only

[100] 21 U.S.C. § 355(b)(1)(A)(i); 21 C.F.R. § 601.2(a), (e); § 601.20(a); *see also* FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* (June 2020); FDA, *Vaccine Development 101*, https://www.fda.gov/vaccines-blood-biologics/development-approval-process-cber/vaccine-development-101 (last visited July 13, 2021).

demonstrate the product "may be effective" and the known and potential benefits outweigh the known and potential risks.[103] Additionally, distribution and testing can occur simultaneously.[104] Although at first blush, the efficiency of an EUA may seem to risk the greater surety of safety and efficacy, the statute anticipates the FDA will impose additional obligations beyond those enumerated. *See* 21 U.S.C. § 360bbb-3(e)(1)(B).

In October 2020, the FDA released industry guidance detailing the benchmark criteria for a COVID-19 vaccine to receive an EUA.[105] Though not legally binding,[106] the industry guidance acknowledged that a COVID-19 vaccine was a "complex biological product[] . . . intended to be administered to millions of individuals, including healthy people, to prevent disease . . . [and has] the potential for broad use under an EUA."[107] Because the virus would only be overcome through the sweeping immunity of the American public, the FDA informed manufacturers that approval would be given to

[106] An industry guidance does not have the force of law, as it does not go through the rulemaking process. However, an industry guidance informs a manufacturer of the criteria the FDA would consider sufficient to receive approval pursuant to their statutory authority. *See, e.g.*, FDA, *Rules, Regulations and Guidance*, https://www.fda.gov/tobacco-products/products-guidance-regulations/rules-regulations-and-guidance (last visited July 18, 2021) (describing industry guidance as informing the tobacco industry of "pathways to legally market new tobacco products").

[107] FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* at 2.

those EUA applications that went beyond the safety and efficacy requirements prescribed by statute, and also expected manufacturers to consult with the FDA on the various non-clinical components of vaccine development and distribution as the clinical trial progressed.[108] The FDA wanted the same level of efficacy data as for full approval, enough safety data to justify providing the vaccine to healthy individuals, and confirmation of the technical procedures and verification steps necessary to support full approval.[109]

Thus, manufacturers were expected to submit "adequate manufacturing information to ensure its quality and consistency" as well as "data from at least one well-designed Phase 3 clinical trial that demonstrates the vaccine's safety and efficacy in a clear and compelling manner"—a heightened bar from the "may be effective" standard prescribed by statute—while still allowing the manufacturers to complete their trials for full authorization.[43] The FDA "strongly encourage[d]" manufacturers to provide interim data and analyses before applications were submitted, and noted that requirements described were "essential to ensure that clinical development of a COVID-19 vaccine has progressed far enough that issuance of an EUA for the vaccine would not interfere with the ability of an ongoing Phase 3 trial to demonstrate effectiveness of the vaccine to support licensure and to continue safety assessments[.]"[43]

---

[108] *See* FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* 6-7, 9 (October 2020); 21 U.S.C. § 360bbb-3(c).

[109] FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* 4, 9 (October 2020).

Although the FDA directs manufacturers to present evidence of efficacy that meet the standards necessary to receive full approval,[43] a key distinction between EUA and full approval remains. To receive full approval for a COVID-19 vaccine, a manufacturer must monitor and submit evidence of "serious and other medically attended adverse events in all study participants for at least 6 months after completion of all study vaccinations."[110] However, for an EUA, the manufacturer may submit its safety data based on a median two-months follow-up for every individual who completed the vaccine regimen.[111] The FDA concluded that a "2-month median follow-up (meaning that at least half of vaccine recipients in clinical trials have at least 2 months of follow-up) after completion of the full vaccination regimen will allow identification of potential adverse events that were not apparent in the immediate postvaccination period and will also provide greater confidence in their absence, if none are observed."[112] Based on its experience with vaccine studies and approvals, the FDA concluded that "adverse events considered plausibly linked to vaccination generally start within 6 weeks after vaccine receipt," regardless of the type of vaccine received, and thus the median two-month follow-up was justified "by extensive historical experience with adverse events after vaccination, the need for a vaccine to address the current pandemic, and the magnitude of vaccine effectiveness that will be required to support a favorable benefit–risk profile

[110] FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* 15 (June 2020).

[111] *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* 10 (October 2020).

[112] Philip R. Krause & Marion Gruber, *Emergency Use Authorization of Covid Vaccines – Safety and Efficacy Follow-up Considerations*, 383 N. Engl. J. Med. e107(2) (Nov. 5, 2020). Dr. Marion Gruber is the director and Dr. Phillip Krause is the deputy director of the Office of Vaccines Research and Review at the FDA.

for use of a Covid-19 vaccine under an EUA."[111] Thus, in setting these stringent expectations, the FDA invited EUA applications only for vaccines positioned well to receive full approval.[113]

The statute grants the agency flexibility to impose additional requirements necessary to meet the safety and efficacy concerns despite the urgency of a public health emergency. The agency understood that a vaccine designed to be given to hundreds of millions of Americans, healthy and otherwise, required significant safety and efficacy data for approval. The consequences of skimping on these steps, or even adhering to the statutory-minimum requirement of potential effectiveness, was too great; so the FDA directed manufacturers to present evidence of efficacy that led to standards necessary to receive full approval. And true, though the safety follow-up necessary to receive an EUA is much shorter than would otherwise be required, the FDA made this conclusion based on its expert assessment and experience that significant latent negative outcomes associated with vaccinations traditionally occur within six weeks of receipt.[114]

Indiana University closely considered the FDA's EUA requirements when adopting its policy. The specialists on the university restart committee appreciated that

---

[113] The industry guidance has since been superseded twice, once in February 2021 and once in May 2021. FDA, *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* (May 2021). Pfizer, Moderna, and Johnson & Johnson's applications were submitted in accordance with the October 2020 guidance, *see* FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Pfizer-BioNTech)* (2020) (application submitted November 20, 2020); FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Moderna)* (2020) (application submitted November 30, 2020); FDA, *Emergency Use Authorization (EUA) for an Unapproved Product Review Memorandum (Janssen)* (2021) (application submitted February 4, 2021).

[114] Philip R. Krause & Marion Gruber, *Emergency Use Authorization of Covid Vaccines – Safety and Efficacy Follow-up Considerations*, 383 N. Engl. J. Med. e107 (Nov. 5, 2020).

all three COVID-19 vaccines had been "studied in robust multi-centered, international, randomized-controlled trials and proven both effective and safe in millions of people" [Ex. 115 ¶ 60; *see also* Ex. 115 ¶ 24, 61-69]. These specialists explained that the EUA vaccines had been based on technology that has been studied for decades [*id.* ¶ 87]. Though even "small differences in chemical structure can sometimes make very large differences in the type of toxic response that is produced," *McClain v. Metabolife Intern, Inc.*, 401 F.3d 1233, 1246 (11th Cir. 2005); *accord Glastetter*, 252 F.3d at 990, much like the FDA, the university concluded that campus safety reasonably outweighed any lingering risks with the vaccines. This wasn't just any ordinary EUA process, but EUA on proverbial steroids. The university reasonably concluded that the "benefit dwarfs the potential rare risks" [Ex. 115 ¶ 87].

Progress has been made because of the vaccine, not despite it. To the extent that lingering medical and scientific debate remain on this record, the court remains resolved that Indiana University has acted reasonably here in pursuing public health and safety for its campus communities [*cf.* Exs. 115, 116].[115] *See Gonzales*, 550 U.S. at 163 (state

[115] For instance, Dr. McCullough says the vaccine manufacturers "skipped testing" for genotoxity, mutagenicity, teratogen[i]city, and oncogenicity" [Ex. 117 ¶ 36]. Dr. Beeler explains that this claim, including the suspicion about mutagenesis, takes a "backwards view of how RNA works in the cell and [is] not currently supported by consensus opinion" [Ex. 115 ¶ 64]. Concerns about the impact of a vaccine on fertility are largely addressed by the policy because Indiana University allows exemptions for pregnant women [Ex. 115 ¶ 86]. Naturally, truly measuring the impact of any intervention, or disease for that matter, on overall fertility to any degree of certainty requires longitudinal and perhaps even generational studies. Even under the FDA's full approval requirements for a COVID-19 vaccine, a manufacturer is not required to submit data on the long-term impact on overall fertility in the population to receive approval. FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* 7 (June 2020). Instead, the agency recommends conditioning the enrollment of pregnant women and "women of childbearing potential who are not avoiding pregnancy" in a clinical trial on the completion of Developmental and Reproductive Toxicology (DART) studies. FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* 7, 11 (June 2020). A similar recommendation appears in the EUA guidance. *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* 9 (October 2020). Though DART

legislatures have "wide discretion to pass legislation in areas where there is medical and scientific uncertainty"); *Zucht*, 260 U.S. at 176 ("municipality may vest in its officials broad discretion in matters affecting the application and enforcement of a health law").

Today, Indiana University has a rational basis to conclude that the COVID-19 vaccine is safe and efficacious for its students. The vaccine has been used on about 157 million Americans; and data now about eight months later, though it will grow more robust in years to come, is considerable and shows major side effects are rare. Much like over 500 universities and colleges in the United States that have done the same,[116] Indiana

studies review many components of fertility and pregnancy in animal models, FDA, *S5(R3) Detection of Reproductive and Developmental Toxicity for Human Pharmaceuticals Guidance for Industry* (May 2021), the application of these studies to the approval or a COVID-19 vaccine relate to the testing, marketing, and use of vaccines in pregnant women and in women who could imminently become pregnant, *see* FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* 7, 11 (June 2020); *Emergency Use Authorization for Vaccines to Prevent COVID-19: Guidance for Industry* 9 (October 2020). And though DART studies in animals certainly shed light on greater concerns about fertility and are important, full vaccine approval is not conditioned on fertility studies in women or men. *See id.* Instead, the impact of a vaccine on pregnancy and pregnancy outcomes in women is a vital post-approval safety assessment. *see* FDA, *Development and Licensure of Vaccines to Prevent COVID-19: Guidance for Industry* 17 (June 2020). Moderna and Johnson & Johnson submitted DART studies as part of their EUA applications. Both manufacturers identified no fertility or development concerns based on these studies. FDA, *Vaccines and Related Biological Products Advisory Committee December 17, 2020 Meeting Presentation – Emergency Use Authorization (EUA) Application for mRNA-1273* (Dec. 17, 2020); Janssen Biotech, Inc, *Vaccines and Related Biological Products Advisory Committee Meeting February 26, 2021* (Feb. 26, 2021). Pfizer submitted DART results after its EUA was granted. The studies showed the vaccine did not impact female fertility or development, albeit in rats. Christopher J. Bowman *et al.*, *Lack of Effects on Female Fertility and Prenatal and Postnatal Offspring Development in Rats with BNT162b2, a mRNA-based COVID-19 Vaccine*, 103 Reproductive Toxicology 28 (Aug. 2021).

[116] Andy Thomason and Brian O'Leary, *Here's a List of Colleges That Will Require Students or Employees to Be Vaccinated Against Covid-19*, The Chronicle of Higher Education (July 15, 2021), https://www.chronicle.com/blogs/live-coronavirus-updates/heres-a-list-of-colleges-that-will-require-students-to-be-vaccinated-against-covid-19?cid2=gen_login_refresh ("*The Chronicle* has so far identified 583 such campuses."). Generally, courts "should not invade the domain of local authority except when it is necessary to do so" to enforce fundamental rights. *Jacobson*, 197 U.S. at 38. In addition to the Fourteenth Amendment's protections, a wide variety of states have enacted legislation relating to vaccine mandates or vaccine documentation, including Ohio just this last week. *See* 2021 Bill Text OH H.B. 244, Sec. 3792.04(B)(1) (signed into law on July 14, 2021); *cf., e.g.,* Ark. Code Ann. § 20-7-142 (prohibiting vaccine mandate); Fla. Stat. § 381.00316 (prohibiting governmental entities from requiring COVID-19 vaccination documentation and prohibiting educational institutions from requiring that students provide COVID-19 vaccination documentation); 2021 Bill Text CA A.B. 327 (proposed) (bill that would prohibit entities from requiring

University reasonably relies on the vaccine as a measure to return to normal school functioning. The students say the mandate is unreasonable because no other Indiana government agency mandates the vaccine. But just because it has gone above what others have done doesn't make it unreasonable. Indeed, universities are unique places, with lots of people gathered and living together in close quarters for months at a time. That Indiana University's mandate goes beyond what other public universities in Indiana have done doesn't compel a finding that this policy is unreasonable; indeed, other universities in the state have mandated the vaccine, and many others around the country have too.

Indiana University is following the recommendations of other well-established agencies, including the Centers for Disease Control, U.S. Department of Education, and the Indiana State Department of Health. These are reliable sources to assess the reasonableness of measures implemented, though the court must be cautious not to expand the guidance beyond what it says. *See United States v. Newton*, 996 F.3d 485, 489 (7th Cir. 2021); *Mays v. Dart*, 974 F.3d 810, 823 (7th Cir. 2020), *cert. filed*. To be sure, the CDC doesn't recommend that schools "mandate" the vaccine—a point the students make—but such a recommendation isn't consistent with the CDC's purview, which is to act as an informative agency. At the same time, the university's policy isn't inconsistent with the CDC's recommendations. The CDC says institutions of higher learning "can return to full capacity in-person learning, without requiring or recommending masking or physical distancing for people who are fully vaccinated" [Ex. 116 ¶ 12]. The CDC's

COVID-19 vaccination documentation). The court will not overstep into the legislative sphere when the state's or state arm's conduct has complied with the Constitution.

guidance to universities is that "[v]accination is the leading prevention strategy to protect individual from COVID-19 disease and end the COVID-19 pandemic."[117] This will enhance the student body's opportunities, allowing them to have a more fulfilling college experience.

Vaccination helps the university get to herd immunity. As its expert, Dr. Beeler, has said, COVID-19 vaccination is an important tool to help stop the pandemic because widespread vaccination will help achieve "herd immunity," which is when enough people in a community are sufficiently protected from COVID-19 to stem its spread [Ex. 115 ¶ 19-20].[118] To be sure, experts debate whether herd immunity is achievable for COVID-19 [Ex. 115 ¶ 21], but Indiana University rationally believes vaccination is the leading prevention strategy to protect individuals from COVID-19 disease. According to Dr. Beeler, "Indiana has not reached herd immunity" [Ex. 115 ¶ 43; *see also* Exs. 128 at 60, 129 at 23]. As Dr. Beeler explains, "immunity is not static with this virus, and things do change specifically as it relates to variants of concern. . . . The longer that the coronavirus remains in the population, each vulnerable individual that gets infected is the opportunity for further mutations in the virus. And eventually, just by evolutionary theory, the virus will develop ways to bypass the current immune stress" [Ex. 128 at 61]. The mutability of COVID-19 remains higher than other conditions addressed by a single

[117] CDC, *Guidance for Institutions of Higher Education (IHEs)* (last updated June 4, 2021), https://www.cdc.gov/coronavirus/2019-ncov/community/colleges-universities/considerations.html.
[118] *See* CDC, *COVID-19 Vaccines Are Free to the Public* (last visited June 27, 2021), https://www.cdc.gov/coronavirus/2019-ncov/vaccines/no-cost.html; CDC, *Key Things to Know about COVID-19 Vaccines* (last visited June 27, 2021) ("CDC Key Things"), https://www.cdc.gov/coronavirus/2019-ncov/vaccines/keythingstoknow.html.

vaccine, like measles, mumps, and rubella [*id.* at 151-52]. With the variants of concern affecting recent numbers, and based on Dr. Beeler's well-reasoned explanation, the court tends not to credit Dr. McCullough's viewpoint that herd immunity has already been achieved.

Overall, the students' arguments amount to disputes over the most reliable science. But when reasonable minds can differ as to the best course of action—for instance, addressing symptomatic versus asymptomatic virus spread or any number of issues here—the court doesn't intervene so long as the university's process is rational in trying to achieve public health. *See, e.g.*, *Phillips*, 775 F.3d at 542 ("plaintiffs argue that a growing body of scientific evidence demonstrates that vaccines cause more harm to society than good, but as *Jacobson* made clear, that is a determination for the [policymaker], not the individual objectors"). There is a rational basis for making distinctions here. No student, including those not yet exempt, have shown that Indiana University's vaccine mandate as applied to them violates rational basis review. The court thus denies their request to enjoin it preliminarily.

5. *On This Preliminary Record, Exempt Students Haven't Shown a Likelihood of Success on their Claim that Indiana University Lacks a Rational Basis for Its Vaccine Policy, Including Additional Requirements.*

Six students are exempt from the vaccination mandate but challenge the additional measures of mask wearing, testing, and social distancing: Ryan Klaassen (Ex. 100 ¶ 180-81), Jaime Carini (¶ 182-95), Macey Policka (¶ 207-08), Daniel Baumgartner (¶ 196-200), Ashlee Morris (¶ 201-04), and Seth Crowder (¶ 205-06). Collectively, they argue that these requirements, oft-used over the last year, infringe on their bodily autonomy, medical

privacy, religious beliefs, and essentially become a "scarlet letter" targeting them for bullying and scorn from their peers for their medical conditions or religious beliefs.[119]

Indiana University first challenges this argument on a procedural ground. It says these students failed to challenge its masking or testing policies in their complaint. They cite to the well-known legal principle that "a plaintiff is the master of her own complaint," and that courts shouldn't read unalleged assertions into a complaint. *Thornley v. Clearview AI, Inc.*, 984 F.3d 1241, 1246 (7th Cir. 2021); *see also Caterpillar, Inc. v. Williams*, 482 U.S. 386, 398-99 (1987). The complaint isn't so narrowly pleaded. It gives fair notice that the students are challenging the vaccine mandate and the policy's additional requirements. *See* Fed. R. Civ. P. 8(a)(2); *Bell Atl. Corp. v Twombly*, 550 U.S. 544, 555 (2007).

Indiana University's vaccine mandate is multifaceted. It requires all students, faculty, and staff to receive a COVID-19 vaccine and report their vaccination status, or to obtain an exemption and comply with the additional requirements. The university lumps the various parts of this mandate under a general "COVID-19 vaccine requirement" umbrella. For instance, on Indiana University's "frequently asked questions" page about its COVID-19 vaccination requirement, the section provides that vaccinations are required, the deadlines for such vaccinations, the need for students to report vaccination status, the exempted categories, and the additional requirements imposed on exempted students, along with the consequences for failing to get a vaccine [Ex. 118 at 3-6].

[119] The scarlet letter is a literary reference to a mark that identifies one as belonging to a certain group in a scornful or ostracizing way. *See* Nathaniel Hawthorne, *The Scarlet Letter* (1850).

Because the students challenge the additional requirements under substantive due process, the court again begins by first examining the specific right they assert. *See Doe*, 377 F.3d at 768. These students argue that they have rights to refrain from wearing a mask and to refuse nasal testing. But there is no fundamental constitutional right to not wear a mask. *Kelly v. ImagineIF Library Entity*, 2021 U.S. Dist. LEXIS 111958, 8 (D. Mont. June 15, 2021); *Whitfield v. Cuyahoga Cnty. Pub. Library Found.*, 2021 U.S. Dist. LEXIS 92944, 4 (N.D. Ohio May 17, 2021); *Denis v. Ige*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 91037, 14 (D. Haw. May 12, 2021); *W.S. by Sonderman v. Ragsdale*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 98185, 5 (N.D. Ga. May 12, 2021); *Forbes v. City of San Diego*, 2021 U.S. Dist. LEXIS 41687, 11 (S.D. Cal. Mar. 4, 2021); *Stewart v. Justice*, __ F. Supp.3d __, 2021 U.S. Dist. LEXIS 24664, 20 (S.D. W. Va. Feb. 9, 2021); *Oakes v. Collier Cnty.*, 2021 U.S. Dist. LEXIS 15174, 4 (M.D. Fla. Jan. 27, 2021); *Shelton v. City of Springfield*, 497 F. Supp.3d 408, 414 (W.D. Miss. 2020); *see also Ryan v. Cnty. of DuPage*, 45 F.3d 1090, 1092 (7th Cir. 1995) (no constitutional right to *wear* a mask); *United States v. Berglund*, 2021 U.S. Dist. LEXIS 78476, 2 (D. Minn. Apr. 23, 2021) ("Courts have repeatedly found that requiring participants at trial to wear face masks due to the COVID-19 pandemic does not violate a criminal defendant's constitutional rights.").[120] Nor is there a fundamental constitutional right to not be tested for a virus before entering a place of public accommodation. *Aviles v. De Blasio*, 2021 U.S. Dist. LEXIS 38930, 50 (S.D.N.Y. Mar. 2, 2021); *see also Webb v. Johnson*, 2021 U.S. Dist. LEXIS

[120] Plaintiffs cite to a recent Florida state court decision which held, based on its state constitution, that the right to privacy applies to a mask-wearing mandate, triggering strict scrutiny. *See Green v. Alachua Cnty.*, 2021 Fla. App. LEXIS 8634 (Fla. Dist. Ct. App. June 11, 2021). But as this case makes clear, it is based on Florida's state constitution, not the federal constitution. It is thus inapposite here.

95392, 13 (D. Neb. Mar. 2, 2021) (D. Neb. May 19, 2021) (prisoner had no fundamental right to refuse having his temperature taken); *Wilcox v. Lancour*, 2021 U.S. Dist. LEXIS 11968, 23-24 (W.D. Mich. Jan. 22, 2021) (prisoner had no fundamental right to refuse a nasal passage test for COVID-19); *Little Rock Family Planning Servs. v. Rutledge*, 458 F. Supp.3d 1065, 1074 (E.D. Ark. 2020) (applying *Jacobson* to uphold requirement that women obtain negative COVID-19 test before medical procedure).

The court declines the students' invitation to expand substantive due process rights to include the rights not to wear a mask or to be tested for a virus. These aren't rights so "deeply rooted in this Nation's history and tradition" and so "implicit in the concept of ordered liberty" such that "neither liberty nor justice would exist if they were sacrificed." *Washington v. Glucksberg*, 521 U.S. 702, 721 (1997) (quotation omitted); *Khan v. Bland*, 630 F.3d 519, 535 (7th Cir. 2010). These aren't issues of fundamental constitution import, but often transient and trivial inconveniences.

But wait, certain students say: mask wearing and testing violates their religion. The First Amendment says "Congress shall make no law . . . prohibiting the free exercise" of religion. U.S. Const. amend. I. The right to exercise religion is fundamental. *See Cantwell v. Connecticut*, 310 U.S. 296, 303 (1940). As a fundamental right, it would trigger strict scrutiny, but the Supreme Court has held that general regulations that have the effect of incidentally burdening religious practices in general and neutral ways need only be rationally supported by the state. "[T]he right of free exercise does not relieve an individual of the obligation to comply with a valid and neutral law of general applicability on the ground that the law proscribes (or prescribes) conduct that his

religion prescribes (or proscribes)." *Smith*, 494 U.S. at 879 (quotation omitted); *accord Ill. Bible Colleges Ass'n v. Anderson*, 870 F.3d 631, 639 (7th Cir. 2017).

Indiana University's extra requirements fit within the neutral and generally applicable laws protected by *Smith*. The vaccine mandate contains an early reference to religion by way of exemption; but this isn't used to *burden* religion, but instead gives those of religious conviction the *benefit* of freely practicing their religious conviction to refuse the vaccine. *See Listecki v. Official Comm. of Unsecured Creditors*, 780 F.3d 731, 744 (7th Cir. 2015) ("A benefit to religion does not disfavor religion in violation of the Free Exercise Clause."); *see also Smith*, 494 U.S. at 888 (Scalia, J.) (no exemption required). The students who received the religious exemption are subject to the same extra requirements as those who receive the medical exemption.

One may well applaud the university for going beyond what the constitution requires: courts have consistently held that schools that provided a religious exemption from mandatory vaccination requirements did so *above and beyond* that mandated by the Constitution. *See Nikolao*, 875 F.3d at 316; *Phillips*, 775 F.3d at 543; *Workman*, 419 F. Appx. at 356; *Whitlow*, 203 F. Supp.3d at 1084; *Boone*, 217 F. Supp.2d at 954. What the students request now is a religious exemption from the religious exemption, but Indiana University has no obligation to provide this. *See Smith*, 494 U.S. at 879.

On this record, the court finds no merit in the students' contention that wearing masks essentially labels them with a "scarlet letter" that targets them for religious bullying. Indiana University has both medical and religious exemptions, and the same requirements are imposed on both groups. There is no evidence that any exempted

person must reveal publicly which exemption they obtained. Wearing masks thus doesn't signify to others that the individual religiously objects to the vaccination; they could fall within either exempted category, or they could be a vaccinated individual who chooses to take the extra (and unrequired) precaution to wear a mask. A student wearing a mask may well just be precautious in light of COVID-19 variants or because of immunosuppressing conditions. This record is devoid of any evidence of bullying or discrimination.

To be sure, there are some unique circumstances when wearing a mask could negatively impact the student's educational experience. For example, Jaime Carini is pursuing doctorates in organ performance and literature and musicology and, to complete her graduate program, she must perform at organ recitals [Ex. 121 at 22, 27]. She believes performing these recitals while masked will have an impact on her performance as an organist, who use their whole bodies to perform [*id.* 90]. Similarly, Macey Policka is pursuing a degree in theater with an emphasis on acting, and she says the mask requirement is "devastating" to her education [Ex. 125 at 41]. She says wearing a mask has a huge impact on how she can interact with other actors and will put her at a distinct disadvantage to other student actors who don't have to wear masks [*id.*]. Though the court sympathizes with these concerns, these are matters for the university reasonably to address, not matters of constitutional import.

The students once more assert another alleged right—this time the right to the confidentiality of their medical information—to obtain strict scrutiny. But this circuit has never recognized one's constitutional right to privacy to medical information. *Franklin v.*

McCaughtry, 110 F. Appx. 715, 719 (7th Cir. 2004); *Rowe v. Wexford of Ind.*, 2021 U.S. Dist. LEXIS 31766, 3-4 (N.D. Ind. Feb. 22, 2021). This right may exist by statute, but isn't found in the Constitution. And this circuit recognized that such a right, if any, is minimized when in the public context. *See Franklin*, 110 F. Appx. at 719 (describing hospital emergency rooms, doctor's offices, and school infirmaries). The court declines finding such a fundamental right in the context here.

That said, the court applies rational basis review for the extra requirements of masks and testing for the exempted students. Indiana University has a legitimate interest in promoting the health and safety of its students. And the masks and testing are rationally related to achieving those measures. This is true for several reasons.

First, both vaccinated and unvaccinated people can still get the virus. Though health experts differ on the efficacy of masks in preventing the spread of COVID-19, such a dispute is left to the resolution of the policymakers, particularly when studies have shown universal mask wearing resulted in decreases in COVID rates than populations that forewent masks [Ex. 128 at 108]. And social distancing continues to be recommended by the CDC and health experts as effective at eliminating the spread of the disease.[121] The students offer no sound evidence that social distancing isn't effective.

Second, the CDC says schools should account for students, faculty, and staff who aren't vaccinated.[122] And it has continued to recommend masks and social distancing for

[121] CDC, *How to Protect Yourself & Others*, https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/prevention.html (updated June 11, 2021).

[122] CDC, *Guidance for Institutions of Higher Education (IHEs)*, https://www.cdc.gov/coronavirus/2019-ncov/community/colleges-universities/considerations.html#section1 (updated June 4, 2021).

these individuals.[122] This is consistent with what Indiana University has already done for a semester as well.

Third, even students who feel fine and don't have a fever may still have the virus as an asymptomatic individual, so the heightened precautions as to them continue to be rational.[123] Despite the low mortality rates, young adults can still transmit the virus to others [Ex. 115 ¶ 10-11]. For those with milder or even asymptomatic cases, as is more prevalent in this age group, the risk of inadvertent transmission grows [Ex. 115 ¶ 53-55].

Fourth, these measures are reasonable in scope. The testing methods are reasonable for the circumstances: they plan to use a rather non-intrusive saliva test. *See Banks v. United States*, 490 F.3d 1178, 1189 (10th Cir. 2007) ("saliva tests impose minimal intrusions"); *Padgett v. Ferrero*, 294 F. Supp.2d 1338, 1342 (N.D. Ga. 2003) ("bodily intrusion of taking . . . saliva sample is minimal"); *see also Wilson v. Collins*, 517 F.3d 421, 428 (6th Cir. 2008) (saliva sample is less intrusive than blood drawing). Though this form of testing may be less reliable than nasal testing, it is significantly less intrusive—and given that the students' assert their right to bodily autonomy, this is a good thing. Though it may present some inconvenience for the students by taking time away from their studies, this impact is minimal and within the sound discretion of the school.

Fifth, students have lived with mask mandates for over a year now, so it is nothing that is unreasonable, at least not when the risk still exists. These students have worn

[123] *See, e.g.*, Sten H. Vermund & Virginia E. Pitzer, *Asymptomatic Transmission and the Infection Fatality Risk for COVID-19: Implications for School Reopening*, 72(9) Clin. Infect. Dis. 1493-96 (May 1, 2021) (Yale researchers conclude that asymptomatic transmission "likely represents a substantial proportion of total new infections").

masks at school, stores, work, church, and even at a casino. In other contexts, the government has lawfully mandated wearing protective gear, like a mask, when it also provides benefits to the public—like mandated bicycle helmets, hair nets, ear plugs, and any number of personal protective equipment. *See, e.g.*, *Burr v. Atty. Gen. Delaware*, 641 F. Appx. 194, 196 (3d Cir. 2016) (*per curiam*) (seatbelt mandate held constitutional); *Picou v. Gillum*, 874 F.2d 1519, 1519 (11th Cir. 1989) (Powell, J.) (state statute requiring motorcycle riders to wear protective headgear was constitutional). It is no less reasonable here.

B. *Irreparable Harm & Adequate Remedy at Law.*

Irreparable harm is "harm that cannot be repaired and for which money compensation is inadequate." *Orr*, 953 F.3d at 502 (quoting *Graham v. Med. Mut. of Ohio*, 130 F.3d 293, 296 (7th Cir. 1997)) (quotations omitted). To the extent that the students establish a constitutional harm, the law presumes irreparable harm. *See, e.g.*, *Cuomo*, 141 S. Ct. at 67-68 (First Amendment free exercise of religion); *Elrod v. Burns*, 427 U.S. 347, 373 (1976) (First Amendment political association); *Christian Legal Society v. Walker*, 453 F.3d 853, 859 (7th Cir. 2006) ("loss of First Amendment freedoms is presumed to constitute an irreparable injury"); *Ezell v. City of Chicago*, 651 F.3d 684, 699 (7th Cir. 2011) (Second Amendment); *Preston v. Thompson*, 589 F.2d 300, 303 n.3 (7th Cir. 1978) ("The existence of a continuing constitutional violation constitutes proof of an irreparable harm."); *Doe v. Mundy*, 514 F.2d 1179, 1183 (7th Cir. 1975) (right to privacy); *Democratic Nat. Committee v. Bostelmann*, 447 F. Supp.3d 757, 769 (W.D. Wis. 2020); *Planned Parenthood of Ind. v. Commissioner*, 194 F. Supp.3d 818, 835 (S.D. Ind. 2016) (presuming equal protection and substantive due process harms irreparable); 11A Wright & Miller, Federal Practice &

Procedure § 2948.1 (2d ed. 1995) ("When an alleged deprivation of a constitutional right is involved . . . most courts hold that no further showing of irreparable injury is necessary."). That remains true only with the vaccine mandate.

That doesn't mean every alleged harm in this case is irreparable. A delay in collegiate or graduate education isn't typically irreparable harm. *See, e.g.*, *Phillips v. Marsh*, 687 F.2d 620, 622 (2d Cir. 1982); *Hodges v. Bd. of Supervisors*, 2020 U.S. Dist. LEXIS 153949, 7 (E.D. La. Aug. 25, 2020); *Pierre v. University of Dayton*, 143 F. Supp.3d 703, 714 (S.D. Ohio 2015) ("[C]ourts have also held that a suspension is not irreparable."); *Baer v. Nat'l Bd. of Med. Examiners*, 392 F. Supp.2d 42, 49 (D. Mass. 2005) (inability to continue as medical student without interruption is not a harm that is irreparable to potential medical career).

Each exempted student testified that he or she wore masks on many occasions during the pandemic.[124] Any concerns about the hypothetical segregation or discrimination are only speculative and don't constitute irreparable harm. *See Duthie v. Matria Healthcare, Inc.*, 543 F. Supp.2d 958, 960 (N.D. Ill. 2008). Several students have been tested for COVID-19 multiple times with no irreparable harm. And though a few students cite concerns about the safety of nasal testing swabs, Indiana University's testing uses saliva. Though some students say the extra requirements are unnecessary or inconvenient, neither concern rises to the level of irreparable harm. *See, e.g.*, *Students v. United States Dep't of Education*, 2016 U.S. Dist. LEXIS 150011, 125 (N.D. Ill. Oct. 18, 2016); *Right Field Rooftops, LLC v. Chicago Baseball Holdings, LLC*, 87 F. Supp.3d 874, 895 (N.D. Ill.

[124] *See* Ex. 120 at 27 (Ryan Klaassen); Ex. 121 at 44 (Jaime Carini); Ex. 122 at 19-20 (Danial Baumgartner); Ex. 123 at 35-36 (Ashlee Morris); Ex. 124 at 22 (Seth Crowder); Ex. 125 at 17 (Macey Policka); Ex. 126 at 31 (Margaret Roth); Ex. 127 at 29-32 (Natalie Sperazza).

2015) ("inconvenience does not show that harm would be irreparable); *Lewis v. Silverman*, 2005 U.S. Dist. LEXIS 20347, 6-7 (N.D. Ind. Sept. 16, 2005).

Wearing masks, undergoing surveillance testing, and social distancing also aren't indicative of irreparable harm, but consistent with CDC guidelines [Ex. 129 at 28]. *See Orr*, 953 F.3d at 502 (defining irreparable harm). For these particular circumstances, the students also have an adequate remedy at law—money damages. The presumption that money is never an adequate remedy for constitutional violation is wrong. *See Campbell v. Miller*, 373 F.3d 834, 835 (7th Cir. 2004). Such damages would be normal and adequate to address what, even in the most severe light, to be no more than a personal injury. *See id.*

To be inadequate, a remedy needn't be "wholly ineffectual," but it must be "seriously deficient as compared to the harm suffered." *Foodcomm Intern. v. Barry*, 328 F.3d 300, 304 (7th Cir. 2003). If there were to be a constitutional injury here, the court could see that there is no adequate remedy at law if it didn't issue the preliminary injunction. That is less potent when the likelihood of success is so low. *See Adams v. City of Chicago*, 135 F.3d 1150, 1154 (7th Cir. 1998) (if court finds neither irreparable harm nor a likelihood of success, the "analysis ends and the preliminary injunction should not be issued"); *Dish Network LLC v. Cox Media Grp., LLC*, 2020 U.S. Dist. LEXIS 126850, 20 (N.D. Ill. July 20, 2020) (plaintiff's "failure to demonstrate a reasonable likelihood of success on the merits alone is enough to deny its motion"); *Geneva Intern. Corp. v. Petrof, SPOL, S.R.O.*, 529 F. Supp.2d 932, 940 (N.D. Ill. 2007) ("Because [plaintiff] fails to demonstrate irreparable harm, we need not continue to analyze the remaining factors.").

In short, the court presumes the students could establish irreparable harm and the absence of an adequate remedy at law, except as noted here.

C. *The Balance of the Harms and Public Interest Favor Indiana University.*

The balance of harms against the parties and the public interest favor denying the preliminary injunction. This is a sliding scale analysis. The court "weighs the balance of potential harms" against "the movant's likelihood of success." *Turnell*, 796 F.3d at 662. The more likely the plaintiff is to win, the less the balance of harms needs to favor them; the less likely, the more it must weigh in their favor. *Id.* The court has already said the students' likelihood of success is low, and the odds favor the university.

To be sure, the students have a significant liberty interest in refusing unwanted medical treatment. Telling them they must take unwanted medical treatment is a significant intrusion on their liberty. And under the harm principle, "the only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others." John Stuart Mill, *On Liberty* 9 (1859); *see Cassell*, 990 F.3d at 550. If the students' decision to refuse the vaccine affected themselves alone, the balance of harms would almost certainly weigh in favor of granting a preliminary injunction.

But the evidence reasonably shows that they aren't the only ones harmed by refusing to get vaccinated: refusing while also not complying with heightened safety precautions could "sicken and even kill many others who did not consent to that trade-off." *Cassell*, 990 F.3d at 550. This certainly impacts the public interest: the students "are not asking to be allowed to make a self-contained choice to risk only their own health" in

making this decision—their decision necessarily bears on the health of other students, faculty, and staff. *Id.* The balance of harms doesn't weigh in the students' favor here.

And because the students aren't being forced to take the vaccine against their will, the harm is demonstrably less. Though the students may have to forego a semester of school or transfer somewhere else—certainly a difficult and inconvenient choice, and not one lightly tossed aside—they have options. Other colleges in Indiana and around the nation haven't mandated vaccines. Indiana University says it will reassess the mandate after this semester. This mandate will also enhance the academic environment for all students, faculty, and staff by fostering in-person education and a more traditional college experience, educationally and socially. Today, based on this record, the balance of harms tilts heavily in favor of the university.

The public interest also favors denying a preliminary injunction. The court isn't a policymaker: that role is left to the States. On multiple occasions, the Supreme Court has "recognized the role of the States as laboratories for devising solutions to difficult legal problems." *Arizona State Legislature v. Arizona Independent Redistricting Commission*, 576 U.S. 787, 817 (2015) (quoting *Oregon v. Ice*, 555 U.S. 160, 171 (2009)); *United States v. Lopez*, 514 U.S. 549, 581 (1995) (Kennedy, J., concurring) ("States may perform their role as laboratories for experimentation to devise various solutions where the best solution is far from clear"); *New State Ice Co. v. Liebmann*, 285 U.S. 262, 311 (1932) (Brandeis, J., dissenting) ("It is one of the happy incidents of the federal system that a single courageous state may, if its citizens choose, serve as a laboratory; and try novel social and economic experiments without risk to the rest of the country."). Enabling the this state

university to work through these problems reasonably fosters public health and safety in areas of scientific uncertainty. *See Gonzales*, 550 U.S. at 163 (citing *Jacobson*, 197 U.S. at 30-31) (the law gives "wide discretion to pass legislation in areas where there is medical and scientific uncertainty"); *Cassell*, 990 F.3d at 549 ("scientific uncertainty surrounding the pandemic further cautions against enjoining state coronavirus responses unless absolutely necessary"); *see also Cuomo*, 141 S. Ct. at 68 ("Members of this Court are not public health experts").

To be sure, if the students had shown a likelihood that the university was unreasonably infringing on their constitutional rights, enjoining that violation would be in the public interest. *See Joelner v. Village of Washington Park*, 378 F.3d 613, 620 (7th Cir. 2004) ("upholding constitutional rights serves the public interest") (quoting *Newsom v. Albermarle Cnty. Sch. Bd.*, 354 F.3d 249, 261 (4th Cir. 2003)); *Ind. Fine Wine & Spirits, LLC v. Cook*, 459 F. Supp.3d 1157, 1171 (S.D. Ind. 2020) (same). But this concern doesn't apply here because the students have a low likelihood of success.

In short, the balance of harms and the public interest favor Indiana University and the determination that it has reasonably determined the best course of action for the health of its academic community this upcoming fall semester. And in doing so, Indiana University plans to return sooner to normal operations—thus serving much more than just its academic community.

D. *What This Opinion Isn't.*

Don't misread it. The court is not declaring the absolute safety and efficacy of the vaccines, or for all people. People need to understand the risks, remain informed as the

science evolves, monitor the review before the FDA, and determine whether to take a vaccine. The court must decide this case on the evidence before it. The evidence today shows that the students have little chance of success: Indiana University is reasonably pursuing a legitimate aim of public health for its students, faculty, and staff.

This university policy isn't forced vaccination. The students have options—taking the vaccine, applying for a religious exemption, applying for a medical exemption, applying for a medical deferral, taking a semester off, or attending another university. This policy applies for the fall 2021 semester only. Students may make their choice after being advised of the risks and benefits of the vaccines, thereby giving informed consent. The court recognizes that for certain students this may prove a difficult choice, but a choice nonetheless. The choice isn't so coercive as to constitute irreparable constitutional harm. Although it proves a condition to attend this fall, it is reasonable under the Constitution.

This isn't a decision after a final trial on the merits. The court has made this decision based on evidence, testimony, and briefing that the parties produced on an emergent timetable. They and their skilled counsel should be commended for the quality of their submissions, particularly under tight demands. But not every stone has been unturned by the parties. Not every study has been hashed out or submitted for the court to read. Not every witness has testified. Although constituting more than 100 exhibits and testimony from many individuals, including proposed experts, much of which then refers the court to innumerable studies and articles that it has endeavored to review

carefully, much in these five days, this still is a preliminary record, with an opinion issued urgently given the interests of these parties.

The court also isn't saying Indiana University (or any other State or state entity) may do whatever it wants to address COVID-19. Given the liberty at stake for these students here, the university must act reasonably in achieving a legitimate state goal of public health. The Fourteenth Amendment's due process clause checks that authority. Today's decision doesn't provide *carte blanche* authority for Indiana University to do as it pleases without regard to the Constitution. For instance, in the future, the goal of seeing zero or very low new positive cases as a rolling average in attainment of herd immunity may or may not prove reasonable [*see* Ex. 242 at 62-63], but those aren't the circumstances now facing the university, and those aren't the circumstances now presented to the court. Speculative concerns about hypothetical future events don't show irreparable harm. *Duthie v. Matria Healthcare, Inc.*, 543 F. Supp.2d 958, 960 (N.D. Ill. 2008).

The policy will no doubt evolve. The court questioned the parties about the scope of the university's medical exemption. The university's standard vaccination policy, originating from the General Assembly's mandate that public university students receive certain vaccinations, contains an exemption for medical contraindications,[125] with support from a physician's statement [Ex. 229]. Whereas, curiously, the university's COVID-19 policy preserves medical exemptions only for allergies to vaccine ingredients,

[125] A contraindication is any "condition[] in a recipient that increases the risk for a serious adverse reaction." CDC, *General Best Practice Guidelines for Immunization: Best Practices Guidance of the Advisory Committee on Immunization Practices (ACIP)*, https://www.cdc.gov/vaccines/hcp/acip-recs/general-recs/contraindications.html.

not contraindications—ostensibly a narrower basis for exemption for an EUA vaccine than for other decades-existing vaccines.

At oral argument, Indiana University explained that, at the time of adoption, allergies proved the only contraindication and that the university has applied its medical exemption more broadly. There is some evidence for this in the record [*see*, *e.g.*, Ex. 128 at 84-88]. Four physicians on the university medical team consider any requested medical exemption and work with the student's physician to address any immunocompromising condition (and, at times, try to educate the physician on certain pathophysiologies that aren't of concern) [*id.*]. In doing so, the university follows CDC guidance. The university thus has considered for exemption such conditions as vaccine-suppressing medications, pregnancy, steroids, chemotherapy, and organ transplants, to name a few [*id.* at 85-88]. In truth, the medical exemption has been applied more broadly than it is written.

Wisdom might counsel its update to reflect reality and an evolving science. Jumping on this concern, the students call the medical exemption arbitrary in oral argument. The record doesn't bear this out. Indeed, no matter the seeming problematic nature of a narrow medical exemption as written, it has been reasonably broad as applied [*id.*]. The simple truth is that none of the eight students here have sought a medical exemption with the support of a physician's statement to trigger this issue.

Jaime Carini says she wanted a medical exemption, but she never sought one; and she has a religious exemption that she secured in any event [Ex. 121 at 58-60, 69; Tr. 53]. She doesn't present facts that show the university chose to ignore a doctor's recommendation. Margaret Roth has legitimate concerns about taking the vaccine, but

she too hasn't applied for a medical exemption or been denied [Ex. 126 at 26]. Natalie Sperazza believes it unsafe, but she too provides no physician's statement to support this view or shows she applied for a medical exemption [Ex. 127 at 64]. A future case might raise an issue under the medical exemption, but that's not today's case. *See Jacobson*, 197 U.S. at 36-37 (leaving option to challenge vaccine mandate for contraindications). The court won't issue an advisory opinion. *See Brixen*, 908 F.3d at 280.

CONCLUSION

Even assuming in certain respects irreparable harm and an inadequate remedy at law, the students here haven't established a likelihood of success on the merits of their Fourteenth Amendment due process claim, or that the balance of harms or the public's interest favors the extraordinary remedy of a preliminary injunction, before a trial on the merits. The court thus DENIES their preliminary injunction motion [ECF 7].

Recognizing the significant liberty interest the students retain to refuse unwanted medical treatment, the Fourteenth Amendment permits Indiana University to pursue a reasonable and due process of vaccination in the legitimate interest of public health for its students, faculty, and staff. Today, on this preliminary record, the university has done so for its campus communities. That leaves the students with multiple choices, not just forced vaccination.

One might well hale a certain Emersonian self-reliance and self-determination as preference—an unfettered right of the individual to choose the vaccine or not—but, given a preliminary record such as today's, the court must exercise judicial restraint in superimposing any personal view in the guise of constitutional interpretation.

Reasonable social policy is for the state legislatures and its authorized arms, and for the People to demand through their representatives.

From:	Tim Hughes
To:	Tim Hughes
Subject:	TFAH"s Ready or Not report releasing this Wednesday - (Sent by Tim Hughes on behalf of Rhea Farberman)
Date:	Monday, March 8, 2021 3:02:58 PM
Attachments:	New Report Measures States" Health Emergency Preparedness[1].pdf TFAH-2021-ReadyOrNot-FnlEmb.pdf

Dear State Health Official,

TFAH will release its annual report *Ready or Not: Protecting the Public's Health from Diseases, Disasters, and Bioterrorism* measuring states' health emergencies preparedness on Wednesday, March 10. Not surprisingly, this year the report has a special focus on the impact of COVID-19, highlighting the need to increase resources for emergency preparedness. We clarify that our report measures all-hazards preparedness and is not a measure of any state's COVID-19 response.

As we have done in past years, we measure 10 health security indicators in each state and discuss the relationship of each to all-hazard preparedness. We placed states into one of three performance tiers (high, middle and low) based on these indicators. Twenty states and the District of Columbia placed in the high-performance tier, 15 states placed in the middle performance tier and 15 states placed in the low performance tier.

Particularly significant in this year's report is our emphasis on how the pandemic demonstrated the importance of the federal government's role in a health emergency on the scale of a pandemic, the impact of structural racism on a community's resilience during a health emergency, and, the critical need for core public health funding including workforce and infrastructure support.

The report is being shared with news media ahead of the Wednesday morning lift of the embargo. It is likely to be covered in news markets across the country. I recommend you share these materials with your communications staff today so they can prepare for any media requests.

I'd be happy to answer any questions.

Thank you,
Rhea

Rhea K. Farberman, Director

New Report Finds Gaps in States' Preparedness for Public Health Emergencies

COVID-19 Illuminated critical harm of underinvestment in public health infrastructure

(Washington, DC) --- March 10, 2021 – The COVID-19 pandemic has starkly demonstrated that underinvestment in preparedness to respond to public health emergencies can cost hundreds of thousands of lives and wreak havoc on the economy. A new report released today by Trust for America's Health (TFAH) measured states' performance on 10 key emergency preparedness indicators and found room for improvement in every jurisdiction.

The report, *Ready or Not 2021: Protecting the Public's Health from Diseases, Disasters and Bioterrorism* measured states' readiness for health emergencies of any kind (not just the COVID-19 crisis). It placed 20 states and the District of Columbia in a high level of preparedness category, 15 states in a middle preparation tier and 15 states in a low degree of preparation tier.

State performance, by scoring tier, 2020

Performance Tier	States	Number of States
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

For nearly two decades, TFAH has examined the nation's public health emergency preparedness in this annual report. During that time, all states have made improvements in their emergency preparedness, but all continue to have room for additional strengthening of their public health preparedness and response.

"The importance of this report is that it gives states actionable data to adopt policies that save lives. The COVID-19 crisis shows that we have much more work to do to protect Americans from health threats, particularly in the ways in which structural racism create and exacerbate health risks within communities of color," said John Auerbach, President and CEO of Trust for America's Health. "States need to take aggressive steps to shore up their preparedness for all types of public health emergencies."

While the report's findings are not a measure of any state's COVID-19 response, they demonstrate that while states' readiness is important, national health emergencies on the scale of a pandemic require strong federal leadership and coordination, and long-term investment in public health infrastructure and workforce. States alone, even those that rank high in this report, are not sufficiently equipped to respond to a pandemic without federal help, say the report's authors.

The report found:

A majority of states have made preparations to expand healthcare and public health capabilities in an emergency, often through collaboration. Thirty-four states participated in the Nurse Licensure Compact, up from 26 in 2017. The compact allows registered nurses and licensed practical or vocational nurses to practice in multiple jurisdictions with a single license. In an emergency, this enables health officials to quickly increase their staffing levels. In addition, **hospitals in most states have a high degree of participation in healthcare coalitions**. On average, 89 percent of hospitals were in a coalition and 17 states and the District of Columbia had universal participation, meaning every hospital in the jurisdiction was part of a coalition. Such coalitions bring hospitals and other healthcare facilities together with emergency management and public health officials to plan for and respond to incidents. **Every state and the District of Columbia had public health laboratories that had plans for a large influx of testing needs.** This ability to surge laboratory testing capacity during the COVID-19 crisis was extremely critical.

Most states are accredited in the areas of public health, emergency management, or both. As of December 2020, the Public Health Accreditation Board (PHAB) or the Emergency Management Accreditation Program (EMAP) accredited 42 states and the District of Columbia; 29 states and the District of Columbia were accredited by both groups, a net increase of one since November 2019. Both programs help ensure that necessary emergency preparation and response systems are in place and staffed by qualified personnel.

Seasonal flu vaccination rates, while still too low, have risen significantly. The seasonal flu vaccination rate among Americans ages 6 months or older rose from 42 percent during the 2017–2018 season to 52 percent during the 2019–2020 season but is still below the 70 percent target vaccination rate set by *Healthy People 2030.*

In 2019, only 55 percent of employed state residents, on average, used paid time off, the same percentage as in 2018. Those without paid leave are more likely to work when they are sick and risk spreading infection. This became particularly relevant during the COVID-19 pandemic, as isolation and quarantine are important tools for controlling the outbreak.

Most residents who got their household water through a community water system had access to safe water. On average, just 5 percent of state residents used a community water system in 2019 that did not meet all applicable health-based standards.

The report includes recommendations for actions by federal and state policymakers to improve the nation's public health emergency preparedness in seven priority areas:

- Provide stable, sufficient funding for domestic and global public health security.
- Strengthen policies and systems to prevent and respond to outbreaks and pandemics.
- Build resilient communities and promote health equity generally and in preparedness.
- Ensure effective public health leadership, coordination, and workforce.
- Accelerate development and distribution, including last mile distribution, of medical countermeasures.
- Strengthen the healthcare system's ability to respond and recover during and from health emergencies.
- Prepare for environmental threats and extreme weather.

The *Ready or Not* report series is funded by the Robert Wood Johnson Foundation with additional support from The California Endowment, W.K. Kellogg Foundation and The Kresge Foundation.

MARCH 2021

MS-DOH-21-1816-A-000159

EXECUTIVE SUMMARY

Ready or Not 2021

MARCH 2021

Executive Summary

The past year, 2020, will long be remembered as the year more than 2 million people lost their lives due to a global pandemic. Not since the 1918 influenza pandemic has a single event so urgently demonstrated the criticality of a strong public health system. This *Ready or Not* report has tracked the country's level of public health emergency preparedness since 2003. For nearly two decades, it has asked the fundamental question: "are we ready?" Unfortunately, the COVID-19 crisis has provided a clear answer: an emphatic "no."

The COVID-19 crisis has illuminated the urgent need for federal, state, local, tribal, and territorial leaders to take aggressive steps to shore up the nation's preparedness for all types of emergency events. The pandemic put a spotlight on a public health system hollowed-out by years of insufficient funding. Health departments were overstretched, responding to the pandemic with archaic technologies[1] and with overworked staff who faced threats and retribution.[2] These gaps were all the more critical in 2020 because the federal government failed to take an evidence based, leadership role in the pandemic response, with many decisions being left to states that would ordinarily be federally coordinated. It also demonstrated the harm that can be done when science and public health expertise are stifled by political interference and misinformation.

In addition, the pandemic has once again demonstrated and exacerbated the impact of structural racism, both historic and current, on the health and well-being of communities of color and Tribal Nations. Acknowledging the lingering health impacts of slavery and the treatment of native peoples and addressing current day racist policies, systems, and attitudes must be part of building the nation's resilience. In short, equity is not separate from preparedness. Ensuring an equitable opportunity for the health and well-being of all residents before a disaster creates more resilient communities during an emergency. Equity must be an explicit and foundational principle in all emergency planning. Achieving equity in all facets of emergency response requires including equity accountability metrics in emergency preparation and management.

MS-DOH-21-1816-A-000160

Foundational capabilities are necessary throughout the public health system, from the Centers for Disease Control and Prevention (CDC) to state, local, tribal, and territorial health departments, including:[3]

- Health monitoring and assessment, comprising surveillance, epidemiology, and laboratory capacity;
- All-hazards preparedness and response;
- Policy development and support;
- Public communications;
- Community outreach and partnership development;
- Organizational and administrative competencies (i.e., leadership, governance, and health equity); and
- Accountability and performance management.[4]

Today, only half of Americans are protected by a comprehensive local public health system.[5] The Public Health Leadership Forum estimates a $4.5 billion annual shortfall in the spending necessary to meet the infrastructure needs of public health agencies nationwide.[6] This shortfall was on display throughout the COVID-19 pandemic, as decades of chronic underfunding hindered communications, disease surveillance, contact tracing, vaccine delivery, and other key health department activities.

"A powerful aspect of this report is its long history objectively measuring states' preparedness. This year's recommendations are almost identical to past years. Had the nation paid more attention to pandemic threats and TFAH's commonsense and consistent recommendations, this country would be in a very different place today."

Shelley A. Hearne, DrPH
Johns Hopkins University Bloomberg School of Public Health

It is also important to note that the infusion of COVID-19 emergency funding was onetime funding—critical to the pandemic response but not a solution to the system's longtime underinvestment.

This report is designed to give policymakers at all levels of government actionable data and recommendations with which they can target policies and spending to strengthen their jurisdiction's emergency preparedness. The report's 10 key public health preparedness indicators give state officials benchmarks for progress, point out gaps within their states all-hazards preparedness, and provide data to compare states' performance against like jurisdictions. These data points, or ones similar to them, have been the focus of this report for over a decade and are meant to measure readiness for a broad set of health security threats. They are not tailored to an assessment of a given state's response to the COVID-19 pandemic, as widescale political, funding, economic, and social factors all influenced the virus impact and local responses. A state may do well in terms of its ranking in this report but poorly in its response to the COVID-19 pandemic—and vice versa. While no state has been spared, what seems to have mattered most in the pandemic response is a state's socioeconomic and racial profile, as well as the adherence of elected leaders and residents to evidence-based public health guidelines. The pandemic has illustrated that robust and sustained funding, elected officials' leadership, and federal-state coordination and planning are key to protecting Americans' health security. Moreover, there is no substitute at the state or local level for a strong federal response.

MS-DOH-21-1816-A-00161

COVID-19 AND EMERGENCY PREPAREDNESS: TRAGIC LESSONS

TFAH's *Ready or Not: Protecting the Public's Health from Diseases, Disasters and Bioterrorism* report has tracked the nation's readiness to respond to a public health emergency for nearly two decades. During that time, no event highlighted the critical importance of this report's purpose—measuring and promoting readiness to safeguard Americans' health during an emergency—to the degree the COVID-19 crisis has.

The COVID-19 pandemic is an on-the-ground, real-time measure of the nation's public health emergency response system—a test the federal government failed according to most public health experts. An October 2020 report by Columbia University Earth Institute's National Center for Disaster Preparedness estimated that the federal government's inadequate pandemic response led to between 130,000 and 210,00 avoidable deaths. The report submits that if the United States had implemented sufficient testing, earlier lockdowns, a national mask-wearing mandate, and provided federal guidance on social distancing, over 200,000 lives could have been saved.[7]

With a possible single exception (water system safety), all of the readiness indicators measured annually by this *Ready or Not* report played a role in jurisdictions' COVID-19 response. Seven were relevant to the effort to control the pandemic and save lives: (1) nurse licensure compact (allowing jurisdictions to borrow medical personnel when they need to surge capacity), (2) hospital participation in healthcare coalitions, (3) public health and emergency management accreditation, (4) public health funding, (5) access to paid time off, (6) flu vaccination rates (as a proxy for a community's vaccination infrastructure and receptivity), and (7) laboratory surge capacity. TFAH will continue to measure states on these indicators, as they play a central role in the standing-ready, public health protection capacity that every state needs.

The pandemic has also spotlighted a number of issues not currently measured by the report but critical and dramatically apparent if absent during a health emergency: federal and state political leadership, interagency coordination, consistent and well-executed public communications, and health equity.

Importance of Federal Leadership

Government at multiple levels shares responsibility for emergency planning and response. Under this tiered structure, when an event requires a larger response than a local entity can provide, government from the tier above it—typically a tribal, territorial or state agency—provides assistance. When a state's response resources are not enough to meet demands during an emergency, the federal government provides support. For a public health emergency as significant and contagious as COVID-19, clear communication and strong leadership and coordination by the federal government are essential, elements

MS-DOH-21-1816-A-000162

that were lacking during the initial months of the pandemic response. Instead, inconsistent messages between federal agencies and the White House; lack of centralized coordination, such as for procurement of personal protective equipment (PPE); and political interference with guidance from scientific agencies—all led to confusion and contradictory policies among states and weakened the emergency response.

TFAH has made a number of policy recommendations designed to ensure robust and nonpartisan federal leadership during future public health emergencies, including:

- Create a White House Health Security Directorate, including senior advisors to the president with public health expertise on health security issues. This directorate would oversee the national biodefense strategy and all interagency emergency responses.
- Ensure full transparency and consistency in federal messaging from the White House, CDC, ASPR, FDA, and National Institutes of Health (NIH) concerning public health issues to ensure message clarity, avoid confusion, and build trust.
- Ensure that federal public health officials are fully empowered to make decisions based on science and without undue political influence. Efforts to infuse politics into public health decision-making puts the public's health at risk.
- HHS should strengthen leadership by working with states and suppliers to ensure adequate stockpiling and distribution of medical countermeasures and ancillary emergency response products, such as personnel protective equipment.

Overcoming the Legacy of Racism

The legacy of slavery, genocide, and centuries of racism, combined with current day interpersonal and structural racism, is at the root of the disproportionate impact COVID-19 has had on communities of color and Tribal Nations. These systemic inequities, in access to healthcare, housing, education, transportation, and employment, existed before the pandemic and have been exacerbated by it. Health inequities due to disadvantages experienced by racial, ethnic, or other population groups are preventable differences in the burden of disease, injury, and health emergencies and to opportunities to achieve good health.[8] Addressing issues at the root of health inequity is imperative to ensuring all people, regardless of their race or ethnicity or where they live, have the opportunity for good health and are protected during a health emergency.

TFAH has called on the administration and Congress to make advancing health equity and eliminating health disparities a national priority by:

- Ensuring that all COVID-19 response actions prioritize advancing health equity, including access to COVID-19 testing and vaccinations.
- Creating a Truth, Racial Healing, and Transformation Commission, and provide funding to communities to begin the process of acknowledging a history of racism and working to dismantle the myth of hierarchy based on race.
- Expanding funding for initiatives serving communities that have been marginalized by disinvestment, and ensure that federal funding supports processes that meaningfully engage the most affected communities in the planning and implementation of such initiatives.
- Developing a White House led strategy focused on addressing the root causes of disease and on promoting health equity.
- Creating a *social determinants of health* line item at the Centers for Disease Control and Prevention (CDC), authorized and fully funded by Congress, with sufficient funding to guarantee grant-funded efforts throughout the nation.
- Requiring all agencies to collect, disaggregate, and report health data in such a way that the impact of health conditions, policies, or interventions on specific population groups are known, including health status data by race, ethnicity, sexual orientation, gender identity, primary language, and disability status.

The tragedy of the COVID-19 pandemic, including over 500,000 deaths in the United States (as this publication was being prepared) and unprecedented harm to the economic security of millions of American families, will forever be a painful reminder of the critical importance of pre-event public health emergency preparations, investments in public health infrastructure, and evidence-based policy and communications. The pandemic has undeniably demonstrated that historical discrimination coupled with current-day racism impacts a community's health status and ability to weather a disaster. The COVID-19 crisis has also painfully reinforced that national leadership must be grounded in science and committed to addressing structural racism, both of which are imperative to saving lives during an emergency.

MS-DOH-21-1816-A-00163

This edition of the *Ready or Not series* finds that states have made progress in most of the report's measured areas, especially rates of seasonal flu vaccination. However, improvement in other areas—such as paid time off for workers and hospital patient safety—has stalled. In this 2021 report, Trust for America's Health (TFAH) found that three states improved their standing compared with last year, while eight fell behind. Three states improved by one tier, six states dropped one tier, and two dropped two tiers.

TABLE 1: Top-Priority Indicators of State Public Health Preparedness

INDICATORS			
1	**Incident Management:** Adoption of the Nurse Licensure Compact.	6	**Water Security:** Percentage of the population that used a community water system that failed to meet all applicable health-based standards.
2	**Cross-Sector Community Collaboration:** Percentage of hospitals participating in healthcare coalitions.	7	**Workforce Resiliency and Infection Control:** Percentage of employed population that used paid time off.
3	**Institutional Quality:** Accreditation by the Public Health Accreditation Board.	8	**Countermeasure Utilization:** Percentage of people ages 6 months or older who received a seasonal flu vaccination.
4	**Institutional Quality:** Accreditation by the Emergency Management Accreditation Program.	9	**Patient Safety:** Percentage of hospitals with a top-quality ranking ("A" grade) on the Leapfrog Hospital Safety Grade.
5	**Institutional Quality:** Size of the state public health budget compared with the past year.	10	**Health Security Surveillance:** The public health laboratory has a plan for a six- to eight-week surge in testing capacity.

Notes: The National Council of State Boards of Nursing organizes the Nurse Licensure Compact. The federal Hospital Preparedness Program of the U.S. Office of the Assistant Secretary for Preparedness and Response supports healthcare coalitions. The U.S. Environmental Protection Agency assesses community water systems. Paid time off includes sick leave, vacation time, or holidays, among other types of leave. The Leapfrog Group is an independent nonprofit organization. TFAH drew every indicator, and some categorical descriptions, from the National Health Security Preparedness Index, with one exception: public health funding. See "Appendix A: Methodology" for a description of TFAH's funding data-collection process, including its definition.

Source: National Health Security Preparedness Index [9]

The *Ready or Not* report groups states and the District of Columbia into one of three tiers (high, middle, low) based on their performances across the 10 indicators. This year, 20 states and the District of Columbia scored in the high-performance tier, 15 placed in the middle-performance tier, and 15 were in the low-performance tier (see Table 2). (See "Appendix A: Methodology" for more information on the scoring process.)

Three states showed notable improvement, moving up a tier: Georgia, Montana, and Rhode Island. Georgia, which rose from the middle tier to the high tier, improved its standing by achieving accreditation by the Emergency Management Accreditation Program and by having a greater share of its hospitals receive high marks on patient safety. Montana, which elevated from the low tier to the middle tier, increased its public health funding level in fiscal year 2020. And Rhode Island, which rose from the middle tier to the high tier, did so by dramatically increasing its community drinking-water security.

Two states fell from the high tier to the low tier: Missouri and Pennsylvania. Missouri cut its public health funding in FY 2020 and saw an increase in the share of its residents that used a community water system with one or more health-based violations. Its flu vaccination rate ticked up marginally, but by less than the nation as a whole. Likewise, Pennsylvania also cut its public health funding level, and its share of hospitals that received an "A" rating—one of the highest in the nation—rose by slightly less than the national average. Other steps it could take to improve its standing include joining the Nurse Licensure Compact or increasing its below-average share of residents who take paid time off from work.

Five states fell from the high tier to the middle tier: Alabama, Illinois, Iowa, New Jersey, and Tennessee. These states did not experience significant backsliding overall, but they lost ground, as a number of other states took greater steps that increased their standing.

One state fell from the middle tier to the low tier: Arizona. Arizona's below-average flu vaccination rate rose, but by less than the nation overall, so its overall standing fell back.

MS-DOH-21-1816-A-000164

TABLE 2: State Public Health Emergency Preparedness State performance, by scoring tier, 2020		
Performance Tier	**States**	**Number of States**
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

Note: See "Appendix A: Methodology" for scoring details. Complete data were not available for U.S. territories.

TFAH's Analysis Found:

A majority of states have made preparations to expand healthcare and public health capabilities in an emergency, often through collaboration. Thirty-four states participated in the Nurse Licensure Compact, up from 26 in 2017,[10] with Indiana and New Jersey being the most recent adopters.[11] The compact allows registered nurses and licensed practical or vocational nurses to practice in multiple jurisdictions with a single license. In an emergency, this enables health officials to quickly increase their staffing levels. For example, nurses may cross state lines to work at evacuation sites or other healthcare facilities. In addition, **hospitals in most states have a high degree of participation in healthcare coalitions.** On average, 89 percent of hospitals were in a coalition, and 17 states and the District of Columbia had universal participation, meaning every hospital in the jurisdiction was part of a coalition. Such coalitions bring hospitals and other healthcare facilities together with emergency management and public health officials to plan for and respond to incidents or events requiring extraordinary action. This increases the likelihood that providers serve patients in a coordinated and efficient manner during an emergency. What's more, **every state had public health laboratories that had plans for how to manage a large influx of testing needs.** States had a plan to surge public health laboratory capacity for six to eight weeks as necessary during overlapping emergencies or large outbreaks, an increase of six states since 2017.

Most states are accredited in the areas of public health, emergency management, or both. As of December 2020, the Public Health Accreditation Board (PHAB) or the Emergency Management Accreditation Program (EMAP) accredited 42 states and the District of Columbia; 29 states and the District of Columbia were accredited by both groups, a net increase of one since November 2019. (EMAP has now accredited Delaware and Georgia; Maryland transitioned from being accredited by both bodies to the PHAB only, with the EMAP providing conditional accreditation.) Eight states (Alaska, Hawaii, Indiana, New Hampshire, South Dakota, Texas, West Virginia, and Wyoming) were not accredited by either group. Both programs help ensure that necessary emergency prevention and response systems are in place and staffed by qualified personnel.

MS-DOH-21-1816-A-000165

Seasonal flu vaccination rates, while still too low, have risen significantly. The seasonal flu vaccination rate among Americans ages 6 months or older rose from 42 percent during the 2017–2018 season to 52 percent during the 2019–2020 season.[12] However, *Healthy People 2030*, a set of federal 10-year objectives and benchmarks for improving the health of all Americans by 2030, set a seasonal influenza vaccination-rate target of 70 percent annually.[13]

In 2019, only 55 percent of employed state residents, on average, used paid time off, the same percentage as in 2018. Those without paid leave are more likely to work when they are sick and risk spreading infection. In the past, the absence of dedicated paid sick leave has been linked to or has exacerbated some infectious disease outbreaks.[14] This became particularly relevant during the COVID-19 pandemic, as isolation and quarantine were important tools for controlling the outbreak. The Families First Coronavirus Response Act helped address this issue during the early stages of the pandemic for employers with fewer than 500 employees and certain public employers, temporarily requiring employees to be paid up to 80 hours of sick leave benefits under certain conditions.[15] In January 2021, the Biden administration economic stimulus package proposal included extending paid sick leave to over 100 million U.S. workers.

Only 31 percent of hospitals, on average, earned a top-quality patient safety grade, up slightly from 30 percent in 2019. Hospital safety scores measure performance on such issues as healthcare-associated infection rates, intensive-care capacity, and an overall culture of error prevention. In January 2021, the Biden administration's economic aid package included extending paid sick leave to over 100 million U.S. workers.

Most residents who received their household water through a community water system had access to safe water. On average, just 5 percent of state residents used a community water system in 2019 (latest available data) that did not meet all applicable health-based standards, down slightly from 7 percent in 2018. Water systems with such violations increase the chances of water-based emergencies in which contaminated water supplies place the public at risk.

Based on its policy research and analysis, consultation with experts, and review of progress and gaps in federal and state preparedness—with a particular focus on the preparation gaps and shortfalls identified by the COVID-19 pandemic—**TFAH is recommending policy action in seven priority areas:**

1. **Provide stable, sufficient funding for domestic and global public health security.**
2. **Strengthen policies and systems to prevent and respond to outbreaks and pandemics.**
3. **Build resilient communities and promote health equity generally and in preparedness.**
4. **Ensure effective public health leadership, coordination, and workforce.**
5. **Accelerate development and distribution, including last-mile distribution, of medical countermeasures.**
6. **Strengthen the healthcare system's ability to respond to and recovery from health emergencies.**
7. **Prepare for environmental threats and extreme weather.**

MS-DOH-21-1816-A-000166

Report Purpose and Methodology

TFAH's annual *Ready or Not* report series tracks states' readiness for public health emergencies based on 10 key indicators that collectively provide a checklist of top-priority issues and action items for states and localities to continuously address. By gathering together timely data on all 50 states and the District of Columbia, the report assists states in benchmarking their performance against comparable jurisdictions. TFAH completed this research after consultation with a diverse group of subject-matter experts and practitioners.

Ready or Not and the National Health Security Preparedness Index

The indicators included in this report were drawn from, and identified in partnership with, the National Health Security Preparedness Index (NHSPI),[16] with one exception: a measure of state public health funding-level trends, which reflects how well-resourced key agencies are to prepare and respond to emergencies. The NHSPI is a joint initiative of the Robert Wood Johnson Foundation, the University of Kentucky, and the University of Colorado. (See "Appendix A: Methodology" for a detailed description of how TFAH selected and scored the indicators.)

While state placements in *Ready or Not* and the NHSPI largely align, there are some important differences. The two projects have somewhat different purposes and are meant to be complementary, rather than duplicative. With more than 100 indicators, the Index paints a broad picture of national health security, allowing users to zoom out and holistically understand the extent of both individual states' and the entire nation's preparedness for large-scale public health threats. In slight contrast, *Ready or Not,* with its focus on 10 select indicators, focuses attention on state performances on a subset of the Index and spotlights important areas for stakeholders to prioritize. TFAH and the NHSPI work together to help federal, state, and local officials use data and findings from each project to make Americans safer and healthier.

Earning Vaccine Confidence in Communities of Color

Interview with Claude A. Jacob, Dr.PH(c), MPH, the chief public health officer at the Cambridge, Massachusetts, Public Health Department, and **Maria Lemus,** the executive director of Visión y Compromiso, about barriers—both historic and contemporary—to COVID-19 vaccinations within communities of color. This interview was conducted in December 2020.

TFAH: As this report is being finalized, the United States is nearing a time when many Americans, particularly those at the highest risk of infection or the most serious impact if infected, can be vaccinated. What are the barriers to high rates of vaccination in communities of color and among Tribal nations?

Dr. Jacob: We are fortunate in Cambridge. Flu vaccine participation is strong and childhood vaccine compliance is also very high, which we view as rough proxies for COVID-19 vaccine acceptance. That being said, there is a long and sordid history of abuse and mistreatment of these communities by the U.S. government and healthcare system. That many Black and Brown people continue to feel deep mistrust of the healthcare system is understandable. All of us in healthcare and public health must understand that this mistrust goes back to slavery for Black Americans and the genocide perpetuated against indigenous people that lasted for centuries.

We have strong relationships with community organizations, leaders in the faith community, and others who are well known and trusted among communities of color, and we will partner with them to overcome these barriers to vaccine uptake. Recent national and state surveys have told us that Americans view their personal physician as the most trusted voice on COVID-19. Given this finding, we plan to work closely with our hospitals, ambulatory sites, and healthcare providers to help spread the message.

Ms. Lemus: There are many barriers. The ones I'm most concerned about are myths and misinformation, including crazy social media propaganda, fear of adverse reactions, and problems with vaccine accessibility. High rates of the uninsured among some populations groups and misconceptions about who is at risk are additional concerns.

TFAH: The pace of COVID-19 vaccines development has been quicker than many people expected. In some communities this may mean that the vaccine will be available before communications programs about the vaccine's safety and availability have fully taken root. What do those responsible for vaccine distribution need to do when distributing the vaccine under these circumstances?

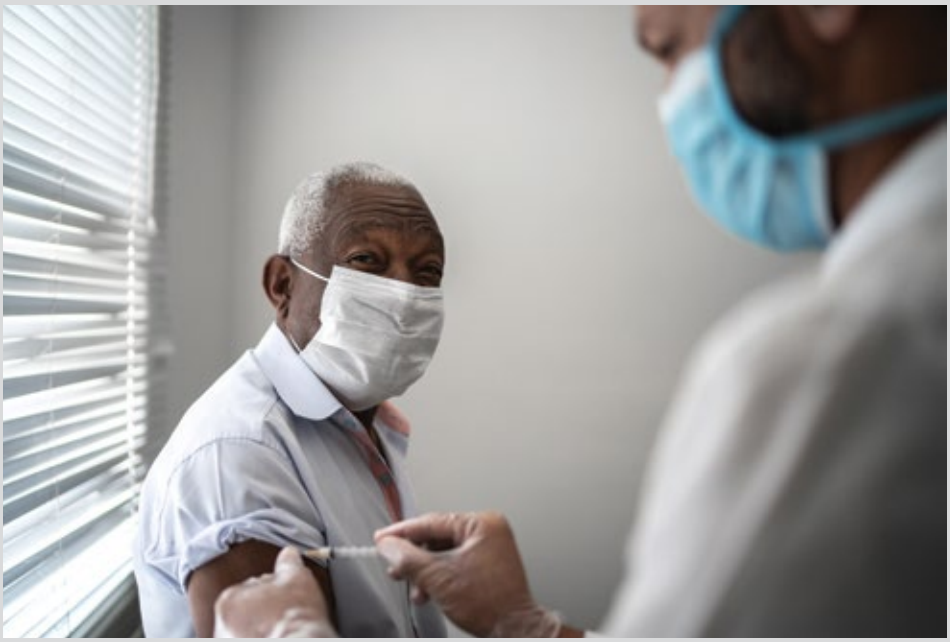
Dr. Jacob: First of all, we need to celebrate the news that, so far, two vaccines have received FDA emergency use authorization. That two vaccines were developed, tested, and manufactured in less than 12 months is a breathtaking achievement. While we can't let down our guard on physical distancing, wearing masks,

MS-DOH-21-1816-A-000168

and continuing to practice good hand hygiene, the COVID-19 vaccine marks a watershed moment in the pandemic. We now see the light at the end of the tunnel. At the same time, it's understandable that people have many questions and deep concerns given how quickly the vaccine was developed and approved. For communities of color, the concern over safety comes with a long-standing, entrenched, and well-placed mistrust of the healthcare system.

Communication will be pivotal in educating everyone, especially communities of color, about the safety and importance of this vaccine. To start, we need to have communities of color and physicians of color at the decision-making table to inform and ensure a vaccine rollout that is equitable for all members of our community. Messaging around the vaccine also needs to be informed by, and tested with, communities of color to make sure that these communication efforts resonate. We have a superb opportunity to work with those on the front line of this pandemic, especially doctors, nurses, and physicians' assistants, to help amplify the message in core communities. By all accounts, frontline medical workers are the most trusted source of health information and they are the first to be vaccinated, starting this past December. We should use their voices of trust and reason to speak to communities of color about the safety and critical importance of getting this vaccine.

Ms. Lemus: It will be imperative to share data about the vaccine without jargon and to have trusted messengers deliver the information. I heard a quote recently in response to the question, "Do you know what's in Tylenol?": "No, but I trust it will help me."



TFAH: A woeful history of mistreatment of people of color by government and the healthcare system is at the root of much of the lack of trust in the COVID-19 vaccine within those communities but there are other barriers to vaccine access. What are they and how can they be overcome?

Ms. Lemus: The understandable distrust of government is going to be a huge barrier to the vaccine. A specific example for my community is the Bracero Program, which between 1942 and 1964, based on a series of bilateral agreements between the U.S. and Mexican governments, brought nearly 4.6 million Mexican citizens to work on U.S. farms, railroads, and factories. Those workers experienced racial and wage discrimination and were forced to live and work in substandard conditions. More recently, there have been allegations of unnecessary hysterectomies being performed in ICE detention centers.

The only way to overcome these histories will be to first acknowledge them. Leaders must acknowledge and speak to these injustices; they must denounce them and support remedies. They need to give real-time examples of the efforts being made to engage with and empower communities and to correct past wrongs. Only then will government be able to be heard and only by using trusted messengers and community navigators.

It's also important to remember that the reasons for distrust of government within underrepresented communities is not only about historical legacies; it is based on current-day events and climates. However, it can be corrected. My organization, Visión y Compromiso, has as its mission providing leadership-development and capacity-building opportunities for *promotores* and community health workers in over 4,000 communities. These community-based *promotores* will have a critical role to play in reducing vaccine hesitancy in communities of color. Messaging to convince people to be vaccinated has to feature their heroes, their community leaders, their voices.

MS-DOH-21-1816-A-000169

Dr. Jacob: Communities of color have historically had difficulty accessing healthcare. Lack of transportation, work schedules, childcare needs, and competing financial interests—such as paying rent and bills—pose significant barriers to healthcare, as do other social determinants of health, such as poverty and lack of education. Even with the Affordable Care Act—which greatly expanded access to health insurance for everyone—Hispanic, Black, and some Asian communities have lower insurance coverage rates than any other population. Many of them remain uninsured altogether.

The cost of the vaccine is being covered by the federal government through tax dollars, but providers can charge to administer the vaccine, if they choose. We need to do everything we can and work with providers to eliminate fees they may charge in the interest of overcoming this public health emergency. When it is available, we need to bring the vaccine to the public rather than making people come to the vaccine. In Cambridge, the public health department, through its partnership with the city's first-responders and others, have made free COVID-19 testing available to all residents (regardless of symptoms) since July 2020. Starting in November 2020, this "no-barrier," city-funded testing program expanded to seven days a week (from two days/week) and from two neighborhood sites to four. These testing sites are geographically dispersed, and all but one are located in neighborhoods with disproportionately high rates of new COVID-19 infections.

TFAH: What is the importance of where the COVID-19 vaccine is available in your community?

Ms. Lemus: Where the vaccine will be available is another critical issue. The credibility, location, hours, accessibility, relationship to community, their staff, and emissaries are important to individual and families' decision to be vaccinated. *Promotores* are important also in gathering information to contribute to the vaccine distribution and administration, planning implementation, and communications. Community-based organizations must be included in all planning and execution; they are a big part of the solution. Partnering with community-based organizations allows local officials to scale means and resources.

Dr. Jacob: As I have already mentioned, the Cambridge Public Health Department has had enormous success with COVID-19 testing and flu vaccinations by bringing these services to people in the communities where they live and work. We have taken a traditional grassroots approach—going door to door in harder-hit neighborhoods and providing information in eight languages—to build trust and understanding. We need to use this same approach with the COVID-19 vaccine and build on these robust community linkages, which are anchored to the long-standing relationships that we have with partners on the ground.

TFAH: As the chief public health officer for the city of Cambridge, Massachusetts, what is your department's role in increasing vaccine uptake in your community? What resources do you need to be successful?

Dr. Jacob: Local public health has an important role and responsibility in educating communities about the safety and importance of the COVID-19 vaccine, as it does with all vaccinations. Once the vaccine is made available to the general public, the Cambridge Public Health Department, through its partnership with city agencies and the private sector, will be ready to provide vaccines to residents. Throughout the pandemic, our department has worked hand in hand with city partners, especially first-responders, to provide testing and flu shots, and we will rely on this strong, successful relationship to provide the COVID vaccine. It is critically important to note that we could not do our work without strong financial support. Our city manager, Louis A. DePasquale, and the Cambridge City Council have provided financial resources to fight this pandemic and keep our residents and those who work in Cambridge safe. They have long been committed to the important work of the public health department, which is enhanced by the Cambridge Health Alliance led by Dr. Assaad Sayah, who is the commissioner of public health for the city of Cambridge.

Dr. Claude A. Jacob is the chief public health officer for the City of Cambridge, Massachusetts. He served as the president of the National Association of City and County Health Officials in 2016–2017.

Maria Lemus is the executive director of Visión y Compromiso, headquartered in San Francisco, California. Visión y Compromiso provides leadership, advocacy, and capacity-development training to community health workers.

MS-DOH-21-1816-A-000170

Assessing State Preparedness

Every state needs to be prepared to respond to a variety of potential public health emergencies; such readiness requires understanding an individual state's preparedness strengths, risks, and vulnerabilities. To help states assess their readiness, and to highlight a checklist of top-priority concerns and action areas, this report examines a set of 10 select indicators. The indicators, used consistently year to year, draw heavily from the National Health Security Preparedness Index (NHSPI), a joint initiative of the Robert Wood Johnson Foundation, the University of Kentucky, and the University of Colorado. They capture core elements of emergency preparedness.

Based on states' standing across the 10 indicators (see "Appendix A: Methodology" for scoring details), TFAH placed states into three performance tiers: high, middle, and low. (See Table 3.)

TABLE 3: State Public Health Emergency Preparedness
State performance, by scoring tier, 2020

Performance Tier	States	Number of States
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

Note: See "Appendix A: Methodology" for scoring details. Complete data were not available for U.S. territories.

Importantly, the implications of this assessment, and responsibility for continuously improving, extend beyond any one state or local agency. Such improvement typically requires sustained engagement and coordination by a broad range of policymakers and administrators. Moreover, some indicators are under the direct control of federal and state lawmakers, whereas improvement in other indicators requires multisector, statewide efforts, including by residents.

MARCH 2021

MS-DOH-21-1816-A-000171

INDICATOR 1: ADOPTION OF NURSE LICENSURE COMPACT

KEY FINDING: 34 states participate in the Nurse Licensure Compact.

Workforce shortages can impair a state's ability to effectively manage disasters or disease outbreaks, potentially resulting in poorer health outcomes for those affected. This reality was starkly illuminated by the COVID-19 pandemic as healthcare capacity in some parts of the country was overwhelmed by the number of people needing care. In an event like a pandemic, the ability to quickly surge qualified medical personnel by bringing healthcare workers from out of state is a key component of healthcare readiness.

This indicator examines whether states have adopted legislation to participate in the Nurse Licensure Compact (NLC). Launched in 2000 by the National Council of State Boards of Nursing, the NLC permits registered nurses and licensed practical nurses to practice with a single multistate license—physically or remotely—in any state that has joined the compact. The NLC provides standing reciprocity, with no requirement that an emergency be formally declared.

Throughout much of 2020, the COVID-19 pandemic placed extraordinary pressure on hospitals across the country as surging infections sent admissions soaring. States that were members of the NLC were well positioned to bring in nurses from other member states, without harmful delays, or to send nurses to other member states that were experiencing acute shortages. For example, New Jersey, which experienced one of the most severe outbreaks in spring 2020, began implementing the NLC, immediately qualifying out-of-state nurses with a multistate license to practice.[17] "I think the COVID-19 outbreak is going to cause the states that are not in the compact now to really take a second look at it," says NLC Director Jim Puente. "If the NLC was expanded to all 50 states, none of the guesswork with emergency orders would be necessary because nurses could travel to other states where they are needed. No applications, fees, or background checks would be necessary."

As of December 2020, 34 states had adopted the NLC, with Indiana and New Jersey being the most recent adopters.[18] This was a net increase of two since 2019 and eight since 2017. Toni Herron, the education compliance officer of the Indiana State Board of Nursing, which joined the compact on July 1, 2020, said that the NLC "presents innovative ways for our Indiana nurses to improve both access to care for patients, while simultaneously reducing the regulatory burden on licensees." [19]

MS-DOH-21-1816-A-000172

TABLE 4: 34 States Participate in the Nurse Licensure Compact

Participants and nonparticipants, 2020

Participants			Nonparticipants	
Alabama	Louisiana	North Dakota	Alaska	Nevada
Arizona	Maine	Oklahoma	California	New York
Arkansas	Maryland	South Carolina	Connecticut	Ohio
Colorado	Mississippi	South Dakota	District of Columbia	Oregon
Delaware	Missouri	Tennessee	Hawaii	Pennsylvania
Florida	Montana	Texas	Illinois	Rhode Island
Georgia	Nebraska	Utah	Massachusetts	Vermont

MS-DOH-21-1816-A-00173

INDICATOR 2: HOSPITAL PARTICIPATION IN HEALTHCARE COALITIONS

KEY FINDING: Widespread hospital participation in healthcare coalitions was common in 2017*; only four states (California, New Hampshire, Ohio, and South Carolina) reported 70 percent or less of their hospitals participated in coalitions supported by the HHS Hospital Preparedness Program.

The federal Hospital Preparedness Program (HPP), which is managed by the HHS Office of the Assistant Secretary for Preparedness and Response, provides cooperative agreements to states, localities, and territories to develop regional coalitions of healthcare organizations that collaborate to prepare for, and in many cases respond to, medical surge events.[21] Coalitions prepare members with critical tools, including medical equipment and supplies, real-time information, enhanced communication systems, and exercises and training for healthcare personnel.[22] A healthcare coalition must contain a minimum of two acute-care hospitals, emergency medical services, emergency management, and public health agencies.[23] Healthcare coalitions invest in local capacity to prepare for and respond to events, reducing jurisdictions' reliance on federal medical assets during disasters.

Broad and meaningful participation by hospitals in healthcare coalitions means that when disaster strikes, systems are in place to coordinate the response, freeing hospitals to focus on clinical care. In the past, healthcare coalitions have assisted in patient transfer, evacuations, and information sharing in events such as Hurricane Harvey in 2017.[24] More recently, the COVID-19 pandemic presented the most intense, widespread, and prolonged test of U.S. hospital systems in a century, threatening at several points to overwhelm facilities' capacities. Healthcare coalitions performed roles such as facilitating the transport of equipment and supplies, sharing information about available beds and ICU capacity, and training healthcare workers on PPE use, treatments, and testing guidelines.[25] During a pandemic, coordination across a region is essential to alleviate pressure on any single facility, to promote cooperation and information sharing for supplies and bed availability, and to facilitate training of healthcare personnel.[26] The extent to which healthcare systems leveraged the resources of their coalitions during the pandemic is a subject that requires further research.

On average, 89 percent of hospitals in states belonged to a healthcare coalition in 2017, with universal participation, meaning every hospital in the state was part of a coalition, in 17 states (Alaska, Colorado, Connecticut, Delaware, Hawaii, Louisiana, Minnesota, Mississippi, Nevada, North Dakota, Oregon, Rhode Island, South Dakota, Utah, Vermont, Virginia, and Washington) and the District of Columbia. (See Table 5.) However, some states, such as Ohio (25 percent) and New Hampshire (47 percent) lagged behind.

The pandemic exposed major gaps in healthcare preparedness, mentioned in TFAH's 2020 report, including coordinating surge capacity across the healthcare system;[27] building and maintaining preparedness for high-consequence infectious diseases;[28] preparedness of facilities that serve people at higher risk, such as long-term care facilities; and lack of training and preparedness for events in healthcare.[29] Experts have also identified additional gaps, such as pediatric surge capacity,[30] burn capacity and other specialty

MS-DOH-21-1816-A-000174

care needed for emerging threats, and ongoing stress on the healthcare system's ability to provide emergency care. While healthcare coalitions can help address some of these vulnerabilities, systemwide approaches to preparedness are needed.

**This summary reflects the latest available data (2017). Because these data are no longer being updated, TFAH will consider replacing this measure in future assessments.*

TABLE 5: Widespread Participation of Hospitals in Healthcare Coalitions

Percent of hospitals participating in healthcare coalitions, 2017

States	Percent of Participating Hospitals
AK, CO, CT, DC, DE, HI, LA, MN, MS, NV, ND, OR, RI, SD, UT, VT, VA, WA	100%
ID, WI	98%
GA, WV	97%
KS	96%

MS-DOH-21-1816-A-00175

INDICATORS 3 AND 4: ACCREDITATION

KEY FINDING: Most states are accredited by one or both of two well-regarded bodies—the Public Health Accreditation Board and the Emergency Management Accreditation Program—but eight are not accredited by either.

The Public Health Accreditation Board (PHAB), a nonprofit organization that administers the national public health accreditation program, advances quality within public health departments by providing a framework and a set of evidence-based standards against which they can measure their performance. Among standards with direct relevance to emergency preparedness are assurances of laboratory, epidemiologic, and environmental expertise to investigate and contain serious public health problems, policies, and procedures for urgent communications and maintenance of an all-hazards emergency operations plan.[32] Through the process of accreditation, health departments identify their strengths and weaknesses, increase their accountability and transparency, and improve their management processes, which all promote continuous quality improvement.[33]

Emergency management, as defined by the Emergency Management Accreditation Program (EMAP), encompasses all organizations in a given jurisdiction with emergency or disaster functions, which may include prevention, mitigation, preparedness, response, and recovery. The EMAP helps applicants ensure—through self-assessment, documentation, and peer review—that they meet national standards for emergency response capabilities.[34]

The PHAB and the EMAP each provide important mechanisms for improving evaluation and accountability. Accreditation by these entities demonstrates that a state's public health and emergency management systems are capable of effectively responding to a range of health threats. The priority capabilities that the PHAB and the EMAP test include identification, investigation, and mitigation of health hazards; a robust and competent workforce; incident, resource, and logistics management; and communications and community-engagement plans.[35,36] States sometimes aim to meet applicable standards but do not pursue accreditation.

As of December 2020, 29 states and the District of Columbia were accredited by both the PHAB and the EMAP—a net increase of one (Delaware and Georgia are now accredited by the EMAP; Maryland transitioned from being accredited by both bodies to the PHAB only, with the EMAP providing conditional accreditation) since November 2019. Nevada is once again accredited by the EMAP, alongside an additional 12 states that have received accreditation from one or the other. (See Table 6.) "Over the last eighteen months we have worked diligently to review our processes, plans, and relationships," said the director of Delaware's Emergency Management Agency, A.J. Schall. "Over that time, we learned a tremendous amount and modernized procedures."[37]

Just eight states (Alaska, Hawaii, Indiana, New Hampshire, South Dakota, Texas, West Virginia, and Wyoming) received no accreditation from either body. A state without an accreditation has not necessarily been denied accreditation; the state may not have pursued accreditation. This analysis includes state-level accreditations only, it does not include accredited local or tribal health departments. In some instances, local public health departments have an accreditation in states that do not.

MS-DOH-21-1816-A-000176

TABLE 6: 42 States and the District of Columbia Accredited by the PHAB and/or EMAP

Accreditation status by state, December 2020

PHAB and EMAP			PHAB only	EMAP only	No Accreditation
Alabama	Idaho	New Mexico	Maine	Kentucky	Alaska
Arizona	Illinois	New York	Maryland	Michigan	Hawaii
Arkansas	Iowa	North Dakota	Minnesota	Nevada	Indiana
California	Kansas	Ohio	Montana	North Carolina	New Hampshire
Colorado	Louisiana	Oklahoma	Oregon	South Carolina	South Dakota
Connecticut	Massachusetts	Pennsylvania	Washington	Tennessee	Texas
Delaware	Mississippi	Rhode Island		Virginia	West Virginia
District of Columbia	Missouri	Utah			Wyoming
Florida	Nebraska	Vermont			
Georgia	New Jersey	Wisconsin			
29 states + DC			**6 states**	**7 states**	**8 states**

Note: These indicators track accreditation by the PHAB and the EMAP. TFAH classified states with conditional or pending accreditation at the time of data collection as having no accreditation. States sometimes aim to meet applicable standards but do not pursue accreditation.

MS-DOH-21-1816-A-00177

INDICATOR 5: STATE PUBLIC HEALTH FUNDING TRENDS

Key Finding: Most states held their public health funding steady or increased it in FY 2020, but seven reduced funding.

The COVID-19 pandemic showed how sufficient and sustained funding for a comprehensive public health system is integral to preparedness and response, including the ability to detect, prevent, and control disease outbreaks and mitigate the health consequences of disasters. General public health capabilities—such as those pertaining to epidemiology, environmental hazard detection and control, infectious disease prevention and control, and risk communications—and targeted emergency response resources are necessary to ensure that officials maintain routine capabilities and that surge capacity is readily available for emergencies. A trained and standing public health workforce, and one that knows its community, is critical to the surge capacity that is so often necessary during an emergency.

According to the Public Health Activities and Services Tracking project at the University of Washington, state public health programming and services span six core areas:[39]

1. **Communicable disease control.** Public health services related to communicable disease epidemiology, hepatitis, HIV/AIDS, immunization, sexually transmitted diseases, tuberculosis, etc.
2. **Chronic disease prevention.** Public health services related to asthma, cancer, cardiovascular disease, diabetes, obesity, tobacco, etc.
3. **Injury prevention.** Public health services related to firearms, motor vehicles, occupational injuries, senior fall prevention, substance-use disorder, other intentional and unintentional injuries, etc.
4. **Environmental public health.** Public health services related to air and water quality, fish and shellfish, food safety, hazardous substances and sites, lead, onsite wastewater, solid and hazardous waste, zoonotic diseases, etc.
5. **Maternal, child, and family health.** Public health services related to the coordination of services; direct service; family planning; newborn screening; population-based maternal, child, and family health; supplemental nutrition; etc.
6. **Access to and linkage with clinical care.** Public health services related to beneficiary eligibility determination, provider or facility licensing, etc.

The overall infrastructure of public health supports states' ability to promote health equity, build resilience in the population, and carry out emergency response activities. But public health funding is typically discretionary, making it vulnerable to neglect or retrenchment, especially when times are tight. This can undermine emergency preparedness activities and weaken response and recovery efforts. State investment in public health is important for the operations of health agencies: about 28 percent of state and territorial health department revenues are from state sources,[40] while 21 percent of local health department revenue is from state sources, on average.[41]

Fortunately, 43 states and the District of Columbia maintained or increased public health funding in FY 2020. (See Table 7.) But seven states reduced the money they directed to these vital activities, increasing the likelihood that they will be less prepared and less responsive in the moments that matter most. (This indicator does not assess the adequacy of states' public health funding. It should also be noted that due to inflation and population growth, stable funding is in some cases a funding reduction.) The COVID-19 economic recession has already had a severe impact on state revenue,[42] which could constrain state public health funding levels over the coming years.

MS-DOH-21-1816-A-000178

TABLE 7: State Public Health Funding Held Stable or Increased in 43 states and DC

Public Health Funding, by state FY 2019 – 2020

State	Percentage Change
Alabama	-4%
Alaska	118%
Arizona	52%
Arkansas	-2%
California	40%
Colorado	9%
Connecticut	8%

floridastock

Note: While states received federal one-time COVID response funding, those funds are not included in these tallies, as all federal funds are excluded from this measure. However, in some cases, state funding for pandemic response may have been included in the data reported to TFAH. For some states, COVID response funding may have resulted in an increase in the state's overall public health expenditure for the year. Other states may have reallocated money from one line to another with little impact on the overall funding level.

Owing to differences in organizational responsibilities and budgeting, funding data are not necessarily comparable across states. See "Appendix A: Methodology" for a description of TFAH's data-collection process, including its definition of public health funding.

Source: TFAH analysis of states' publicly available funding data.

MS-DOH-21-1816-A-000179

INDICATOR 6: COMMUNITY WATER SYSTEM SAFETY

KEY FINDING: Few Americans drink from community water systems that are in violation of applicable health-based standards required by the Safe Drinking Water Act. But room for improvement remains.

Access to safe water is essential for consumption, sanitation, and the efficient operation of the healthcare system. In the United States, the vast majority of the population gets water from a public water system,[43] and the U.S. Environmental Protection Agency (EPA) sets legal limits on contaminants in drinking water, including microorganisms, disinfectants, and their byproducts, chemicals, and radionuclides;[44] the EPA also requires states to periodically report drinking-water quality information.[45] Water systems must report any violations, such as failing to follow established monitoring and reporting schedules, failing to comply with mandated treatment techniques, violating any maximum contaminant levels, and failing to meet customer-notification requirements.[46]

The United States has one of the safest public drinking-water supplies in the world, but some communities, particularly low-income communities, struggle to maintain constant access to safe water. When water safety issues occur, it can require a multisector emergency response, as well as a long-term public health response. The most prominent water-contamination crisis in recent years occurred in Flint, Michigan, where a 2014 change in water supply caused distribution pipes to corrode and to leach lead and other contaminants into the drinking water. Tens of thousands of residents, including young children, were exposed to high levels of lead and other toxins.[47] In 2019, residents of Newark, New Jersey, had to rely on bottled water due to high levels of lead in their tap water.[48] In children, even low levels of lead exposure can damage the nervous system and contribute to developmental delays, learning disabilities, weight and hearing loss.[49] These incidents could have long-term consequences on the health and brain development of children, as well as the mental health and trust of the community.

As climate change contributes to more frequent wildfires, a residual danger is the release of toxic chemicals into community water systems. For example, months after the deadly Camp Fire in Paradise, California, in 2018, experts still advised residents not to drink or cook with the water due to concerns about benzene contamination.[50,51] Among the health effects of long-term exposure to unsafe levels of benzene is a decrease in red blood cells, which can lead to anemia. It can also cause excessive bleeding and can affect the immune system, increasing the chance for infection.[52]

Other water-related emergencies and concerns in the United States include harmful algal blooms,[53] which can impact human and animal health, the safety of seafood, damage the economies of affected communities, increase the presence of toxic chemicals like per- and polyfluoroalkyl substances (PFAS), and reduce the availability of clean water during power outages,[54] a particular concern in rural areas where smaller utilities may not have enough backup power to meet the demands of the water and sewage services. Water shortages can have a particularly dire impact on healthcare systems, which rely on clean water for many procedures and hygiene practices.

MS-DOH-21-1816-A-000180

New CDC data indicate waterborne pathogens cause nearly 7,000 deaths, seven million illnesses and more than $3 billion in healthcare costs each year. The risks around drinking water disproportionately threaten communities of color, highlighting the impact historical structural racism and continued institutional bias can have on a critical resource most Americans take for granted. In some areas, redlining has kept peri-urban communities of color, tribal lands and rural agricultural areas out of municipal water systems, thereby increasing their potential exposure to waterborne illness. In addition, older buildings are more vulnerable to waterborne pathogens in their pipes.[55]

According to the EPA, across the nation, 5 percent of state residents on average used a community water system in 2019 that failed to meet all applicable health-based standards, down from 7 percent in 2018. That share was 0 to 1 percent in Hawaii, Maryland, Minnesota, Nevada, North Dakota, Vermont, and Washington. (See Table 8.) But in four states (New Jersey, New York, Oregon, and West Virginia), more than 15 percent of residents used a community water system with health-based violations.

TABLE 8: Few Americans Used Contaminated Community Water Systems
Percent of state populations who used a community water system in violation of health-based standards, 2019

States	Percent of Population
HI, MD, MN, ND, NV, VT, WA	0%
CA, ID, IL, IN, ME, OH	1%
AL, CO, DE, MI, NC, NE, NH, WY	2%
CT, FL, SC, VA	3%
AK, IA, KY, RI, SD, TN, TX,	4%
AZ, DC, KS, UT, WI	5%
NM	6%
GA, MA	7%
AR, MS, MT	8%
MO, PA	9%
LA	13%
OK	15%
NJ, OR, WV	16%
NY	45%

Note: The EPA estimates that more than 13 million American households get their drinking water from private wells.[56] The data reported by this indicator do not reflect the water quality of those households. Only regulated contaminants are measured. These data do not include water safety on Indian reservations.

According to health officials in New York, a drinking water system in New York City is in violation because of an uncovered reservoir, but it has no current violations with respect to contaminants.

Source: NHSPI analysis of data from the EPA.[57]

MS-DOH-21-1816-A-00181

INDICATOR 7: USE OF PAID TIME OFF

KEY FINDING: Just over half of workers in states, on average, used some type of paid time off—sick leave, vacation, holidays—in 2019. Most states were closely clustered to that midpoint, with few outliers.

Note: The specification of this indicator has been adjusted slightly from a measure of those who received paid time off to a measure of those who used it.

The need for paid time off was obvious during the pandemic, when frontline and essential workers—people who could not work from home during the outbreak—were often compelled to work when sick themselves or caring for a sick family member. Black and Hispanic workers typically have less access to paid sick leave and are overrepresented in groups of frontline workers.[58]

When workers without paid leave get sick, they face the choice of going to work and potentially infecting others or staying home and losing pay—or even their jobs. They encounter similarly impossible decisions when a child or another dependent family member gets sick. Therefore, access and the ability to use job-protected paid time off, especially dedicated paid sick leave, can strengthen infection control and resilience in communities by reducing the spread of contagious diseases and bolstering workers' financial security. This is particularly important for industries and occupations that require frequent contact with the public. For example, people working in food service, older adults and nursing care facilities and childcare commonly have no paid sick leave.[59] Low-wage workers[60] and workers of color are also less likely to have access to paid leave compared with white and higher-earning workers.[61] This often leads employees to work throughout an illness or return to work before their symptoms have fully subsided, when time off could have dramatically reduced the potential of workplace infections.[62,63]

The public health benefit is clear: at a societal level, flu rates have been shown to be lower in cities and states that mandate paid sick leave.[64,65] When employees who previously did not have access are granted paid or unpaid sick leave, rates of flu infections decrease.[66]

During the COVID-19 pandemic, studies consistently showed that access to paid sick leave helped slow the spread of the virus.[67] The Families First Coronavirus Response Act helped temporarily address this issue for employers with fewer than 500 employees and certain public employers, temporarily requiring employees to be paid sick leave benefits under certain conditions. This helped reduce the spread of the virus in workplaces and communities by removing a barrier to employees staying home when necessary. However, these protections expired on December 31, 2020, despite the ongoing need for the use of paid leave to control the pandemic; instead, Congress provided a tax credit for employers to offer paid sick leave.[68]

But many workers, particularly low-wage workers, did not have access to paid sick leave during the pandemic and were therefore left to make impossible choices between protecting their health and that of their family or protecting their financial security. State paid leave laws helped in a few jurisdictions. Beginning in March 2020, two states with existing state paid sick leave policies, California and Rhode Island, experienced large increases in temporary disability and family caregiving leave claims. California claims rose by 43 percent between February and March 2020.[69] Rhode Island claims nearly tripled between February and March 2020.[70] A January Biden administration proposal, if adopted by Congress, would provide paid leave to people who are: sick with

MS-DOH-21-1816-A-000182

Covid-19 symptoms; quarantining because of Covid-19 exposure; needing time off to get the vaccine; caring for family members who are sick with Covid-19 symptoms; caring for children whose school or day care center is closed because of the pandemic; caring for older relatives or adult dependents whose long-term care facility is closed because of the pandemic.[71]

Paid time off also increases access to preventive care among workers and their families, including routine checkups, screenings, and immunizations. Delaying or skipping such care can result in poor health outcomes and can ultimately lead to costlier treatments. Workers without paid sick days are less likely to get a flu shot, and their children are less likely to receive routine checkups, dental care, and flu shots.[72]

In 2019, 55 percent of workers in states, on average, took some type of paid time off—the same percentage as in 2018—according to the Current Population Survey, which is sponsored jointly by the U.S. Census Bureau and the U.S. Bureau of Labor Statistics.[73] Connecticut (64 percent), the District of Columbia (65 percent), Mississippi and Oregon (63 percent), and Texas (68 percent) stood out as states where relatively high percentages of workers used such benefits, whereas fewer workers used them in Arkansas (45 percent), South Carolina (45 percent), South Dakota (44 percent), Utah (45 percent), and Wyoming (47 percent).[74] (See Table 9.)

TABLE 9: 55 Percent of Workers, On Average, Used Paid Time Off

MS-DOH-21-1816-A-000183

INDICATOR 8: FLU VACCINATION RATE

KEY FINDING: Flu vaccination coverage rose for the second consecutive year during the 2019–2020 season, with a greater share of every age group analyzed receiving a vaccine. Overall, 52 percent of U.S. residents ages 6 months or older received vaccinations—still well below the overall target level of 70 percent of the population vaccinated annually.

The CDC recommends that, with few exceptions, everyone ages 6 months or older get vaccinated for seasonal influenza annually; yet, year after year, even with a steady increase among adults over the past three decades, coverage estimates indicate that just over half of Americans do.[76] *Healthy People 2030* set federal 10-year benchmarks for improving the health of all Americans, including an overall seasonal influenza vaccination-rate target of 70 percent annually.[77]

Vaccination is the long-standing best prevention against the seasonal flu, particularly for people at high risk of severe flu-related outcomes, including people with certain chronic health conditions and older adults, groups that are also at higher risk from COVID-19. In addition to protecting Americans from the seasonal flu, establishing a cultural norm of vaccination, building vaccination infrastructure, and establishing policies that support vaccinations can help prepare the country to vaccinate all Americans quickly during the pandemic. A major concern as the 2020–2021 flu season opened was that a high incidence of seasonal flu coupled with the amount of illness caused by the pandemic would overwhelm health systems. During 2021, as the country works to deliver the COVID-19 vaccine, seasonal flu vaccination programs provide important process lessons, networks, communications strategies, and goals for the COVID-19 vaccination effort.

Under the Affordable Care Act, all routine vaccines recommended by the Advisory Committee on Immunization Practices, including flu vaccines, are fully covered when provided by in-network providers, except in states that have not expanded their Medicaid programs in accordance with the act. Some barriers to flu vaccination may

MS-DOH-21-1816-A-000184

include a belief that the vaccine does not work very well; misconceptions about the safety of the vaccine;[78] or a belief that the flu does not carry serious risks.[79] State laws may also make it more difficult for parents to get their children vaccinated by a pharmacist, as some states do not allow children to get flu vaccines at a pharmacy and even more have age restrictions and/or require a physician's prescription.

During the 2019–2020 flu season, 52 percent of residents ages 6 months or older were vaccinated, according to the CDC, the highest rate in at least a decade. This was a notable uptick from 42 percent during the 2017–2018 flu season. One possible explanation is the increased awareness of the public, clinicians, and public health officials about the importance of vaccination, owing to the high number of illnesses and deaths two years prior. The major role that vaccination will play in the country's—and the world's—recovery from the extraordinarily deadly COVID-19 pandemic will, hopefully, make an indelible impression on all Americans about the value of vaccination.

Across the country, states have taken noteworthy actions to vaccinate residents against seasonal flu. For example, during the 2018–2019 flu season, the Tennessee Department of Health organized statewide Fight Flu TN events with vaccination clinics, and last year, it launched a statewide media campaign.[80] The state's flu vaccine rate (ages 6 months or older) increased from 36 percent during the 2017–2018 flu season to 49 percent during the 2019–2020 season. Indiana's Department of Health has also engaged in focused efforts to increase vaccination rates, particularly among people who are uninsured or underinsured. One way it has done this is by partnering with local health departments and pharmacies to provide vaccinations, and by working with the Indiana Immunization Coalition to create education and outreach materials and social media messaging.[81] Indiana's flu vaccination rate (ages 6 months or older) improved from 37 percent for the 2017–2018 flu season to 51 percent for the 2019–2020 season.

Rhode Island (61 percent), Connecticut (61 percent), and Massachusetts (61 percent) had the highest coverage, while vaccination rates were lowest in Nevada (44 percent), Florida (45 percent), and Idaho (45 percent). (See Table 10.)

Children, particularly young children, were more likely to receive vaccinations than were adults. Nearly 64 percent of those ages 6 months to 17 years received vaccinations in 2019–2020, compared with 48 percent of adults.[82]

TABLE 10: Just Over Half of Americans Received a Seasonal Flu Vaccination

States' seasonal flu vaccination rates for people ages 6 months or older, 2019–2020

State	Vaccination Rate, Ages 6 Months or Older
Rhode Island	60.9
Connecticut	60.7
Massachusetts	60.6
Virginia	58.8
South Dakota	58.7
Nebraska	58.3
Wisconsin	58.3
Maryland	57.8

MS-DOH-21-1816-A-000185

INDICATOR 9: PATIENT SAFETY IN HOSPITALS

KEY FINDING: On average, 31 percent of hospitals received an "A" grade in the fall 2020 hospital safety assessment administered by the Leapfrog Group, a nonprofit advocate for safety, quality, and transparency in hospitals.

Every year, hundreds of thousands of people die from hospital errors, injuries, accidents, and infections, collectively making such incidents a leading cause of death in the United States.[85,86] Keeping hospital patients safe from preventable harm is an important element of preparedness; those hospitals that excel in safety are less likely to cause or contribute to a public health emergency and are better positioned to handle any emergencies that put routine quality standards to the test.

During the COVID-19 pandemic, hospitals were an active setting for viral transmission, threatening the safety of patients, staff and visitors, and also discouraging people in need of urgent or emergency care from going to the ER, likely contributing to overall excess mortality.[87] But universal masking and availability and proper use of PPE, in addition to other steps, such as adequate ventilation, limiting the sharing of patient rooms, and universal hand hygiene, proved to be critical in preventing outbreaks in hospitals.

The Leapfrog Group calculates its hospital safety score by using 28 evidence-based metrics that measure the success of healthcare processes and outcomes. The measures track such issues as healthcare-associated infection rates, the number of available beds and qualified staff in intensive-care units, patients' assessments of staff communications and responsiveness, and a hospital's overall culture of error prevention.[88] These measures are especially critical for health systems' readiness for emergencies and outbreak prevention and control, which include workforce training and availability, surge capacity, and infection-control practices.

In the Leapfrog Group's fall 2020 assessment, 31 percent of general acute-care hospitals across the United States, on average, met the requirements for an "A" grade—a slight increase from fall 2018, when the share was 28 percent. But results varied widely state to state, from no hospitals in Alaska, North Dakota, or South Dakota receiving the top score, to a majority of hospitals doing so in Maine (63 percent), Idaho (58 percent), Delaware (57 percent), Massachusetts (57 percent), Oregon (55 percent), Virginia (53 percent), and North Carolina (52 percent). (See Table 11.)

MS-DOH-21-1816-A-000187

INDICATOR 10: STATE SURGE CAPACITY

KEY FINDING: Every state reported having a plan in 2020 for a six- to eight-week surge in laboratory-testing capacity to respond to an outbreak or other public health event.

Public health laboratories have been essential to emergency response and effective disease surveillance systems throughout the pandemic. They help detect and diagnose health threats as they emerge, and they track and monitor the spread of those threats, which can help public health officials learn how to control them. Public health labs exist in every state and territory and are the backbone of the Laboratory Response Network (LRN), a national network of laboratories that provide the infrastructure and capacity to respond to public health emergencies.[90]

When a disaster or disease outbreak strikes, public health laboratories must be able to surge to meet increased demand, just like hospitals and other responders. The Association of Public Health Laboratories defines internal surge capacity as a "sudden and sustained increase in the volume of testing that a LRN reference laboratory can perform in an emergency situation, implementing substantial operational changes as defined in laboratory emergency response plans and using all resources available within the laboratory."[91] Surging capacity can require staff movement or reassignment, extra shifts, and hiring. Labs also have to plan for infrastructure factors, such as sufficient biological safety cabinets and chemical fume hoods; amount and type of supplies; space for intake, processing, and storage of samples; versatility and capacity of analytical equipment and instruments; availability of PPE; and power supply.[92] It should also be noted that while the existence of surge plans are important, these plans have to be funded, tested, and regularly updated.

State public health laboratories have been critical assets throughout the COVID-19 pandemic, especially in early 2020, when they were the only laboratories outside the CDC authorized to conduct testing.[93] Despite early challenges in the tests rolled out to states, at least one public health laboratory in every state, DC, Puerto Rico, and Guam was able to test for COVID-19 as of June 2020.[94] Testing capacity increased over time, as private labs received authorization and ramped up capacity, and as a variety of rapid molecular tests were manufactured and approved for use at home; but the processing of the CDC's 2019-nCoV Real-Time RT-PCR Diagnostic Panel assisted officials throughout with monitoring the course of the pandemic. Still, the country's testing capacity never reached what most experts argued was necessary to allow for comprehensive, timely surveillance of the virus's spread during the height of the pandemic. This problem was most acute in spring 2020, when an estimated one in 10 infections were confirmed, improving somewhat to roughly one in three in late 2020.[95,96]

In addition, public health laboratories are studying the genetic sequencing of the COVID-19 virus to identify variants. Such genomic surveillance is critical to understanding and preventing the spread of the virus but more federal funding is needed to support the work.[97]

Going forward, some challenges to the effectiveness of public health laboratory preparedness include funding gaps to invest in infrastructure and modernization, workforce shortages, a lack of standardized platforms to exchange data electronically, and a limited ability to detect radiological, nuclear, and chemical threats.[98]

In 2020, the District of Columbia and all states reported to the Association of Public Health Laboratories that they had a plan for a six- to eight-week surge in testing capacity, a net increase of six since 2017 and 2018. (See Table 12.)

MS-DOH-21-1816-A-000188

TABLE 12: Every State Planned for a Laboratory Surge.

State public health laboratories with a plan for a six- to eight-week surge in testing capacity, 2020

Had a Plan

MS-DOH-21-1816-A-00191

Recommendations for Policy Actions

As 2020 has shown, saving lives and protecting the country's economic stability during a pandemic requires pre-event investment and planning, a strong public health system, federal leadership, and a coordinated response. The same is true for all types of public health emergencies. Effective preparedness and response require sufficient funding, a trained workforce, and multisector teamwork. Authentic engagement with community-based leaders and organizations are also necessary.

TFAH based the following policy recommendations on research and analysis, consultation with experts, and a review of gaps in federal and state preparedness. TFAH offers the following recommendations for federal, state, local, tribal, and territorial policymakers and other stakeholders to improve public health emergency readiness.

Priority Area 1: Provide Stable, Sufficient Funding for Domestic and Global Public Health Security

The COVID-19 pandemic has uncovered the tragic consequences of the nation's long-term neglect of public health capacity at the global, federal, state, local, tribal, and territorial levels. Understaffed health departments are in some cases using 20th-century tools, such as telephones and fax machines,[100,101] to respond to a 21st-century pandemic.[102] At the same time, funding for the Public Health Emergency Preparedness cooperative agreement, a critical source of funding for health departments to build capabilities to effectively respond to a range of public health threats, has been cut by just over one-quarter since FY 2003, or about half, after adjusting for inflation.[103] The HPP, the only federal source of funding to help the healthcare delivery system prepare for and respond to disasters, has been cut by nearly half over the same time period, or by nearly two-thirds, after adjusting for inflation.[104] Therefore, health departments were already working from a deficit when the pandemic emerged. Federal policymakers need to rapidly improve the COVID-19 response and build back a system currently unprepared to address future emergencies. Short-term investments made through COVID response funding legislation cannot fill the gap left by ongoing public health funding shortfalls, nor can they address underlying health inequities that are making the nation less resilient.

MS-DOH-21-1816-A-000192

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Rebuild and modernize the public health system, including by creating a mandatory $4.5 billion per year Public Health Infrastructure Fund to support foundational public health capabilities at the state, local, territorial, and tribal levels (STLT).** Strong foundational capabilities would improve the protection of all communities across a range of threats. However, a nationwide funding shortage, exacerbated by the pandemic, has prevented health departments across the country from developing and maintaining these capabilities. An additional funding limitation is that health departments receive very little funding that is not tied to specific diseases or categories. Congress should invest in cross-cutting public health capabilities, such as proposed in the Public Health Infrastructure Saves Lives Act.[105] Congress must also increase funding for specific programs that support health security, including the Public Health Emergency Preparedness and the HPP cooperative agreements. These state and local preparedness programs have demonstrated their value by saving lives, improving the speed and quality of response during emergencies, and ensuring that local authorities can adequately respond to most local health emergencies and outbreaks without federal assistance. Congress should provide additional funding to modernize public health and response functions at the CDC and ensure the agency has the capacity to respond to any event.

- **Invest in sustained public health data modernization.** Sustained investment in health data systems at the federal, state, and local levels is imperative. The CDC is the world's premier public health agency, yet years of inadequate funding has meant that the agency and its partners are reliant on archaic data systems. Americans felt the pain of delayed and disjointed disease surveillance throughout the pandemic, as the public health surveillance infrastructure relied on antiquated, disconnected systems and methods for tracking and responding to diseases. Congress wisely invested $500 million in the Coronavirus Aid, Relief, and Economic Security Act (P.L.116-136) and $50 million in the FY 2020 and FY 2021 appropriations bills as a down-payment on the CDC's data modernization initiative. These investments will help build the foundations for data sharing across public health, modernize the CDC's services and systems, leverage new data sources, and ensure public health can act on innovative data analytics. However, these advancements must be augmented and sustained, making up for decades of neglect. Congress should build on these initial investments with at least $450 million in immediate funding and at least $100 million per year to the CDC's data modernization initiative to modernize and sustain these systems. New data systems should be interoperable and cloud-based.

- **Ensure complete, disaggregated demographic data collection and reporting during public health emergencies.** The gaps in COVID-19 data reporting by race, ethnicity, sexual identity, gender identity, primary language, disability status, the intersections of these demographics, and other factors hindered the response and masked the true breadth of inequities during the pandemic. These gaps exposed long-standing shortcomings in demographic data collection and reporting in public health. Congress should invest in data modernization for STLT public health to enable accurate and comprehensive data collection. In addition, HHS should stand up a task force—including the Office of the Assistant Secretary for Planning and Evaluation, CDC, Office of the National Coordinator on Health Information Technology, Office of Minority Health,

MS-DOH-21-1816-A-00193

and CMS, in consultation with state, local, territorial and tribal agencies and private-sector stakeholders—to identify and address barriers to the collection and regular reporting of disaggregated, detailed demographic data during the pandemic and beyond. If needed, Congress should provide HHS agencies the authority to require jurisdictions to report race and ethnicity during public health emergencies.[106]

- **Accelerate crisis responses through a standing public health emergency response fund and faster supplemental funding.** In addition to stable core funding, the federal government needs readily available funds on hand to enable a rapid response while Congress assesses the necessity for supplemental funding. Congress should continue a no-year infusion of funds into the Public Health Emergency Rapid Response Fund and/or the Infectious Disease Rapid Response Fund to serve as available funding that would provide a temporary bridge between preparedness and supplemental emergency funds. Congress should replenish such funding on an annual basis, and funding should not come from existing preparedness resources, as response capacity cannot substitute for adequate readiness. The HHS secretary should only use such funding for acute emergencies that require a rapid response to save lives and protect the public.

- **Demonstrate a long-term commitment to global health security.** The United States should recommit to partnerships with international bodies such as the WHO, and Congress should solidify America's role as a global health leader, commit to implementing the Global Health Security Strategy,[107] and provide sustained annual funding for global health security programs at the CDC and the U.S. Agency for International Development. Congress should fund and the CDC should implement the modernization of the U.S. quarantine system, including IT systems, quarantine stations, regulatory framework, and traveler engagement and information.

Editor's note: on January 21, 2021, the Biden administration restored U.S. membership in the WHO.

RECOMMENDATION FOR FEDERAL AND STATE GOVERNMENT:

- **Enable efficient use of emergency funding.** During an emergency, responding agencies at all levels of government must be able to adapt spending policies. States should review their administrative preparedness to ensure they can efficiently use emergency monies, including speeding up contracting and hiring procedures. In addition, Congress may allocate emergency funding to multiple federal agencies. However, differing agency policies and practices can impede speed and coordination of funding across agencies. This can lead to disconnected and less effective emergency responses on the ground. The Office of Management and Budget, HHS, and FEMA should allow waivers of regulatory or administrative requirements to awardees of emergency response funding to allow funding braiding, to encourage coordination between programs and funding streams with similar goals, to provide flexibility to best meet the needs of the affected populations, and to increase efficiencies and reduce administrative duplication, such as in grant reporting.

MS-DOH-21-1816-A-000194

Priority Area 2: Prevent Outbreaks and Pandemics

Infectious diseases represent a threat to the health, safety, and economic and social stability of the country. The COVID-19 pandemic has cost the nation hundreds of thousands of lives and at least $16 trillion in losses to the U.S. gross domestic product as of October 2020.[108] The toll in lost educational achievement and long-term mental health impacts have yet to be fully understood. As TFAH, scientists, and public health experts have warned for many years, the nation was not prepared for a severe pandemic. At the same time as the nation battles the worst pandemic in a century, public health and medical providers continue to respond to "everyday" outbreaks: seasonal influenza, vaccine-preventable diseases, healthcare-associated infections, and antibiotic resistance continue to pose threats to health and safety. The United States must be able to prevent and respond to both major pandemics and localized outbreaks.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT, HEALTHCARE, AND AGRICULTURE:

- **Support the vaccine infrastructure.** The CDC's immunization program, sometimes called the "317 program," supports state and local immunization systems to increase vaccination rates among uninsured and underinsured adults and children, to respond to outbreaks, to educate the public, to target hard-to-reach populations, to improve vaccine confidence, to establish partnerships, and to improve information systems. Yet, funding has not kept up with needs, as states have to spend immunization dollars to respond to outbreaks,[109] deal with increases in the numbers of residents who lack health insurance,[110] and attempt to manage the impact of vaccine underutilization. State, local, and tribal health departments are depending on this underfunded infrastructure to distribute and dispense the COVID-19 vaccine, yet COVID funding was not distributed until January 2021. Congress should monitor the COVID-19 vaccination progress and provide additional funding, if needed. Congress should also increase annual funding for the CDC's immunization program as well as the seasonal influenza program and post-licensure vaccine safety monitoring. Congress should also provide needed resources to HHS to study the causes of vaccine resistance and to educate clinical providers on methods for improving vaccine acceptance, such as those proposed in the VACCINES Act.[111]
- **Ensure first-dollar coverage for recommended vaccines under Medicaid, Medicare, and commercial insurance.** Public and private payers should ensure that all vaccines recommended by the Advisory Committee on Immunization Practices (ACIP) are fully covered, as cost sharing, such as co-pays, can be a significant barrier to vaccination.[112] Congress should require zero cost sharing in Medicare Part D and B plans, and CMS should incentivize Part D plans to eliminate cost sharing and increase receipt of vaccines.[113] An example of legislation that takes steps to improve senior vaccination rates is the Protecting Seniors Through Immunization Act. CMS should encourage state Medicaid plans in states that have not expanded Medicaid to cover all ACIP-recommended vaccines without cost sharing.[114]
- **Significantly increase investments in public health initiatives to combat antibiotic resistance.** Congress should increase funding for innovative prevention methods of detecting and containing outbreaks supported by the Antibiotic Resistance Solutions Initiative at the CDC. The CDC is investing in prevention measures in every state to strengthen lab capacity, track infections across healthcare systems, detect new threats, disrupt pathogens, coordinate prevention strategies, educate healthcare providers on appropriate antibiotic use, and advocate for other innovations. To fully address the scope of AR spread, particularly in healthcare settings, Congress should increase funding for healthcare associated infection/antibiotic resistance programs and activities at state and local health departments. In addition, increases in funding are necessary to build global capacity to prevent and detect resistant infections and to combat the threat to national security.
- **Create incentives for new-product discovery to fight resistant infections.** It is extremely challenging for companies to earn a return on their investments for the development of new antibiotics: (1) antibiotics are typically given for a short duration; (2) the most highly resistant infections are still relatively rare; and (3) new antibiotics must be used judiciously to preserve their effectiveness. These

MS-DOH-21-1816-A-000195

factors have resulted in nearly all major pharmaceutical companies exiting the antibiotics market, leaving the critical innovation domain of discovering and developing new antibiotics to small biotech companies with limited budgets and limited research and development capacity. Legislation, such as the DISARM Act, would strengthen the market for antibiotic developers, improving patient access for those who need it most.

- **Eliminate overuse of antibiotics in agriculture.** The FDA should enforce rules regarding veterinary oversight and the judicious use of antibiotics in food animals, ensure data collection and publication, promote antibiotic stewardship programs, and track the impact of these policies on resistance patterns. Farmers and the food industry should stop using medically important antibiotics to promote growth and prevent disease in healthy animals, as recommended by the WHO,[115] and they should invest in research to develop and adopt husbandry practices that reduce the need for routine antibiotics.
- **Decrease over-prescription of antibiotics through implementation of antibiotic stewardship and antibiotic-use reporting.** The CDC estimates that improving prescribing practices and preventing infections could save 37,000 lives over five years.[116] CMS should finalize, implement, and enforce requirements for all CMS-enrolled facilities to have effective antibiotic stewardship programs that align with the CDC's Core Elements guidance and to work with public health stakeholders to track progress in prescribing rates and resistance patterns.[117] All relevant facilities must drastically improve their reporting of antibiotic use and resistance through the National Healthcare Safety Network and should adopt stewardship programs that meet the CDC's Core Elements.[118]
- **Fund the CDC to support state and local public health laboratories.** The CDC should be sufficiently funded to strengthen the Laboratory Response Network and to support state and local public health laboratories; currently, the Epidemiology and Laboratory Capacity grant is only funding approximately half of what laboratories and health department epidemiologists nationwide have requested.

RECOMMENDATIONS FOR FEDERAL AND STATE GOVERNMENT:

- **Provide job-protected paid leave.** The pandemic has called attention to the fact that paid family and medical leave are important infection-control measures, protecting both workers and customers, in addition to creating economic security. Workers are unable to adhere to public health guidance to isolate if they risk losing their jobs or paychecks. While Congress temporarily expanded access to paid leave during the pandemic, a permanent fix is needed. Congress should enact a permanent federal paid family and medical leave policy and dedicated paid sick days protections, and states should ensure effective implementation by passing paid leave laws and/or removing preemption exemptions.
- **Minimize state vaccine exemptions for schoolchildren and increase vaccination of healthcare workers.** States should enact policies that enable universal childhood vaccinations to ensure children, their classmates, educators, and the general public are protected from vaccine-preventable diseases. This includes eliminating nonmedical exemptions and opposing legislation to expand exemptions.[119] States should ensure medical vaccine exemptions are only given when appropriate and are not used as a de facto personal-belief exemption in states where those exemptions have been eliminated. States should require healthcare personnel to receive all ACIP-recommended vaccinations to protect staff and patients, assure continuity of operations in the event of an outbreak, and achieve necessary healthcare infection control. As this report was being prepared for publication, the COVID-19 vaccine was not an ACIP-required vaccine. Healthcare facilities should ensure access to vaccines for all staff and contractors, and they should remove any barriers to staff receiving vaccines. Healthcare facilities should also report healthcare worker vaccination status, such as for seasonal flu and COVID-19, to the CDC's National Healthcare Safety Network.

MS-DOH-21-1816-A-000196

Priority Area 3: Build Resilient Communities and Promote Health Equity in Preparedness

Social, economic, and health disparities impact how people within specific communities' experience disasters and how quickly they can recover. Unfortunately, the disproportionate impact of COVID-19 on communities of color and Tribal Nations was foreseeable: underlying health conditions driven by years of structural racism; uneven access to prevention and care during the pandemic; increased risk of exposure due to being frontline workers, such as in food processing, food service, or healthcare;[120] increased risk of exposure due to living in crowded or inadequate housing;[121] and more severe economic impacts for lower-income workers has meant that people of color and Tribal Nations are bearing a disproportionate burden from the pandemic. When intersectional issues, such as homelessness, incarceration, disability, age, lack of access to paid leave, LGBTQ+ status, and immigration status are also at play, the inequities are more pronounced. Addressing underlying inequities and intentionally and meaningfully engaging with the people and communities most likely to be impacted throughout the emergency planning and response process are critical to reducing vulnerability and ensuring that all receive appropriate services, regardless of circumstance. Equity must be an explicit and foundational principle in all emergency planning. Some communities have taken steps to integrate principles of equity throughout public health emergency activities,[122] but more needs to be done.

RECOMMENDATIONS FOR FEDERAL, STATE, AND LOCAL GOVERNMENT:

- **Examine and address gaps in equity in response capabilities.** An external body (such as the GAO or the National Academy of Sciences, Engineering and Medicine) should conduct an assessment of the pandemic specifically focused on gaps in equitable response, including inequities in allocation of scarce resources, healthcare capacity, data collection and reporting, and planning for communities at higher risk, underserved communities, and communities of color.
- **Invest in policies and capacity to address the social determinants of health (SDOH):** People at highest risk during disasters and those who have the hardest time recovering are often those with unstable or unhealthy housing, those with limited access to transportation, and those who live in low-socioeconomic-status communities,[123] all of which bore out during the COVID-19 pandemic. Addressing SDOH can improve resilience, but it must be a cross-sector effort to increase healthy, affordable housing; improve transportation access; fight poverty; and implement other policies proven to advance health. Congress should fund a public health approach to address SDOH, such as the approach proposed in the Improving Social Determinants of Health Act. The legislation would strengthen SDOH capacity at the CDC and enable grants to public health agencies to build cross-sector partnerships and develop community solutions to SDOH. For further discussion on policy options to address SDOH, see TFAH's Blueprint and PHACCS reports.[124,125]
- **Provide resources and technical assistance to communities to enhance equity and resilience before, during, and after an event.** Rather than a top-down approach to promote equity and resilience, policymakers should support an asset-based approach that relies on communities identifying and leveraging their assets. Congress should direct targeted resources to community-based organizations and existing community health networks that focus on the health of communities of color and other groups that bear a disproportionate burden during disasters. Evacuation plans should be inclusive of the community as a whole by meeting and enforcing the requirements of the Americans with Disabilities Act. Grants should support culturally and linguistically appropriate public health campaigns that address prevention and treatment, providing community leaders the opportunity to fully participate in planning activities, allowing organizations to hire and engage community members so emergency plans better reflect the community, and improving data collection and sharing. Federal and other grant makers and states should ensure that existing grants and sub-awards reach the grassroots level and communities most in need.
- **Public health agencies should strengthen their health equity leadership and adopt strategies and accountability metrics to incorporate equity into preparedness.** Equity must not be considered separate from preparedness activities but must serve as the foundation for a more resilient

MS-DOH-21-1816-A-000197

community. Ensuring equity is central to all preparedness activities and requires integrating equity accountability measures into all elements of emergency response. Congress should provide the CDC funding to extend its COVID-19 Health Equity Strategy[126] to ongoing preparedness and response work at the agency and with partners. All state and local governments, including health departments, should build up internal infrastructure to drive equity, including by identifying a chief health equity officer who has a leadership role in the emergency operations center and/or incident command structure for all-hazards events and is engaged in every emergency operation center activation. Health equity and emergency preparedness officials should work across programs to incorporate equity issues and goals into preparedness policies and plans;[127] to improve staff capacity to understand how the legacies of discrimination, current-day racial trauma, and other structural inequities affect disaster resilience and recovery; develop and disseminate communications materials that are culturally and linguistically tailored; and to collect and leverage data to identify unique community assets and advance equity before and during events.

RECOMMENDATIONS FOR STATE AND LOCAL GOVERNMENT AND COMMUNITY LEADERS:

- **Plan *with* communities, not for them, and empower their involvement with resources.** Emergency planners must conduct meaningful engagement, partnerships, and listening efforts as well as ongoing inclusion and local hiring (especially from communities typically at higher risk in disasters) in emergency planning and response. Officials should establish relationships with services and organizations that serve these populations before emergencies take place, and government should fund community leaders and community-based organizations to participate in preparedness efforts. Health departments and emergency management agencies should rely on the expertise, community trust, and networks of those who may bear a disproportionate risk, such as older adults, people with disabilities, and individuals with chronic health conditions to ensure emergency plans, procedures, and evacuation shelters meet the needs of all in the community.
- **Address mental health and substance use gaps, bolster crisis resources, and incorporate mental health first-aid and long-term treatment into disaster response and recovery strategies.** Emergencies can exacerbate existing mental health and substance use concerns and disrupt access to care. During the COVID-19 pandemic, there have been reports of increases in a number of mental health concerns,[128] including suicide ideation[129] and drug overdoses.[130] Short-term regulatory relief, like take-home medication for opioid use disorder[131] and waivers for telehealth,[132] have helped, but coordination among state, local, and federal agencies remains vital to delivering resources to affected communities. Policymakers should also incorporate behavioral health needs into disaster planning, as required by the Pandemic and All-Hazards Preparedness and Advancing Innovation Act.

MS-DOH-21-1816-A-000198

Priority Area 4: Ensure Effective Leadership, Coordination, and Workforce

The political polarization and contradictory messaging exhibited throughout the pandemic contributed to a wide variation in how individuals and communities responded. Issues such as face coverings, business- and school-closure decisions, and even the mortality numbers became matters for debate by a vocal minority of Americans.[133] Clear national leadership and communication, following the advice of public health and scientific experts, is needed to ensure consistent policies and messaging during a situation as complicated and dangerous as a public health emergency. Perhaps more important than any technology or invention is the presence of trained, experienced people, from the frontline responder to the top of government. The nation's local public health departments responded to the pandemic with an estimated 26,000 fewer public health workers compared with before the 2008 recession.[134] The state budget cuts likely to continue in the years following the pandemic threaten to intensify this workforce shortage. Effective crisis response requires coordination, cooperation, and leadership—elements that governments must build and sustain over time.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Strengthen federal leadership, guidance and regulatory authorities for public health emergencies.** During the COVID-19 pandemic, authority and decision-making over the response was ceded to states to an unprecedented degree. This diffusion of responsibility meant wide variation in policy and response decisions regarding business closures, mask mandates, testing strategies, and other tactics. The CDC must be empowered to lead the public health response during a pandemic and issue clear, feasible guidance and regulations for state, local, tribal, and territorial officials and to the public to minimize variation across jurisdictions. The optimal approach is a federal-state partnership rooted in shared decision-making and a clear division of labor.
- **Rebuild trust in federal public health agencies.** The COVID-19 pandemic has damaged faith in federal agencies, including public health agencies such as the CDC and the FDA. Policy decisions from the federal to the local level should be based on the best available science, led by public health experts, and free from any perception of political interference. The president, the HHS secretary, and the leadership of federal public health and emergency response agencies, including the CDC, ASPR, DHS, FEMA and the FDA, must conduct a thorough review on the independence and performance of these agencies. Leaders should establish procedures and policies to ensure the scientific integrity and independence of the agencies, without political interference, and they must correct any errors made during the COVID-19 response. At the same time, elected leaders must publicly support public health to rebuild confidence in those agencies and officials. All federal messages and messengers about public health issues must be consistent and based in science.

MS-DOH-21-1816-A-00199

Sundry Photography

- **Invest in public health communications.** Congress must make a significant investment in effective public health communications, including research into best practices for different audiences. The CDC and other federal, state, and local public health agencies should engage with a diverse group of stakeholders to research and test effective public health messaging. From vaccines to mask-wearing, there are subgroups of Americans who are skeptical, hesitant, or confused about COVID-19 public health guidance for various reasons. While some will be recalcitrant, many Americans are simply hesitant or have not been properly engaged. While the substance of communications should be consistent, messages must acknowledge the historical context of distrust and be linguistically and culturally tailored for different populations, and trusted, nongovernmental messengers should receive funding to help deliver messages.

- **The White House should reestablish a health security directorate with public health expertise.** The White House should ensure senior advisors to the president have a strong background in public health and/or biodefense, and the White House should ensure that senior-level interagency cooperation is progressing before, during, and after public health emergencies.

Editor's note: on January 20, 2021, the Biden administration reestablished a National Security Council Directorate for Global Health Security and Biodefense.

- **Clarify and restore roles and responsibilities for government's emergency support functions.** The White House, HHS, CDC, ASPR, U.S. Department of Homeland Security, FEMA, and FDA should work together to clarify roles and responsibilities to improve the nation's emergency preparedness and response capacity.

- **Fund the recruitment and training of public health personnel.** The health security enterprise requires trained, experienced personnel. Federal, state, and local governments must prioritize stable, long-term funding for recruitment and retention of a diverse workforce, including one with experience in public health informatics, laboratory science, health equity, and epidemiology. Congress should also invest in public health workforce development and retention programs, such as student loan repayment and other incentives, especially in underserved areas. Public health schools should incorporate health equity and cultural competency into their preparedness curricula.

MS-DOH-21-1816-A-000200

Priority Area 5: Accelerate Development and Distribution of Medical Countermeasures

A robust Public Health Emergency Medical Countermeasures Enterprise (PHEMCE)[135] could negate a range of health threats, but a drug or vaccine is only effective if it reaches the right person at the right time. Medical countermeasures (MCM) are FDA-regulated products that could be used in the event of a public health emergency; they include biologics, drugs, and devices.[136] The challenges faced in distributing scarce medical resources during the pandemic as well as the deployment of COVID-19 vaccine demonstrate the urgency of the right-product/right-time equation. During the first ten months of the pandemic, there was a notable gap in federal coordination, with many federal responsibilities being left to states or to the private sector. The federal government circumnavigated or significantly modified established MCM and medical supply-chain coordination and distribution channels at various points in the pandemic, contributing to confusion and chaos. For example, the lack of federal coordination and transparency left individual hospitals and states to compete with each other for scarce resources,[137] and FEMA and the U.S. Department of Defense were brought in to manage some supply-chain operations despite long-standing systems in place at HHS. Clear federal coordination is necessary during the pandemic, with an eye toward preventing future shortages and shortfalls.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Provide significant, long-term funding for the entire MCM enterprise.** The MCM enterprise involves research, manufacturing, surveillance, delivery, training, and monitoring. Long-term coordinated and transparent funding to the Biomedical Advance Research and Development Authority, Strategic National Stockpile, CDC, FDA, NIH, and other components of the PHEMCE would offer more certainty to the biotechnology industry and researchers, would strengthen public-private partnerships, and would enable the purchase of ancillary medical supplies, such as PPE. The United States should grow its investment in innovative, flexible technologies and platforms that will enable faster production of products for a range of biothreats, rather than focusing on products for a single pathogen.[138]

- **Prioritize the distribution and dispensing of MCMs.** It is important that MCMs reach the right person at the right time during emergencies; the challenges in mass vaccination were predicted by the CDC's MCM Operational Readiness Review.[139,140] HHS along with state, local, tribal, and territorial health departments should be properly resourced and require integration of private-sector healthcare supply distributors and supply-chain partners into planning, exercises, and emergency responses to better leverage existing systems and resources. Once

the COVID-19 vaccination campaign is complete, HHS should access and address gaps in vaccine development, procurement, maintenance, deployment and administration; and improve the training of state and local personnel to ensure vaccine administration is well-coordinated.

- **Clarify and strengthen MCM and supply-chain management for emergencies.** HHS must maintain primary authority over public health emergency response, including deployment of the Strategic National Stockpile and emergency medical supply-chain management, in coordination with other federal agencies and in consultation with private-sector and public health partners. Federal agencies should also explore all available authorities, such as through the Defense Production Act, and communicate strategies with stakeholders to bolster the supply chain during emergencies. The HHS secretary should clarify roles and responsibilities for supply-chain management throughout the pandemic and, moving forward, should develop and disseminate best practices for supply management.[141] HHS should strengthen the PHEMCE's work, including regular interagency meetings; engagement with private-sector, supply-chain partners; and improved transparency and communication with state, local, tribal, and territorial partners.

RECOMMENDATIONS FOR FEDERAL, STATE, AND LOCAL GOVERNMENTS AND PARTNERS:

- **Improve MCM guidance and communications for groups at higher risk during an event.** HHS, including the CDC, should consult with experts and work with healthcare professionals and state, local, and tribal partners to develop standardized guidance for dispensing MCMs to groups such as children, older adults, people with disabilities, and people who are homebound. And HHS and state, local, and tribal agencies should work with organizations that reach the public, especially communities at disproportionate risk—such as groups representing older Americans, people with disabilities, and limited English-proficient communities—to improve communications around MCM issues before an event. Communities need to be engaged before an outbreak or event to ensure their understanding of the risks, benefits, and distribution challenges of introducing a medical product to a large portion of the population and ultimately improving acceptance and access to MCMs. It is important to provide clear and accurate guidance to the public in multiple formats and languages, via trusted sources and multiple communications channels, including formats that are accessible to people with hearing or vision loss.

MS-DOH-21-1816-A-000202

Priority Area 6: Ready the Healthcare System to Respond and Recover

In the 2019 and 2020 *Ready or Not* reports, TFAH warned that medical surge capacity for a pandemic remained a major gap in the nation's preparedness. The COVID-19 pandemic has placed tremendous strain on the healthcare system, from acute-care facilities[142] to long-term care facilities[143] to small outpatient clinics.[144] Overcrowded facilities, exhausted workforces, disruptions in the supply chain, shortages of PPE and other supplies, interruptions in primary and preventive care, lack of situational awareness, and loss of revenue have been among the significant challenges to the nation's healthcare system. The toll in lives lost due to these compounding issues has yet to be calculated. The NHSPI has consistently found that healthcare delivery readiness scores are in the lowest levels among preparedness domains, with little progress in the past five years.[145] Policymakers need to strengthen existing systems and consider long-term mechanisms to create sustainable healthcare readiness across systems and across geographic borders.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT AND HEALTHCARE:

- **Strengthen the Hospital Preparedness Program and fund regional coordination.** HPP can help build strong healthcare coalitions capable of engaging and supporting members during disaster responses, but the program has been severely underfunded. Congress must provide more robust annual funding—which it has cut in half over the past decade. HHS and the awardees should ensure healthcare leaders takes the lead on HPP planning and implementation to the extent possible, with support and coordination from public health, emergency management, and others, and awardees should ensure as much funding as possible is reaching healthcare coalitions. Healthcare administrators should ensure their facilities have tools and support for meaningful participation in healthcare coalitions, including the ability to share information and resources across the coalition and with public health agencies. Congress should provide additional funding for a tiered regional disaster system to coordinate across coalitions and states,[146] to map specialized disaster care (such as burn or pediatric care) across the country, and to leverage those assets in a coordinated way.[147] Congress should also provide increased funding for healthcare surveillance through CDC's National Healthcare Safety Network—which is the nation's domestic tracking and response system to identify emerging and enduring threat across 37,000 healthcare facilities, including COVID-19, healthcare-associated infections (HAIs), and antibiotic-resistant (AR) infections. These data drive improvements in patient safety and monitor the surge capacity of healthcare facilities to confront new threats.
- **Create incentives and ramifications to build sustainable preparedness and surge capacity across healthcare systems.** The shortages of beds, healthcare personnel, and equipment during the pandemic underscores the need for cooperation among healthcare entities, across systems, and across geographic borders. Although there has been progress in developing healthcare coalitions in many regions and progress in meeting CMS and other accreditation preparedness standards by individual healthcare facilities, these existing mechanisms have not provided enough incentive for many healthcare facilities to create meaningful surge capacity and cooperation across competing entities. Similarly, the Joint Commission's preparedness standards apply to individual facilities and not to the readiness of the healthcare system as a whole.[148] In addition to strengthening existing systems, Congress and HHS should consider long-term sustainability for building healthcare readiness across the system, including meaningful incentives and disincentives, including:
  - An external self-regulatory body, in alignment with federal policy goals, could set, validate, and enforce standards for healthcare facility readiness, stratified by facility type, with authority for financial ramifications.[149]
  - Payment incentives could sustain preparedness, surge capacity, regional disaster partnerships, and reward facilities that maintain specialized disaster care.

MS-DOH-21-1816-A-000203

- **Expand access to healthcare.** Access to healthcare is always important and particularly so during a pandemic or disaster. Federal and state governments must ensure every person has access to healthcare, including robust insurance coverage. Millions of Americans still lack insurance coverage, and disparities by race, ethnicity, sexual or gender identity, and other factors have been exacerbated by the pandemic-induced recession.[150] Congress and the administration should strengthen incentives for states to expand Medicaid, make marketplace coverage more affordable, and improve outreach and marketing for enrollment.[151]

- **Assess impact of CMS Preparedness Standards and improve transparency.** An external review by the GAO or a similar entity should assess how CMS preparedness standards have affected overall healthcare readiness, and HHS should begin tracking progress on preparedness measures over time. CMS should also strengthen preparedness standards by adding medical surge capacity and other capabilities, including infection prevention and control, stratified by facility type, as a necessary requirement within the next iteration of the rule.[152]

RECOMMENDATIONS FOR STATE GOVERNMENT AND HEALTHCARE:

- **Integrate healthcare delivery into emergency preparedness and response.** Jurisdictions should engage and integrate the healthcare sector into emergency planning and responses, including plugging healthcare coalitions and other entities representing private healthcare and the healthcare supply chain into emergency planning and response and incident command. Health systems, healthcare coalitions, and public health should develop memoranda of understanding ahead of disasters to improve situational awareness across healthcare and to enable movement of patients, personnel, and supplies. Private-sector healthcare leadership should prioritize preparedness moving forward, including training and workforce protections, surveillance for emerging threats, stockpiling of supplies ahead of disasters, and full engagement in regional collaborations and coalitions.

- **Strengthen state policies regarding disaster healthcare delivery.** States should review credentialing standards to ensure healthcare facilities can call on providers from outside their states, and health systems should ensure they can receive outside providers quickly during a surge response. States should also adopt policies that promote healthcare readiness and ease the ability to surge care and services, such as the NLC, the Interstate Medical License Compact, the Recognition of EMS Personnel Licensure Interstate CompAct,[153] the Uniform Emergency Volunteer Health Practitioners Act,[154] emergency prescription refill laws and protocols, and implementation and education of providers regarding crisis standards of care guidelines.[155,156]

MS-DOH-21-1816-A-000204

Priority Area 7: Prepare for Environmental Threats and Extreme Weather

Climate change, environmental hazards, and extreme weather pose serious threats to human health. According to a December 2020 report by TFAH and the Johns Hopkins Bloomberg School of Public Health, many of the states most at risk from climate change are also the least ready to deal with it (see sidebar on page 60). Environmental health involves detecting and protecting communities from hazardous conditions in air, water, food, and other settings, and it is therefore a critical component of the nation's health security. Environmental hazards impact communities differently and exacerbate disparities among people living in poverty, people of color, people with underlying health conditions, and children and older people—all of whom are at particular risk.[157]

RECOMMENDATIONS FOR FEDERAL AND STATE GOVERNMENT:

- **Enact legislation requiring a national strategic plan.** The United States urgently needs a strategic action plan to address the health impacts of climate change. Policymakers should enact legislation requiring HHS to develop such a plan and to fund development and ongoing maintenance of health system capacity specifically for this purpose.
- **Support public health climate-adaptation efforts.** Funding for the CDC's Climate and Health program stands at $10 million per year, while the annual health costs of climate change events were estimated to be more than $14 billion in 2008.[158] Climate-informed health interventions include identifying likely climate impacts, potential health effects associated with these impacts, and the most at-risk populations and locations.[159] Congress should increase funding for environmental health programs, including the CDC's Climate and Health program and environmental health tracking to conduct surveillance and target interventions.
- **Develop sustainable state and local vector-control programs.** As the threat and geographic distribution of mosquitos, ticks, and other vectors changes, Congress should expand funding for the vector-borne disease program at the CDC to support state and local capacity to prevent and detect vector-borne diseases, such as Zika, West Nile Virus, and Lyme disease.
- **Guarantee clean water for all U.S. residents, including after disasters.** The administration and Congress should restore the Clean Water Rule, which includes measures to protect a safe water supply, such as addressing the ongoing problem of lead, per- and polyfluoroalkyl substances, and other toxins in drinking water; taking steps to reduce the potential for waterborne illnesses; and increasing protection against potential acts of terrorism on America's drinking and agricultural water. All states should include water security and sewage removal in their preparedness plans, and they should build relationships among health departments and local environmental and water agencies. The CDC should include national guidance and metrics for planning for a range of water-related crises.

RECOMMENDATIONS FOR STATE GOVERNMENT:

- **Every state should have a comprehensive climate vulnerability assessment and adaptation plan that incorporates public health.** Public health and environmental agencies should work together to track concerns, coordinate risk-management and communications, and prioritize necessary capabilities to reduce and address threats. States and localities should investigate what additional capacities are necessary and identify vulnerable populations and communities. State and local public health officials should incorporate environmental health into emergency operations planning and incident command.
- **Complete all steps of the CDC's Building Resilience Against Climate Effects, or "BRACE," framework, and continuously work to enhance and refine preparations for climate change.** State agencies must conduct and facilitate rigorous vulnerability assessments at the state and local levels. The assessments should focus especially on populations at highest risk and the health threats most pertinent to them. States must also push ahead to complete all steps of the framework, including identifying and implementing evidence-based interventions to protect residents. Finally, as agencies implement interventions, they should continually evaluate effectiveness and strive for quality improvement.

MS-DOH-21-1816-A-000205

Year in Review – 2020 Health Threats Incidents and Actions

This section reviews 2020's major events, research, and policy actions related to global and domestic health security.

Disease Outbreaks

Notable Incidents

- **COVID-19**
  - The novel coronavirus SARS-CoV-2, the virus that causes COVID-19, emerged internationally in late 2019. As of late February 2021, as this report was being prepared for publication, over 28 million cases; and over 500,000 deaths have been reported in the U.S. alone.[160] Globally, there have been over 109 million confirmed cases of COVID-19, and over two million deaths, reported to the World Health Organization (WHO).[161] The number of cases and the number of deaths from COVID-19 is higher in the United States than in any other country.[162] In the United States, slightly more women than men have been infected, but deaths in men are disproportionate (54 percent to 46 percent).[163] Black people account for nearly 16 percent of COVID-19 deaths, where race is known, despite representing 13 percent of the U.S. population.[164] Hispanic or Latino people account for 18 percent of reported COVID-19 cases in the U.S. as of late January 2021, a proportion approximately equal to their percentage of the U.S. population.[165] In addition, research indicates a significant level of asymptomatic cases, so true infection counts are likely higher than confirmed cases.[166] Deaths may also be underreported due to inadequate testing and given that the pandemic response itself may have indirectly caused mortality due to limited access to healthcare during pandemic surges and due to those who avoided seeking care in hospitals.[167,168] The Centers for Disease Control and Prevention (CDC) found that in the 10 weeks following declaration of the COVID-19 national emergency, emergency department visits declined 23 percent for heart attack, 20 percent for stroke, and 10 percent for hyperglycemic crisis.[169]
  - Those at highest risk for severe disease and death are the elderly and people with underlying medical conditions, but COVID-19 has severely sickened and killed many young and otherwise healthy individuals, as well. Researchers are trying to determine if certain genetic characteristics are responsible for severe versus mild disease.[170] The disease in young children is usually mild, but in rare cases it is associated with multisystem inflammatory syndrome in children, in which different body parts can become inflamed, including the heart, lungs, kidneys, brain, skin, eyes, or gastrointestinal organs.[171] National data reported between March and July 2020 showed that MIS-C disproportionately impacted Black and Latino children.[172] The long-term effects of COVID-19 infection aren't fully known, but findings show heart

and lung damage in some patients, and many patients report lingering fatigue, shortness of breath, and confusion.[173]

- In June 2020, the U.S. Department of Health and Human Services (HHS) Office of Minority Health announced Morehouse School of Medicine as the awardee for a new $40 million initiative to fight COVID-19 in racial- and ethnic-minority, rural, and socially vulnerable communities. The initiative—the National Infrastructure for Mitigating the Impact of COVID-19 within Racial and Ethnic Minority Communities (NIMIC)—is a three-year project designed to work with community-based organizations nationwide to deliver education and information on resources to help fight the pandemic. Its aim is to strengthen efforts to link communities to COVID-19 testing, healthcare, and social services and to share and implement effective response, recovery, and resilience strategies.[174]
- The United States has undertaken unprecedented efforts to accelerate the development, manufacturing, and distribution of COVID-19 vaccines and therapeutics through significant federal investments and scientific cooperation, while maintaining standards for safety and efficacy.[175] Usually, vaccines take years of research and testing before they are available to the public. As of December 2020, two vaccines, one developed and manufactured by Pfizer-BioNTech, the other by Moderna, received emergency-use authorization (EUA) from the U.S. Food and Drug Administration (FDA).[176] Initial administration of the vaccine to priority groups, including healthcare workers and residents of nursing homes, also began in December 2020.

nycshooter

- The Trump Administration created a centralized system to order, distribute, and track COVID-19 vaccines.[177] States can order vaccine quantities (as supply allows) from the CDC. Airlines worldwide are providing transportation for billions of doses of vaccine that must be stored in frigid temperatures. FedEx and UPS are installing ultracold freezers near their air-cargo hubs, and dry-ice producers are increasing production to support vaccine distribution.[178] The U.S. Department of Defense and HHS coordinated the shipment of the initial doses to states.[179] The CDC released a playbook for state, tribal, territorial, and local jurisdictions on how to plan and operationalize a vaccination response to COVID-19 within their jurisdictions.[180] The Advisory Committee on Immunization Practices recommended priority groups to receive the initial doses of the vaccines,[181] but the final decisions on population prioritization and logistics

MS-DOH-21-1816-A-000207

are up to the states to determine, with most states prioritizing healthcare providers and long-term care facility residents in the initial phase.[182]

- While shipping of the vaccine began shortly after the FDA issued emergency-use authorizations, the initial administration of the newly approved vaccines fell far short of projected goals. As of December 30, 2020, 12.4 million vaccine doses had been distributed to states, but only 2.6 million had been administered. Experts called on the federal government to provide more coordination and resources to the states to increase their capacity to quickly administer the vaccine to more people.[183] The challenges in initial administration of the vaccine likely occurred for many reasons, including: funding for states to administer the vaccine was not signed into law until December 27, 2020, which hindered planning, communications, hiring, and training; the lack of a centralized planning effort; the lack of federal leadership; the lack of communication between federal, state, and local planners on the number of initial doses available and when; slow engagement with local partners; and the sheer immensity and complexity of the project.[184,185] HHS is partnering with pharmacies, including CVS and Walgreens, to deliver vaccines on-site at nursing homes and assisted-living facilities. Following distribution to the initial critical populations, states are planning for COVID-19 vaccines to be available in a phased approach to the priority groups in the broader population at locations such as retail pharmacies, healthcare facilities, and vaccination sites, but as this report was being finalized, a specific time frame for availability of the vaccine to the general population was unclear and may be different from state to state.[186]

Editor's note: In January 2021, the Biden administration set a goal and put in place a plan to administer 100 million vaccine doses during its first 100 days in office.[187] That goal was later increased to 150 million doses. FEMA and National Guard troops went to work in many states to assist in the vaccination effort. As of March 1, 2021, 96,402,490 vaccine doses had been distributed nationwide and 76,899,987 had been administered.[188] However, based on preliminary data from 17 states, during the first two months of vaccine distribution, Blacks and Hispanics were being vaccinated at a much lower rate than were whites.[189]

- **Seasonal flu.** As TFAH was preparing this report, flu rates for the 2020–2021 flu season were lower than usual for major regions of the country.[190] The 2019–2020 flu season was of "moderate severity"; however, the severity of the season in some age groups was higher: hospitalization rates among children ages 0 to 4 years old and adults ages 18 to 49 years old were higher than observed during the 2009 H1N1 pandemic.[191] The CDC estimates found that the 2019–2020 flu accounted for approximately 38 million illnesses, 405,000 hospitalizations, and 22,000 flu deaths.[192] Seasonal flu vaccine coverage rates increased modestly across all age groups in 2019–2020, with vaccine rates among adults increasing 3.1 percentage points over the previous season and up 1.2 percentage points among children—but that was still far below Healthy People 2020 and 2030 goals.[193] The CDC estimates that influenza vaccination prevented 7.5 million illnesses, 3.7 million medical visits, 105,000 hospitalizations, and 6,300

MS-DOH-21-1816-A-000208

deaths due to influenza during the 2019–2020 season.[194] The low 2020–2021 seasonal flu activity was likely a result of the mitigation measures to reduce the spread of COVID-19.[195]

- **Hepatitis A.** In 2020, 27 states experienced outbreaks of the Hepatitis A virus, driven in part by increases among those who reported drug use and homelessness.[196] Hepatitis A is a highly transmissible infection.[197] The Hepatitis A vaccine is recommended for certain populations; in 2019, the Advisory Committee on Immunization Practice updated its recommendations to include people experiencing homelessness in the populations who should receive the vaccine.[198] Hepatitis A infections had been going down between 2000 and 2012 but increased in 2013, 2016, and 2018.[199] As of December 4, 2020, there have been 36,848 reported cases that lead to 22,546 hospitalizations and 348 deaths since the ongoing outbreak began in 2016.[200]

- **Measles outbreaks, United States.** In 2020, U.S. measles cases were low—only 13 confirmed cases in eight jurisdictions, as of November 30, 2020.[201] Conversely, 31 states confirmed 1,282 individual cases of measles in 2019.[202] Measles is a highly contagious disease that predominantly affects young children and can cause hospitalization, and death and serious complications, such as pneumonia, encephalitis.[203] It can cause up to a 90 percent chance of disease contraction in unimmunized individuals.[204] Outbreaks have been linked to the sustained spread of measles among unvaccinated communities.[205]

- **Measles outbreaks, global.** The WHO reported that during 2019, there were more measles cases reported worldwide than in any year since 1996—869,770 confirmed cases and an estimated 207,500 deaths.[206] Fortunately, as of September 2020, the number of confirmed cases worldwide was much lower, though the Democratic Republic of the Congo, Brazil, and Nigeria reported high numbers and there were ongoing outbreaks in other nations.[207] However, COVID-19 is increasing the risk of measles outbreaks, following the suspension of measles vaccination campaigns in 26 countries. On the current trajectory, experts predict more child deaths from measles than from COVID-19 in Africa.[208]

- **The Democratic Republic of Congo Ebola outbreak.** On June 1, 2020, the Democratic Republic of the Congo declared its 11th outbreak of Ebola virus disease.[209] In November 2020, it was declared over, following a total of 130 cases and 55 deaths.[210]

- **Candida auris.** C. auris is an emerging drug-resistant fungus that has led to severe illnesses in hospitalized patients. A majority of reported cases in 2020 were in New Jersey, New York, and Illinois. Infection by this multi-drug-resistant fungus has a mortality rate close to 60 percent and presents a serious global health threat.[211] As of November 30, 2020, in the United States, there were 1,595 reported clinical cases of C. auris and an additional 3,056 patients identified with C. auris. There is transmission in multiple countries, as well.[212] With the increase of patient transfers from long term care facilities to ICUs due to COVID-19, the CDC said that it expects C. auris and other fungal infections to remain an infection control challenge for healthcare facilities in the U.S. and around the world.[213]

- **Cholera.** Cholera, an acute intestinal infection, is rare in the United States, but cases have increased steadily since 2005 globally,[214] and it is a major cause of epidemic diarrhea in the developing world. Regions with humanitarian crises, high rates of poverty, and a lack of water and sanitation infrastructure are at higher risk. In 2020, Yemen and Somalia faced serious outbreaks.[215] Researchers estimate that every year, there are 1.3 to 4.0 million cases and 21,000 to 143,000 deaths worldwide due to cholera.[216]

- **Polio.** In August 2020, the African Continent was certified wild poliovirus free by the World Health Organization, making the world poliovirus free except for Pakistan and Afghanistan.[217] After months of severe disruptions from the COVID-19 pandemic, polio vaccination campaigns have resumed in both countries as of August 2020. UNICEF estimates up to 50 million children missed their vaccinations when efforts were halted in March 2020 to minimize transmission of COVID-19.[218]

- **Foodborne illnesses.** In 2020, multistate foodborne illness outbreaks resulted from mushrooms, peaches, onions, clover sprouts, deli meats, and bagged salads. The pathogens involved include several strains of Salmonella and E. coli, as well as Listeria and Cyclospora.[219] The CDC estimates that 48 million people get sick, 128,000 are hospitalized, and 3,000 die from foodborne illness each year in the United States.[220] The five most common pathogens that cause foodborne illness are: (1) Norovirus, (2) Salmonella, (3) Clostridium perfringens, (4) Campylobacter, and (5) Staphylococcus aureus.[221]

Notable Events and Policy Actions:

COVID RESPONSE

- **Public Health Emergency Declaration and early COVID-19 response.** On January 31, 2020, U.S. Health and Human Services Secretary Alex Azar declared a public health emergency for the United States for the 2019 novel coronavirus.[222] Since then, HHS has renewed the declaration several times. The declaration allowed some flexibilities for states, such as temporary reassignment of personnel to the response. Before the declaration and before the Trump administration requested emergency funding, Secretary Azar tapped $105 million from the Infectious Disease Rapid Response Reserve Fund for the initial response.[223] The WHO issued a public health emergency declaration of international concern in January and labeled the outbreak as a pandemic in March, 2020.[224] [225]

- **COVID Response Legislation.** Congress has enacted several public laws providing funding and authorities to assist in the response to the pandemic:[226,227]

  - **Coronavirus Preparedness and Response Supplemental Appropriations Act (P.L. 116-123).** The President signed the act into law on March 6, 2020, providing $8.3 billion in emergency funding for public health measures, including the development of medical countermeasures and grants for public health agencies.

  - **The Families First Coronavirus Response Act (P.L. 116-127).** The President signed the act into law on March 18, 2020; it included the Second Coronavirus Preparedness and Response Supplemental Appropriations Act. The legislation expanded food and nutrition programs, unemployment benefits, and emergency family and medical leave; it also required certain employers to provide paid sick leave for workers unable to work due to COVID-19, and it provided access to COVID-19 testing with no cost to the individual.

  - **The Coronavirus Aid, Relief, and Economic Security (CARES) Act (P.L. 116-136).** The President signed the act into law on March 27, 2020, providing over $2.2 trillion in relief to individuals; businesses; state, local, and federal agencies; and industry sectors affected by the COVID-19 pandemic and the government-led effort to limit its public health impact. It also included a variety of oversight provisions designed to increase the information available to Congress regarding the federal government's implementation of the CARES Act and response to the COVID-19 pandemic.[228]

  - **The Paycheck Protection Program and Health Care Enhancement Act (P.L. 116-139).** The President signed the act into law on April 24, 2020; it included Additional Emergency Appropriations for Coronavirus Response. The bill extended the Paycheck Protection Program and small-business loans and allocated funding for healthcare providers and COVID-19 testing.

  - **The Coronavirus Response and Relief Supplemental Appropriations Act, 2021 (P.L. 116-26).** Congress passed and the President signed the act with the fiscal year (FY) 2021 appropriations bills and signed it into law on December 27, 2021. The bill provided $900 billion in emergency appropriations, including $73 billion for HHS, of which $8.75 billion will support the vaccination campaign.

- **Payments to healthcare providers.** The CARES Act, Paycheck Protection Program and Health Care Enhancement Act, and the Coronavirus Response and Relief Supplemental Appropriations Act allocated $178 billion for a provider relief fund for hospitals, clinics, and other healthcare providers to recover some revenue lost due to the pandemic.[229] In addition, changes in HHS telehealth policies were put in place to expand access to telehealth services during the pandemic.[230]

COVID-19 Vaccine

- **COVID-19 Vaccine.** As of December 2020, two vaccines—one developed and manufactured by Pfizer-BioNTech, the other by Moderna—received emergency-use authorization from the FDA (see COVID sidebar, on page 55).

MS-DOH-21-1816-A-000210

COVID RESPONSE

Additional COVID-19 Response Actions:

- **Medical supply shortages.** The quantities of medical supplies in the Strategic National Stockpile and through the private-sector supply chain were not sufficient for a pandemic as widespread as COVID-19. Shortages of PPE,[231] ventilators,[232] testing supplies,[233] and other medical supplies and products reached critical levels at different phases of the pandemic. President Trump invoked the Defense Production Act in April 2020 to try to spur private-sector production of these supplies.[234]
- **National Special Pathogen System.** In March 2020, ASPR expanded the Regional Ebola Treatment Network to become the National Special Pathogen System (NSPS) through COVID-19 emergency supplemental funding. The NSPS builds on the Regional Ebola Treatment Network and was originally created to support the urgent preparedness and response needs of hospitals, health systems, and healthcare providers on the front lines of the COVID-19 outbreak. The system is designed to to help prepare hospitals and health systems to identify, isolate, assess, transport, and treat patients with COVID-19 or other special pathogens or persons under investigation for such illnesses. The long-term vision of the NSPS is to create a nationwide systems-based network approach, similar to other national systems (e.g., the national trauma system) for all special pathogens.
- **Crisis standards of care.** Major surges in COVID-19 patients caused hospitals and intensive-care units to exceed capacity. Hospitals canceled admissions and nonemergency procedures and established alternate care sites. In December 2020, 10 national organizations issued a statement outlining urgent action for states, healthcare systems, and health departments to implement crisis standards of care, including legal protections for healthcare workers, statewide information sharing, distribution of patients and resources, and care coordination across jurisdictions.[235]

Vaccines: Earning Trust and Access in Communities of Color and Tribal Nations

The reported hesitance among some populations of color and Tribal Nations toward COVID-19 vaccines[236] has a basis in historic mistreatment and the effect of current-day structural racism. These experiences could have long-term impacts on vaccine confidence and vaccination rates in these groups. In October 2020, TFAH, the National Medical Association, and UnidosUS partnered to host an expert convening on how to earn vaccine trust and increase vaccine access within communities of color and Tribal Nations. The experts concluded that earning such trust will require working with leaders in those communities to use their agency as trusted messengers. Leaders from these communities must have a place at the planning table and be provided the resources needed to engage with and share information with their stakeholders. All vaccine education messaging must be culturally and linguistically appropriate. Messaging campaigns must feature trusted messengers, and education programs should take advantage of existing health communications networks. Read the full policy brief, *Building Trust in and Access to a COVID-19 Vaccine Within Communities of Color and Tribal Nations*, or find it on the TFAH website.[237]

MS-DOH-21-1816-A-00021

- **Ending the HIV epidemic.** In FY 2020, the Trump administration awarded funding to its *Ending the HIV Epidemic: A Plan for America Initiative,* which aims to reduce the number of new HIV infections in the United States by 90 percent by 2030. In December 2019, Congress approved the largest increase to domestic HIV/AIDS-prevention programs from multiple federal sources, including the CDC, in decades, bringing federal funding in FY 2020 for HIV/AIDS (across multiple programs) to just over $28 billion.[238,239] In addition, HHS, through the Health Resources and Services Administration (HRSA), awarded more than $2 billion in Ryan White HIV/AIDS Program grants to cities, counties, states, and local community-based organizations. This funding supports a comprehensive program of HIV primary medical care, medication, and essential support services with the goal of improving the health quality of more than half a million people with HIV in the United States.[240]

- **Emerging infectious diseases.** The National Institute of Allergy and Infectious Diseases (NIAID), within NIH, awarded 11 grants totaling approximately $17 million to establish the Centers for Research in Emerging Infectious Diseases. The new global network will involve multidisciplinary investigations into how and where viruses and other pathogens emerge from wildlife and spillover to cause disease in people. NIAID intends to provide approximately $82 million over five years to support the network.[241]

- **Viral hepatitis strategic plan.** HHS released the Viral Hepatitis National Strategic Plan for the United States: A Roadmap to Elimination 2021–2025, which serves as a roadmap to hepatitis elimination. HHS sought input from a broad mix of stakeholders on whether the plan's goals, objectives, and strategies appropriately address the viral hepatitis epidemic and whether there are any critical gaps.[242]

- **National Action Plan for Combating Antibiotic-Resistant Bacteria (CARB).** Antimicrobial resistance, the rise of superbugs that are resistant to existing medicines, is a major threat to health. Originally released in 2015, the 2020–2025 CARB builds on the original by expanding evidence-based activities that have been shown to stop the spread of antibiotic resistance, such as increasing infection prevention and control and improving the way antibiotics are used. Developed by the HHS Office of the Assistant Secretary for Planning and Evaluation and authored by agencies within the CARB Task Force, which is co-chaired by HHS, the U.S. Department of Agriculture, and the U.S. Department of Defense, the plan's purpose is to guide U.S. government activities, as well as action by public health, healthcare, and veterinary partners to address urgent and serious antibiotic-resistant threats that affect people in the United States and globally.[243]

- **United States officially withdraws from the World Health Organization.** In July 2020, President Trump formally announced his intention to withdraw the United States from the WHO, effective July 6, 2021.[244]

Editor's note: on January 21, 2021, the Biden administration restored U.S. membership in the WHO.

MS-DOH-21-1816-A-000212

- **Food safety.** In July 2020, the FDA released its *New Era of Smarter Food Safety Blueprint*, which reflects input from a variety of stakeholders and outlines a path forward building on the implementation of the FDA Food Safety Modernization Act.[245] Its four core elements are: (1) tech-enabled traceability and foodborne outbreak response—using technologies, data streams, and approaches that will greatly reduce the time it takes to trace the origin of a contaminated food; (2) smarter tools and approaches for prevention—identifying new tools, processes, and communications to inform prevention efforts; (3) new business models and retail modernization—advancing the safety of both new business models, such as e-commerce and home delivery of food, and traditional business models, such as retail food establishments; and (4) food safety culture—supporting and strengthening cultures that embrace food safety within the FDA, on farms, and in facilities.[246]

Notable Research Findings, Meetings, and Federal Hearings:

- **Malaria treatment and prevention.** In May 2020, the FDA approved artesunate for injection to treat severe malaria in adult and pediatric patients.[247] Treatment of severe malaria with intravenous artesunate should always be followed by a complete treatment course of an appropriate oral antimalarial regimen. According to the CDC, approximately 2,000 cases of malaria are diagnosed in the United States each year, with 300 of those infected having severe disease.[248] In addition, the first phase 1 clinical trial, testing the safety and effectiveness of a monoclonal antibody against malaria, began. If effective, it would prevent malaria infections for several months with a single dose—a benefit to tourists, medical workers, and military personnel.[249]
- **Eastern Equine Encephalitis vaccine.** In June 2020, Bavarian Nordic announced topline results from the first-in-human trial of a prophylactic vaccine candidate against three equine encephalitis viruses (EEEV): western, eastern, and Venezuelan. The study, although small, showed that the vaccine was well tolerated and immunogenic across all dose groups, with injection-site pain as the most common vaccine-related adverse event.[250]
- **Ebola treatment.** In October 2020, the FDA approved Inmazeb, a mixture of three monoclonal antibodies made by Regeneron. This is the first FDA-approved treatment for Ebola virus infection in adult and pediatric patients, following a U.S. government-supported trial and expanded-access protocol in the Democratic Republic of the Congo.[251]
- **Universal flu vaccine study.** A universal influenza vaccine, FLU-v, which could confer long-lasting immunity from multiple influenza subtypes among all age groups, demonstrated immunogenicity and safety in its phase 2b study and will enter a larger phase 3 trial.[252] The FLU-v vaccine is designed to stimulate the production of flu-specific cytotoxic T lymphocytes, which kill and remove influenza-infected cells, by targeting internal viral proteins that are not as variable as the constantly mutating surface proteins currently targeted in seasonal flu vaccines.[253]

Severe Weather and Natural Disasters

Notable Incidents:

- **Tornados.** In early March 2020 in the Nashville area, 24 people were killed by two tornadoes, one of which was an EF-4 traveling at 60 miles per hour (mph)—significantly harder to outrun (or take cover from) than a typical tornado's 10 to 20 mph speed.[254] Also during a two-day period in mid-March, over 100 tornadoes ravaged the South and Southeast,[255] causing over $450 million in damage and 32 fatalities.[256]

- **Extreme heat.** In the United States, extreme heat kills more people than any other weather-related threat.[257] July 2020 nearly tied July 2019's record of the hottest month ever recorded on Earth—coming in just 0.02 degrees shy.[258,259] In August 2020, Death Valley reached 130 degrees Fahrenheit, and on September 6, 2020, Los Angeles County recorded its highest temperature ever, at 121 degrees Fahrenheit.[260] September 2020 was also the hottest September on record.[261]

- **Hurricanes.** The 2020 Atlantic hurricane season was the most active—breaking the record for the most named storms in a season, including six major hurricanes.[262] In the United States, Hurricane Isaias made landfall in North Carolina as a Category 1 and killed nine people as it moved up the coast,[263] causing more than $4 billion in damage.[264] Laura formed in the Caribbean, leaving nine dead, before developing into a Category 4 storm and making landfall in Louisiana, where it killed 27 people[265] and caused an estimated $10 to $12 billion in damage.[266] In September 2020, Hurricane Sally hit Alabama as a Category 2 and caused major flooding but no deaths,[267] though damage is estimated at $8 to $10 billion.[268] Hurricane Delta hit Louisiana in October 2020, killing at least four.[269] Central America was hit hard in 2020 with two back-to-back Category 4 storms: just weeks after Hurricane Eta made landfall and killed over 130 people, Hurricane Iota (a massive Category 5 storm while in the Atlantic) hit the same area. Together, the storms killed over 200 people.[270] In addition, the pandemic made hurricane preparations, evacuations, and sheltering more difficult.

- **Iowa derecho.** A powerful derecho—a fast wind storm associated with strong thunderstorms—tore through central Iowa in August 2020. Winds topped 100 mph and destroyed miles of crops, homes, businesses, and vehicles, and killed four people. The derecho was officially the costliest thunderstorm event in recorded U.S. history—estimated at $7.5 billion in damages.[271]

- **Wildfires in California and other states.** Several states experienced wildfires in 2020, including California, Oregon, and Colorado.[272,273] California experienced another historic fire season in 2020—five of the six largest wildfires since 1932 in California happened in 2020.[274] As of November 29, 2020, over 4 million acres had burned, compared with just under 260,000 acres burned during the same period in 2019.[275] Thirty-three people, including four firefighters, died in California in 2020 due to wildfires.[276] California's average temperature has increased by about 3 degrees Fahrenheit over the past century, which is three times the global temperature increase of 1 degree Fahrenheit.[277] Heavy spring rains promoted extensive vegetation growth, which withered in the heat and became fuel for wildfires to spread quickly through dry land.[278] In addition, the 2020 season was a La Niña cycle—colder than average surface-water temperatures in the Pacific—which often trigger hotter and drier weather in the Southwest.[279] Oregon also experienced an especially destructive wildfire season: 4,009 homes burned down in 2020, compared with 93 homes total from 2015 to 2019.[280] In Colorado, wildfires have consumed 9 percent of Rocky Mountain National Park and destroyed several historic buildings.[281] Exacerbating these fires is an ongoing pine-beetle outbreak, which has increased the number of dead trees for fuel.[282] Across the United States, 9.5 million acres have burned as of December 4, 2020, compared with 4.6 million acres for the same period in 2019.[283]

- **California power outages.** In an attempt to reduce the risk of overloading the power grid during an extreme heatwave, California's Independent System Operator, which manages the state's power supply, ordered utilities to impose temporary blackouts for the first time in 19 years.[284] While these outages only lasted an hour or two,[285] there is potential for unplanned and planned outrages to create health emergencies for some residents, including by presenting significant risks to patients in healthcare and long-term care facilities; people with electrically dependent medical equipment or medicines, such as oxygen, wheelchairs, and insulin; and the safety of food and water.[286]

MS-DOH-21-1816-A-000214

Notable Events and Policy Actions:

- **Public health emergency declarations.** In January 2020, HHS Secretary Azar declared a public health emergency for Puerto Rico following the late-December 2019 earthquakes and continuing aftershocks.[287] Azar declared emergencies in Louisiana and Texas due to Hurricane Laura and in Oregon and California due to wildfires. The declarations and related waivers give HHS's Centers for Medicare & Medicaid Services (CMS) beneficiaries and their healthcare providers and suppliers greater flexibility in meeting emergency health needs.[288,289]

- **Health center support.** In September 2020, HHS, through HRSA, awarded more than $79 million in construction and other capital support for 165 HRSA-funded health centers impacted by Hurricanes Florence and Michael, Typhoon Mangkut, and Super Typhoon Yutu, as well as for wildfires and earthquakes that occurred in 2018 and tornadoes and floods that occurred in 2019.[290]

Notable Research Findings, Meetings, and Federal Hearings:

- **Extreme rain.** Research from the National Oceanic and Atmospheric Administration on all Atlantic hurricanes affecting the southeastern and eastern United States during the 20th century found that extreme rain risk is highest after hurricanes weaken into tropical storms. The heaviest rainfall over the largest areas occurs after major hurricanes become tropical storms, not during the hurricanes—even major hurricanes—themselves.[291]

- **National Risk Index.** In November 2020, the Federal Emergency Management Agency (FEMA) released the National Risk Index, an online tool to help illustrate the nation's communities most at risk of natural hazards. It provides a holistic view of community-level risk nationwide by combining 18 hazards with socioeconomic and built-environment factors. The tool determines risk by reviewing a community's expected annual loss, by measuring hazard frequency, exposure, and historic loss rate; social vulnerability, by measuring the susceptibility of impacted social groups; and community resilience, by measuring the ability of a community to recover from the impacts of natural hazards. These data can help in developing a FEMA-approved hazard-mitigation plan to help increase community resilience, which is a prerequisite for applying for FEMA's mitigation grants.[292]

- **Climate reports.** The United Nations' World Meteorological Organization released two reports on climate in 2020. The State of Climate Services (2020) found that between 1970 and 2019, 79 percent of disasters worldwide involved weather-, water-, and climate-related hazards, which accounted for 56 percent of deaths and 75 percent of economic losses from disasters. The report highlights progress made in early warning systems' capacity, and it identifies where and how governments can invest in effective early warning systems to strengthen countries' resilience to multiple weather-, water-, and climate-related hazards. United in Science 2020, a new multi-agency report from leading science organizations, highlights the increasing and irreversible impacts of climate change and documents how COVID-19 has impeded the ability to monitor these changes through the global observing system.[293]

MS-DOH-21-1816-A-000215

CLIMATE CHANGE & HEALTH: MEASURING STATES' VULNERABILITY AND PREPAREDNESS

TFAH and JHU Bloomberg School of Public Health study reports on states' vulnerability to and readiness for the health impacts of climate change.

Climate change poses serious, immediate threats to human health. Catastrophic impacts are well-understood, such as death and injury from more frequent and more intense hurricanes and wildfires. Many dangers, however, lack a singular, spectacular event and are therefore more insidious: longer-lasting heatwaves; poorer air quality; chronic flooding; increases in vector-, water-, and food-related infections; and the toll all of this takes on people's mental health and well-being.

The release of greenhouse gases through human activities over the past two centuries has made some level of global warming inevitable. Humans must learn to live with the effects of this change (adaptation), even as they pursue the essential objective of minimizing future warming by reducing greenhouse gas emissions (mitigation).

Climate change, however, does not affect all people and places equally. A person's experience depends, in large part, on where she lives. Many health outcomes are linked to environmental factors and, therefore, sensitive to changes in climate. Social and demographic factors also drive vulnerability, meaning that the health of some communities or people could be more affected than others. In many cases, vulnerability reflects existing health risk factors and disparities, which are in turn tied to structural and systemic racism.

Fortunately, important opportunities to protect people's health from the impacts of climate change exist at the state and local level. Adaptation, which seeks to reduce injuries, illness, death, and suffering, is an extension of public health approaches that emphasize prevention and preparedness. Many of these actions are driven by state-level plans, policies, and programs, which provide a critical foundation and supply of resources to support additional efforts at the community level.

Given the size and diversity of the country, each state and its communities will experience climate change differently. State leaders must understand their particular risks and vulnerabilities in order to plan effectively. In areas of a state where vulnerability is higher, state leaders should invest more in adaptation and preparedness. Likewise, states that are more vulnerable overall should go to greater lengths to adapt to climate-related hazards.

A December 2020 report, *Climate Change & Health: Assessing State Preparedness*, by TFAH and the Johns Hopkins Bloomberg School of Public Health, examined states' readiness to protect residents from the health impacts of climate change in light of the nature and level of risks they face.[294] While every state had engaged in at least some level of planning and preparation, there was significant variation, and, in many places, a great deal of room for improvement. Of greatest concern, states with the highest

MS-DOH-21-1816-A-000216

levels of vulnerability—predominantly located in the Southeast—tended to be among the least prepared. (See Table 14.)

Leaders at all levels of government must act with urgency and persistent focus to ensure that their people, particularly those who are most vulnerable, are safe and secure. The report offers federal and state policy and program recommendations, including enacting legislation requiring a national strategic plan, fully funding the CDC's Climate and Health program, bolstering states' core public health preparedness capabilities, and establishing ongoing, dedicated state funding and staff for climate-related preparations.

Table 14. States Grouped by Level of Vulnerability and Preparedness

Vulnerability Group	State	Vulnerability Score Least Vulnerable: 3.4-4.7 More Vulnerable: 4.8-5.3 Most Vulnerable: 5.4-6.3	Preparedness Score Least Prepared: 4.0-5.0 More Prepared: 5.1-5.8 Most Prepared: 5.9-6.6
Least Vulnerable	Utah	3.8	6.6
	Maryland	4.4	6.3
	Vermont	4.3	6.3
	Colorado	4.0	6.2
	Wisconsin	4.4	6.1
	New Hampshire	4.1	6.0
	District of Columbia	4.5	5.9
	Maine	4.5	5.9
	Minnesota	4.4	5.8
	Washington	4.5	5.8
	Michigan	4.7	5.8
	Alaska	3.4	5.4
	North Dakota	4.1	5.2
	Nebraska	4.6	5.1
	Idaho	4.2	5.0
	Montana	4.3	4.8
	Wyoming	4.2	4.5
More Vulnerable	Virginia	4.8	6.3
	Massachusetts	4.9	6.2
	Rhode Island	4.9	6.0
	Illinois	4.9	6.0
	New York	5.3	5.9
	Pennsylvania	5.3	5.9
	Connecticut	4.9	5.9
	Oregon	4.8	5.8
	Delaware	4.9	5.7
	Kansas	5.1	5.3
	Iowa	4.9	5.3
	Indiana	5.0	5.0
	Ohio	5.1	5.0
	New Jersey	5.2	4.9
	Hawaii	5.3	4.8
	Nevada	4.9	4.6
	South Dakota	4.8	4.5
Most Vulnerable	North Carolina	5.5	6.0
	Arizona	5.4	5.9
	Alabama	5.8	5.8
	California	5.5	5.8
	Louisiana	5.9	5.7
	New Mexico	5.8	5.7
	Arkansas	6.1	5.5
	Missouri	5.4	5.5
	Florida	6.3	5.1
	Tennessee	5.5	4.9
	Georgia	5.6	4.9
	Kentucky	5.9	4.8
	South Carolina	5.9	4.8
	Texas	5.5	4.6
	Mississippi	5.9	4.5
	Oklahoma	5.5	4.5
	West Virginia	5.8	4.0

"Most prepared," among states that were "least vulnerable."

"Least prepared," among states that were "least vulnerable."

MS-DOH-21-1816-A-000217

All Hazards Events and Policy Actions

Notable Incidents:

- **E-cigarette and vaping injuries and deaths.** According to the CDC, as of February 18, 2020, a total of 2,807 hospitalized e-cigarette or vaping-associated lung injuries (EVALI) or deaths were reported to the CDC from all 50 states, DC, Puerto Rico, and the U.S. Virgin Islands. Sixty-eight deaths have been confirmed in 29 states and DC. Due to continued declines in new EVALI cases since September 2019, and the identification of vitamin E acetate as a likely primary cause of EVALI, the CDC is no longer collecting case reports.[295]

- **Mass shootings.** During 2020, in the United States, there were 611 mass shootings—defined as an incident in which at least four people are shot, excluding the shooter—in 2020.[296] This is a significant increase since 2019, when there were 417 total mass shootings.[297] These events have long-term health effects on communities and survivors, including post-traumatic-stress disorder, substance abuse, anxiety, and depression.[298]

- **Terror attacks.** On Christmas day, a bomb detonated in downtown Nashville, damaging over 40 businesses in the area and injuring three people. Quick evacuations by first-responders likely saved lives in the area.[299] While the motivation for the Christmas Day bombing is not known, the Center for Strategic and International Studies reported that white supremacists and other like-minded extremists conducted two-thirds of terrorist plots and attacks in the United States as of October 2020.[300]

Notable Events and Policy Actions:

- **Animal disease research.** The U.S. Department of Homeland Security is transferring a new facility—the National Bio and Agro-Defense Facility, which will research foreign animal diseases—to the U.S. Department of Agriculture. Foreign animal diseases pose a risk to livestock (and in rare cases, people) and the facility will develop countermeasures for these diseases. A report by the Government Accountability Office (GAO) found that it may not be ready to open in December 2022 as planned, despite both departments following practices for a successful transfer.[301]

- **Radiological detection.** The Defense Advanced Research Projects Agency (DARPA) greenlit an automated, networked radiation detection system known as SIGMA for use by the Port Authority of New York and New Jersey, which is theoretically capable of providing counterterrorism support through constant monitoring for radiological and nuclear threats. DARPA has further developed and tested sensors for SIGMA to add chemical, biological, and explosive threat detection to its list of capabilities. SIGMA is based in worn, portable sensors, vehicular-mounted sensors, and stationary sensors at key transportation nodes, and it can be constantly improved through regular software updates. Officials and first-responders can use SIGMA to track alerts and threats in real time, allowing for enhanced coordination.[302]

- **Next Generation 911.** The U.S. Department of Homeland Security Science and Technology Directorate and the U.S. Department of Transportation have begun systems interoperability and compatibility testing for the Next Generation 911 (NG911) through a contract with the Critical Infrastructure Resilience Institute of the University of Illinois at Urbana-Champaign. NG911 will update the current nationwide emergency response system to an Internet Protocol (IP) platform, which will enable voice, video, photographs, text, and future communications technologies to be transmitted to and by the public and first-responders for assistance.[303] No system launch date has been announced.

- **HHS/ASPR Strategic Plan.** In April 2020, the U.S. Office of the Assistant Secretary for Preparedness and Response (ASPR) released the ASPR Strategic Plan for FY 2020-23, which organizes and identifies how ASPR will fulfill its mission of saving lives and protecting Americans from 21st-century health security threats and achieve its strategic vision: "the nation's health care and response systems and the communities they serve are prepared, responsive, and resilient, thereby limiting the adverse health impacts of emergencies and disasters." The plan builds on the successful foundation established by the ASPR strategic plans issued in 2011 and 2014, and aligns with the HHS Strategic Plan FY 2018-2022 and other relevant national strategies and legislation. It is also informed by experience and lessons from real-world incidents, exercises, and training activities occurring over more than a decade. The plan organizes ASPR's efforts under four priority goals: (1) foster strong leadership; (2) sustain robust and reliable public health security capabilities; (3) advance an innovative medical countermeasures enterprise; and (4) build a regional disaster health response system.[304]

MS-DOH-21-1816-A-000218

Notable Research Findings, Meetings, and Federal Hearings:

- **Retention of the public health workforce.** As of November 2020, at least 70 top public health officials had been fired, resigned, or planned to leave their posts since the beginning of the pandemic.[305] The alarming trend often resulted from threats, both in-person and via social media, scapegoating, or political retribution. Even before the pandemic and related recession, state health agencies had lost nearly 10 percent of their full-time equivalent (FTE) workforce from 2012 to 2019,[306] while local health departments lost about 16 percent of their FTE staff from 2008 to 2019.[307]

- **Recruitment and retention of scientists.** A May 2020 GAO report found that HHS has had trouble recruiting and retaining medical, engineering, and other science and technology professionals to support activities like biomedical and clinical research. The 21st Century Cures Act provides additional hiring and retention authority—allowing HHS to hire up to 2,000 scientists with certain specialized graduate degrees and to increase the top pay to hire and retain an expert staff.[308]

- **Rebuilding the Public Health Workforce.** State and local revenue losses due to the COVID-19 economic crisis is likely to lead to budget cuts at the state and local level and is expected to worsen the public health workforce staffing shortfall. COVID response funding did allow for short-term staffing increases but not for the hiring of the permanent public health professionals necessary to meet 21st-century challenges.[309]

- **Antibiotic resistance.** Two novel investigative drugs that target antibiotic-resistant infections began advanced development through the Biomedical Advanced Research and Development Authority to begin phase 2 and 3 clinical trials. One drug tackles Clostridioides difficile (C. difficile) infections, which causes an estimated12,800 deaths per year.[310] The second uses CRISPR technology to kill Escherichia coli (E. coli) bacteria that cause recurring or drug-resistant urinary tract infections. If successful, it would be the first CRISPR-engineered bacteriophage therapy to be FDA-approved.[311] Bacteriophages are viruses that infect and replicate only in bacterial cells. They cannot infect human cells, and because each type of bacteriophage only kills a specific set of bacteria, it's less likely to disturb the beneficial bacteria in the human body.[312] In addition, the FDA approved cefiderocol for hospital-acquired, ventilator-associated bacterial pneumonia due to multidrug-resistant gram-negative bacteria.[313]

- **Legislative pandemic preparation blueprint.** In July 2020, then–Senate Health, Education, Labor and Pensions (HELP) Committee Chairman Lamar Alexander released "Preparing for the Next Pandemic," a legislative blueprint with five recommendations for legislators to address future pandemics based on lessons learned from COVID-19 and the past 20 years of pandemic planning. The five recommendations involve: (1) accelerated research and development for tests, treatments, and vaccines; (2) expanded disease surveillance; (3) improved stockpile capacity and distribution process; (4) improved state and local response capacity; and (5) improved federal coordination.[314] Leading public health experts sent the committee over 350 recommendations of short-term and long-term proposals to address future pandemics on a range of topics, including sustaining onshore manufacturing, creating and sustaining state stockpiles, and improving the federal stockpile.[315]

- **Preparedness Summit.** In August 2020, more than 1,300 attendees—who work in all levels of government, emergency management, volunteer organizations, healthcare coalitions, and academia—participated in the first ever virtual Preparedness Summit, "Fixing Our Fault Lines: Addressing Systemic Vulnerabilities." Attendees participated in more than 115 demonstrations, workshops, and educational sessions, and heard from expert-led panels, which provided an opportunity to prepare for, respond to, and recover from the waves of the COVID-19 pandemic and the many other threats to public health and health security.[316]

- **COVID-19 and Achieving Health Equity Report.** In September 2020, then–Senate HELP Committee Ranking Member Patty Murray also released a report, "COVID-19 & Achieving Health Equity: Congressional Action is Necessary to Address Racism and Inequality in the U.S. Health Care System." The report included 30 recommendations to Congress, including dedicated funding for COVID-19 relief for communities of color, requiring an equitable vaccine distribution plan, and a federal right to paid sick days and family and medical leave.[317]

MS-DOH-21-1816-A-000219

Appendix B: Methodology

Trust for America's Health (TFAH) made major refinements to its methodology for Ready or Not in 2018. For more information, see the 2019 edition of the series, Appendix A: Methodology.[318]

To meet TFAH's criteria, each indicator must be:

- **Significant.** The indicator needed to be a meaningful measure of states' public health emergency preparedness. The NHSPI first measured significance by using a multistage Delphi process with a panel of experts and then again by TFAH through interviews with additional experts.
- **Broadly relevant and accessible.** The indicator needed to be relevant—and timely data needed to be accessible—for every state and the District of Columbia.
- **Timely.** Data for the indicator needed to be updated regularly.
- **Scientifically valid.** Data supporting the indicator needed to be credible and rigorously constructed.
- **Nonpartisan.** The indicator, and data supporting the indicator, could not be rooted in or seen as rooted in any political goals.

Using these criteria, TFAH aims to select a broad set of actionable indicators with which it—and other stakeholders, including states themselves—can continue to track states' progress. (Complete data were not available for U.S. territories.) TFAH will strive to retain all or most of these indicators for multiple years to assist states in tracking their progress against each measure.

TFAH seeks measures that are incorporated in the NHSPI and that most closely meet TFAH's criteria. There is one exception: a measure of state public health funding-level trends that the NHSPI does not track.

Indicator Data Collection

The NHSPI provided TFAH with data for every indicator except five (those data tied to the NLC, public health funding, flu vaccination, hospital patient safety, and laboratory surge capacity). In cases where newer data were available than those modeled in the 2020 edition of the NHSPI, TFAH collected and verified figures from their original sources.

Public Health Funding Data Collection and Verification

To collect public health funding data for this report, TFAH examined states' publicly available funding documents and surveyed state officials. Informed by the Public Health Activities and Services Tracking project at the University of Washington, TFAH defines public health programming and services as inclusive of communicable disease control; chronic disease prevention; injury prevention; environmental public health; maternal, child, and family health; and access to and linkage with clinical care. Specifically, this definition includes:

MS-DOH-21-1816-A-000220

- **Communicable disease control.** Public health services related to communicable disease epidemiology, hepatitis, HIV/AIDS, immunization, sexually transmitted diseases, tuberculosis, etc.
- **Chronic disease prevention.** Public health services related to asthma, cancer, cardiovascular disease, diabetes, obesity, tobacco, etc.
- **Injury prevention.** Public health services related to firearms, motor vehicles, occupational injuries, senior falls prevention, substance-use disorder, other intentional and unintentional injuries, etc.
- **Environmental public health.** Public health services related to air and water quality, fish and shellfish, food safety, hazardous substances and sites, lead, onsite wastewater, solid and hazardous waste, zoonotic diseases, etc.
- **Maternal, child, and family health.** Public health services related to the coordination of services; direct service; family planning; newborn screening; population-based maternal, child, and family health; supplemental nutrition; etc.
- **Access to and linkage with clinical care.** Public health services related to beneficiary eligibility determination, provider or facility licensing, etc.

TFAH excludes from its definition insurance coverage programs, such as Medicaid or the Children's Health Insurance Program, as well as inpatient clinical facilities.

TFAH, under the guidance of state respondents, revised data for the base year. (In this report, that was FY 2019.) For some states, this was necessary to improve comparability between the two years when a reorganization of departmental responsibilities had occurred over the period.

All states and the District of Columbia verified their funding data.

Scoring and Tier Placements

TFAH grouped states based on their performances across the 10 indicators, and TFAH gave partial credit for some indicators to draw finer distinctions among states and within states over time. TFAH placed states into three tiers—high tier, middle tier, and low tier—based on their relative performance across the indicators.

Specifically, TFAH scored each indicator as follows:

- Adoption of the NLC: 0.5 point. No adoption: 0 points.
- Percent of hospitals participating in healthcare coalitions: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - Within one standard deviation above the mean (and states with universal participation): 1 point.
  - Within one standard deviation below the mean: 0.75 point.
  - Between one and two standard deviations below the mean: 0.5 point.
  - Between two and three standard deviations below the mean: 0.25 point.
  - More than three standard deviations below the mean: 0 points.
- Accreditation by the PHAB: 0.5 point. Not accredited: 0 points.
- Accreditation by the EMAP: 0.5 point. Not accredited: 0 points.
- Size of state public health budget compared with the past year (nominally, not inflation-adjusted).
  - No change or funding increase: 0.5 point.
  - Funding decrease: 0 points.
- Percent of population who used a community water system that failed to meet all applicable health-based standards: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - Within one standard deviation above the mean (and states with 0 percent of residents who used a noncompliant community system): 1 point.
  - Within one standard deviation below the mean: 0.75 point.
  - Between one and two standard deviations below the mean: 0.5 point.
  - Between two and three standard deviations below the mean: 0.25 point.
  - More than three standard deviations below the mean: 0 points.
- Percent of employed population with paid time off: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Between one and two standard deviations below the mean: 0.25 point.
  - More than two standard deviations below the mean: 0 points.

MS-DOH-21-1816-A-00021

- Percent of people ages 6 months or older who received a seasonal flu vaccination: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Between one and two standard deviations below the mean: 0.25 point.
  - More than two standard deviations below the mean: 0 points.
- Percent of hospitals with a top-quality ranking ("A" grade) on the Leapfrog Hospital Safety Grade. TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Positive number, more than one standard deviation below the mean: 0.25 point.
  - No hospitals with a top-quality ranking ("A" grade): 0 points.
- Public health laboratory has a plan for a six- to eight-week surge in testing capacity: 0.5 point. Did not report having a plan: 0 points.

The highest possible score a state could receive was 7.5 points.

TFAH placed states whose scores ranked among the top 17 in the high-performance tier. TFAH placed states whose scores ranked between the 18th-highest and 34th-highest in the middle tier. TFAH placed states with scores ranked between the 35th-highest and 51st-highest in the low-performance tier. (Ties in states' scores can prevent an even distribution across the tiers.)

This year, states in the high tier had scores ranging from 6 to 7; states in the middle tier had scores ranging from 5.25 to 5.75; and states in the low tier had scores ranking from 4 to 5.

Assuring data quality

TFAH conducted several rigorous phases of quality assurance to strengthen the integrity of the data and to improve and deepen TFAH's understanding of states' performance, especially that of outliers on specific indicators. During collection of state public health funding data, researchers systematically inspected every verified data file to identify incomplete responses, inconsistencies, and apparent data entry errors. Following this inspection, TFAH contacted respondents and gave them the opportunity to complete or correct their funding data.

The Coronavirus Pandemic: The Mental Health Impacts of Reopening Society

Presented jointly with The World from PRX & GBH

Live stream on Facebook, YouTube, and The Forum site, Tuesday, June 29, 2021, 12pm ET

There is no registration required to watch the event online.

Send questions for the panelists in advance or during the Q&A: theforum@hsph.harvard.edu or post them to Facebook @ForumHSPH or @pritheworld.

We will post the video later on demand on:

- YouTube
- The Forum website
- Facebook

Add event to calendar

After more than a year of measures such as mask mandates and social distancing, Americans are adjusting to a reopening society. But with ongoing concerns about the pandemic's spread, disparate vaccine acceptance rates, and an uncertain future, the coronavirus pandemic continues to cast a long shadow on our mental health. In this live online Q&A, Karestan Koenen, Professor of Psychiatric Epidemiology at the Harvard T.H. Chan School of Public Health, talks with The World's Elana Gordon about well-being and mental health during this transition.

MISSISSIPPI STATE DEPARTMENT OF HEALTH

March 23, 2022

Hart Wood
1030 15th Street NW
Suite B255
Washington, DC 20005
records@americanoversight.org

Re: Public Records Request

Ms. Wood:

With this letter you will find emails and attachments produced by the Mississippi State Department of Health (MSDH) in response to your public records request originally submitted on January 4, 2022. Public records requests at MSDH are governed by Mississippi's Public Records Act (Miss. Code. Ann. § 25-61-1, et seq.) as well as any laws providing exemptions to this Act.

A chart of redactions made in the produced emails and/or their attachments is provided. Note that over 120 emails from the National Biosurveillance Integration Center (NBIC) were completely redacted in alignment with the direction of the U.S. Department of Homeland Security which oversees the NBIC.

Should you have any questions, please reach out to the following agency staff member who helped conduct the review of your documents:

David Trewolla, JD
Director, Data Governance
David.Trewolla@msdh.ms.gov

Sincerely,

DocuSigned by:

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, Surveillance/Informatics Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of recent Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

- Webinars: Abbott BinaxNOW Training [Links]
  - This week, Abbott Laboratories will hold two educational webinars in support of their BinaxNOW COVID-19 tests. These webinars are designed to reinforce the Training Toolkit and highlight key points that should be kept in mind during BinaxNOW COVID-19 and NAVICA implementation. To register for either training, please use the links below:
    - **Wednesday, October 7** at **4:00 pm EDT**: [Link]
    - **Friday, October 9** at **4:00 pm EDT**: [Link]
  - For additional training videos and documents, visit Abbott's website here.
- MMWR Early Release: "Trends in COVID-19 Incidence After Implementation of Mitigation Measures — Arizona, January 22–August 7, 2020" [Attachment, Link]
  - From the summary: *"The number of COVID-19 cases in Arizona stabilized and then decreased after sustained implementation and enforcement of statewide and locally enhanced mitigation measures, beginning approximately 2 weeks after implementation and enforcement of mask mandates and enhanced sanitations practices began on June 17; further decreases were observed during July 13–August 7, after statewide limitations and closures of certain services and businesses."*
- CDC Partner Update Call: Campus Guidebook – Slowing the Spread at US Colleges and Universities [Link]
  - CDC will host a webinar **Monday, October 19** at **3:00 pm EDT**, focusing on COVID-19 at colleges and universities. Dr. Cliff McDonald will share updates on CDC's COVID-19 response, including the latest scientific information available. Additionally, Drs. Greta

Massetti and Lisa Barrios will review CDC COVID-19 guidance for institutes of higher education.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 10/19" in the subject line. The call will be recorded and posted to CDC's website here.
- Reminder: Request for CSTE COVID-19 Call Topics [Link]
    - To ensure timely and relevant information is provided to our members, CSTE has developed a topic submission form, available here. Please submit suggestions for topics (or speakers) to be discussed on future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations.

Emergency Preparedness & Response

Coronavirus Disease (COVID-19)

Centers for Disease Control and Prevention
MMWR
Morbidity and Mortality Weekly Report
Early Release / Vol. 69
October 6, 2020

Trends in COVID-19 Incidence After Implementation of Mitigation Measures — Arizona, January 22–August 7, 2020

M. Shayne Gallaway, PhD[1,2]; Jessica Rigler, MPH[1]; Susan Robinson, MPH[1]; Kristen Herrick, MPH[1]; Eugene Livar, MD[1]; Kenneth K. Komatsu, MPH[1]; Shane Brady, MPH[1]; Jennifer Cunico[1]; Cara M. Christ, MD[1]

Mitigating the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), requires individual, community, and state public health actions to prevent person-to-person transmission. Community mitigation measures can help slow the spread of COVID-19; these measures include wearing masks, social distancing, reducing the number and size of large gatherings, pausing operation of businesses where maintaining social distancing is challenging, working from or staying at home, and implementing certain workplace and educational institution controls (*1*–*4*). The Arizona Department of Health Services' (ADHS) recommendations for mitigating exposure to SARS-CoV-2 were informed by continual monitoring of patient demographics, SARS-CoV-2 community spread, and the pandemic's impacts on hospitals. To assess the effect of mitigation strategies in Arizona, the numbers of daily COVID-19 cases and 7-day moving averages during January 22–August 7, 2020, relative to implementation of enhanced community mitigation measures, were examined. The average number of daily cases increased approximately 151%, from 808 on June 1, 2020 to 2,026 on June 15, 2020 (after stay-at-home order lifted), necessitating increased preventive measures. On June 17, local officials began implementing and enforcing mask wearing (via county and city mandates),* affecting approximately 85% of the state population. Statewide mitigation measures included limitation of public events; closures of bars, gyms, movie theaters, and water parks; reduced restaurant dine-in capacity; and voluntary resident action to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases in Arizona peaked during June 29–July 2, stabilized during July 3–July 12, and further declined by approximately 75% during July 13–August 7. Widespread implementation and enforcement of sustained community mitigation measures informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

ADHS supports surveillance and investigation efforts of local public health departments, compiles surveillance and investigation information across counties, and provides infrastructure statewide to support infectious disease surveillance. Data on laboratory-confirmed and probable (*5*) COVID-19 cases (based on the Council of State and Territorial Epidemiologists case definitions)† were collected in the centralized Medical Electronic Disease Surveillance Intelligence System (MEDSIS),§ which is used by state, tribal, and county public health agencies to report human-based diseases in Arizona. Information was submitted to or entered into MEDSIS by health care providers, laboratories, local health departments, tribal entities, and ADHS. Multiple laboratory tests submitted for a single patient were combined into a single record. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

Temporal trends were examined by comparing the number of daily COVID-19 cases (as of September 1)¶ and 7-day moving averages before, during, and after implementation of enhanced community mitigation measures, defined as the following: limitations on persons' time away from their place of residence

*Mandates and ordinances varied and were county- and city-specific. Enforcement types included educating persons on the dangers of COVID-19 spread, issuing fines to persons and businesses who refused to comply with mandates, and loss of licenses for businesses not enforcing rules or mandates.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-000261

except for essential activities; certain business closures and service limitations (e.g., occupancy limitations, curbside pickup, and delivery of goods); enhanced sanitation practices**; social distancing, employee mask wearing, and symptom screenings for all businesses operating a physical location; limitations on the occurrence and size of public events; and local mandates enforcing mask use. The 7-day moving average was calculated after the cumulative case count exceeded 20 cases and is presented to describe COVID-19 trends.

On March 11, 2020, Arizona declared a public health state of emergency to prepare for, prevent, respond to, and mitigate the spread of SARS-CoV-2. Additional guidance was provided to local officials, businesses, communities, and individual persons to implement social distancing and close schools statewide (March 15); postpone and limit large gatherings to fewer than 50 persons; recommend telework options; restrict access to congregate settings; require restaurants to provide dine-out options only; and close all bars, gyms, and movie theaters in counties with confirmed COVID-19 cases (March 19) (Table). Based on Arizona data and CDC guidance (*1*,*2*), ADHS also recommended limiting persons' time away from their place of residence except for essential activities (i.e., stay-at-home order, "Stay Home, Stay Healthy, Stay Connected")†† (March 31).

During April 1–May 15, the 7-day moving average of daily cases ranged from 154 to 443 (Figure). During April 29–May 11, Arizona initiated a phased approach for retail shops and stores, cosmetologists, and barbers to reopen and operate, and for restaurants to resume dine-in services; the stay-at-home order ended May 15.

Average daily cases increased 151% from June 1 (808) to June 15 (2,026), necessitating an increased focus on preventive measures by businesses, communities, and individual persons. Updated guidance from state officials provided local governments the authority to implement mask policies (June 17) and enforcement measures tailored to local public health needs (local policies were applicable to approximately 85% of the total Arizona population). Before June 17, mask wearing had not been widely mandated or enforced. Arizona limited organized public events to fewer than 50 persons (with some exceptions); closed bars, gyms, movie theaters, and water parks and recreational tubing facilities (June 29); and limited restaurants' indoor dining to <50% capacity, with at least 6 feet of separation between patrons (July 9). The 7-day moving average of daily cases peaked during

** Based on guidance from ADHS, CDC, and the Department of Labor, and Occupational Safety and Health Administration to limit and mitigate the spread of COVID-19, including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

TABLE. Public policies to implement and enforce COVID-19 community mitigation measures and dates of issue/reissue* — Arizona, March 11–August 7, 2020

Mitigation measure	Date of issue/reissue
Declaration of emergency	Mar 11
School closure (on-site learning)	Mar 15
Limits on senior living facilities visitation	Mar 19
Expanded availability and coverage for telemedicine for persons, pets, and animals	Mar 25, Apr 1
Deferred requirements to renew driver license	Mar 20
Stay-at-home order	Mar 30–May 15
Business/Service closures	
Bars	Mar 19, Jun 29, Jul 23
Movie theaters	Mar 19, Jun 29, Jul 23
Indoor gyms and fitness clubs	Mar 19, Jun 29, Jul 23
Restaurants, on-site dining	Mar 19
Pools	Mar 19
Water parks and recreational tubing facilities	Jun 29, Jul 23
Business/Service limits (requirements)	
All businesses operating a physical location (enhanced sanitation,† social distancing, employee mask wearing, symptom screenings)	Jun 17
Retail (limited capacity, social distancing, enhanced sanitation)	Apr 29
Barbers and cosmetologists (employee mask wearing, spaced appointments, enhanced sanitation)	May 4
Restaurants (social distancing, limited capacity, employee mask wearing, patron mask wearing [when not eating or drinking], employee screening, enhanced sanitation)	May 4, Jul 9
Public pools (e.g., at hotels; limited capacity)	Jun 29, Jul 23
Private pools in public areas (e.g., multihousing complexes; limited capacity)	Jun 29, Jul 23
Public events (<50 persons)	Mar 15, Jun 29, Jul 23
Wearing masks (mandatory)	
Local officials able to mandate and enforce wearing masks	Jun 17
Yuma County	Jun 18
Maricopa County	Jun 19
Pima County	Jun 19
Santa Cruz County	Jun 19
Coconino County	Jun 20
>40 other cities/tribal communities	Jun 17–25§

Abbreviation: COVID-19 = coronavirus disease 2019.

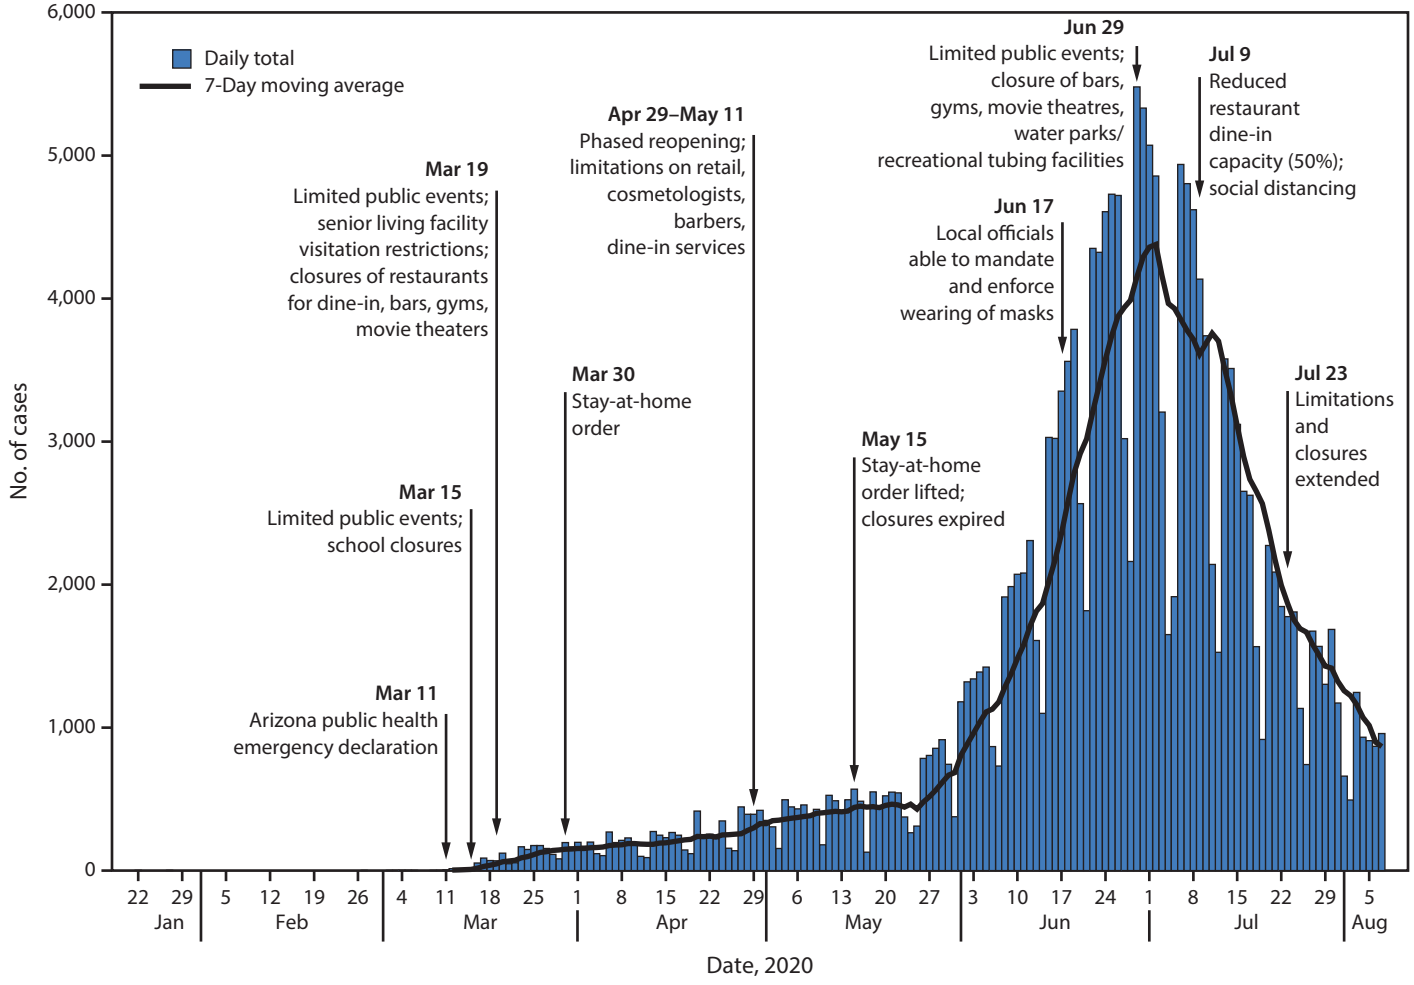
* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† Based on guidance from the Arizona Department of Health Services, CDC, Department of Labor, and Occupational Safety and Health Administration (OSHA) to limit and mitigate the spread of COVID-19 including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

§ Other tribal communities with mask mandates (issued June 18–23) included Fort McDowell Yavapai Nation, Gila River Indian Community, Navajo Nation, Salt-River Pima-Maricopa Indian Community, Tohono O'Odham Nation. Other cities with mask mandates (issued June 17–25) included Avondale, Bisbee, Buckeye, Carefree, Casa Grande, Chandler, Clarkdale, Clifton, Coolidge, Cottonwood, Douglas, Flagstaff, Fountain Hills, Gila Bend, Gilbert, Glendale, Globe, Goodyear, Guadalupe, Jerome, Kingman, Litchfield Park, Mammoth, Mesa, Miami, Nogales, Oro Valley, Paradise Valley, Payson, Peoria, Phoenix, San Luis, Sedona, Scottsdale, Somerton, Superior, Surprise, Tempe, Tolleson, Tucson, Youngtown, Yuma. Several other tribal communities and cities encouraged but did not mandate wearing masks.

MS-DOH-21-1816-A-000262

FIGURE. Selected community mitigation measures* and COVID-19 case counts† and 7-day moving averages§ — Arizona, January 22–August 7, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† As of September 1, 2020. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

§ Plotting of 7-day moving average began when cumulative case count exceeded 20 cases.

June 29–July 2 (range = 4,148–4,377), stabilized during July 3–12 (range = 3,609–4,160), and subsequently decreased 75% from July 13 (3,506) to August 7 (867). Mitigation measures put in place in June were extended through August to further limit transmission.

Discussion

Quantitative data on the effectiveness of community mitigation measures at suppressing the spread of COVID-19 are limited. The primary goal of implementing widespread enhanced mitigation measures in Arizona was to protect and save lives and maintain capacity in the health care system. A combination of voluntary and enforceable measures is more effective than any single measure (*6*). Mitigation measures mandated through public policy can effectively increase social distancing (*7*), and wearing masks has prevented transmission of SARS-CoV-2 (*8*). In Arizona, decreases in daily COVID-19 cases were observed after widespread sustained community mitigation measures that promoted social distancing, limited large gatherings, paused operations of businesses where mask use and social distancing were difficult to maintain, mandated and enforced mask wearing, and promoted voluntary resident actions to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases stabilized and began to decrease approximately 2 weeks after local officials began mandating mask wearing (throughout several counties

MS-DOH-21-1816-A-000263

and cities) and enhanced sanitation practices. Additional declines in case counts were associated with implementation of statewide limitations and closures sustained throughout July and extended into August.

The findings in this report are subject to at least four limitations. First, the relationship between mitigation measures and changes in case counts are temporal correlations and should not be interpreted to infer causality. Other factors that might have influenced the rate of change (e.g., travel restrictions, neighboring state mitigation measures, and individual choices to reduce movement before implementation of mandates) cannot be ruled out. Second, health centers run by tribal entities and federal health facilities (i.e., Indian Health Service, Veteran's Administration, and Department of Defense) in the state are requested but not required to comply with state reporting rules. Many of these health centers and federal health facilities complied with reporting, but the completeness of reporting by these entities is unknown. Third, adherence to mitigation measures was not assessed, nor could the extent to which each individual measure affected the number of incident COVID-19 cases be established. Finally, Arizona might not be representative of other U.S. states, and community mitigation measures might have a different impact in more populous or densely populated states; thus, these findings are not necessarily generalizable to other settings.

Enhanced mitigation measures should be implemented by communities and persons to slow COVID-19 spread, particularly before a vaccine or therapeutic treatment becomes widely available. State, local, and tribal officials are best positioned to continually monitor data and collaborate to determine the level and types of enhanced mitigation required. Mitigation measures, including mask mandates, that are implemented and enforced statewide appear to have been effective in decreasing the spread of COVID-19 in Arizona.

Summary

What is already known about this topic?

Community mitigation measures can help slow the spread of COVID-19.

What is added by this report?

The number of COVID-19 cases in Arizona stabilized and then decreased after sustained implementation and enforcement of statewide and locally enhanced mitigation measures, beginning approximately 2 weeks after implementation and enforcement of mask mandates and enhanced sanitations practices began on June 17; further decreases were observed during July 13–August 7, after statewide limitations and closures of certain services and businesses.

What are the implications for public health practice?

Widespread implementation and enforcement of sustained community mitigation measures, including mask wearing, informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

Sent to State Epidemiologists, CLUE, and the CSTE Executive Board

Thank you for joining this week's CSTE COVID-19 Response Ad Hoc Weekly All State Epi Call. The following call materials have been gathered for your awareness:

- Slides: "Science Agenda Development and Update" [Attachment]
  - Presented by Dr. Chris Braden, CDC
- Resources: Effectiveness of Community Mask Use [Links, Attachments]
  - In response to a request for additional scientific evidence regarding effectiveness of community mask use to support local mandates, please find the attached articles shared with us by Dr. McDonald and Dr. John Brooks. Dr. Brooks also recommended the October 3–9 Weekly Science Review from *Resolve to Save Lives*, available here.
  - Additionally, Dr. McDonald recommended the new *CDC COVID-19 Science Update* publication series, available on CDC's website here. Three of these updates feature either summaries or informative briefs on articles related to masks, and are attached to this email for your convenience.
- Announcement 1: NIOSH Funding Opportunity Announcement for State Occupational Safety and Health Surveillance Programs [Links]
  - The National Institute for Occupational Safety and Health (NIOSH) recently published the funding announcement for the State Occupational Safety and Health Surveillance Program. NIOSH intends to commit $40 million in total costs (direct and indirect) over a five-year period to fund about 30 applications. The letter of intent deadline is **October 30**, and the deadline to apply for this cooperative agreement is **December 16**. Full funding details can be found at grants.gov; for more information, please contact NIOSH Scientific Program Official, CAPT Linda West, at lkw0@cdc.gov.
    - You can find more information about the State Occupational Safety and Health Surveillance Program on NIOSH's website here. For more information on the

grant process, visit the NIOSH Extramural Research and Training Programs website here.

- Announcement 2: NHSN Webinars - "Reporting Results of Point of Care Testing for COVID-19 – A New NHSN Pathway" [Links]
  - CDC's National Healthcare Safety Network (NHSN) team will host two webinars this week to train attendees on its new Long Term Care Facility COVID-19 Pathway laboratory data reporting option. This option will enable nursing homes to enter point of care (POC) SARS-CoV-2 laboratory test data into the NHSN application. NHSN, in turn, will report the nursing home POC laboratory test data electronically to the public health agency—state or local—that has jurisdictional authority and responsibility to receive and use the nursing home's data. Webinar information is below:
    - **Thursday, October 22** at **11:00 am EDT**

***** Now available on-line at intranet.cdc.gov/library/covid19/archive *****

SPECIAL TOPIC: Cloth Face Coverings to Prevent Exhaled SARS-CoV-2

EXECUTIVE SUMMARY

CDC recommends community use of cloth face coverings as one measure to reduce the risk of COVID-19 spread. Infected persons can spread infection before they develop symptoms, and cloth face coverings provide "source control" to reduce spread from the wearer's coughs or exhaled breath. Data are limited on the effectiveness of cloth face coverings in this respect and come primarily from laboratory studies. Future studies are needed that measure the filtering efficiency and extent to which face coverings reduce SARS-CoV-2 transmission from infected persons, especially among persons infected with SARS-CoV-2 who are asymptomatic or pre-symptomatic.

Erratum

An earlier version of this Special Topic Science Update cited an article, 'Effectiveness of Surgical and Cotton Masks in Blocking SARS-CoV-2: A Controlled Comparison in 4 Patients' published in Annals of Internal Medicine on April 6, 2020. This article was retracted June 1, 2020 due the authors' misinterpretation of values below the limit of detection (LOD) by their in-house PCR assay. The LOD is a statistical measure of the lowest quantity of the analyte that can be distinguished from the absence of that analyte. The authors initially concluded that neither surgical nor cotton masks effectively filtered SARS-CoV-2 during coughs from infected patients. However, this conclusion is not valid given the reporting of values below the LOD.

BACKGROUND

A significant proportion of individuals infected with SARS-CoV-2 are asymptomatic or pre-symptomatic, and thus can unknowingly transmit the virus to others. In response, cloth face coverings have been recommended as source control to help prevent transmission, especially in settings where people are in close proximity and social distancing is difficult to maintain.[1] This recommendation excludes surgical masks and N95 respirators so as to not reduce the supply of these devices for first responders and other health care personnel. Face coverings may help prevent acquisition of respiratory viruses by wearers;[2] however, it is unclear if they can protect against SARS-CoV-2 infection, and if so, which materials are most effective.

CAN FACE COVERINGS PREVENT SARS-CoV-2 TRANSMISSION FROM A COUGH OR EXHALED BREATH?

Transmission of SARS-CoV-2 is thought to occur primarily through exposure to respiratory droplets or to fomites on environmental surfaces. Based on data from other human coronaviruses, it's possible that an infected person's normal exhaled breath could also be responsible for transmission by releasing aerosolized viral particles.[3] The evidence for face coverings to provide source control of SARS-CoV-2 is limited; however, studies of source control and community protection from influenza support using face coverings in combination with other preventive measures, such as hand hygiene and social distancing.

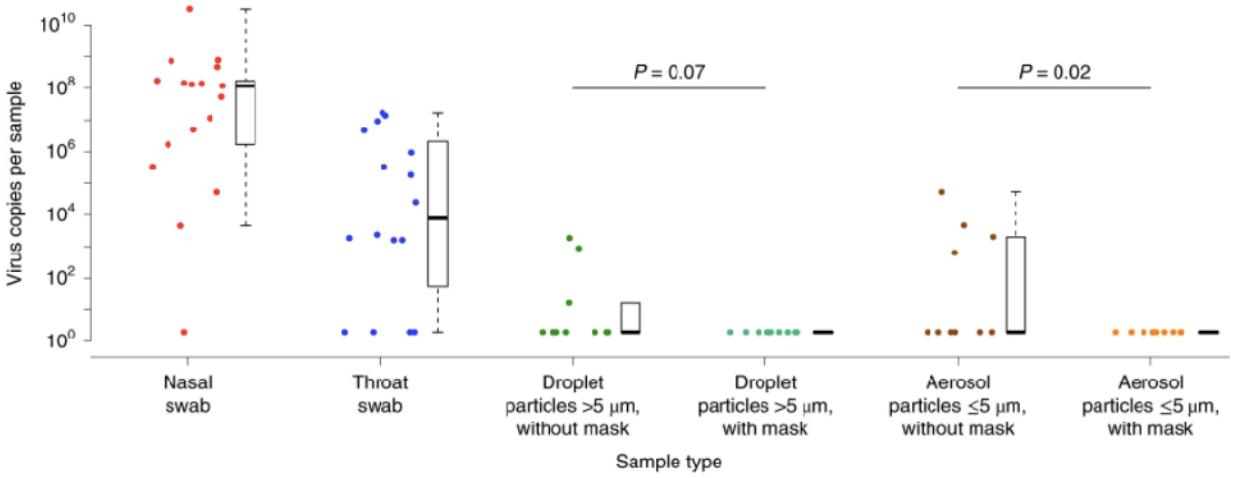
Other Coronaviruses

A study aimed to quantify source control from respiratory viral shedding (viral copies/sample) from a 30-minute exhaled breath sample from patients with seasonal coronaviruses (N=17), influenza virus (N=43), or rhinovirus (N=54).[5]

- In patients with seasonal coronavirus infection documented by viral RNA in nasal and throat swabs, viral RNA was detected in respiratory droplets (3/10 samples) or aerosols (4/10 samples) from patients without surgical face masks. However, viral RNA was not detected in any respiratory or droplet samples from patients wearing surgical face masks (**Figure 3**).
- Surgical face masks significantly reduced influenza virus shedding in droplet particles, but not aerosols. Significant reduction of rhinovirus shedding was not observed.

Limitations: Only surgical masks were tested. Patients were symptomatic, and those with coronaviruses coughed an average 17 times during the exhaled breath collection. RNA, not viral transmissibility, was measured.

Figure 3. Efficacy of surgical face masks in reducing seasonal coronavirus shedding in exhaled respiratory droplets and aerosols of symptomatic patients.



Note: Adapted from Leung *et al.*[5] Viral load from nasal and throat swabs were measured prior to cough (red and blue, respectively). Virus was undetectable in droplets and aerosols (green and orange, respectively) after mask use.

Influenza and Influenza-Like-Illness

In a pre-print update to a previously published Cochrane systematic review,[6] the effect of face mask use as source control was investigated in 14 randomized trials.[7] Nine trials compared masks with no masks: seven included people living in the community and two included healthcare workers. Only one of the nine studies compared cloth masks to other types of masks, and in health care workers only. All studies were in non-pandemic settings.

- Comparing mask use alone with no mask, there were no significant reductions in influenza-like illness (RR 0.93; 95% CI 0.83 to 1.05) or influenza infection (RR 0.84; 95% CI 0.61 to 1.17) in the pooled analysis.
- *Limitations*. Nearly all studies compared surgical face masks, not cloth face coverings. The authors indicated that the studies reviewed were limited by poor design and reporting and had few events. In some studies, the impact of measures like hand hygiene could not be distinguished from the impact of source control from mask use alone.

A pre-print review cited several studies from the influenza literature supporting use of cloth face coverings, in combination with other preventive measures, that are likely translatable to the current COVID-19 pandemic.[8]

- Three randomized controlled trials and one intervention trial found that use of face masks by infected persons, along with other non-pharmaceutical interventions such as intensified hand hygiene, could reduce transmission of influenza and influenza-like illnesses.[9-12]
- One observational study in Hong Kong reported that SARS-CoV cases were less likely to have worn face masks frequently in public venues compared to negative controls.[13] The contribution of masks as source control versus protection from exposure was not examined.

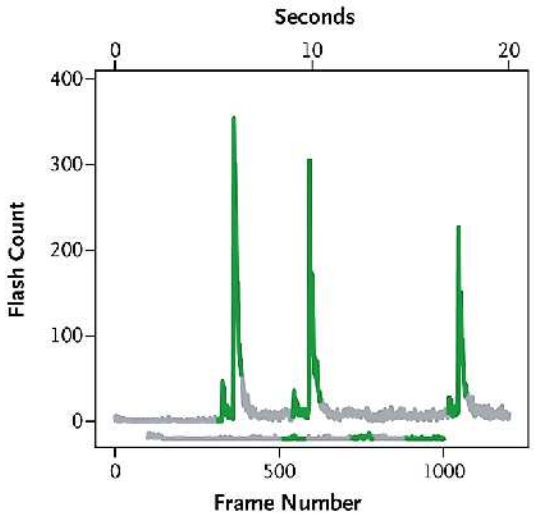
HOW WELL DO DIFFERENT MATERIALS FILTER DROPLETS AND AEROSOLS?

The ability of different types of material to effectively filter viral particles (whether as source control for exhaled virus or as protection against inhaled virus) has been simulated and measured under various laboratory conditions. In addition to types of materials used, many factors can contribute to the potential for reducing exhalation of virus, including design, fit, quality, and particle size. At this time, evidence demonstrating a reduction in viral transmissibility is inadequate.

A study to quantify speech-generated droplet emission in a laser light-scattering experiment measured exhaled droplets as a person verbalized a phrase three times. The investigator counted the flashes produced by droplets as they passed through a laser light sheet.[8]

- When the speaker used a damp[14] or dry[15] cloth mask and repeated the phrase, droplet emission was reduced to baseline (**Figure 4**).

Figure 4. Flash count corresponding to the number of droplets produced when speaking with and without wearing a damp cloth.



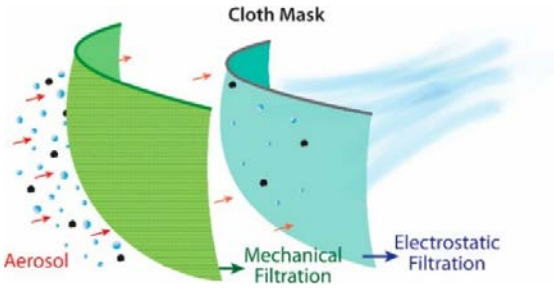
Note: Adapted from Anfinrud *et al.* Three green peaks reflect when person said "stay healthy" three times without a cloth mask. When spoken holding a damp cloth over the speaker's mouth, emission of droplets was substantially reduced (lower plot).[14]

Another study measured filtration of NaCl-based aerosols with particle sizes from 0.01 to 6 μm, a technique widely used for testing respirators.[16,17] Filtration efficiencies varied based on materials, layers of the same material, layers of different materials (hybrids) and particle size (< 0.3 μm and > 0.3 μm) (**Figure 5**).

- Most of these experiments were conducted under gapless conditions, simulating a fit-tested mask. The following are descending order of performance:
  - 2 layers consisting of cotton (80 twists per inch [TPI]) and chiffon, flannel, or silk
  - 2 layers of 80 TPI cotton
  - 1 layer of 80 TPI cotton

- When a gap was introduced (to simulate a non-fit-tested, loose mask) for the cotton/silk hybrid, the filtration efficiency dropped ~60%. However, some filtration was retained at both particle sizes (37% and 32% respectively).
- A gap was introduced only for the cotton/silk hybrid, limiting interpretation of filtration efficiencies of other materials and hybrids.
    - Filtration improved with multiple layers of the same materials and hybrids of different materials. Hybrid material layering likely increased filtration via both mechanical and electrostatic filtration.[17]

Figure 5. Filtration efficiencies were measured for both like and different materials and different particle sizes under laboratory conditions.



Note: Adapted from Konda *et al.*[17]

Another laboratory study used an aerosolized low pathogenic avian influenza strain to assess the percentage blocked by a homemade mask/covering (four layers of kitchen paper towels and one layer of polyester) compared to N95 and medical (surgical) masks under simulated breathing conditions.

- The homemade mask performed favorably compared with the N95 and medical masks (**Table 1**), and the authors noted it was more breathable than the N95.[18]

Table 1. Percentage of avian influenza virus blocked by masks under laboratory conditions.

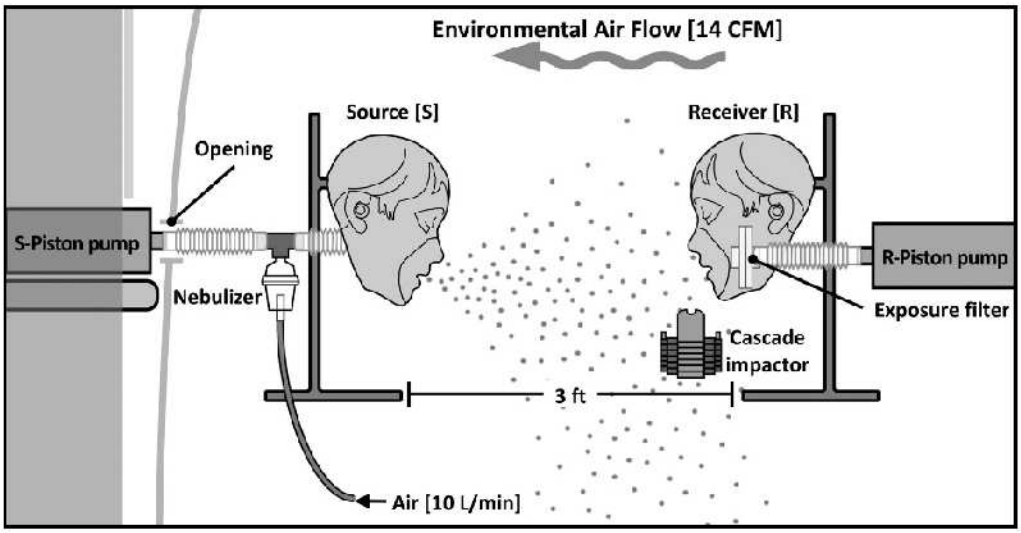
	C_t increase ($\bar{X} \pm SD$)	Percentage blocked (95% CI)
N95 mask	12.49 ± 0.33	99.98% (99.98%-99.99%)
Medical mask	5.13 ± 0.98	97.14% (94.36%-98.55%)
Homemade mask	4.37 ± 0.90	95.15% (90.97%-97.39%)

Note: Adapted from Ma *et al.* [18] Homemade mask was constructed of four layers of kitchen paper towels and one layer of polyester. Abbreviations: C_t, threshold cycle= increasing threshold cycle is inversely related to viral RNA detection by RT-PCR. SD=standard deviation; CI=confidence interval.

Another laboratory study created a chamber that simulated exhalation of contaminated aerosols during normal breathing from a source with and without a surgical mask or N95, and measured exposure to a receiver (**Figure 6**).[19] The exhaled particles were similar in size to exhaled droplets *in vivo* and exhaled into an environment with 6 air changes per hour to simulate flows typically found in public environments. The source and receiver were setup 3 feet apart to mimic 2 individuals in a room.

- A mask placed on the *source* resulted in a significant reduction in exposure to the receiver.
- A mask placed on the *receiver* did not significantly reduce exposure from the source when compared to no mask.

Figure 6. Schematic representation of experimental setup.

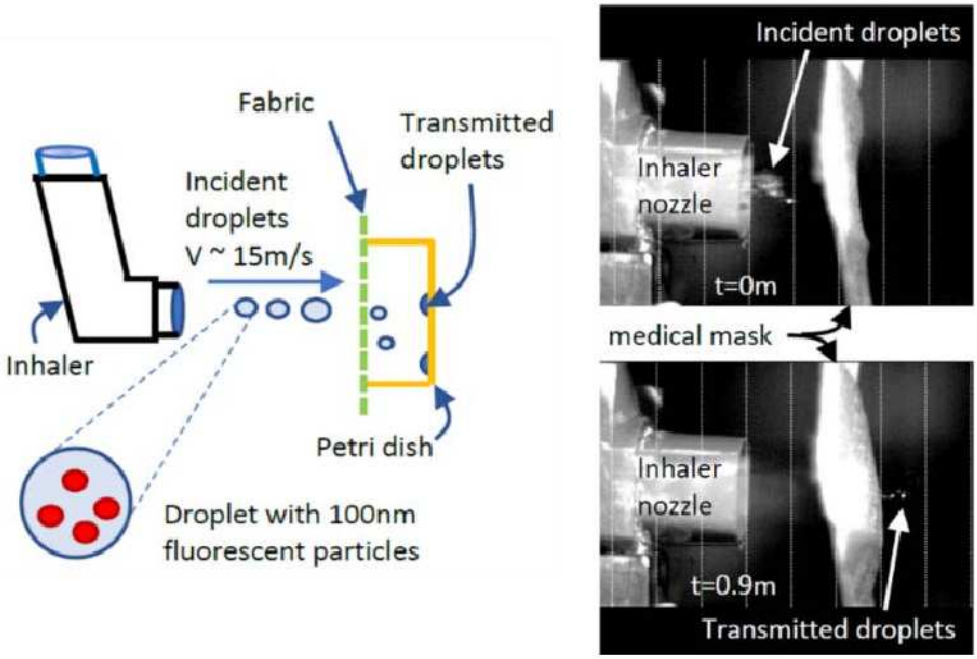


Note: Adapted from Diaz *et. al.* [19] Breathing pattern of both source and receiver: tidal volume 500 mL, rate 15 breaths/min.[19]

Lastly, in a pre-peer-reviewed manuscript, investigators described experiments to measure the ability of various fabrics that can be used to fashion homemade masks to filter a suspension of 0.10 µm fluorescent beads in distilled water to mimic SARS-CoV-2.[20] The suspension was loaded and dispersed by a metered-dose inhaler through various fabrics into a petri dish (**Figure 7**). Particle velocity was measured with a high-speed camera and quantified using a confocal laser scanning microscope.

- Cotton and cotton blend t-shirts' 'blocking ability' ranged from 43% to >90% (comparable to surgical masks); however, it's uncertain whether these results would be consistent in a clinical setting.

Figure 7. High speed camera snapshots of droplets hitting and penetrating mask materials.



Note: Adapted from Aydin *et al.*[20] A metered-dose asthma inhaler is loaded with the test solution and used to expel the solution into the fabric. The figure depicts the experimental set-up. The upper photograph shows expelled particles hitting the surgical mask. The lower photograph shows expelled particles penetrating the surgical mask.

IMPLICATIONS AND FUTURE RESEARCH

Limited evidence exists that quantifies the effectiveness of face coverings (cloth or other materials) for source control to reduce SARS-CoV-2 transmission via coughing or exhaled breath from COVID-19 patients. However, studies on source control from influenza and influenza-like illnesses support the use of cloth face coverings in combination with other preventive measures.

- Face coverings for source control and community protection from SARS-CoV-2 should be used in combination with other preventive measures, such as hand hygiene and social distancing.
- Studies of SARS-CoV-2 transmission among patients using different face covering materials are needed outside of laboratory settings and in the context of coughing, sneezing, and normal breathing.

A limited report that described deposition of SARS-CoV-2 on the outside of masks worn by infected persons who were asked to cough requires confirmation**.**

SARS-CoV-2 is widely thought to spread via respiratory droplets, but may also be spread by smaller aerosol particles. These smaller particles may be found in a normal exhaled breath, and thus have relevance to asymptomatic and pre-symptomatic spread.

- Studies are needed to better understand the fraction and particle size variability of exhaled SARS-CoV-2, and their potential infectivity and contribution to transmission, especially smaller aerosol particles.

Did you know?

French surgeon Paul Berger is credited with being the first to use a surgical mask during an operation in 1897.

> *"For several years I have been worried as to the part that drops of liquid projected from the mouth of the operator or his assistants may exercise on the outbreaks of infection which one still sees from time to time under conditions of surgical asepsis which are apparently satisfactory."*

Epidemiology

PEER-REVIEWED

Association of daily wear of eyeglasses with susceptibility to coronavirus disease 2019 infection. Zeng *et al.* JAMA Ophthalmology (September 16, 2020).

Key findings:

- A review of 276 COVID-19 patients found 16 (5.8%; 95% CI, 3.04% – 8.55%) wore glasses.
- The prevalence of SARS-CoV-2 infection for people who wear glasses (5.8%) was lower than the population prevalence described in a previous study (31.5%).
- Underlying diseases as well as COVID-19 symptoms and severity were not significantly different between patients who did and did not wear eyeglasses.

Methods: Cross-sectional evaluation of 276 hospitalized patients with SARS-CoV-2 infection in Suizhou, China between January 27 and March 13, 2020. The proportion of hospitalized persons who wore eyeglasses for more than 8 hours a day (wearing glasses for an extended period) were compared with the regional proportion of people with myopia from a 1985 study of 7 to 22-year-old students who by 2020 comprised an age-matched comparison cohort. *Limitations*: Single center study with small sample size; comparison to previous study of youth rather than a contemporary age-matched comparison group.

Implications: Whether SARS-CoV-2 is transmitted through the ocular route and what protective measures are needed remain a source of debate. This study suggests eyeglasses may provide some protection, however, as noted in an accompanying editorial, caution is needed as association may not imply causation, and additional data are needed to confirm this finding.

Case-control study of use of personal protective measures and risk for severe acute respiratory syndrome coronavirus 2 infection, Thailand. Doung-ngern *et al.* Emerging Infectious Diseases (September 14, 2020).

Key findings:

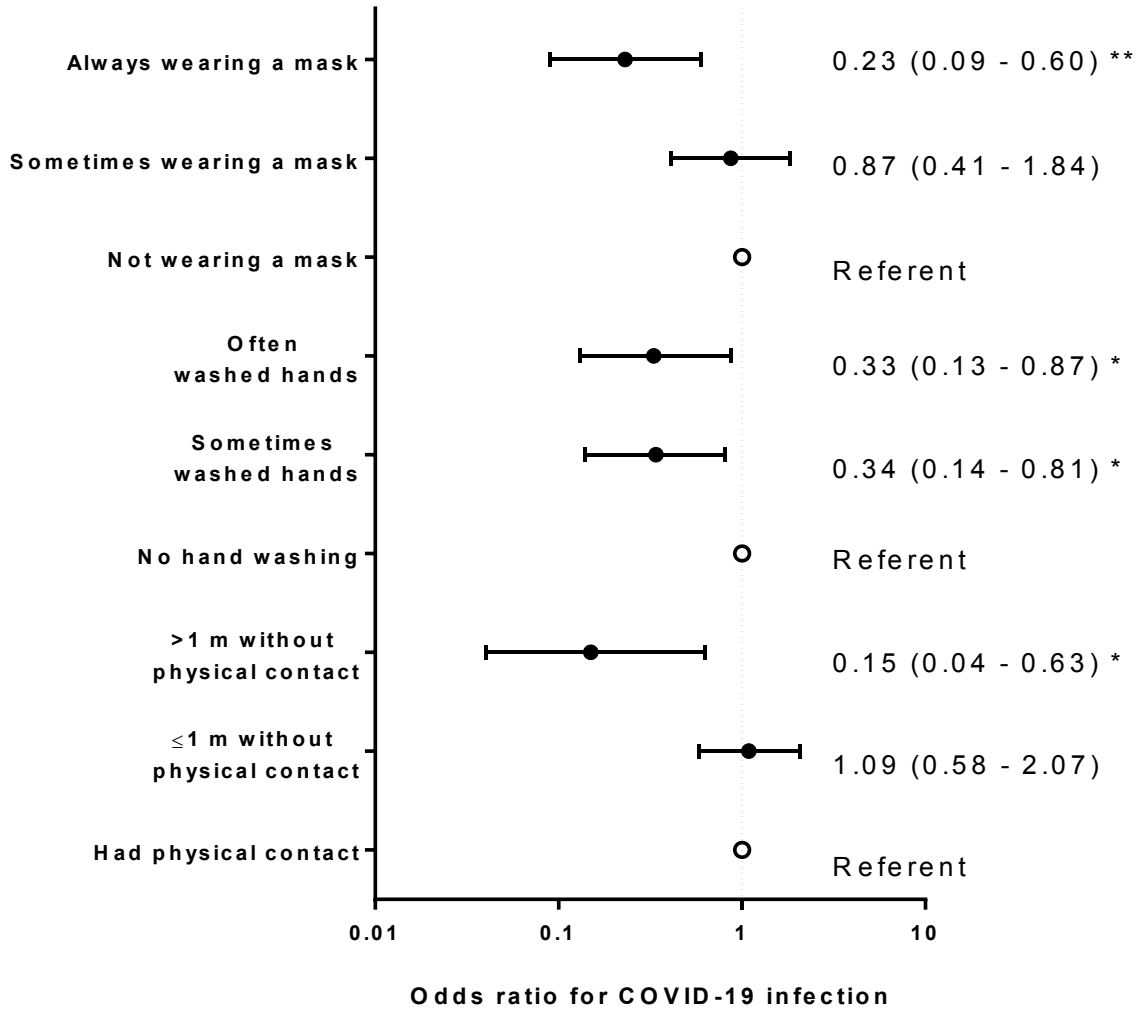
- Among 1,050 persons in three clusters, 211 (20.1%) tested positive for SARS-CoV-2 and were classified as cases, while 839 (79.9%) never tested positive and were classified as controls (Figure).
- Multivariate analysis showed low odds ratios for developing COVID-19 among those who maintained ≥1m distance from a contact (adjusted OR 0.15, 95% CI 0.04 – 0.63) and who frequently washed their hands (aOR 0.33, 95% CI 0.13 – 0.87) (Figure).
    - Always wearing a mask was more protective than sometimes wearing a mask (aOR 0.23, 95% CI 0.09 – 0.60 vs aOR 0.78, 95% CI 0.41 – 1.84, respectively).

MS-DOH-21-1816-A-000276

Methods: A retrospective case-control study of 1,050 asymptomatic people in 3 large COVID-19 clusters in Thailand between March and April 2020. People who had contact with COVID-19 index patients were questioned on mask wearing, social distancing, and hand hygiene. *Limitations*: Analysis from three settings might not be generalizable; estimated odds ratios were based on reported contact with the primary index case and did not evaluate the probability of having contact with other infected individuals; only 89% of defined controls were tested and the remainder could have been positive and confounded results.

Implications: This analysis supports recommendations for consistent and correct mask-wearing, proper social distancing and hand washing to lower risk of SARS-CoV-2 infection.

Figure:



Note: Adapted from Doung-ngern *et al*. Adjusted odds ratios for factors associated with SARS-CoV-2 infection among persons identified through contact tracing in Thailand, March – April 2020. ** p-value <0.01, * p-value<0.05. Open access journal; all content freely available.

Epidemiological and clinical findings of short-term recurrence of SARS-CoV-2 RNA PCR positivity in 1282 discharged COVID-19 cases: A multi-center, retrospective, observational study. Chen *et al.* Open Forum Infectious Diseases (September 13, 2020).

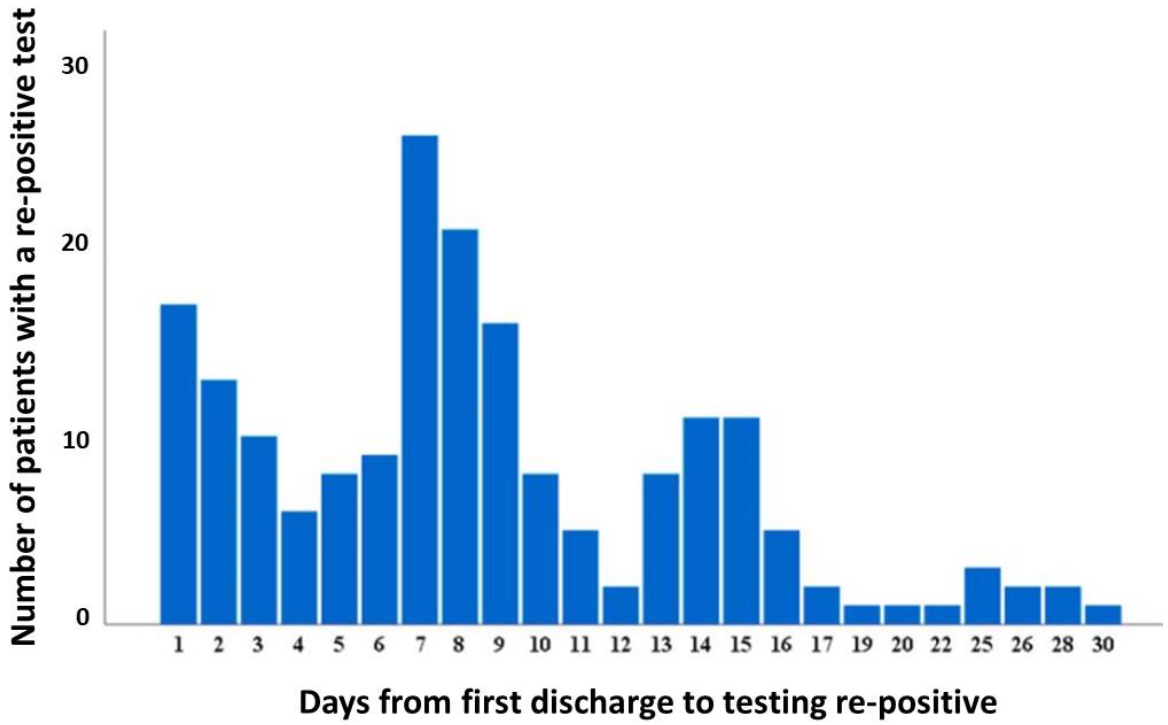
Key findings:

- 189 (14.7%) discharged patients re-tested positive for SARS-CoV-2 RNA.
  - 90.5% tested re-positive within 15 days of discharge (Figure 1).
  - Compared with patients who did not test re-positive, re-positive patients were more likely to be <40 years (63.5% vs 40.4%), had more moderate symptoms initially (95.8% vs 84.4%, p <0.001), were less likely to report comorbidities (11.1% vs 22.7%, p <0.001), and had shorter median length of primary hospitalization (17 days vs 19 days, p = 0.013).
- Most patients (80.4%) were readmitted only because of a positive test and had no symptoms.
  - 87.8% of re-positive patients had a negative test following the re-positive test within 20 days of hospital readmission (median 8 days) (Figure 2).
- No close contacts of re-positive patients developed symptoms and all tested negative for SARS-CoV-2.

Methods: Retrospective observational study of 1,282 COVID-19 patients discharged from 32 hospitals in China between January 14 and March 10, 2020 and followed for 28 days. All COVID-19 patients were discharged after 2 consecutive negative RT-PCR tests and thereafter tested at least weekly and reported symptoms daily, per provincial policy. *Limitations*: Viral genotyping was not conducted; the small number of close contacts may not be enough to look at risk of transmission from re-positive patients.

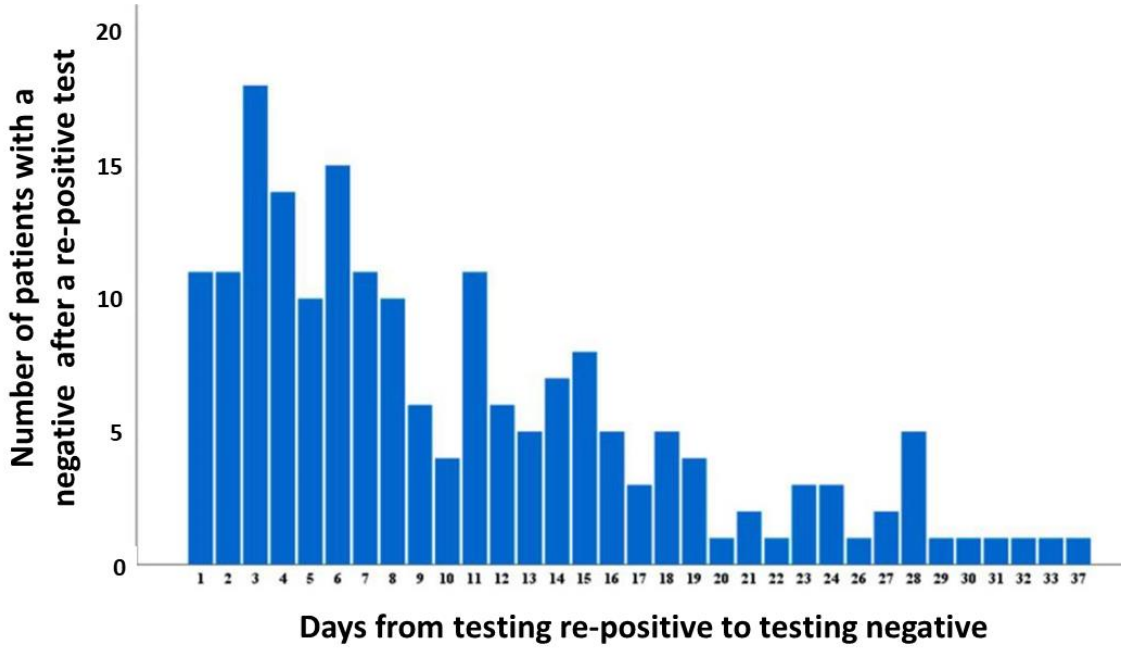
Implications: This study suggests that short-term recurrence of detectable SARS-CoV-2 RNA in discharged patients is not a relapse of COVID-19 and risk of ongoing transmission was not demonstrated.

Figure 1



Note: Adapted from Chen *et al*. Number of patients with a re-positive test for SARS-CoV-2 by the number of days after hospital discharge (n = 189). Licensed under CC BY-NC-ND.

Figure 2



Note: Adapted from Chen *et al*. Number of patients who had a negative test after a re-positive test in days (n = 188). Licensed under CC BY-NC-ND.

Modeling & Transmission

PEER-REVIEWED

Projected health-care resource needs for an effective response to COVID-19 in 73 low-income and middle-income countries: A modelling study. Tan-Torres Edejer *et al*. Lancet Global Health (September 9, 2020).

Key findings:

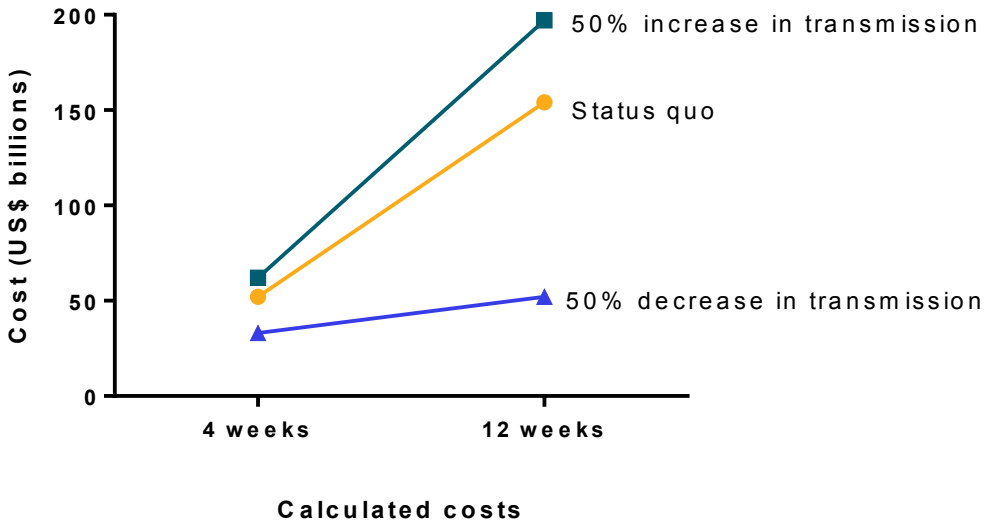
- In a modelling exercise, investigators found the main cost drivers for an effective COVID-19 response were case management (52%), maintaining essential services (21%), rapid response and case investigation (14%), and infection prevention and control (9%).
- Total healthcare cost estimates at baseline for 4 weeks was $52 billion (US$) for the status quo scenario, $33 billion for 50% decrease in transmission scenario, and $62 billion for the 50% increase in transmission scenario (Figure).
- At 12 weeks, under the 50% reduction in transmission scenario, costs were projected to be equivalent to the 4-week status quo scenario costs.
    - Under the status quo or increasing transmission scenarios, costs were projected to triple the 4-week costs (Figure).

Methods: Cost analysis model of COVID-19 strategic preparedness and response costs in 73 low and middle-income countries at two time periods: baseline for 4 weeks (June, 2020 to July, 2020) and 12 weeks (July, 2020 to September, 2020) under 3 scenarios regarding transmission (status quo, 50% increase, 50% decrease). Costs included costs for laboratories and health facilities, personal protective equipment, diagnostic supplies, pharmaceuticals, and labor costs. *Limitations:* Only costs borne by healthcare sector were included; costs for

quarantine and isolation for mild to moderate COVID-19 cases not included; sensitivity analyses were limited to 50% changes in transmission.

Implications: COVID-19 response costs quickly escalate if public health measures are relaxed and transmission increases. Public health measures to reduce transmission can reduce these future costs to sustain the response. Costs for case management services were the biggest drivers of COVID-19 response costs in low- and middle-income countries.

Figure:



Note: Adapted from Tan-Torres Edejer *et al*. Calculated cost estimates for a COVID-19 response in billions of US dollars for low- and middle-income countries. Costs were estimated for three scenarios: **status quo**, **+50% transmission**, and **-50% transmission** at 4 and 12 weeks. Licensed under CC-BY-NC-ND.

Diabetes-related COVID-19 Mortality

Early in the pandemic diabetes was recognized as a risk for poor COVID-19 outcomes. Below we present two studies that describe COVID-19-related mortality rates stratified by type of diabetes in England.

PEER-REVIEWED

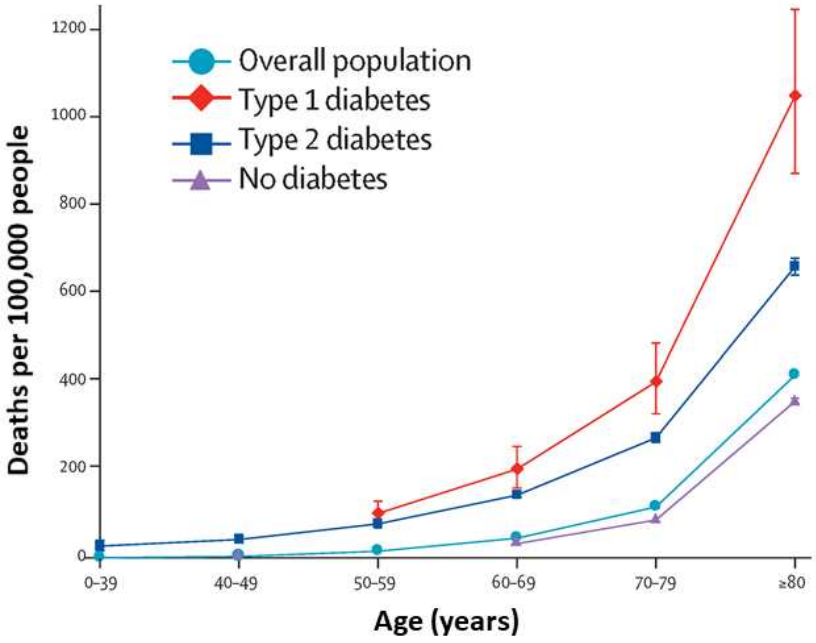
A. **Associations of type 1 and type 2 diabetes with COVID-19 related mortality in England: A whole-population study.** Barron *et al.* Lancet Diabetes & Endocrinology (August 13, 2020).

Key findings:

- Persons with diabetes comprise 5.2% of the population in England but comprised 33.6% (7,867/23,698) of all COVID-19 deaths.
- Both type 1 and type 2 diabetes were independently associated with increased odds of COVID-19 death after adjusting for age, sex, ethnicity, socioeconomic status, and region: type 1 diabetes adjusted OR 3.51 (95% CI 3.16 – 3.90), type 2 diabetes aOR 2.03 (95% CI 1.97 – 2.09).
- There was a strong association between death and age; this effect was more pronounced among those with type 1 diabetes compared with type 2 diabetes (Figure).

Methods: Whole-population study looking at risk of COVID-19-related in-hospital death associated with diabetes status in the England from March 1 to May 11, 2020 in all individuals registered with a general practice. *Limitations*: Because the outcome was in-hospital death, the association of diabetes with COVID-19 mortality was likely underestimated.

Figure:



Note: Adapted from Barron *et al*. Unadjusted in-hospital COVID-19 mortality rates, March 1 to May 11, 2020, for the **Overall population**, **Type 1 diabetes**, **Type 2 diabetes**, and **No diabetes**. Whisker bars show 95% CIs. Data for age groups 0 – 39 years and 40 – 49 years for type 1 diabetes and 0 – 39 years and 50 – 59 years for no diabetes were excluded because of small numbers of events (one to four), to comply with data protection regulations. Permission request in process.

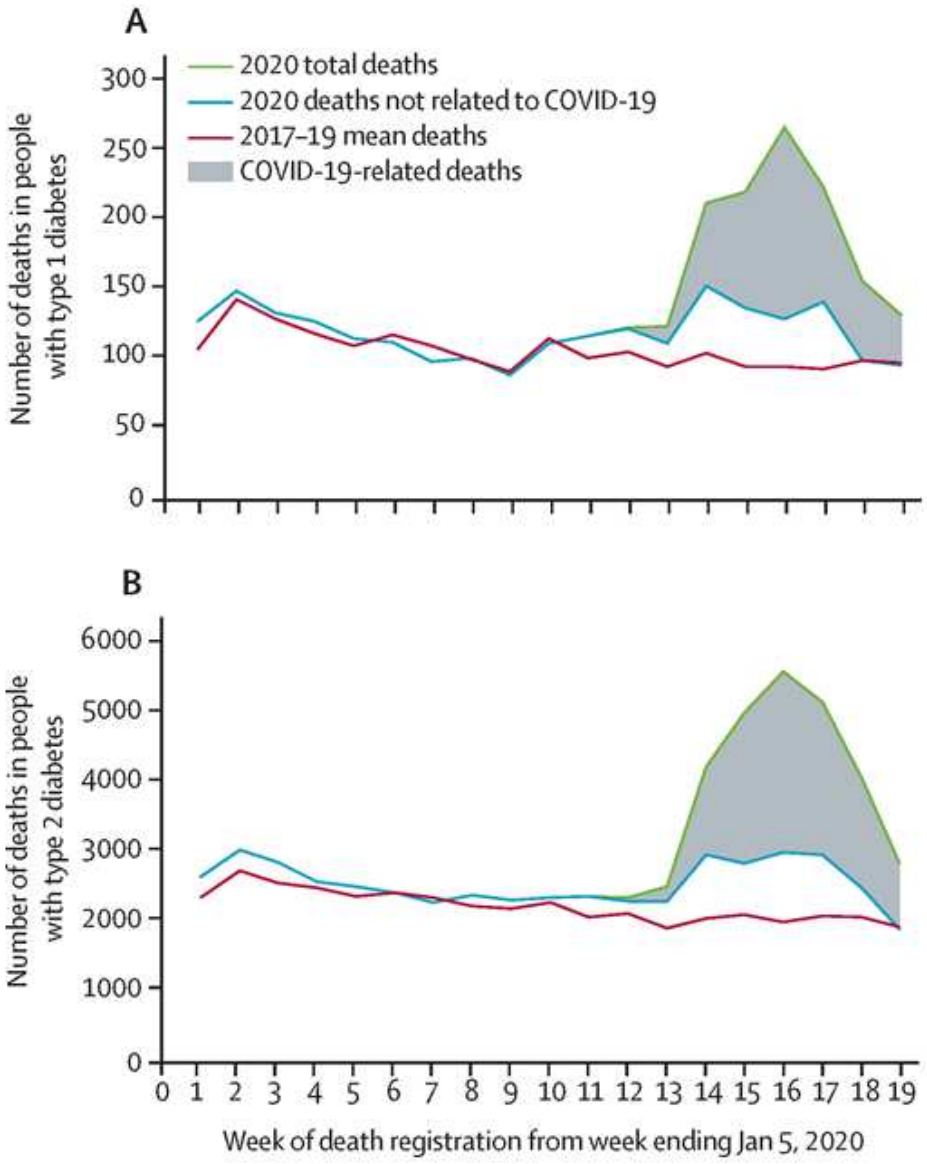
B. Risk factors for COVID-19-related mortality in people with type 1 and type 2 diabetes in England: A population-based cohort study. Holman *et al.* Lancet Diabetes & Endocrinology (August 13, 2020).

Key findings:

- During early 2020, the number of deaths among persons with type 1 and type 2 diabetes increased by 50.9% and 64.3% respectively, compared with the mean number of deaths during the previous three years for that period (Figure 1).
    - There were 464 (69%) additional deaths in persons with type 1 diabetes and 10,525 (65.5%) additional deaths in persons with type 2 diabetes listed as COVID-19-related.
- Factors identified that increased risk for mortality included BMI, renal function, and blood sugar control.

Methods: Population-based cohort study and survival analysis among people with diabetes registered in 6,774 general practices, from January 2, 2017, to May 11, 2020. The weekly number of deaths among persons with diabetes was calculated for the first 19 weeks of 2020 and compared to the same time period in 2017, 2018, and 2019. During the 2020 study period, potential risk factors for COVID-19-related deaths were examined. *Limitations*: Possible under-recognition of COVID-19-related mortality; cohort in this study may be part of Barron *et al*. study, summarized above.

Figure 1



Note: From Holman *et al.* Weekly numbers of deaths registered from week 1 to week 19 in people with type 1 (**A**) and type 2 (**B**) diabetes in England, **mean deaths from 2017–19** and 2020. Deaths in 2020 are stratified into **deaths not related to COVID-19** and **total deaths**. Note different scale on y axes for the 2 graphs. Permission request in process.

Implications for 2 studies (Barron *et al*. & Holman *et al*.): During the COVID-19 pandemic, diabetes has been associated with increased risk for death with mortality largely attributable to COVID-19. However, rates of non-COVID-19 mortality for diabetics have also increased, possibly due to avoidance of care, other demographic and social factors in diabetic patients or under-recognition of contribution of COVID-19 as a cause of death. As discussed in COVID-19 and diabetes: a co-conspiracy, poor blood sugar control impairs host immunity and has been associated with infections in general and worse outcomes with COVID-19. Supporting people with diabetes in effective self-management during the pandemic is an important measure to aid in mitigating the effects of SARS-CoV-2 infection.

Clinical Treatment & Management

PEER-REVIEWED

Pediatric lung imaging features of COVID-19: A systematic review and meta-analysis. Nino *et al*. Pediatric Pulmonology (September 14, 2020).

Key findings:

- 35.7% of pediatric COVID-19 patients had normal chest CT scans.
- Most common chest CT findings in pediatric COVID-19 patients were ground-glass opacities 37.2%, (95% CI 29.3% – 45%), pneumonic infiltrates or consolidations 22.3%, (95% CI 17.8% – 26.9%), and bilateral involvement 27.7% (95% CI 19.9% – 35.6%) (Table).
- Typical lung imaging features of viral infections in the pediatric population, such as perihilar markings and hyperinflation, were not present in pediatric COVID-19 patients.

Methods: A meta-analysis of 29 studies including 1,026 children 0-18 years with RT-PCR-confirmed SARS-CoV-2 to obtain the pooled chest CT scan features. *Limitations*: Variation in CT reporting practices could have influenced results; only one database was included in the systematic search limiting the inclusion of international studies; a risk-of-bias assessment was not done; authors did not describe methods for data transformation or synthesis.

Implications: CT scan abnormalities in the pediatric COVID-19 population are distinct from typical lung images of viral respiratory infections. When compared with adults, children with COVID-19 had greater variability in CT findings and more commonly had normal chest CT scans.

Table:

	Children with COVID-19 (n = 1,026)	Adults with COVID-19 (n = 4,121)	Adults with COVID-19 (n = 2,738)
Normal lung imaging (%)	35.7	8.4	10.24
Bilateral compromise (%)	27.7	73.8	78.2
Ground-glass opacities (%)	37.2	68.1	83.3
Consolidation, infiltrates (%)	22.3	32	44

Note: Adapted from Nino *et al*. Comparison between most common pediatric and adult CT findings. Permission request in process.

Convalescent plasma treatment of severe COVID-19: A propensity score–matched control study. Liu *et al.* Nature Medicine (September 15, 2020).

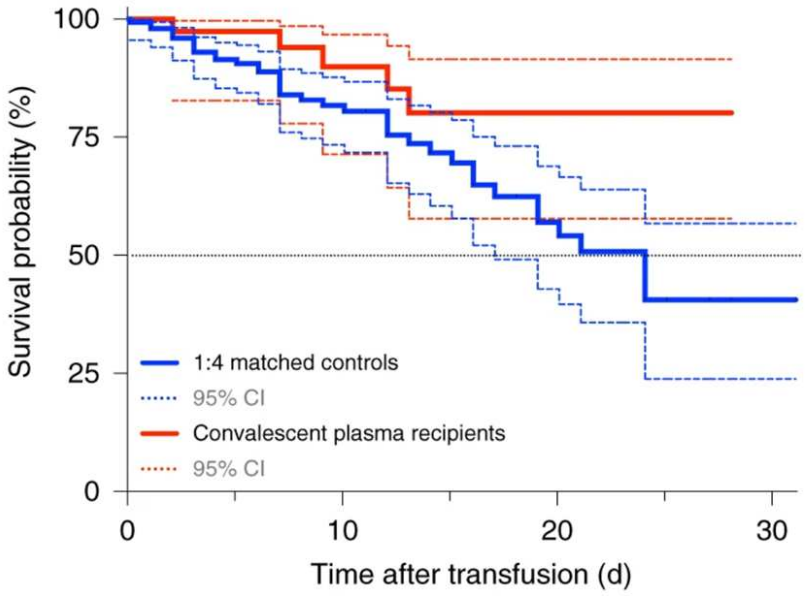
Key findings:

- Fewer patients who received convalescent plasma (CP) died (5/39, 12.8%) than matched controls (38/156, 24.4%).
- CP was associated with improved survival in patients who were not intubated (HR 0.23; 95% CI 0.05 – 0.98, p = 0.046), had symptoms for less than 1 week (HR 0.33; 95% CI 0.11 – 0.93, p = 0.035), or received anticoagulation (HR 0.28; 95% CI 0.10 – 0.80, p = 0.018).
    - Patients who were intubated showed no improved survival (HR 0.79; 95% CI 0.22 – 2.79, p = 0.716).
- Survival rates improved in CP recipients compared with the control patients (HR 0.34; 95% CI 0.13 – 0.89, p = 0.027).

Methods: Retrospective case-control study analyzing the effectiveness of CP treatment in patients hospitalized at Mount Sinai Hospital with severe COVID-19 between March 24 and April 8, 2020. Propensity-score matched analysis was performed on data from baseline, up to the day of CP transfusion and from the day of CP transfusion forward while in care. *Limitations*: Cannot exclude the possibility that CP recipients benefitted from more assertive clinical management.

Implications: Results from nonrandomized case series such as this one suggest a benefit of CP in selected patients; high quality data from randomized controlled trials are needed to confirm these findings.

Figure:



Note: Modified from Liu *et al*. Survival probability of patients **receiving CP transfusion** vs **control arm**. Solid lines represent the survival curve, dashed lines represent 95% CI. Reprinted by permission from Springer Nature Customer Service Centre GmbH: Springer Nature, Nature Medicine. Liu *et al*. Convalescent plasma treatment of severe COVID-19: a propensity score–matched control study. https://doi.org/10.1038/s41591-020-1088-9, COPYRIGHT 2020.

Laboratory Science

PEER-REVIEWED

Detection and infectivity potential of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) environmental contamination in isolation units and quarantine facilities. Ben-Shmuel *et al.* Clinical Microbiology and Infection (September 9, 2020).

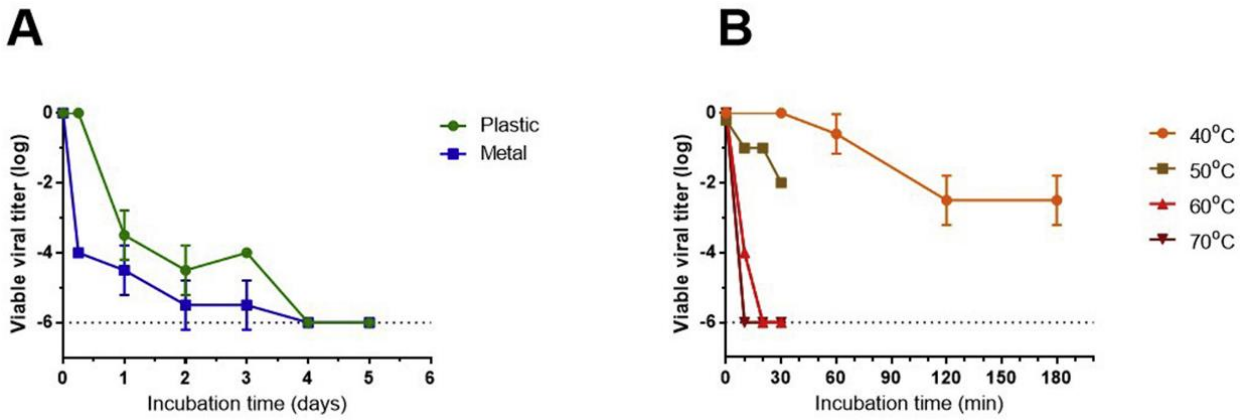
Key findings:

- At room temperature, SARS-CoV-2 lost infectivity on inoculated non-porous surfaces by day 4, and the rate of viral decay increased at higher temperatures (Figure).
- Viral RNA was detected in 46% (45/97) of environmental surface and air samples from three facilities housing COVID-19 patients; none of the samples contained infectious SARS-CoV-2.

Methods: Plastic and metal surfaces were inoculated with virus and infectivity was assessed at varying times and temperatures. Air and surface samples were collected from two hospital COVID-19 isolation wards and one hotel quarantine facility in Israel. RT-PCR identified viral RNA, and Vero E6 cytopathic assay assessed infectivity. *Limitations*: When rooms were being sampled, some patients may not have been shedding viable virus; very low levels of viable virus may not have been detected; remnants of surface cleaning materials and disinfectants may have inactivated virus; small sample size.

Implications: The lack of infectious SARS-CoV-2 detected from environmental samples in healthcare facilities suggests environmental contamination plays a minor role in the spread of infection in this setting. Staff should prioritize strengthening prevention measures interrupting direct person-to-person and droplet transmission.

Figure:



Note: From Ben-Shmuel et al. **A:** Reduction in SARS-CoV-2 titers over time (days) at 22°C (room temperature) following inoculation on **plastic** and **metal**. **B:** Reduction in SARS-CoV-2 titers over time (minutes) at (**40°C**, **50°C**, **60°C**, **70°C**) following inoculation on plastic. Licensed under CC-BY-NC-ND.

In Brief

Epidemiology

PEER-REVIEWED

COVID-19 and psychologic distress—changes in internet searches for mental health issues in New York during the pandemic. Stijelja *et al.* JAMA Internal Medicine (October 5, 2020).

Key findings:

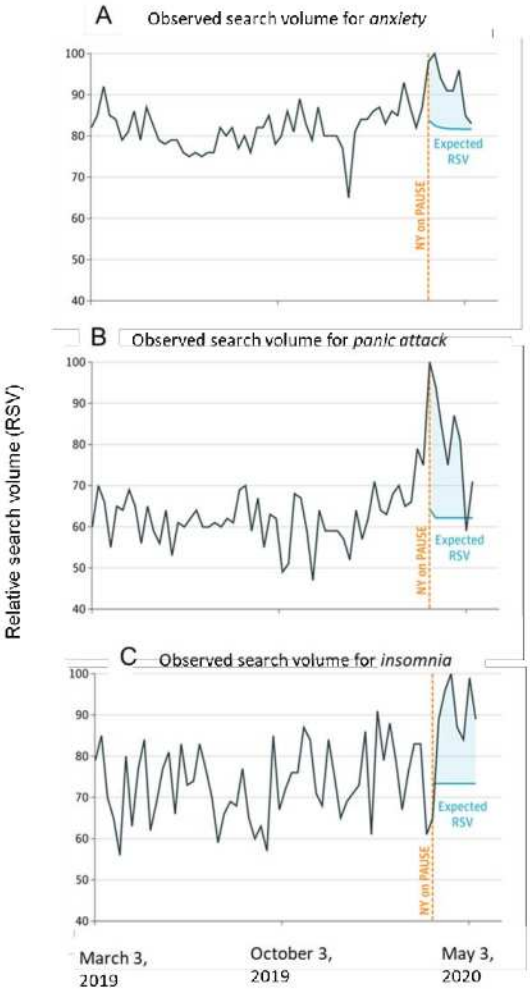
- Internet searches were higher than expected based on historical search data for the topics *anxiety*, 18% (95% prediction interval [PI] 5%-29%), *panic attack,* 56% (95% PI 37%-97%), and *insomnia,* 21% (95% PI 1%-55%) after March 22, 2020, and remained high for up to 5 weeks (Figure).
- Searches for the topics *suicide* and *depression* did not increase above expected.
    - Searches for *suicide* increased during the week of April 25 to May 2, matching the time frame of a publicized suicide of a New York physician.

Methods: Google Trend was used to examine relative search volumes (RSV) and forecasts between March 23 and May 14, 2020 for internet search terms including *suicide, anxiety, panic attack, insomnia*, and *depression* in New York State. Weekly RSV forecasts were computed with 95% PIs. *Limitations*: Does not estimate the number of individuals experiencing symptoms; many people with mental health issues may not have access the internet.

Implications: There is the potential to monitor the mental health of a population during emergencies using internet search trends to identify areas needing targeted resources for mental health support.

MS-DOH-21-1816-A-000287

Figure:



Note: Adapted from Stijelja *et al.* Observed search volume and **excess search volume** for the terms *anxiety* **(A)**, *panic attack* **(B)**, or *insomnia* **(C)**. **Orange dotted line** indicates start of New York State lockdown. Reproduced with permission from JAMA Internal Medicine. Stijelja *et al.*, COVID-19 and psychologic distress—changes in internet searches for mental health issues in New York during the pandemic. The impact of the COVID-19 pandemic on healthcare acquired infections with multidrug resistant organisms. Cole *et al.* American Journal of Infection Control (October 1, 2020).

Key findings:

- 25% increase in hand sanitizer and hand soap use among health care personnel in the second quarter (Q2) of 2020 compared to the first quarter (Q1).
- 35% decrease in hospital-acquired multidrug resistant infection rates from 0.3/1,000 person-days in Q1 to 0.2/1,000 person-days in Q2, (p = 0.03); specifically:
    - 80% decrease in vancomycin-resistant *Enterococcus*.
    - 41% decrease in methicillin-resistant *Staphylococcus aureus*.
    - 21% decrease in extended-spectrum beta-lactamase *Enterobacteriaceae* infections.

Methods: Analysis of multidrug resistant infections diagnosed in hospital patients ≥4 days following admission based on isolates from urine, blood, wound, and sputum specimens in four hospitals in Los Angeles County during the first six months of 2020. *Limitations*: demographics of patients and frequencies of type of specimens not included.

Implications: Increased awareness and use of basic infection control practices by health care providers, including effective hand hygiene, can reduce hospital-acquired and other healthcare-associated infections.

PEER-REVIEWED

SARS-CoV-2 outbreak investigation in a German meat processing plant. Günther *et al.* EMBO Molecular Medicine (October 4, 2020).

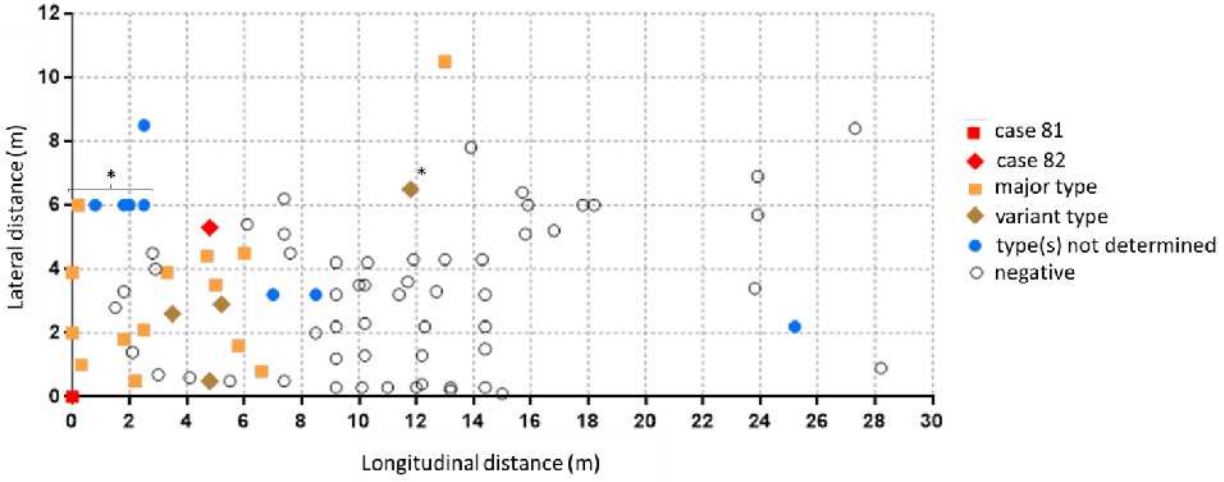
Key findings:

- Based on viral genome relatedness, a cluster of 29 infections among 147 workers from a single shift was attributable to a single index case (Figure).
    - Follow-up screening and testing identified ongoing transmission with more than 1,400 cases identified through June.
- Workers within an 8-meter radius of the index case were at highest risk for infection ($p < 0.001$).
- Infection was associated with working at fixed stations at which air conditioners recirculated air above workers, fans recirculating the air did not have filters and fresh-air exchange rates were low (<1 exchange per hour).
- Sharing a bedroom ($p = 0.039$) and sharing both an apartment and transportation ($p = 0.048$), were associated with infection.

Methods: Report of a large outbreak in a meat processing plant in Germany between May and June 2020, with genome sequencing of virus from cases. *Limitations*: All data on workers, including workplace location, sharing of housing, or transportation, were provided by the employer with no independent verification; genome type was not determined for all cases.

Implications: SARS-CoV-2 super spreading events have occurred in meat processing plants. In the absence of good ventilation, physical distance of 2 meters (6 feet) did not prevent transmission of SARS-CoV-2.

Figure:



Note: Adapted from Günther *et al.* Distance (in meters) of co-workers from the suspected **index case 81**. For workers without fixed position in the beef processing plant (marked with an asterisk) coordinates indicate estimated average location. Squares and diamonds denote major or variant SARS-CoV-2 genotypes, respectively. **Filled blue circles** denote cases for which viral genomes were not sequenced. Case 82 tested positive at the same time as case 81, but genome sequencing did not link this case to the outbreak. Licensed under CC-BY-4.0.

Clinical Treatment & Management

PEER-REVIEWED

Follow-up of adults with non-critical COVID-19 two months after symptoms' onset. Carvalho-Schneider *et al.* Clinical Microbiology and Infection (October 5, 2020).

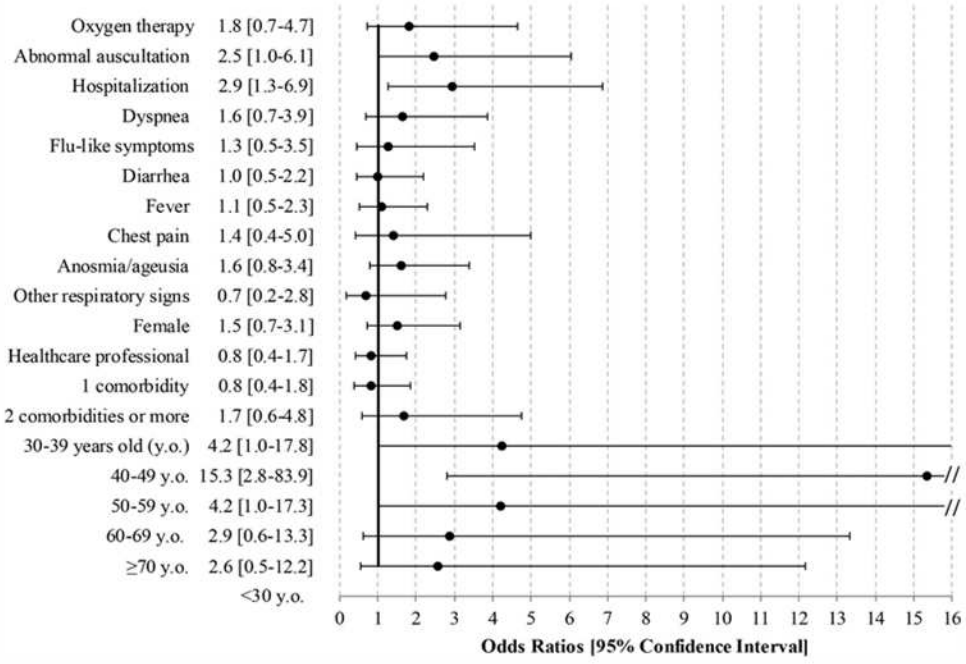
Key findings:

- Two-thirds of non-critical COVID-19 patients experienced prolonged symptoms, and some felt worse later in the disease course than at symptom onset.
    - Loss of smell and taste were the most frequent persistent symptoms at day 60 (22.7%).
- Persisting clinical symptoms were significantly associated with being admitted to the hospital, having an abnormal chest exam (auscultation), and being 40–60 years old at time of symptom onset (Figure).

Methods: Follow-up of 150 patients with non-critical RT-PCR-confirmed COVID-19 admitted to hospitals or seen as outpatients up to 60 days after symptom onset in France, between March 17 and June 3, 2020. Demographic, clinical, and laboratory data were collected from medical records and phone interviews. ***Limitations***: Baseline characteristics partially collected retrospectively; some data for contributing factors were missing limiting analysis; smoking status was not available.

Implications: Clinicians and patients should be aware of the potential need for prolonged medical follow-up even among those with mild initial clinical courses.

Figure:



Note: Adapted from Carvalho-Schneider *et al.* Odds Ratios and 95% CIs of acute-infection and demographic related factors associated with persisting symptoms at day 60 after symptom onset. This article was published in Clinical Microbiology and Infection, Carvalho-Schneider *et al.*, Follow-up of adults with non-critical COVID-19 two months after symptoms' onset. DOI: https://doi.org/10.1016/j.cmi.2020.09.052. October 5, 2020. Copyright European Society of Clinical Microbiology and Infectious Diseases 2020. This article is currently available at the Elsevier COVID-19 resource centre: https://www.elsevier.com/connect/coronavirus-information-center.

Neuropathology of patients with COVID-19 in Germany: A post-mortem case series. Matschke *et al.* Lancet Neurology (October 5, 2020).

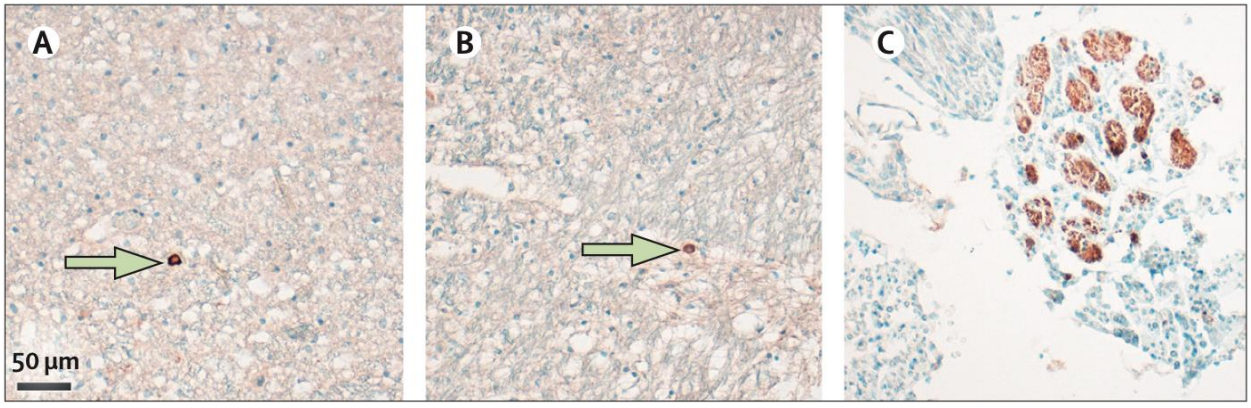
Key findings:

- There was substantial evidence of destruction of neurons (astrogliosis) in all autopsied patients.
  - 86% had astrogliosis in all brain regions tested.
- Infiltration by cytotoxic T lymphocytes and microglia (cells that act as immune defense for the brain and spinal cord) were most prominent in the brainstem and cerebellum.
  - Mild (n = 28) and moderate (n = 6) infiltration of meningeal compartments by cytotoxic T lymphocytes was identified in 79% of patients.
- SARS-CoV-2 RNA or proteins were detected in the brain tissues of 53% of patients tested (21/40), (Figure).
  - Both SARS-CoV-2 RNA and protein were detectable in 20% of patients.
  - SARS-CoV-2 presence did not correlate with the severity of neuropathological alterations.

Methods: Post-mortem case series of neural autopsies of 43 SARS-CoV-2-confirmed patients performed between March 13 and April 24, 2020 in Hamburg, Germany. Neural tissue from six brain regions were evaluated for pathology and for the presence and distribution of SARS-CoV-2 mRNA and protein. *Limitations*: 93% of patients had relevant pre-existing chronic medical conditions, and 30% had pre-existing neurological disease; no controls; small sample.

Implications: These data show that SARS-CoV-2 can infiltrate the central nervous system. Frank *et al.,* discuss the importance of understanding if neuropathological alterations with COVID-19 are from viral-induced cell destruction or from sequelae of an overstimulated systemic immune response, since these different causes would require different treatments.

Figure:



Note: From Matschke *et al.* Viral protein-positive cells (**green arrows**) in the medulla oblongata detected by anti-nucleocapsid protein antibody **(A)** or anti-spike protein antibody **(B)**. **(C)** SARS-CoV-2 nucleoprotein (**brown staining**) in cranial nerves. PREPRINTS (NOT PEER-REVIEWED)

Temporal analysis of COVID-19 convalescent plasma donations reveals significant decrease in neutralizing capacity over time. Girardin *et al.* medRxiv (October 6, 2020).

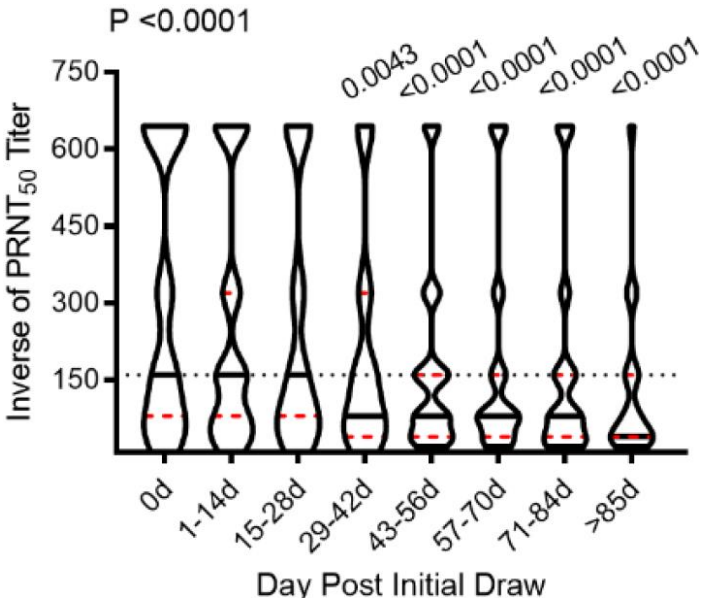
Key findings:

- Of the initial donations of plasma from COVID-19 convalescent patients,79.5% of specimens that neutralized 50% of virus in a plaque reduction neutralization test ($PRNT_{50}$) did so at a plasma IgG titer of at least 1:80, the US Food and Drug Administration (FDA) *minimum titer* for convalescent plasma (CP).
    - 51.4% of specimens with a $PRNT_{50}$ met the FDA *recommended* plasma titer of at least 1:160.
- At 85 days after the initial donation, only 48.8% of specimens with $PRNT_{50}$ met the minimum plasma titer cutoff (Figure 1).
    - The most significant decreases in $PRNT_{50}$ titer occurred at ≥43 days after initial donation.
- When using an FDA-approved IgG test that is a suggested surrogate for virus neutralization, 100% of samples with an IgG signal-to-noise ratio ≥12 (the qualifying cutoff for CP) neutralized virus at a titer ≥1:80 (Figure 2).

Methods: A total of 196 specimens meeting the FDA standard of a minimum $PRNT_{50}$ titer of 1:80 or more were selected at random from CP pools from the Wadsworth Center, New York. Neutralizing capacity of donated CP was measured by PRNT assay. IgG antibodies were detected using the Ortho VITROS SARS-CoV-2. *Limitations*: Information is based on time since initial donation rather than time since infection

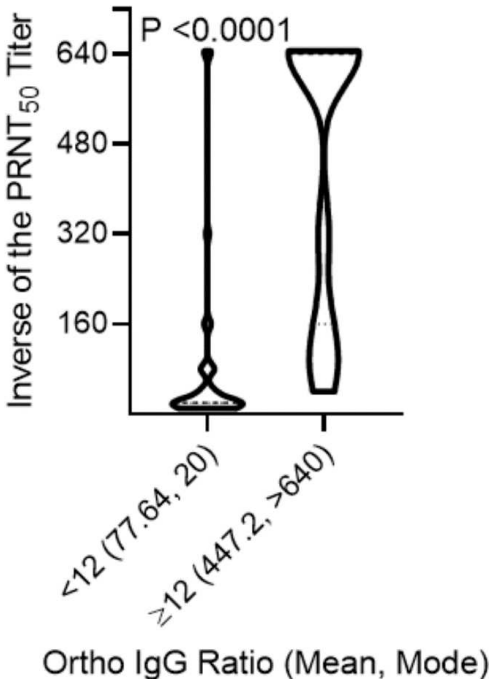
Implications: The decrease in virus neutralization potential in donor CP suggests a limited time frame for CP donation because of potential loss of immunity over time. This also suggests that the donors themselves have waning immunity in this time frame. As assays to measure neutralization are cumbersome and require biosafety level-3 facilities, an antibody test that can be used as a surrogate will facilitate more laboratories to provide rapid turnaround of CP neutralization results. The Ortho IgG ELISA used here is the only FDA-approved surrogate for viral neutralization, and these data confirm the correlation between this test and live SARS-CoV-2 neutralization.

Figure 1



Note: From Girardin *et al*. Change in $PRNT_{50}$ titers over time within two-week strata. Data are presented as inverse titers (i.e. a titer of 1:640 is graphed as 640, so that samples with more neutralizing antibody are higher on the y-axis). Dotted horizontal line represents the FDA recommended titer of 1:160 for use as convalescent plasma. Solid black lines represent median titers, dashed red lines represent 95% CI. Licensed under CC-BY-NC-ND 4.0.

Figure 2



Note: From Girardin *et al*. Distribution of $PRNT_{50}$ titers in groups versus IgG ratios (signal to noise) using the FDA cut-off for CP. Licensed under CC-BY-NC-ND 4.0.

Laboratory Science

PEER-REVIEWED

Upper respiratory tract levels of SARS-CoV-2 RNA and duration of viral RNA shedding do not differ between patients with mild and severe/critical COVID-19. Yilmaz *et al.* Journal of Infectious Diseases (October 6, 2020).

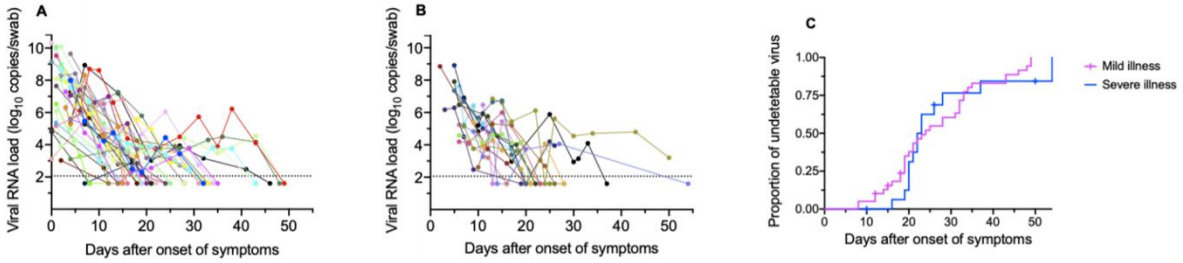
Key findings:

- Highest viral loads were observed early after symptom onset in persons with mild and severe COVID-19 and decreased over time (Figure).
- Median duration of viral shedding in individuals with mild and severe COVID-19 was similar, 24 vs 22.5 days, respectively (Figure).
- Most mild symptomatic cases (26/34) continued to be PCR-positive for 2 to 14 days after resolution of symptoms.

Methods: Retrospective cohort study of 59 individuals diagnosed with either mild or severe COVID-19 between February 25 and April 23, 2020, in Gothenburg, Sweden. Serial NP and throat swabs were collected, relative viral load was calculated, and statistical analysis was performed. *Limitations*: Small sample size from only one location; may not be generalizable.

Implications: Viral shedding was not associated with the severity of disease, indicating the potential for equal transmissibility of virus regardless of disease severity. However, further studies would have to be performed to determine if this is the case.

Figure:



Note: From Yilmaz *et al*. Viral load in nasopharyngeal and throat swabs in patients with COVID-19. Longitudinal viral loads for 39 patients with mild disease **(A)**, and 17 with severe/critical disease **(B)**. Horizontal dotted line in **(A)** and **(B)** mark detection limit of PCR assay. **C:** Time to viral RNA clearance for those with **mild** and **severe/critical** COVID-19. Permission request in process.

Vaccine Development

An effective vaccine will be key in controlling the COVID-19 pandemic, and multiple clinical trials are underway testing SARS-CoV-2 vaccine candidates. Some of these candidates have been given Fast-Track status by the US Food and Drug Administration (FDA) to accelerate licensing. While Fast-Track is an existing systematic approach to accelerate evaluation of vaccines and therapeutics, there is public concern about "rushing" a SARS-CoV-2 vaccine through this process. These two articles document public attitudes towards potential SARS-CoV-2 vaccines.

PEER-REVIEWED

Caregivers' willingness to accept expedited vaccine research during the COVID-19 pandemic–A cross sectional survey. Goldman *et al*. Clinical Therapeutics (October 3, 2020).

Key findings:

- Less than half (43%) of caregivers reported they were willing to accept a COVID-19 vaccine that is approved via Fast-Track status by the US Food and Drug Administration.
- Independent factors associated with willingness to accept expedited vaccine research included:
  - Children up to date on their vaccination schedule (OR 1.72, 95% CI 1.29-2.31, p <0.001).
  - Being worried that the caregivers themselves were sick with COVID-19 (OR 1.1, 95% CI 1.05-1.15, p <0.001).
- Mothers were less likely to accept expedited vaccine development than fathers (OR 0.64, 95% CI 0.53-0.78).

Methods: A cross-sectional survey of 2,557 caregivers arriving with their children (0–18 years of age) to 17 pediatric Emergency Departments in 6 countries between March 26 and June 30, 2020 to determine caregivers' level of support of abridged COVID-19 vaccine testing. *Limitations*: Caregivers completed the survey before the approval of any COVID-19 vaccine; levels of acceptability may change as new information on candidate vaccines becomes available.

Influences on attitudes regarding potential COVID-19 vaccination in the United States. Pogue *et al.* Vaccines. (October 3, 2020).

Key findings:

- 69% of respondents indicated they were open to receiving a COVID-19 vaccine.
    - Positive attitudes towards a COVID-19 vaccine were higher if the vaccine spent longer in clinical testing, had high efficacy, and was developed in the US.
    - Respondents who are current on vaccines recommended by their physician, whose children are current on vaccines, and who perceive that COVID-19 is an important problem in the US were more likely to indicate that they would take a COVID-19 vaccine.
- COVID-19 vaccine attitudes were unrelated to understanding of vaccines, demographics, COVID-19 knowledge, and number of people known with COVID-19 diagnosis.

Methods: Anonymous online survey on attitudes and behaviors related to potential COVID-19 vaccine in 316 respondents selected by age, race, and sex to reflect US population. Factor analysis and structural equation modeling were used. *Limitations*: Survey questions were not piloted or tested for understandability; vaccine history was self-reported; attitudes and beliefs are likely to evolve as more information about investigational vaccines emerge.

Implications for 2 studies (Pogue *et al.* & Goldman *et al*.): In both surveys, people already willing to vaccinate themselves or their child were more accepting of an accelerated SARS-CoV-2 vaccine, suggesting that motivation for COVID-19 vaccines may be driven by attitudes about vaccines in general more than control of the pandemic. Public health messaging around what "Fast Track" means may help quell some fears, but overall vaccine messaging will be needed to reap the full benefits of a COVID-19 vaccine, fast-tracked or not.

October 6, 2020

Trends in COVID-19 Incidence After Implementation of Mitigation Measures — Arizona, January 22–August 7, 2020

M. Shayne Gallaway, PhD[1,2]; Jessica Rigler, MPH[1]; Susan Robinson, MPH[1]; Kristen Herrick, MPH[1]; Eugene Livar, MD[1]; Kenneth K. Komatsu, MPH[1]; Shane Brady, MPH[1]; Jennifer Cunico[1]; Cara M. Christ, MD[1]

Mitigating the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), requires individual, community, and state public health actions to prevent person-to-person transmission. Community mitigation measures can help slow the spread of COVID-19; these measures include wearing masks, social distancing, reducing the number and size of large gatherings, pausing operation of businesses where maintaining social distancing is challenging, working from or staying at home, and implementing certain workplace and educational institution controls (*1*–*4*). The Arizona Department of Health Services' (ADHS) recommendations for mitigating exposure to SARS-CoV-2 were informed by continual monitoring of patient demographics, SARS-CoV-2 community spread, and the pandemic's impacts on hospitals. To assess the effect of mitigation strategies in Arizona, the numbers of daily COVID-19 cases and 7-day moving averages during January 22–August 7, 2020, relative to implementation of enhanced community mitigation measures, were examined. The average number of daily cases increased approximately 151%, from 808 on June 1, 2020 to 2,026 on June 15, 2020 (after stay-at-home order lifted), necessitating increased preventive measures. On June 17, local officials began implementing and enforcing mask wearing (via county and city mandates),* affecting approximately 85% of the state population. Statewide mitigation measures included limitation of public events; closures of bars, gyms, movie theaters, and water parks; reduced restaurant dine-in capacity; and voluntary resident action to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases in Arizona peaked during June 29–July 2, stabilized during July 3–July 12, and further declined by approximately 75% during July 13–August 7. Widespread implementation and enforcement of sustained community mitigation measures informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

ADHS supports surveillance and investigation efforts of local public health departments, compiles surveillance and investigation information across counties, and provides infrastructure statewide to support infectious disease surveillance. Data on laboratory-confirmed and probable (*5*) COVID-19 cases (based on the Council of State and Territorial Epidemiologists case definitions)† were collected in the centralized Medical Electronic Disease Surveillance Intelligence System (MEDSIS),§ which is used by state, tribal, and county public health agencies to report human-based diseases in Arizona. Information was submitted to or entered into MEDSIS by health care providers, laboratories, local health departments, tribal entities, and ADHS. Multiple laboratory tests submitted for a single patient were combined into a single record. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

Temporal trends were examined by comparing the number of daily COVID-19 cases (as of September 1)¶ and 7-day moving averages before, during, and after implementation of enhanced community mitigation measures, defined as the following: limitations on persons' time away from their place of residence

*Mandates and ordinances varied and were county- and city-specific. Enforcement types included educating persons on the dangers of COVID-19 spread, issuing fines to persons and businesses who refused to comply with mandates, and loss of licenses for businesses not enforcing rules or mandates.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-000300

except for essential activities; certain business closures and service limitations (e.g., occupancy limitations, curbside pickup, and delivery of goods); enhanced sanitation practices**; social distancing, employee mask wearing, and symptom screenings for all businesses operating a physical location; limitations on the occurrence and size of public events; and local mandates enforcing mask use. The 7-day moving average was calculated after the cumulative case count exceeded 20 cases and is presented to describe COVID-19 trends.

On March 11, 2020, Arizona declared a public health state of emergency to prepare for, prevent, respond to, and mitigate the spread of SARS-CoV-2. Additional guidance was provided to local officials, businesses, communities, and individual persons to implement social distancing and close schools statewide (March 15); postpone and limit large gatherings to fewer than 50 persons; recommend telework options; restrict access to congregate settings; require restaurants to provide dine-out options only; and close all bars, gyms, and movie theaters in counties with confirmed COVID-19 cases (March 19) (Table). Based on Arizona data and CDC guidance (*1*,*2*), ADHS also recommended limiting persons' time away from their place of residence except for essential activities (i.e., stay-at-home order, "Stay Home, Stay Healthy, Stay Connected")†† (March 31).

During April 1–May 15, the 7-day moving average of daily cases ranged from 154 to 443 (Figure). During April 29–May 11, Arizona initiated a phased approach for retail shops and stores, cosmetologists, and barbers to reopen and operate, and for restaurants to resume dine-in services; the stay-at-home order ended May 15.

Average daily cases increased 151% from June 1 (808) to June 15 (2,026), necessitating an increased focus on preventive measures by businesses, communities, and individual persons. Updated guidance from state officials provided local governments the authority to implement mask policies (June 17) and enforcement measures tailored to local public health needs (local policies were applicable to approximately 85% of the total Arizona population). Before June 17, mask wearing had not been widely mandated or enforced. Arizona limited organized public events to fewer than 50 persons (with some exceptions); closed bars, gyms, movie theaters, and water parks and recreational tubing facilities (June 29); and limited restaurants' indoor dining to <50% capacity, with at least 6 feet of separation between patrons (July 9). The 7-day moving average of daily cases peaked during

** Based on guidance from ADHS, CDC, and the Department of Labor, and Occupational Safety and Health Administration to limit and mitigate the spread of COVID-19, including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

†† https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

TABLE. Public policies to implement and enforce COVID-19 community mitigation measures and dates of issue/reissue* — Arizona, March 11–August 7, 2020

Mitigation measure	Date of issue/reissue
Declaration of emergency	Mar 11
School closure (on-site learning)	Mar 15
Limits on senior living facilities visitation	Mar 19
Expanded availability and coverage for telemedicine for persons, pets, and animals	Mar 25, Apr 1
Deferred requirements to renew driver license	Mar 20
Stay-at-home order	Mar 30–May 15
Business/Service closures	
Bars	Mar 19, Jun 29, Jul 23
Movie theaters	Mar 19, Jun 29, Jul 23
Indoor gyms and fitness clubs	Mar 19, Jun 29, Jul 23
Restaurants, on-site dining	Mar 19
Pools	Mar 19
Water parks and recreational tubing facilities	Jun 29, Jul 23
Business/Service limits (requirements)	
All businesses operating a physical location (enhanced sanitation,† social distancing, employee mask wearing, symptom screenings)	Jun 17
Retail (limited capacity, social distancing, enhanced sanitation)	Apr 29
Barbers and cosmetologists (employee mask wearing, spaced appointments, enhanced sanitation)	May 4
Restaurants (social distancing, limited capacity, employee mask wearing, patron mask wearing [when not eating or drinking], employee screening, enhanced sanitation)	May 4, Jul 9
Public pools (e.g., at hotels; limited capacity)	Jun 29, Jul 23
Private pools in public areas (e.g., multihousing complexes; limited capacity)	Jun 29, Jul 23
Public events (<50 persons)	Mar 15, Jun 29, Jul 23
Wearing masks (mandatory)	
Local officials able to mandate and enforce wearing masks	Jun 17
Yuma County	Jun 18
Maricopa County	Jun 19
Pima County	Jun 19
Santa Cruz County	Jun 19
Coconino County	Jun 20
>40 other cities/tribal communities	Jun 17–25§

Abbreviation: COVID-19 = coronavirus disease 2019.

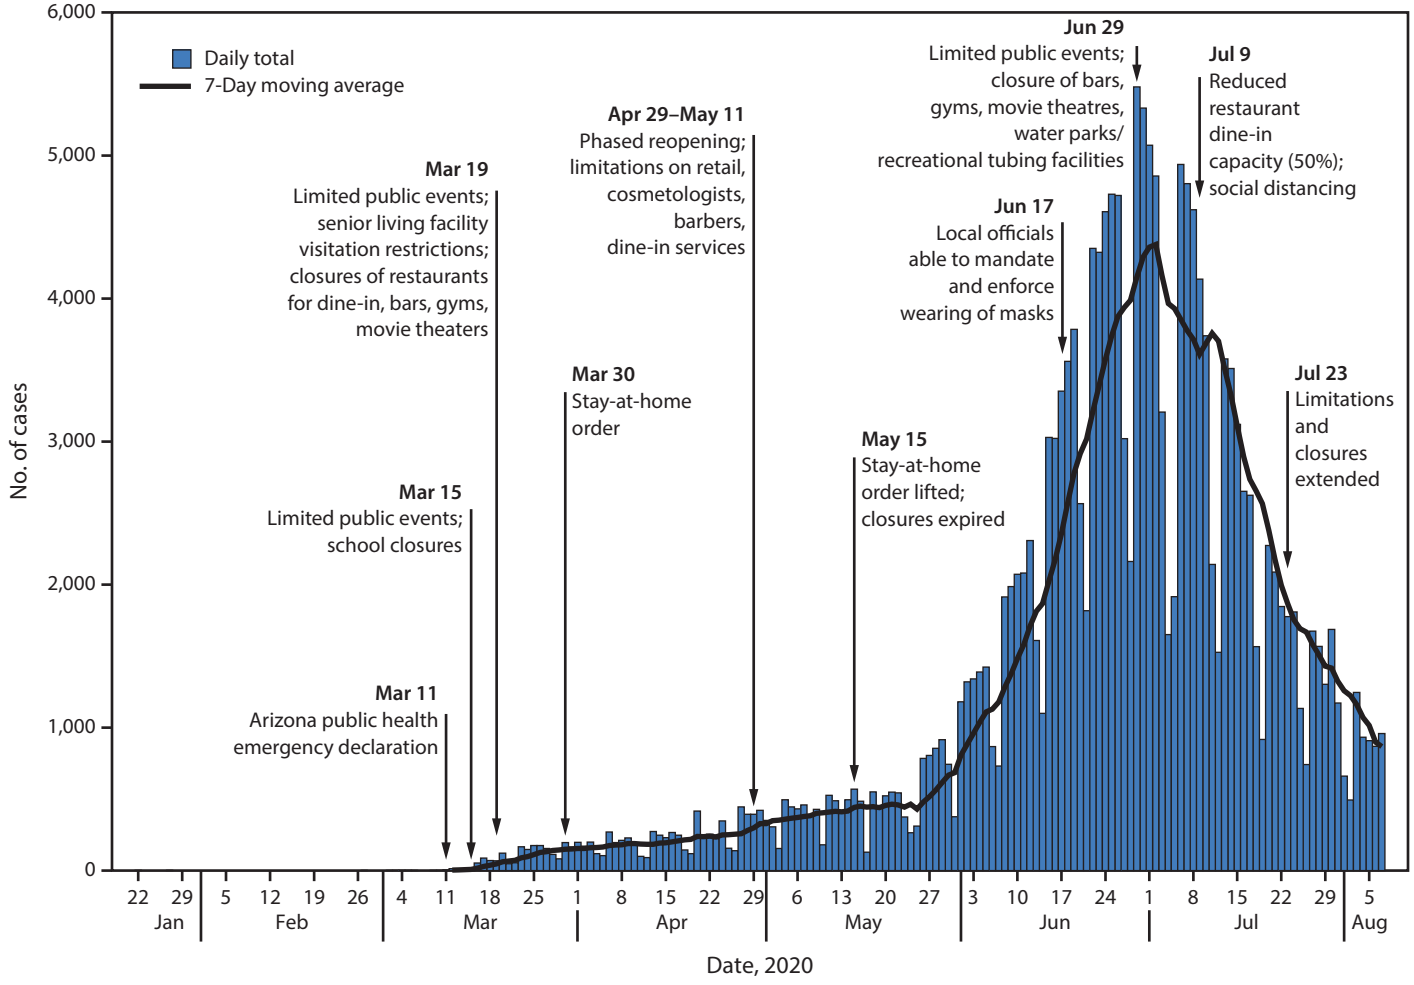
* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† Based on guidance from the Arizona Department of Health Services, CDC, Department of Labor, and Occupational Safety and Health Administration (OSHA) to limit and mitigate the spread of COVID-19 including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

§ Other tribal communities with mask mandates (issued June 18–23) included Fort McDowell Yavapai Nation, Gila River Indian Community, Navajo Nation, Salt-River Pima-Maricopa Indian Community, Tohono O'Odham Nation. Other cities with mask mandates (issued June 17–25) included Avondale, Bisbee, Buckeye, Carefree, Casa Grande, Chandler, Clarkdale, Clifton, Coolidge, Cottonwood, Douglas, Flagstaff, Fountain Hills, Gila Bend, Gilbert, Glendale, Globe, Goodyear, Guadalupe, Jerome, Kingman, Litchfield Park, Mammoth, Mesa, Miami, Nogales, Oro Valley, Paradise Valley, Payson, Peoria, Phoenix, San Luis, Sedona, Scottsdale, Somerton, Superior, Surprise, Tempe, Tolleson, Tucson, Youngtown, Yuma. Several other tribal communities and cities encouraged but did not mandate wearing masks.

MS-DOH-21-1816-A-000301

FIGURE. Selected community mitigation measures* and COVID-19 case counts† and 7-day moving averages§ — Arizona, January 22–August 7, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† As of September 1, 2020. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

§ Plotting of 7-day moving average began when cumulative case count exceeded 20 cases.

June 29–July 2 (range = 4,148–4,377), stabilized during July 3–12 (range = 3,609–4,160), and subsequently decreased 75% from July 13 (3,506) to August 7 (867). Mitigation measures put in place in June were extended through August to further limit transmission.

Discussion

Quantitative data on the effectiveness of community mitigation measures at suppressing the spread of COVID-19 are limited. The primary goal of implementing widespread enhanced mitigation measures in Arizona was to protect and save lives and maintain capacity in the health care system. A combination of voluntary and enforceable measures is more effective than any single measure (*6*). Mitigation measures mandated through public policy can effectively increase social distancing (*7*), and wearing masks has prevented transmission of SARS-CoV-2 (*8*). In Arizona, decreases in daily COVID-19 cases were observed after widespread sustained community mitigation measures that promoted social distancing, limited large gatherings, paused operations of businesses where mask use and social distancing were difficult to maintain, mandated and enforced mask wearing, and promoted voluntary resident actions to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases stabilized and began to decrease approximately 2 weeks after local officials began mandating mask wearing (throughout several counties

MS-DOH-21-1816-A-000302

and cities) and enhanced sanitation practices. Additional declines in case counts were associated with implementation of statewide limitations and closures sustained throughout July and extended into August.

The findings in this report are subject to at least four limitations. First, the relationship between mitigation measures and changes in case counts are temporal correlations and should not be interpreted to infer causality. Other factors that might have influenced the rate of change (e.g., travel restrictions, neighboring state mitigation measures, and individual choices to reduce movement before implementation of mandates) cannot be ruled out. Second, health centers run by tribal entities and federal health facilities (i.e., Indian Health Service, Veteran's Administration, and Department of Defense) in the state are requested but not required to comply with state reporting rules. Many of these health centers and federal health facilities complied with reporting, but the completeness of reporting by these entities is unknown. Third, adherence to mitigation measures was not assessed, nor could the extent to which each individual measure affected the number of incident COVID-19 cases be established. Finally, Arizona might not be representative of other U.S. states, and community mitigation measures might have a different impact in more populous or densely populated states; thus, these findings are not necessarily generalizable to other settings.

Enhanced mitigation measures should be implemented by communities and persons to slow COVID-19 spread, particularly before a vaccine or therapeutic treatment becomes widely available. State, local, and tribal officials are best positioned to continually monitor data and collaborate to determine the level and types of enhanced mitigation required. Mitigation measures, including mask mandates, that are implemented and enforced statewide appear to have been effective in decreasing the spread of COVID-19 in Arizona.

Summary

What is already known about this topic?

Community mitigation measures can help slow the spread of COVID-19.

What is added by this report?

The number of COVID-19 cases in Arizona stabilized and then decreased after sustained implementation and enforcement of statewide and locally enhanced mitigation measures, beginning approximately 2 weeks after implementation and enforcement of mask mandates and enhanced sanitations practices began on June 17; further decreases were observed during July 13–August 7, after statewide limitations and closures of certain services and businesses.

What are the implications for public health practice?

Widespread implementation and enforcement of sustained community mitigation measures, including mask wearing, informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

- The sharp increase in confirmed coronavirus cases in the US Sun Belt has led investors to worry about renewed broad lockdowns with large negative effects on GDP. But there are also other ways to reduce infections, including stringent bans on large gatherings and greater use of face masks.
- In particular, we argue that a national face mask mandate could partially substitute for renewed lockdowns. We start by showing that a national mandate would likely increase face mask usage meaningfully, especially in states such as Florida and Texas where masks remain largely voluntary to date.
- We then investigate the link between face masks and coronavirus outcomes. Our analysis includes 1) a US regional panel in which we relate the growth rate of infections and fatalities to the introduction of state face mask mandates, 2) a large country-level cross section in which we relate cumulative infections and fatalities to the lag between the onset of spread and the introduction of a face mask mandate, and 3) a smaller country-level panel in which we relate the growth rate of infections and fatalities to lagged mask usage.
- We find that face masks are associated with significantly better coronavirus outcomes. Since this is true across all three of our models and the results are robust to the inclusion of a number of control variables, it seems to reflect a largely causal impact of masks rather than correlation with other factors (such as reduced mobility or avoidance of large gatherings). Our baseline estimate is that a national mandate could raise the percentage of people who wear masks by 15pp and cut the daily growth rate of confirmed cases by 1.0pp to 0.6%.
- Finally, we translate our results into GDP terms by asking how much our Effective Lockdown Index (ELI) would need to increase in order to cut infections by as much as a national mask mandate, and then converting the ELI impact into a GDP impact using the estimated cross-country relationship between the two. These calculations imply that a face mask mandate could potentially substitute for lockdowns that would otherwise subtract nearly 5% from GDP.

Investors should consider this report as only a single factor in making their investment decision. For Reg AC certification and other important disclosures, see the Disclosure Appendix, or go to www.gs.com/research/hedge.html.

Face Masks and GDP[1]

New US coronavirus cases have risen sharply in recent weeks, with most of the deterioration concentrated in the "Sun Belt," including Florida, Texas, Arizona, and California. This has led investors to worry that renewed lockdowns will again depress economic activity. By our estimates, the increase in our Effective Lockdown Index (ELI)—a combination of official restrictions and actual social distancing data—subtracted 17% from US GDP between January and April, and other countries with even more aggressive restrictions saw even larger economic effects.

Since the first infection wave in March and April, however, it has become clear that broad lockdowns are not the only way to lower virus transmission significantly. For one thing, public health experts have long believed that bans on large gatherings can bring disproportionate benefits. This belief has only grown with a multitude of studies documenting the importance of "super spreader" events, such as those associated with the Shinjeonji Church in South Korea, the Austrian ski resort Ischgl, various European soccer matches, and the celebrations in New Orleans for Mardi Gras.

A more abrupt shift has occurred in the official view on face masks. As late as March 30, the World Health Organization advised that there was "no specific evidence to suggest that the wearing of masks by the mass population has any potential benefit."[2] Since then, however, the public health community's thinking has changed dramatically and many governments have started to require the wearing of face masks.

Should the United States follow these countries and adopt a national face mask mandate? This is inherently a political decision, but we can use our analytical tools to answer three questions that are relevant to it. First, how effective is a face mask mandate in increasing face mask usage? Second, does increased face mask usage lower virus transmission, and if so by how much? And third, how economically valuable is a face mask mandate in terms of reducing the need for broad lockdowns with their well-documented negative effects on GDP?

Face Mask Mandates and Usage

At present, the United States is among the less restrictive countries with respect to face mask mandates. The federal government did issue a national "recommendation" to wear masks in public settings in April, and many state and local governments have taken more stringent measures. However, a recommendation is not a mandate and the governors of both Florida and Texas—the two most heavily affected large states—recently reiterated their opposition to a statewide mask mandate. By contrast, many European countries now have national mask mandates in place, as shown in Exhibit 1, and much of East Asia has strong social norms of mask wearing when sick and during pandemics.

[1] We thank Sid Bhushan and Dan Milo for valuable help with this report.

What about actual mask usage? In this respect, the US scores somewhat better than one might expect, at least when looking at the national self-reported average. As shown in Exhibit 2, the share of respondents saying that they wear a face mask in public is nearly 90% in East Asia, 80% in Southern Europe, just below 70% in the US and Germany, 30% in the UK, and as low as 10% in Scandinavia. Most countries, including the US, have seen large increases in self-reported mask usage since the start of the pandemic.

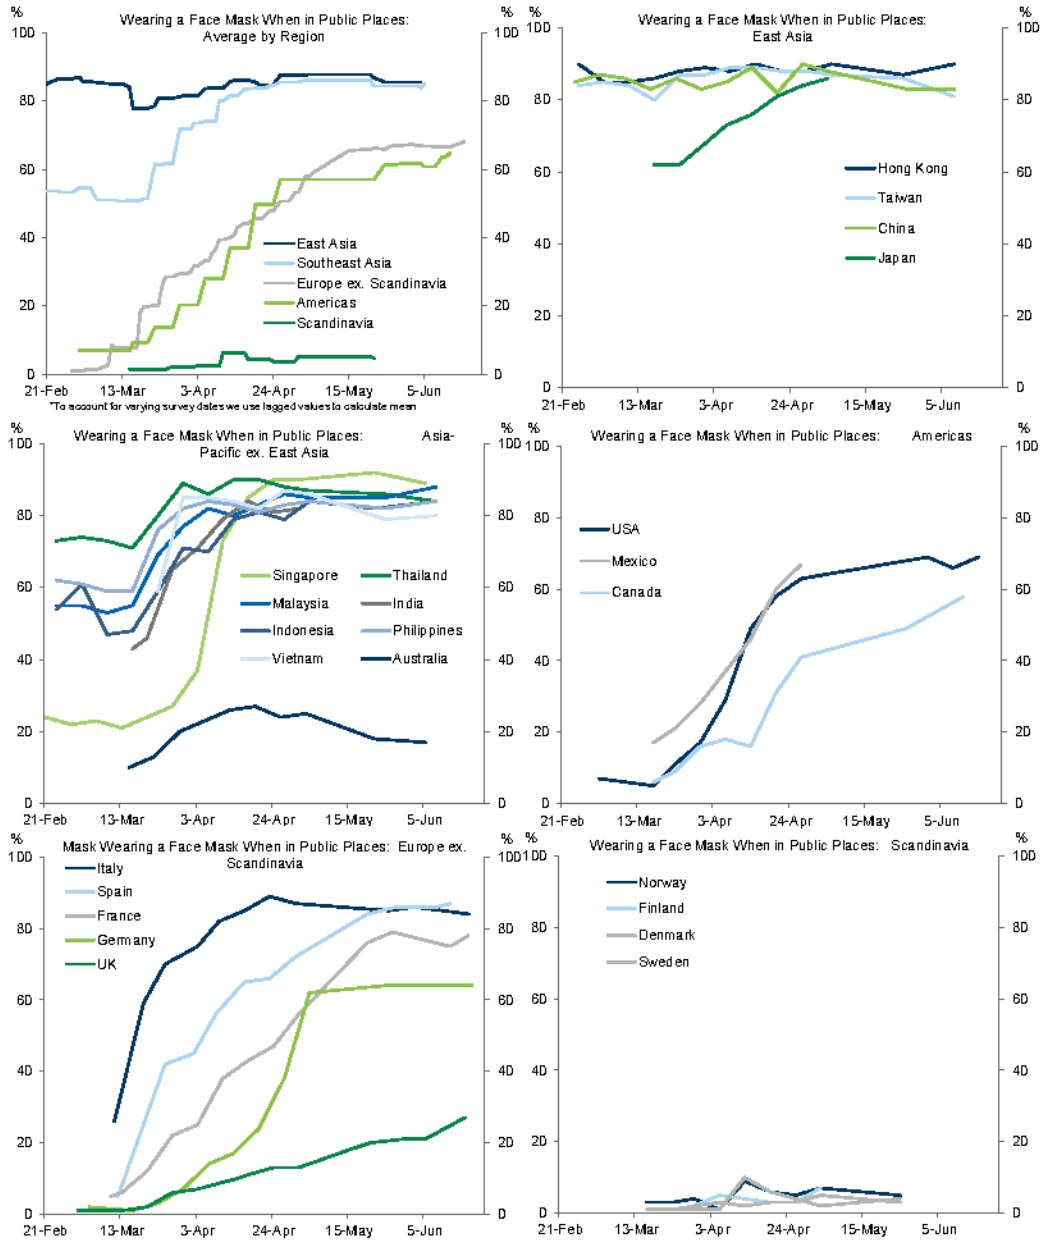
Exhibit 2: The Percentage of People Saying That They Wear a Face Mask in Public Ranges from Less than 10% in Scandinavia to Nearly 90% in East Asia



Source: YouGov, Goldman Sachs Global Investment Research

However, the national data don't tell the full story. As shown in Exhibit 3, face mask usage is highest in the Northeast, where the virus situation has improved dramatically in recent months, and generally lower in the South, where the numbers have deteriorated.[3] For example, only about 40% of respondents in Arizona say that they "always" wear face masks in public, compared with nearly 80% in Massachusetts.

[3] As an aside, note that Minnesota has the lowest self-reported rate of mask usage among larger states in the US. This is interesting because the state is home to a large population of Scandinavian-Americans and Scandinavia has some of the lowest rates of face mask usage in the world.

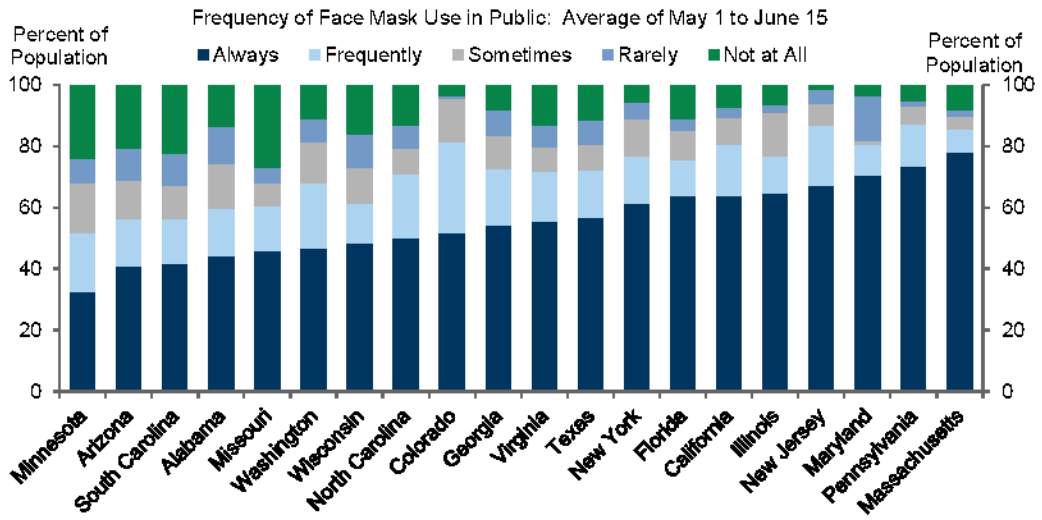
Exhibit 3: The Share "Always" Wearing a Face Mask in Public Ranges from Around 40% in Minnesota and Arizona to 80% in Massachusetts



Source: YouGov, Goldman Sachs Global Investment Research

How effective would a national mask mandate be in pushing mask usage to Southern European or East Asian levels? To investigate this, we turn to a statistical event study that relates the adoption of mask mandates across US states to subsequent changes in self-reported mask usage.

We analyze the impact of face mask mandates issued by 20 US states plus DC between April 8 and June 24 in a state panel. We collect the announcement dates of mask mandates from a study in Health Affairs by Wei Lyu and George Wehby and construct statewide time series of face mask usage outside the home using YouGov Covid-19 Behaviour Tracker respondent-level data. We regress state-level mask usage on various event time dummies around the announcement and include state fixed effects and time fixed effects.[4]

Exhibit 4 shows our estimates of a large and highly significant impact of mandates on mask usage. We estimate that statewide mask mandates gradually raise the percentage of people who "always" or "frequently" wear masks by around 25pp in the 30+ days after signing (left panel). The percent of respondents who "always" wear masks rises by nearly 40pp 30+ days after, reflecting some people switching from "frequently" and other categories to "always" (right panel).

[4] Our mask usage regressions are weighted by state population, focus on states with more than 4 million people (given the small samples in the respondent-level data) and use robust standard errors at the state level. Our sample starts on April 2nd when respondent-level data become available. We also control for cumulative cases per million and cumulative deaths per million.

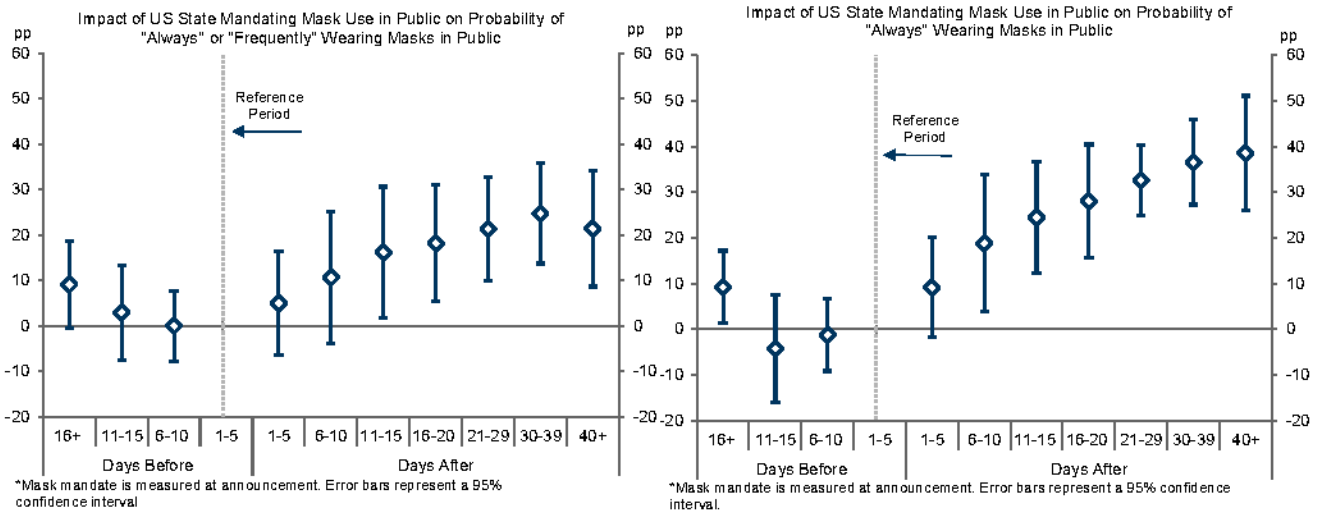
Exhibit 4: Mask Mandates Raise the Percentage of People Who "Always" or "Frequently" Wear Masks by Around 25pp in the 30+ Days After Signing



Source: YouGov, Goldman Sachs Global Investment Research

Exhibit 4 suggests that a national mask mandate could increase US face mask usage by statistically significant and economically large amounts, especially in states such as Florida and Texas that currently don't have a comprehensive mandate and are seeing some of the worst outbreaks. Specifically, we estimate that a national mandate would increase the national average share of people who "always" or "frequently" wear masks by 15pp. This estimate is based on two assumptions. First, we assume that states that currently don't have a mandate—which account for 50% of the population—experience a 25pp rise in mask usage in line with the average response to statewide mandates. Second, we assume that states which already have a state mandate see a 5pp increase in mask usage because of increased focus on the issue.

Face Masks and Virus Outcomes

Approach 1: US County Panel

Does increased face mask usage lower virus transmission, and if so by how much? To investigate this, we turn to three statistical approaches relating face mask usage and mandates to virus spread and fatalities.

Our first approach extends our event study analysis of US state-level mandates to the impact on the growth rate of infections and fatalities. Specifically, we regress county-level growth rates of infections and fatalities on event time dummies around the announcement and control for state fixed effects, time fixed effects, and a rich set of county-level controls.[5]

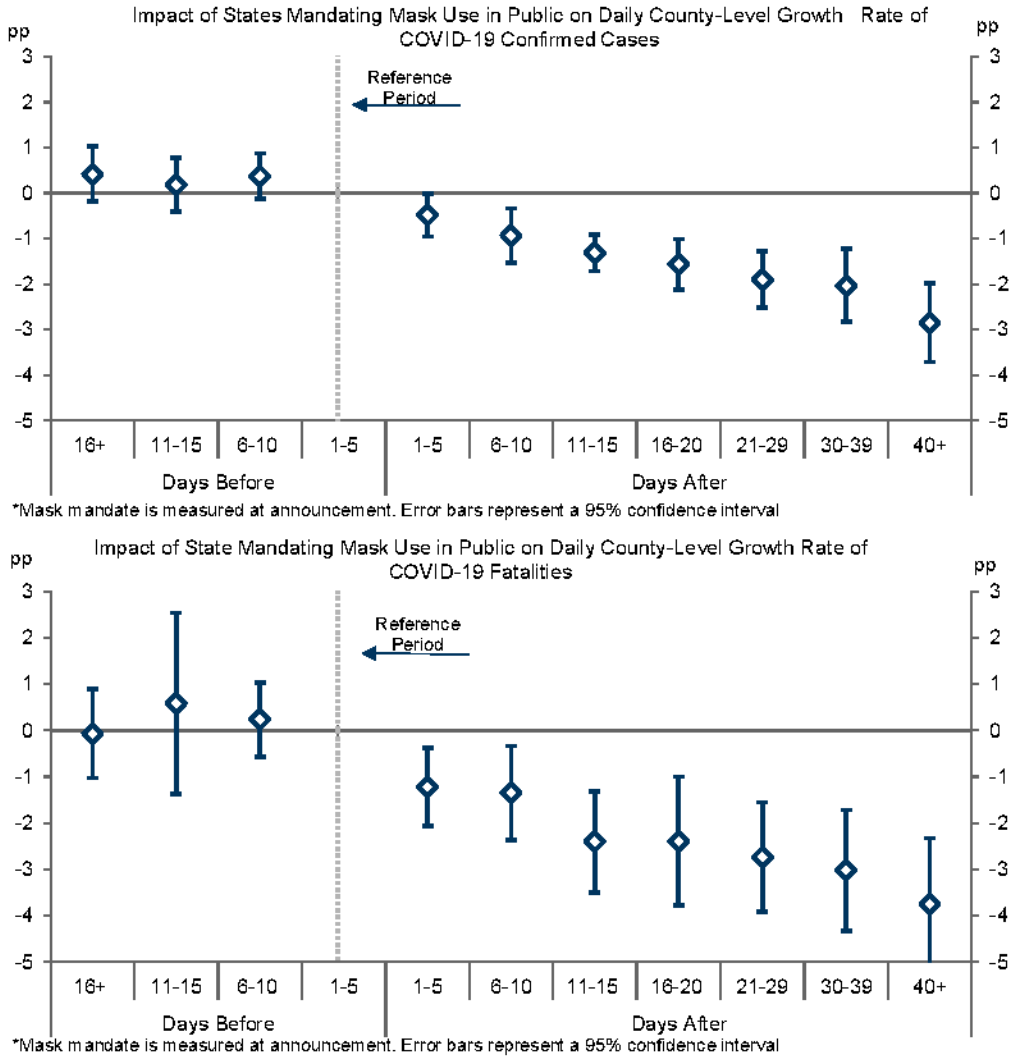
As shown in Exhibit 5, we estimate that face mask mandates have large and highly

[5] The county-level controls are population density, median house value, median household income, homeownership, pollution, maximum summer temperature, and maximum winter temperature, educational attainment, mean Body Mass Index, and the share of population over 65. We use county population weights and cluster robust standard errors at the state level. Our sample covers 2,373 counties and extends from March 31 to June 24. See Lyu and Wehby (2020).

For the exclusive use of BRENDAN.GRIBBONS@TREASURY.GOV

statistically significant effects on health outcomes. Our estimates imply that mask mandates lower the infection growth rate by 1.3pp in the 11-15 days after announcement. Relative to the 5.4% average infection growth rate prior to announcement, the growth rate of infections is cut by 25%. We also estimate significant and somewhat larger declines in the growth rate of COVID-19 fatalities of 2.4pp in the 11-15 days after announcement and of 3.7pp in the 21-29 days after.

Exhibit 5: Mask Mandates Are Associated with Large Declines in COVID-19 Case and Fatality Growth



Source: YouGov, Goldman Sachs Global Investment Research

Approach 2: Large Country Cross-Section

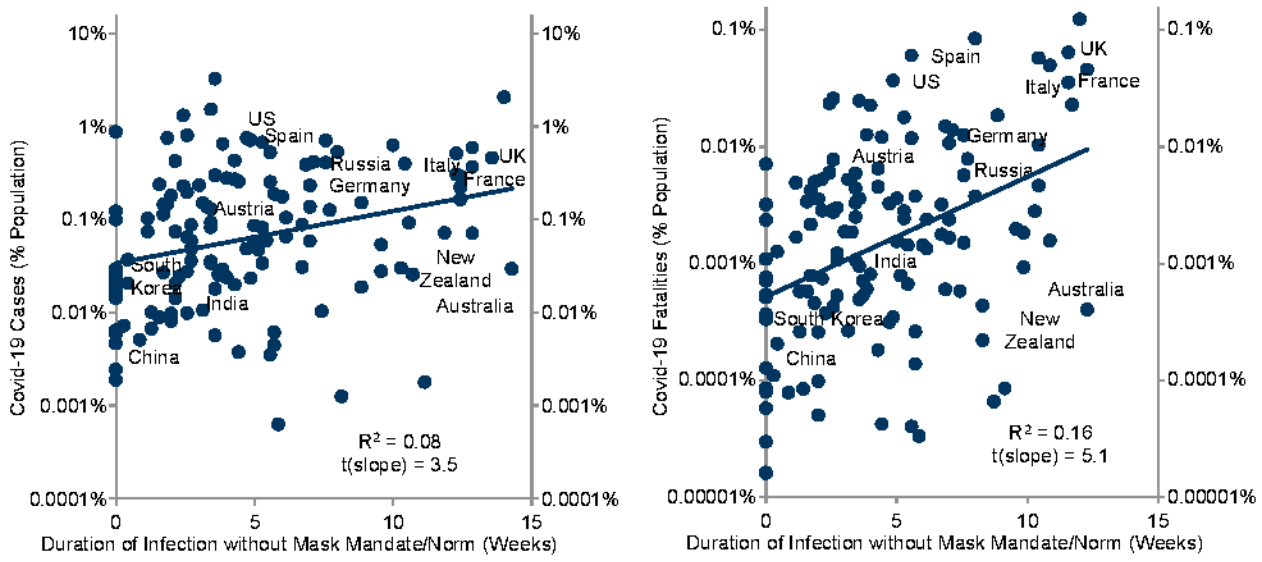
Our second approach is a large country cross section in which we relate cumulative case counts and fatalities to the lag between the onset of spread and the introduction of a face mask mandate, building on a study by Christopher Leffler and co-authors.

Exhibit 6 presents the descriptive relationships graphically by plotting the length of the outbreak before masks were widely adopted against cumulative cases per capita (left panel) and cumulative fatalities per capita (right panel). We measure the start of the outbreak as the day of the first fatality. Both graphs show a positive and statistically

For the exclusive use of BRENDAN.GRIBBONS@TREASURY.GOV

significant slope, indicating that countries which took longer to reach widespread mask usage (whether by policy or cultural norms) suffered more virus cases and fatalities. The better fit for fatalities than cases likely reflects the relatively better measurement of fatalities.

Exhibit 6: Countries Which Took Longer to Reach Widespread Mask Usage Experienced More COVID-19 Cases and Fatalities



Source: masks4all.co, Leffler et al. 2020, Goldman Sachs Global Investment Research

To formalize this finding, Exhibit 7 presents cross-sectional regression models of log cases and log fatalities for around 125 countries. In both regressions, we find statistically significant negative effects of masks on cumulative cases and fatalities after including controls such as the obesity rate, population density, age structure, and testing policy. Our numerical estimates are that cumulative cases grow 17.3% per week without a mask mandate but only 7.3% with a mask mandate, and that cumulative fatalities grow 29% per week without a mask mandate but only 16% with a mask mandate.

Source: World Bank, Blavatnik School of Government: Oxford, Leffler et al. 2020, Masks4all.co, Goldman Sachs Global Investment Research

Approach 3: Country Panel

Our third approach consists of a smaller country panel in which we relate the daily growth rate of infections and fatalities to lagged self-reported mask usage, plus a number of control variables. There are three main results, illustrated in Exhibit 8.

First, face masks have a large negative impact on infections and fatalities, controlling for population density and income inequality (columns 1 and 4). This negative and significant impact of face masks is robust to controlling for our Effective Lockdown Index (ELI), the share of the population that say they avoid crowded public places (columns 2 and 5), and country and time fixed effects (columns 3 and 6). Our estimates suggest that a 25pp increase in the self-reported mask usage, for instance as a result of a mask mandate, lowers the growth rate of cumulative cases by 1.9pp and the growth rate of cumulative fatalities by 0.8pp.[6]

Second, the share of respondents that avoid crowded public places also has a large and highly significant negative impact on infections and fatalities. This not only suggests a significant role for "super spreader" events, but also strengthens our main results because it implies that the face mask result is not just driven by the correlation between face masks and other risky activities.

Third, the virus impact of mask usage is large, not just in absolute terms but also relative to the effect of economically costly shutdowns (as measured by our ELI). In fact, the coefficients on the percentage of self-reported mask usage are slightly bigger than those on the ELI, which is interesting as both variables are on a 0-100 scale.

[6] Relative to the sample average growth rates of 3.8% and 2.8%, these estimates imply that a mask mandate raising mask usage by 25pp cuts the growth rates of infections and fatalities by nearly one half and one quarter respectively.

The Impact of a Mandate on Infections

Before we translate our statistical results into a baseline estimate of the impact of face mask mandates on virus outcomes, we need to address two potential concerns about our analysis up front.

The first concern is that the correlation between face masks and virus outcomes might reflect the effect of other unobserved forms of cautious behavior that are correlated with mask mandates or usage, instead of a truly *causal* effect of masks. But there are some reasons to believe that this type of bias in not a big issue for our analysis. Not only do we obtain remarkably similar estimates across our three approaches, but we also control for a number of other observable forms of cautious behavior. Specifically, our cross-country results on masks include our Effective Lockdown Index among the explanatory variables, and they are largely unchanged when we include the share of respondents who say they stay home from work, don't touch objects, improve personal hygiene, avoid contact with tourists, avoid raw meat, and don't send their children to school.[7]

The second potential concern is that our main results are based on confirmed infections, which can be distorted by a lack of testing. However, it is important to note that this would, if anything, lead to an *understatement* of the effect assuming that increases in testing are positively correlated with increases in mask usage. Moreover, we control for

[7] The cross-country panel and cross-county panel results are also robust to controlling for the lagged levels of fatalities and infections per capita, which helps address the concern that the mask effects pick up the impact of other forms of unobserved cautious behavior in response to the size of the outbreak.

For the exclusive use of BRENDAN.GRIBBONS@TREASURY.GOV

testing regime indicators in our cross-sectional regression, and we obtain generally similar estimates for fatalities—which are better measured—across all three of our approaches.

So what is a reasonable baseline estimate of the impact of a US national mask mandate on the growth rate of confirmed infections? To generate such an estimate, we apply our country panel results separately to two groups of US states, namely ones with and without a state-level mask mandate in place.

States that currently don't have a state-level mandate account for 40% of US total confirmed cases, 45% of US GDP, half of the population, and two-thirds of new infections. This group has also experienced an average daily growth rate in confirmed infections of 2.9% in the past 7 days. Based on our analysis of state-level mandates, we estimate that a national mask mandate would raise mask usage by 25pp in these states. Our country panel shows that a 25pp increase in self-reported mask usage lowers the infection growth rate by 1.9pp (or just over 60%). The national mandate could therefore lower the daily growth rate in the group of states without a mandate from 2.9% to just over 1%.

States that currently do have a mandate have experienced a lower average daily growth rate in confirmed infections of 0.8% in the past 7 days. Combined with our assumption that a national mandate would lead to a smaller increase in mask usage of 5pp through extra awareness in this group of states, our country panel suggests a 0.4pp decline in the infection growth rate to 0.4-0.5%.

Combining the estimates for these two groups of states, we estimate that a national mandate could cut the national average growth rate of infections by nearly 1.0pp to 0.6-0.7%.

The Impact of a Mandate on GDP

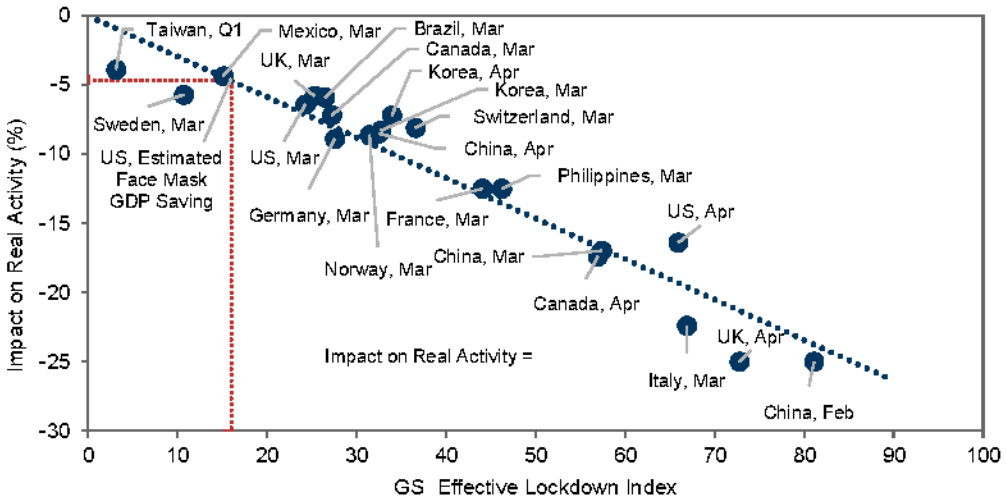
If a face mask mandate meaningfully lowers coronavirus infections, it could be valuable not only from a public health perspective but also from an economic perspective because it could substitute for renewed lockdowns that would otherwise hit GDP.

How big is this potential effect? To generate an answer, we proceed in two steps. First, we use our cross-country panel analysis to ask how much our effective lockdown index (ELI) would need to increase in order to lower the daily case growth rate by 1.0pp, i.e. the estimated impact of a national face mask mandate. The answer is an increase in our ELI of 16pp.

Second, we ask how much a 16pp ELI increase would subtract from the level of GDP. As shown in Exhibit 9, the cross-country relationship implies that such an increase might reduce GDP by just under 5%.

For the exclusive use of BRENDAN.GRIBBONS@TREASURY.GOV

Exhibit 9: A Close Relationship Between the ELI and GDP



Note: Impact on real activity is estimated where data is not available.

References to China are to Mainland China

Source: Goldman Sachs Global Investment Research

Thus, the upshot of our analysis is that a national face mask mandate could potentially substitute for renewed lockdowns that would otherwise subtract nearly 5% from GDP. It is important to recognize that this estimate is quite uncertain because it is based on a number of statistical relationships that are all measured with error. Despite the numerical uncertainty, however, our analysis suggests that the economic benefit from a face mask mandate and increased face mask usage could be sizable.

So will the US adopt a national face mask mandate? This is uncertain, partly because masks have become such a politically and culturally charged issue. However, even in the absence of a national mandate, state and local authorities might well broaden mandates in ways that ultimately mimic the impact of a national mandate. Either way, our analysis suggests that the economy could benefit significantly from such moves, especially when compared with the alternative of a return to broader lockdowns.

Reg AC

We, Jan Hatzius, Daan Struyven and Isabella Rosenberg, hereby certify that all of the views expressed in this report accurately reflect our personal views, which have not been influenced by considerations of the firm's business or client relationships.

Unless otherwise stated, the individuals listed on the cover page of this report are analysts in Goldman Sachs' Global Investment Research division.

Disclosures

Regulatory disclosures

Disclosures required by United States laws and regulations

See company-specific regulatory disclosures above for any of the following disclosures required as to companies referred to in this report: manager or co-manager in a pending transaction; 1% or other ownership; compensation for certain services; types of client relationships; managed/co-managed public offerings in prior periods; directorships; for equity securities, market making and/or specialist role. Goldman Sachs trades or may trade as a principal in debt securities (or in related derivatives) of issuers discussed in this report.

The following are additional required disclosures: **Ownership and material conflicts of interest:** Goldman Sachs policy prohibits its analysts, professionals reporting to analysts and members of their households from owning securities of any company in the analyst's area of coverage. **Analyst compensation:** Analysts are paid in part based on the profitability of Goldman Sachs, which includes investment banking revenues. **Analyst as officer or director:** Goldman Sachs policy generally prohibits its analysts, persons reporting to analysts or members of their households from serving as an officer, director or advisor of any company in the analyst's area of coverage. **Non-U.S. Analysts:** Non-U.S. analysts may not be associated persons of Goldman Sachs & Co. LLC and therefore may not be subject to FINRA Rule 2241 or FINRA Rule 2242 restrictions on communications with subject company, public appearances and trading securities held by the analysts.

Additional disclosures required under the laws and regulations of jurisdictions other than the United States

The following disclosures are those required by the jurisdiction indicated, except to the extent already made above pursuant to United States laws and regulations. **Australia:** Goldman Sachs Australia Pty Ltd and its affiliates are not authorised deposit-taking institutions (as that term is defined in the Banking Act 1959 (Cth)) in Australia and do not provide banking services, nor carry on a banking business, in Australia. This research, and any access to it, is intended only for "wholesale clients" within the meaning of the Australian Corporations Act, unless otherwise agreed by Goldman Sachs. In producing research reports, members of the Global Investment Research Division of Goldman Sachs Australia may attend site visits and other meetings hosted by the companies and other entities which are the subject of its research reports. In some instances the costs of such site visits or meetings may be met in part or in whole by the issuers concerned if Goldman Sachs Australia considers it is appropriate and reasonable in the specific circumstances relating to the site visit or meeting. To the extent that the contents of this document contains any financial product advice, it is general advice only and has been prepared by Goldman Sachs without taking into account a client's objectives, financial situation or needs. A client should, before acting on any such advice, consider the appropriateness of the advice having regard to the client's own objectives, financial situation and needs. A copy of certain Goldman Sachs Australia and New Zealand disclosure of interests and a copy of Goldman Sachs' Australian Sell-Side Research Independence Policy Statement are available at: https://www.goldmansachs.com/disclosures/australia-new-zealand/index.html. **Brazil:** Disclosure information in relation to CVM Instruction 598 is available at https://www.gs.com/worldwide/brazil/area/gir/index.html. Where applicable, the Brazil-registered analyst primarily responsible for the content of this research report, as defined in Article 20 of CVM Instruction 598, is the first author named at the beginning of this report, unless indicated otherwise at the end of the text. **Canada:** Goldman Sachs Canada Inc. is an affiliate of The Goldman Sachs Group Inc. and therefore is included in the company specific disclosures relating to Goldman Sachs (as defined above). Goldman Sachs Canada Inc. has approved of, and agreed to take responsibility for, this research report in Canada if and to the extent that Goldman Sachs Canada Inc. disseminates this research report to its clients. **Hong Kong:** Further information on the securities of covered companies referred to in this research may be obtained on request from Goldman Sachs (Asia) L.L.C. **India:** Further information on the subject company or companies referred to in this research may be obtained from Goldman Sachs (India) Securities Private Limited, Research Analyst - SEBI Registration Number INH000001493, 951-A, Rational House, Appasaheb Marathe Marg, Prabhadevi, Mumbai 400 025, India, Corporate Identity Number U74140MH2006FTC160634, Phone +91 22 6616 9000, Fax +91 22 6616 9001. Goldman Sachs may beneficially own 1% or more of the securities (as such term is defined in clause 2 (h) the Indian Securities Contracts (Regulation) Act, 1956) of the subject company or companies referred to in this research report. **Japan:** See below. **Korea:** This research, and any access to it, is intended only for "professional investors" within the meaning of the Financial Services and Capital Markets Act, unless otherwise agreed by Goldman Sachs. Further information on the subject company or companies referred to in this research may be obtained from Goldman Sachs (Asia) L.L.C., Seoul Branch. **New Zealand:** Goldman Sachs New Zealand Limited and its affiliates are neither "registered banks" nor "deposit takers" (as defined in the Reserve Bank of New Zealand Act 1989) in New Zealand. This research, and any access to it, is intended for "wholesale clients" (as defined in the Financial Advisers Act 2008) unless otherwise agreed by Goldman Sachs. A copy of certain Goldman Sachs Australia and New Zealand disclosure of interests is available at: https://www.goldmansachs.com/disclosures/australia-new-zealand/index.html. **Russia:** Research reports distributed in the Russian Federation are not advertising as defined in the Russian legislation, but are information and analysis not having product promotion as their main purpose and do not provide appraisal within the meaning of the Russian legislation on appraisal activity. Research reports do not constitute a personalized investment recommendation as defined in Russian laws and regulations, are not addressed to a specific client, and are prepared without analyzing the financial circumstances, investment profiles or risk profiles of clients. Goldman Sachs assumes no responsibility for any investment decisions that may be taken by a client or any other person based on this research report. **Singapore:** Further information on the covered companies referred to in this research may be obtained from Goldman Sachs (Singapore) Pte. (Company Number: 198602165W). **Taiwan:** This material is for reference only and must not be reprinted without permission. Investors should carefully consider their own investment risk. Investment results are the responsibility of the individual investor. **United Kingdom:** Persons who would be categorized as retail clients in the United Kingdom, as such term is defined in the rules of the Financial Conduct Authority, should read this research in conjunction with prior Goldman Sachs research on the covered companies referred to herein and should refer to the risk warnings that have been sent to them by Goldman Sachs International. A copy of these risks warnings, and a glossary of certain financial terms used in this report, are available from Goldman Sachs International on request.

European Union: Disclosure information in relation to Article 6 (2) of the European Commission Delegated Regulation (EU) (2016/958) supplementing Regulation (EU) No 596/2014 of the European Parliament and of the Council with regard to regulatory technical standards for the technical arrangements for objective presentation of investment recommendations or other information recommending or suggesting an investment strategy and for disclosure of particular interests or indications of conflicts of interest is available at https://www.gs.com/disclosures/europeanpolicy.html which states the European Policy for Managing Conflicts of Interest in Connection with Investment Research.

Japan: Goldman Sachs Japan Co., Ltd. is a Financial Instrument Dealer registered with the Kanto Financial Bureau under registration number Kinsho 69, and a member of Japan Securities Dealers Association, Financial Futures Association of Japan and Type II Financial Instruments Firms Association. Sales and purchase of equities are subject to commission pre-determined with clients plus consumption tax. See company-specific disclosures as to

any applicable disclosures required by Japanese stock exchanges, the Japanese Securities Dealers Association or the Japanese Securities Finance Company.

Global product; distributing entities

The Global Investment Research Division of Goldman Sachs produces and distributes research products for clients of Goldman Sachs on a global basis. Analysts based in Goldman Sachs offices around the world produce research on industries and companies, and research on macroeconomics, currencies, commodities and portfolio strategy. This research is disseminated in Australia by Goldman Sachs Australia Pty Ltd (ABN 21 006 797 897); in Brazil by Goldman Sachs do Brasil Corretora de Títulos e Valores Mobiliários S.A.; Ombudsman Goldman Sachs Brazil: 0800 727 5764 and / or ouvidoriagoldmansachs@gs.com. Available Weekdays (except holidays), from 9am to 6pm. Ouvidoria Goldman Sachs Brasil: 0800 727 5764 e/ou ouvidoriagoldmansachs@gs.com. Horário de funcionamento: segunda-feira à sexta-feira (exceto feriados), das 9h às 18h; in Canada by either Goldman Sachs Canada Inc. or Goldman Sachs & Co. LLC; in Hong Kong by Goldman Sachs (Asia) L.L.C.; in India by Goldman Sachs (India) Securities Private Ltd.; in Japan by Goldman Sachs Japan Co., Ltd.; in the Republic of Korea by Goldman Sachs (Asia) L.L.C., Seoul Branch; in New Zealand by Goldman Sachs New Zealand Limited; in Russia by OOO Goldman Sachs; in Singapore by Goldman Sachs (Singapore) Pte. (Company Number: 198602165W); and in the United States of America by Goldman Sachs & Co. LLC. Goldman Sachs International has approved this research in connection with its distribution in the United Kingdom and European Union.

European Union: Goldman Sachs International authorised by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and the Prudential Regulation Authority, has approved this research in connection with its distribution in the European Union and United Kingdom.

General disclosures

This research is for our clients only. Other than disclosures relating to Goldman Sachs, this research is based on current public information that we consider reliable, but we do not represent it is accurate or complete, and it should not be relied on as such. The information, opinions, estimates and forecasts contained herein are as of the date hereof and are subject to change without prior notification. We seek to update our research as appropriate, but various regulations may prevent us from doing so. Other than certain industry reports published on a periodic basis, the large majority of reports are published at irregular intervals as appropriate in the analyst's judgment.

Goldman Sachs conducts a global full-service, integrated investment banking, investment management, and brokerage business. We have investment banking and other business relationships with a substantial percentage of the companies covered by our Global Investment Research Division. Goldman Sachs & Co. LLC, the United States broker dealer, is a member of SIPC (https://www.sipc.org).

Our salespeople, traders, and other professionals may provide oral or written market commentary or trading strategies to our clients and principal trading desks that reflect opinions that are contrary to the opinions expressed in this research. Our asset management area, principal trading desks and investing businesses may make investment decisions that are inconsistent with the recommendations or views expressed in this research.

We and our affiliates, officers, directors, and employees, will from time to time have long or short positions in, act as principal in, and buy or sell, the securities or derivatives, if any, referred to in this research, unless otherwise prohibited by regulation or Goldman Sachs policy.

The views attributed to third party presenters at Goldman Sachs arranged conferences, including individuals from other parts of Goldman Sachs, do not necessarily reflect those of Global Investment Research and are not an official view of Goldman Sachs.

Any third party referenced herein, including any salespeople, traders and other professionals or members of their household, may have positions in the products mentioned that are inconsistent with the views expressed by analysts named in this report.

This research is focused on investment themes across markets, industries and sectors. It does not attempt to distinguish between the prospects or performance of, or provide analysis of, individual companies within any industry or sector we describe.

Any trading recommendation in this research relating to an equity or credit security or securities within an industry or sector is reflective of the investment theme being discussed and is not a recommendation of any such security in isolation.

This research is not an offer to sell or the solicitation of an offer to buy any security in any jurisdiction where such an offer or solicitation would be illegal. It does not constitute a personal recommendation or take into account the particular investment objectives, financial situations, or needs of individual clients. Clients should consider whether any advice or recommendation in this research is suitable for their particular circumstances and, if appropriate, seek professional advice, including tax advice. The price and value of investments referred to in this research and the income from them may fluctuate. Past performance is not a guide to future performance, future returns are not guaranteed, and a loss of original capital may occur. Fluctuations in exchange rates could have adverse effects on the value or price of, or income derived from, certain investments.

Certain transactions, including those involving futures, options, and other derivatives, give rise to substantial risk and are not suitable for all investors. Investors should review current options and futures disclosure documents which are available from Goldman Sachs sales representatives or at https://www.theocc.com/about/publications/character-risks.jsp and https://www.fiadocumentation.org/fia/regulatory-disclosures_1/fia-uniform-futures-and-options-on-futures-risk-disclosures-booklet-pdf-version-2018. Transaction costs may be significant in option strategies calling for multiple purchase and sales of options such as spreads. Supporting documentation will be supplied upon request.

Differing Levels of Service provided by Global Investment Research: The level and types of services provided to you by the Global Investment Research division of GS may vary as compared to that provided to internal and other external clients of GS, depending on various factors including your individual preferences as to the frequency and manner of receiving communication, your risk profile and investment focus and perspective (e.g., marketwide, sector specific, long term, short term), the size and scope of your overall client relationship with GS, and legal and regulatory constraints. As an example, certain clients may request to receive notifications when research on specific securities is published, and certain clients may request that specific data underlying analysts' fundamental analysis available on our internal client websites be delivered to them electronically through data feeds or otherwise. No change to an analyst's fundamental research views (e.g., ratings, price targets, or material changes to earnings estimates for equity securities), will be communicated to any client prior to inclusion of such information in a research report broadly disseminated through electronic publication to our internal client websites or through other means, as necessary, to all clients who are entitled to receive such reports.

All research reports are disseminated and available to all clients simultaneously through electronic publication to our internal client websites. Not all research content is redistributed to our clients or available to third-party aggregators, nor is Goldman Sachs responsible for the redistribution of our research by third party aggregators. For research, models or other data related to one or more securities, markets or asset classes (including related services) that may be available to you, please contact your GS representative or go to https://research.gs.com.

Disclosure information is also available at https://www.gs.com/research/hedge.html or from Research Compliance, 200 West Street, New York, NY 10282.

Face Masks, Public Policies and Slowing the Spread of COVID-19: Evidence from Canada
Alexander Karaivanov, Shih En Lu, Hitoshi Shigeoka, Cong Chen, and Stephanie Pamplona
NBER Working Paper No. 27891
October 2020
JEL No. C23,I12,I18

ABSTRACT

We estimate the impact of mask mandates and other non-pharmaceutical interventions (NPI) on COVID-19 case growth in Canada, including regulations on businesses and gatherings, school closures, travel and self-isolation, and long-term care homes. We partially account for behavioral responses using Google mobility data. Our identification approach exploits variation in the timing of indoor face mask mandates staggered over two months in the 34 public health regions in Ontario, Canada's most populous province. We find that, in the first few weeks after implementation, mask mandates are associated with a reduction of 25 percent in the weekly number of new COVID-19 cases. Additional analysis with province-level data provides corroborating evidence. Counterfactual policy simulations suggest that mandating indoor masks nationwide in early July could have reduced the weekly number of new cases in Canada by 25 to 40 percent in mid-August, which translates into 700 to 1,100 fewer cases per week.

1 Introduction

When government policies to stem the spread of COVID-19 were introduced in early 2020, the best available evidence supporting them was provided by studies of previous epidemics, epidemiological modeling, and case studies (OECD, 2020). Even when the efficacy of a given precaution in reducing COVID-19 transmission has been established, significant doubts regarding the usefulness of specific policy measures may persist due to uncertainty regarding adherence to the rules and other behavioral responses. For example, even though several observational studies, mostly in medical setting, have shown that face masks reduce the transmission of COVID-19 and similar respiratory illnesses (see Chu et al. (2020) for a comprehensive review), a face mask mandate may not be effective in practice if it fails to increase the prevalence of mask wearing (compliance), or if it leads to increased contacts due to a false sense of security. It is therefore important to directly evaluate and quantify the relationship between various policy measures and the rate of propagation of COVID-19.

The low cost and high feasibility of mask mandates relative to other containment measures for COVID-19 has generated keen interest worldwide for studying their effectiveness. This attention has been compounded by substantial variation, across jurisdictions and over time, in official advice regarding the use of masks. Figure B1 in the Appendix plots self-reported mask usage in select countries (Canada, United States, Germany and Australia) in the left panel, and across Canadian provinces in the right panel. The figure shows large differences in mask usage, both across countries and within Canada.[1]

We estimate and quantify the impact of mask mandates and other non-pharmaceutical interventions (NPI) on the growth of the number of COVID-19 cases in Canada. Canadian data has the important advantage of allowing two complementary approaches to address our objective. First, we estimate the effect of mask mandates by exploiting within-province geographic variation in the timing of indoor face mask mandates across 34 public health regions (PHUs) in Ontario, Canada's most populous province with a population of nearly 15 million or roughly 39% of Canada's population (Statistics Canada, 2020). The advantage of this approach is that it exploits variation over a relatively small geographic scale (PHU), holding all other province-level policies or events constant. In addition, the adoption of indoor face mask mandates in these 34 sub-regions was staggered over approximately two months, creating sufficient intertemporal policy variation across the PHUs.

[1] We show mask usage for the U.S. and Germany because related work by Chernozhukov et al. (2020) and Mitze et al. (2020) studies the effect of mask mandates in these countries respectively. We show Australia as an example of a country which did not mandate mask usage, except for Melbourne in late July. See Hatzius et al. (2020) for more cross-country comparisons of mask usage.

MS-DOH-21-1816-A-000322

Second, we evaluate the impact of NPIs in Canada as a whole, by exploiting variation in the timing of policies across the country's ten provinces. By studying inter-provincial variation, we are able to analyze the impact of not only mask mandates, but also other NPIs, for which there is little or no variation across Ontario's PHUs (regulations on businesses and gatherings, schooling, travel and long-term care). In addition, our province-level data include both the closing period (March-April) and the gradual re-opening period (May-August), providing variation from both the imposition and the relaxation of policies.

Our panel-data estimation strategy broadly follows the approach of Chernozhukov, Kasahara and Schrimpf (2020), hereafter CKS (2020), adapted to the Canadian context. We allow for behavioural responses (using Google Community Mobility Reports geo-location data as proxy for behaviour changes and trends), as well as lagged outcome responses to policy and behavioral changes. Our empirical approach also allows current epidemiological outcomes to depend on past outcomes, as an information variable affecting past policies or behaviour, or directly, as in the SIR model framework.

We find that, in the first few weeks after their introduction, mask mandates are associated with an average reduction of 25 to 31% in the weekly number of newly diagnosed COVID-19 cases in Ontario, holding all else equal. We find corroborating evidence in the province-level analysis, with a 36 to 46% reduction in weekly cases, depending on the empirical specification. Furthermore, using survey data, we show that mask mandates increase self-reported mask usage in Canada by 30 percentage points, suggesting that the policy has a significant impact on behaviour. Jointly, these results suggest that mandating indoor mask wear in public places is a powerful policy measure to slow the spread of COVID-19, with little associated economic disruption at least in the short run.[2]

Counterfactual policy simulations using our empirical estimates suggest that mandating indoor masks nationwide in early July could have reduced weekly new cases in Canada by 25 to 40% on average by mid-August relative to the actually observed numbers, which translates into 700 to 1,100 fewer cases per week.

We also find that the most stringent restrictions on businesses and gatherings observed in our data are associated with a decrease of 48 to 57% in weekly cases, relative to a lack of restrictions. The business/gathering estimates are, however, noisier than our estimates for mask mandates and do not retain statistical significance in all specifications; they appear driven by the smaller provinces and the re-opening period (May to August). School closures and travel restrictions are associated with a large decrease in weekly case growth in the

[2]Hatzius et al. (2020) estimate that a national mask mandate in the USA could replace alternative restrictions costing 5% of GDP.

MS-DOH-21-1816-A-000323

closing period. Our results on business/gathering regulations and school closure suggest that reduced restrictions and the associated increase in business or workplace activity and gatherings or school re-opening can offset, in whole or in part, the estimated effect of mask mandates on COVID-19 case growth, both in our sample and subsequently.

An additional contribution of this research project is to assemble, from original official sources only, and make publicly available a complete dataset of COVID-19 cases, deaths, tests and policy measures in all 10 Canadian provinces.[3] To this end, we constructed, based on official public health orders and announcements, time series for 17 policy indicators regarding face masks, regulations on businesses and gatherings, school closures, travel and self-isolation, and long-term care homes.

Our paper relates most closely to two recent empirical papers on the effects of mask mandates using observational data.[4] CKS (2020) and Mitze et al. (2020) study the effect of mask mandates in the United States and Germany, respectively. CKS (2020), whose estimation strategy we follow, exploit U.S. state-level variation in the timing of mask mandates for employees in public-facing businesses, and find that these mandates are associated with 9 to 10 percentage points reduction in the weekly growth rate of cases. This is substantially smaller that our estimates, possibly because the mask mandates that we study are much broader: they apply to all persons rather than just employees, and most apply to all indoor public spaces rather than just businesses. Mitze et al. (2020) use a synthetic control approach and compare the city of Jena and six regions in Germany that adopted a face mask policy in early to mid April 2020, before their respective state mandate. They find that mandatory masks reduce the daily growth rate of cases by about 40%.

Our paper has several advantages compared to the above two papers. First, we exploit both regional variation within the same province (like Mitze et al., 2020) and provincial variation in the whole country (like CKS, 2020), and find similar results, which strengthens the validity of our findings. Second, we show that self-reported mask usage has increased after introducing mask mandates. We view this "first-stage" result on mask usage as informative, as the effectiveness of any NPI or public policy critically depends on the compliance rate. Moreover, this result mitigates possible concerns that the estimated mask mandate effect on COVID-19 case growth may be caused by factors other than mask policy. Third, a key

[3]All data are available for download at https://github.com/C19-SFU-Econ. The COVID-19 cases, deaths and tests data that we collected and use in this paper incorporate all official ex-post revisions as of mid-August, unlike data from the Government of Canada COVID-19 website or other aggregator websites.

[4]Howard et al. (2020), a comprehensive review of the medical literature, stresses that "no randomized controlled trial (RCT) on the use of masks as source control for SARS-CoV-2 has been published." It is unlikely that an RCT on masks' effectiveness against COVID-19 will be feasible or ethical during the pandemic.

difference between our paper and CKS (2020) is that we evaluate the effect of *universal* (or *community*) mandatory indoor mask wearing for the public rather than the effect of mandatory mask wearing for *employees only*.[5] While other factors such as differences in mask wear compliance between Canada and the U.S. may contribute to the different estimated magnitude of the policy impact, our results suggest that more comprehensive mask policies can be more effective in reducing the case growth rate.

Other Related Literature

Abaluck et al. (2020) discuss the effectiveness of universal adoption of homemade cloth face masks and conclude that this policy could yield large benefits, in the $3,000–$6,000 per capita range, by slowing the spread of the virus. The analysis compares countries with pre-existing norms that sick people should wear masks (South Korea, Japan, Hong Kong and Taiwan) and countries without such norms.[6]

In the medical literature, Prather et al. (2020) argue that masks can play an important role in reducing the spread of COVID-19. Howard et al. (2020) survey the medical evidence on mask efficiency and recommend public use of masks in conjunction with existing hygiene, distancing, and contact tracing strategies. Greenhalgh et al. (2020) provide evidence on the use of masks during non-COVID epidemics (influenza and SARS) and conclude that even limited protection could prevent some transmission of COVID-19. Leung et al. (2020) study exhaled breath and coughs of children and adults with acute respiratory illness and conclude that the use of surgical face masks could prevent the transmission of the human coronavirus and influenza virus from symptomatic individuals. Meyerowitz et al. (2020) present a recent comprehensive review of the evidence on transmission of the virus and conclude that there is strong evidence from case and cluster reports indicating that respiratory transmission is dominant, with proximity and ventilation being key determinants of transmission risk, as opposed to direct contact or fomite transmission.

Our paper also complements recent work on COVID-19 policies in Canada. Mohammed et al. (2020) use public opinion survey data to study the effect of changes in mask-wear policy recommendations, from discouraged to mandatory, on the rates of mask adoption and public trust in government institutions. They show that Canadians exhibit high compliance with mask mandates and trust in public health officials remained consistent across time. Yuksel et al. (2020) use an outcome variable constructed from Apple mobility data along

[5]Lyu and Wehby (2020) provide suggestive evidence that community mask mandates are more effective than employees-only mandates.

[6]The authors report average daily case growth rate of 18% in countries with no pre-existing mask norms vs. 10% in countries with such norms. On a weekly basis, this translates to a reduction of 49 log points ($100(\log(1.18^7) - \log(1.1^7))$) in case growth, or 39% reduction in weekly cases.

with weather data and lagged COVID-19 cases or deaths as dependent variables to study compliance with social distancing measures.

2 Data

We use three main data sources, respectively for epidemiological variables, NPI and mask mandates, and behavioral responses. The time period is from the start of detected community transmission in Canada in March to mid-August, 2020.

We located and accessed the original official sources to collect a complete dataset of COVID-19 cases, deaths, tests and policy measures in all ten Canadian provinces.[7] In addition, our data include cases and policy measure indicators for each of the 34 public health units (PHUs) in Ontario. A detailed description is provided in the data source files shared at the project's Github webpage.

Implementation dates of NPIs and other public policies were collected from government websites, announcements, public health orders and staged re-opening plans collected from their official sources. In the national data, the raw policy measures data contain the dates or enactment and relaxation (if applicable) of 17 policy indicators including: mandatory mask wear; closure and re-opening of retail and non-essential businesses, restaurants, recreation facilities, and places of worship; school closures; limits on events and gatherings; international and domestic travel restrictions and self-isolation requirements; restrictions on visits and staff movement in long-term care homes. All policy indicator variables are defined in Table C1 in the Appendix.[8] Since many of these indicators are highly correlated with each other, we combine them into five policy aggregates in the empirical analysis (see Table A17 and Section 3.2). In the Ontario PHU data, the implementation dates of mask mandates and the relaxation dates of policies for businesses and gatherings vary across PHUs. Decisions about the former were made at the PHU level, while decisions about the latter were made by the province, which classified PHUs into three groups, with some exceptions.

Regarding behavioral responses, we use the Google COVID-19 Community Mobility Reports, which summarize daily cellphone geo-location data for each province as indices calculated relative to the median value for the same day of the week in the five-week baseline

[7] The provinces differ in the ease of accessibility of their official time series of COVID-19 cases, deaths and test numbers. In some cases, we located and used the hidden json sources feeding the public dashboard charts. In few instances in which data were not available, we used the numbers reported in the daily provincial government announcements. All COVID-19 outcome data sources are referenced and web-linked in Appendix Table C3.

[8] Additional survey data on mask usage is described and used in Section 4.4.

MS-DOH-21-1816-A-000326

period January 3 to February 6, 2020.[9] In Ontario, these location data are available for each of the 51 first-level administrative divisions (counties, regional municipalities, single-tier municipalities and districts).[10]

3 Empirical method

We follow the approach of CKS (2020), but modify and adapt it to the Canadian context. The empirical strategy uses the panel structure of the outcome, policy and behavioral proxy variables, and includes lags of outcomes as information, following the causal paths suggested by the epidemiological SIR model (Kermack and McKendrick, 1927). Specifically, we estimate the effect of policy interventions on COVID-19 outcomes while controlling for information and behaviour. In contrast to CKS (2020) and Hsiang et al. (2020), who study variation in NPIs across U.S. states or across countries, our identification strategy exploits policy variation at the sub-provincial level (Ontario's PHUs) in addition to cross-province variation, and our data captures both the closing down and gradual re-opening stages of the epidemic.

3.1 Estimation strategy

The main data used in our empirical analysis are summarized below; Section 3.2 describes the variables in detail. Everywhere i denotes province for national analysis, and health region (PHU) for Ontario analysis, and t denotes time measured in days.

1. Outcomes, Y_{it} – growth rate of weekly cases or deaths.

2. Information, I_{it} – lagged outcomes, i.e. past levels or growth rate of cases (or deaths). We also consider a specification that includes the past cases/deaths and case/death growth at the national level as additional information variables.

3. Behavioral responses, B_{it} – Google mobility data capturing changes in people's geolocation relative to a baseline period in January-February.

4. Policy/NPIs, P_{it} – for the national analysis, five policy aggregates by province and date; for the Ontario analysis, two policy variables (mask mandates and regulation on business and gathering) by PHU and date.

[9] The reports are available for download at https://www.google.com/covid19/mobility/.

[10] Each of these divisions is either entirely (in most cases) or predominantly located within a single PHU. In cases where a PHU corresponds to multiple divisions, 2016 Census population counts were used as weights to compute the PHU's mobility index.

MS-DOH-21-1816-A-000327

5. Controls, W_{it} – province or PHU fixed effects, growth rate of weekly new COVID-19 tests, and a time trend.

To assess and disentangle the impact of NPIs and behavioral responses on COVID-19 outcomes, we estimate the following equation:

$$Y_{it} = \alpha B_{it-l} + \pi P_{it-l} + \mu I_{it} + \delta_Y W_{it} + \varepsilon_{it}^Y \tag{1}$$

where l denotes a time lag measured in days. Equation (1) models the relationship between COVID-19 outcomes, Y_{it}, and lagged behaviour, B_{it-l}, lagged policy measures, P_{it-l} and information (past outcomes), $I_{it} = Y_{it-l}$. For case growth as the outcome, we use $l = 14$. For deaths growth as the outcome, we use $l = 28$.[11] The choice of these lags is discussed in Appendix D.

By including lagged outcomes, our approach allows for possible endogeneity of the policy interventions P_{it}, that is, the introduction or relaxation of NPIs based on information on the level or growth rate of cases or deaths. Also, past cases may be correlated with (lagged) government policies or behaviors that may not be fully captured by the policy and behaviour variables.

In Appendix Table A18, we also report estimates of the following equation:

$$B_{it} = \beta P_{it} + \gamma I_{it} + \delta_B W_{it} + \varepsilon_{it}^B \tag{2}$$

which models the relationship between policies P_{it}, information, I_{it} (weekly levels or growth of cases or deaths) and behaviour, B_{it}. It is assumed that behaviour reacts to the information without a significant lag. We find strong correlation between policy measures and the Google mobility behavioral proxy measure.

Equation (1) captures both the direct effect of policies on outcomes, with the appropriate lag, as well as the potential indirect effect on outcomes from changes in behaviour captured by the changes in geo-location proxy B_{it-l}. In Appendix Tables A19 and A20, we also report estimates of equation (1) without including the behavioral proxy, that is, capturing the total effect of policies on outcomes. Since our estimates of the coefficient α in equation (1) are not significantly different from zero, the results without controlling for the behavioral proxy are very similar to those from estimating equation (1).

[11] Our lag for deaths is one week longer than that used by CKS (2020). The difference is due to additional evidence from the medical literature and the construction of the weekly variables (see Appendix D).

MS-DOH-21-1816-A-000328

3.2 Variables and descriptive analysis

Outcomes. Our main outcome of interest is the growth rate of weekly new positive COVID-19 cases as defined below.[12] We use weekly outcome data to correct for the strong day-of-the-week effect present in COVID-19 outcome data.[13] Weekly case growth is a metric that can be helpful in assessing trends in the spread of COVID-19, and it is highlighted in the World Health Organization's weekly epidemiological updates (see, for example, World Health Organization (2020)).

Specifically, let C_{it} denote the cumulative case count up to day t and define ΔC_{it} as the weekly COVID-19 cases reported for the 7-day period ending at day t:

$$\Delta C_{it} \equiv C_{it} - C_{it-7}.$$

The weekly case (log) growth rate is then defined as:

$$Y_{it} = \Delta \log(\Delta C_{it}) = \log(\Delta C_{it}) - \log(\Delta C_{it-7}), \tag{3}$$

that is, the week-over-week growth in cases in region i ending on day t.[14] The weekly death growth rate is defined analogously, using cumulative deaths data.

Policy. In the Ontario analysis, we exploit regional variation in the timing of indoor mask mandates staggered over two months in the province's 34 regions ("public health units" or PHUs). Figure 1 displays the gradual introduction of mask mandates across the 34 PHUs in Ontario. The exact implementation dates of the mask mandates are reported in Table C2. Mandatory indoor masks were introduced first in the Wellington-Dufferin-Guelph PHU on June 12 and last in the Northwestern PHU on August 17.[15]

[12] We also report results using the growth rate of deaths as supplemental analysis in Section 4.5.

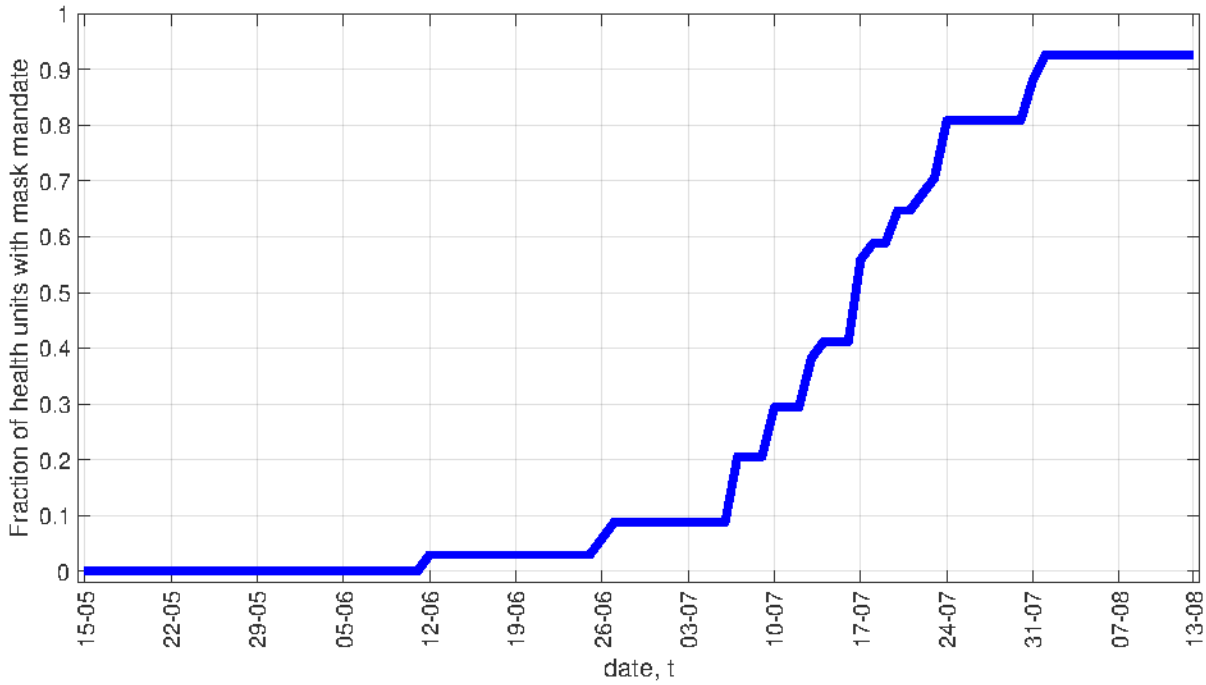
[13] Figures B9 and B10 in the Appendix respectively display the weekly and daily cases, deaths and tests in each Canadian province over time. There are markedly lower numbers reported on weekends or holidays.

[14] To deal with zero weekly values, which mostly occur in the smaller regions, as in CKS (2020), we replace log(0) with -1. We also check the robustness of our results by adding 1 to all ΔC_{it} observations before taking logs, by replacing log(0) with 0, and by using population weighted least squares; see Tables A5 and A8.

[15] There is no PHU-wide mask mandate in Lambton as of August 31, but its main city, Sarnia, enacted a mask mandate on July 31.

MS-DOH-21-1816-A-000329

Figure 1: Ontario - mask mandates over time



Notes: There are a total of 34 public health units (PHU) in Ontario. See Table C2 for the exact date of mask mandate implementation in each PHU.

In the province-level analysis, we assign numerical values to each of the 17 policy indicators listed in Table C1 in Appendix C. The values are on the interval [0,1], with 0 meaning no or lowest level of restrictions and 1 meaning maximal restrictions. A policy value between 0 and 1 indicates partial restrictions, either in terms of intensity (see more detail and the definitions in Table C1) or by geographical coverage (in large provinces). The numerical values are assigned at the daily level for each region (PHU or province, respectively for the Ontario and national results), while maintaining comparability across regions.

Many NPIs were implemented at the same time, both relative to each other and/or across regions (especially during the March closing-down period), which causes many of the policy indicators to be highly correlated with each other (see Appendix Table A4). To avoid multi-collinearity issues, we group the 17 policy indicators into 5 policy aggregates via simple averaging: (i) *travel*, which includes international and domestic travel restrictions and self-isolation rules; (ii) *school*, which is an indicator of provincial school closure; (iii) *business/gathering*, which comprises regulations and restrictions on non-essential businesses and retail, personal businesses, restaurants, bars and nightclubs, places of worship, events,

gyms and recreation, and limits on gathering; (iv) *long-term care (LTC)*, which includes NPIs governing the operation of long-term care homes (visitor rules and whether staff are required to work on a single site) and (v) *mask* which takes value 1 if an indoor mask mandate has been introduced, 0 if not, or value between 0 and 1 if only part of a province has enacted such policy.[16]

The five policy aggregates are constructed at the daily level and capture both the closing-down period (an increase in the numerical value from 0 toward 1) and the re-opening period (decrease in the numerical value toward zero). In comparison, the policy indicators compiled by Raifman (2020) for the USA used in CKS (2020) are binary "on (1)"/"off (0)" variables.[17] For consistency with the weekly outcome and information variables and the empirical model timing, we construct the policy aggregates P_{it}^{j} used in the regressions (where j denotes policy type) by taking a weekly moving average of the raw policy data, from date $t-6$ to date t.

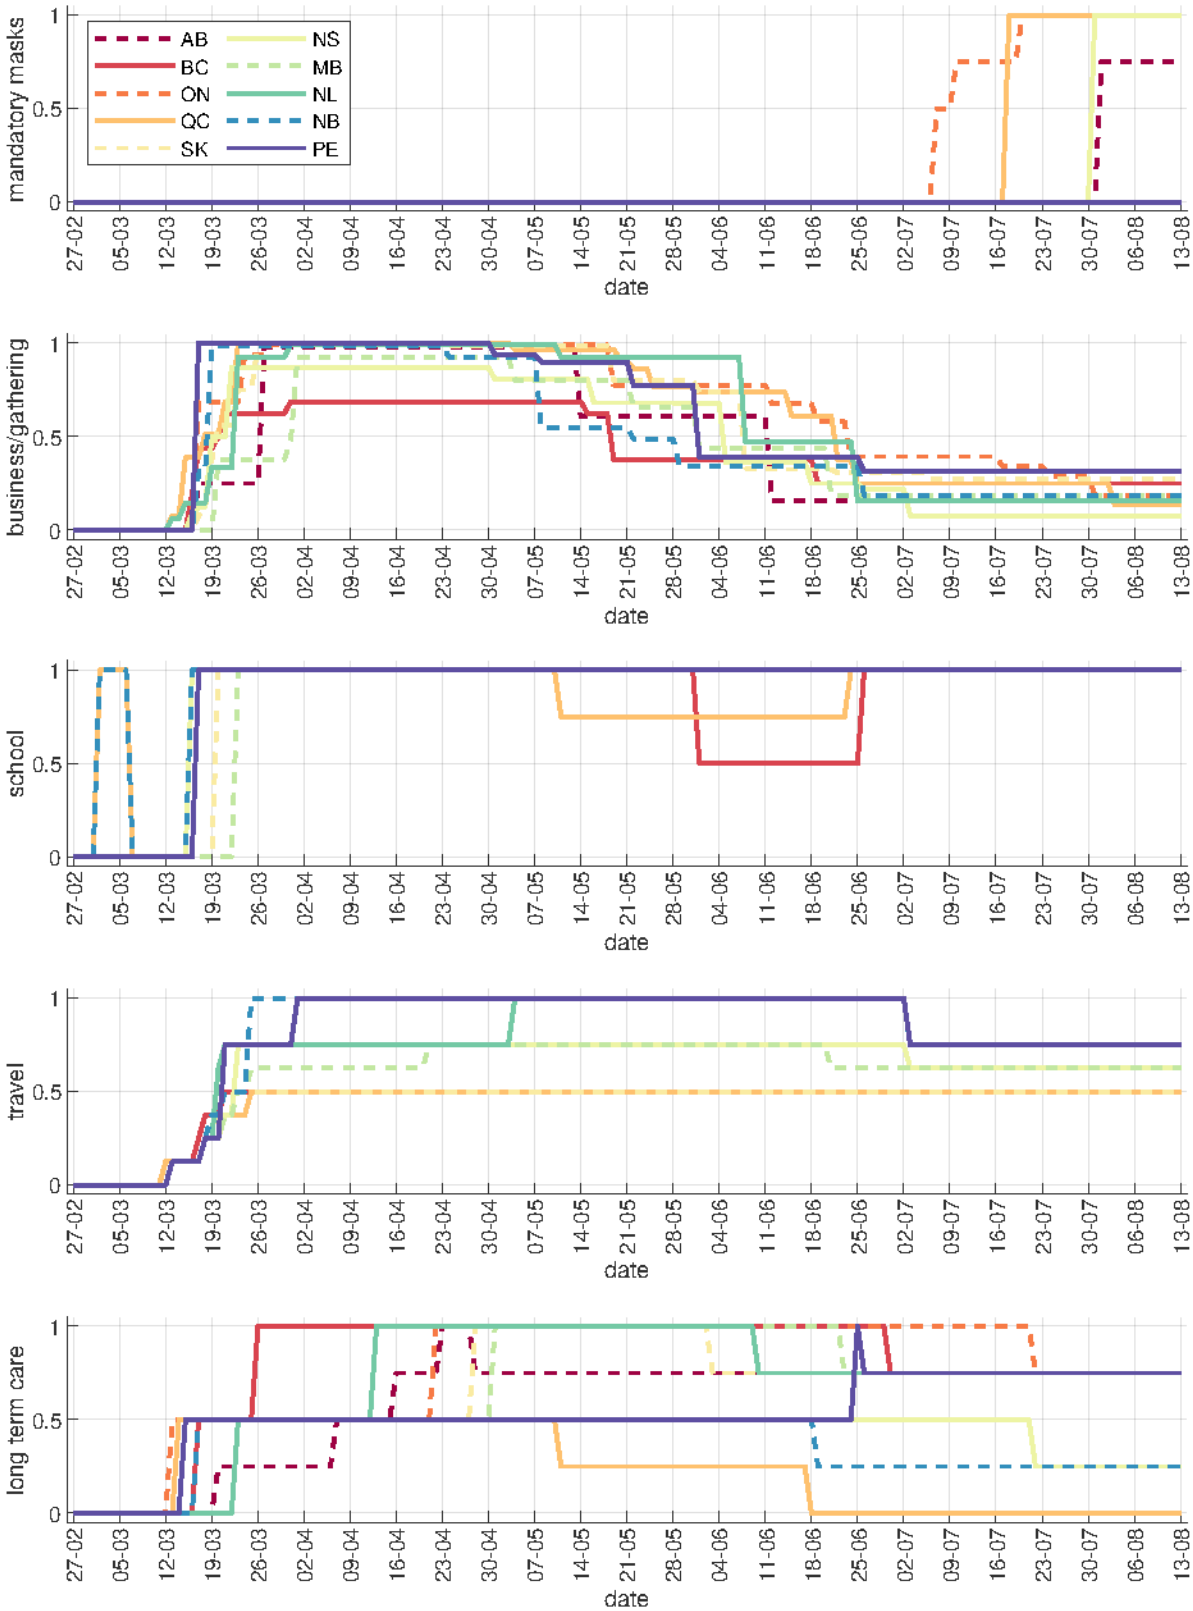
Figure 2 plots the values of the 5 policy aggregates over time for each of the 10 provinces. Travel restrictions, school closures (including Spring and Summer breaks) and business closures were implemented in a relatively short period in the middle of March. There is some variation in the travel policy aggregate since some Canadian provinces (the Atlantic provinces and Manitoba) implemented inter-provincial domestic travel or self-isolation restrictions in addition to the federal regulations regarding international travel. Restrictions on long-term care facilities were introduced more gradually. In the re-opening period (May-August), there is also more policy intensity variation across the provinces, especially in the business and gatherings category, as the different provinces implemented their own re-opening plans and strategies. Mask mandates were first introduced in Ontario starting from June in some smaller PHUs and early July in the most populous PHUs such as Toronto, Ottawa and Peel (see Appendix Table C2). In Quebec, indoor masks were mandated province-wide on July 18. Nova Scotia and Alberta's two main cities implemented mask mandates on July 31 and August 1, respectively.

[16] We do not use provincial declarations of emergency in our analysis as they are mostly legal tools enabling other restrictions rather than restrictions *per se*.

[17] The daily numerical values for each of the 17 basic policy indicators and the 5 policy aggregates for each province and date are available on the project's Github repository.

MS-DOH-21-1816-A-000331

Figure 2: Policy aggregates - Canada



Notes: The figure plots the numerical values of the 5 policy aggregates (Mask, Business /gathering, School, Travel and Long-term care, LTC) over time, for each of the 10 provinces. The mask policy values for ON reflect the gradual adoption of mandates and the respective PHUs population sizes.

MS-DOH-21-1816-A-000332

There are two empirical challenges specific to our Canadian context and data. The first challenge is the presence of small provinces and sub-regions with very few COVID-19 cases or deaths. In Section 4.3, we perform a number of robustness checks using different ways of handling the observations with very few cases (in particular zero cases). The second data limitation is that there are only 10 provinces in Canada and 34 public health units in Ontario, unlike the 51 U.S. jurisdictions in CKS (2020). To account for the resulting small number of clusters in the estimation, we compute and report wild bootstrap standard errors and p-values, as proposed by Cameron et al. (2008).[18] On the flip side, our data has the advantage of a longer time horizon (March to August) and non-binary, more detailed policy variables compared to Raifman et al. (2020).

Behaviour proxy. We follow CKS (2020) and other authors in interpreting the location change indices from the Google Community Mobility reports as proxies for changes in people's behaviour during the pandemic, keeping in mind that location is only one aspect of behaviour relevant to COVID-19. The general pattern in the data (see Figure B3) shows sharply reduced frequency of recorded geo-locations in shops, workplaces and transit early in the pandemic (March), with a subsequent gradual increase back toward the baseline (except for transit), and a flattening out in July and August.

Several of the six location indicators (retail, grocery and pharmacy, workplaces, transit, parks and residential) are highly correlated with each other (see Tables A1 and A2) and/or contain many missing observations for the smaller provinces. To address these data limitations and the possible impact of collinearity on the estimation results, we use as proxy for behavioral changes the simple average of the following three mobility indicators: "retail", "grocery and pharmacy" and "workplaces". To be consistent with the weekly outcome variables and to mitigate day-of-week behavioural variation, we construct the Behaviour proxy B_{it} by taking a weekly moving average of the $\frac{1}{3}$ (retail + grocery and pharmacy + workplaces) data, from date $t-6$ to date t.[19,20] As a result, our empirical analysis uses weekly totals (for cases, tests and deaths) or weekly moving averages (for policies and the behaviour proxy) of all variables recorded on daily basis.[21]

[18] Alternative methods for computing the standard errors are explored in Section 4.3.

[19] We drop the "transit", "parks", and "residential" location indicators because, respectively, 10.6%, 13.7%, and 2.8% of the observations are missing in the provincial data, and 20.7%, 52.1%, and 11.1% are missing in the Ontario data. The "transit" and "residential" variables are also highly correlated with the three indicators we include in our aggregate behaviour proxy B_{it}. Furthermore, the "parks" indicator does not have clear implication for COVID-19 outcomes.

[20] In the Ontario analysis, 1.4% of the B_{it} values are imputed via linear interpolation.

[21] In estimation equation (1), we take moving average from date $t-14$ to date $t-20$ for policies and behaviour when the outcome is weekly case growth, and from date $t-28$ to date $t-34$ if the outcome is

MS-DOH-21-1816-A-000333

Tables A3 and A4 display the correlation between our behaviour proxy B_{it} and the five NPI policy aggregates P_{it}^{j}. Importantly, the behaviour proxy and mask mandate variables are not highly correlated, suggesting that the effect of mask mandates on COVID-19 outcomes should be independent of location behaviour changes.

Information. We use the weekly cases and case growth variables defined above, ΔC_{it} and Y_{it}, to construct the information variables I_{it} in equation (1). Specifically, we use as information the lagged value of the weekly case growth rate Y_{it-l} $(= \Delta \log(\Delta C_{it-l})$ and the log of past weekly cases, $\log(\Delta C_{it-l})$. We also use the lagged provincial (Ontario analysis) or national (Canada analysis) case growth rate and log of weekly cases as additional information variables in some specifications. A two-week information lag $l = 14$ is used in the baseline results. In the supplementary regressions using the death growth rate as the outcome, we use information on past deaths and a four-week lag (see Section 4.5).

Control variables. In all regressions, we control for region fixed effects (PHU or province) and the weekly COVID-19 tests growth rate $\Delta \log(\Delta T_{it})$, where T_{it} denotes cumulative tests in region i until date t and ΔT_{it} is defined analogously to ΔC_{it} above. We include a time trend: our baseline uses a cubic polynomial in days, but we also report results with no time trend and with week fixed effects. Robustness checks also include news or weather variables as controls (see Section 4.3).

Time period. We use the period May 15 to August 13 for the analysis with Ontario PHU level data and the period March 11 to August 13 for the national analysis with provincial data. The end date reflects data availability at the time of empirical analysis and writing. The start date for the Ontario sample (May 15) is approximately two weeks after the last restrictive measures were implemented and four weeks before the first mask mandate was introduced in Ontario. Robustness checks with different initial dates (May 1, June 1 and June 15) are reported in Section 4.3, with our results remaining stable. The initial date for the national sample (March 11) was chosen as the first date on which each province reported at least one COVID-19 test (so that cases could be potentially reported). Again, alternative initial dates are explored in Section 4.3.

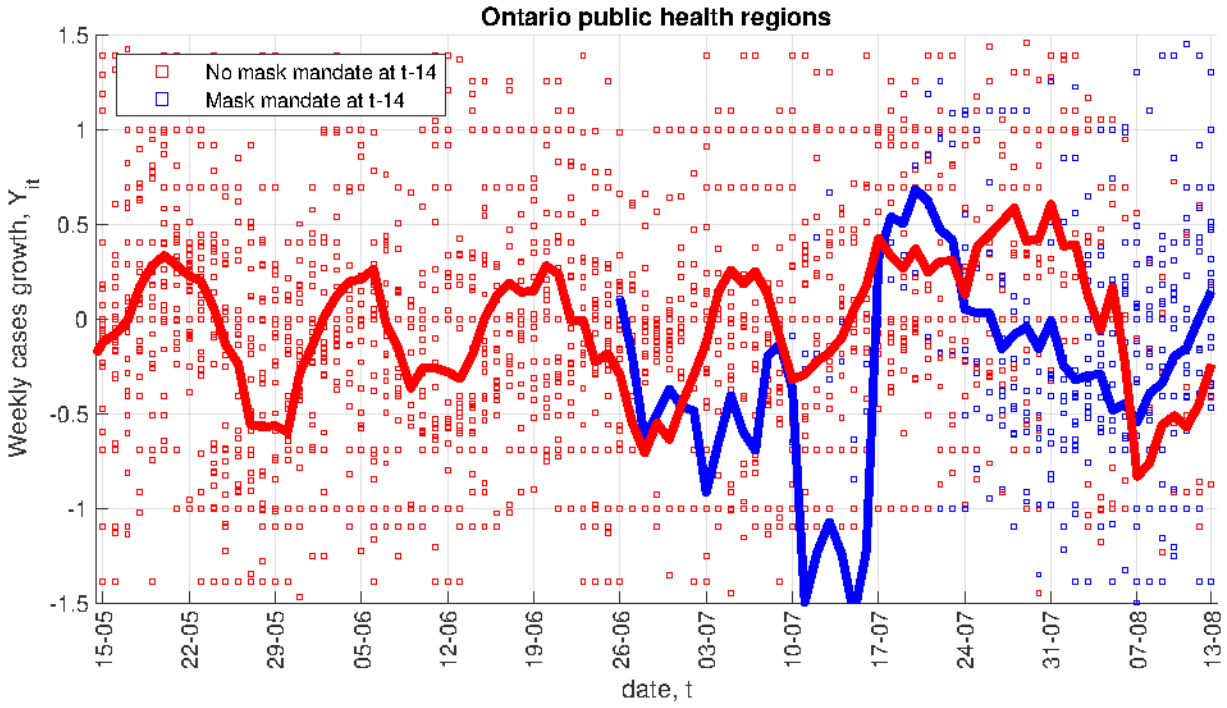
deaths growth. Alternative lags are explored in Section 4.3.

4 Results

4.1 Mask mandates in Ontario public health regions

We start with a simple graphical illustration of the effect of mask mandates on COVID-19 cases growth. Figure 3 displays the average log case growth, $Y_{it} = \Delta \log(\Delta C_{it})$ in Ontario PHUs with or without mask mandates. It shows that, on average, the PHUs with a mask mandate two weeks prior have lower case growth than the PHUs without a mask mandate two weeks prior.

Figure 3: Ontario - mask mandates and weekly case growth



Notes: The figure plots the average log weekly case growth $\Delta\log(\Delta C)$ in the PHUs with mask mandate (blue) vs. without (red) mask mandate 14 days prior.

Table 1 shows the estimates of equation (1), in which we control for other policies, behaviour and information, as explained in Section 3.1.[22] We report wild bootstrap p-values clustered at the PHU level to account for the small number of clusters.[23] The odd-numbered

[22]Mask mandates and regulations on business and gatherings vary at the PHU level. Long-term care policy changed only province-wide. The other policies (schooling and travel) do not vary during the sample period and hence are omitted from the regressions with Ontario PHU data.

[23]Table A6 in the Appendix reports alternative standard error specifications: regular clustering at the PHU level (Stata command "cluster"), wild bootstrap standard errors clustered at the PHU level, and wild

MS-DOH-21-1816-A-000335

columns in Table 1 use lagged cases and lagged cases growth at the PHU level as information; the even-numbered columns also include lagged cases and lagged case growth at the province level as additional information variables. In the tables, *Variable*_14 indicates a 14-day lag of *Variable*.

We present estimates of equation (1) from three specifications that handle possible time effects differently. Columns (1) and (2) in Table 1 are the most basic specifications, without including a time trend. The estimates in columns (1) and (2) suggest that, controlling for behavioural changes, mandatory indoor face masks reduce the growth rate of infections by 29–32 log points ($p < 0.05$), which is equivalent to a 25–28% reduction in weekly cases.[24]

In order to control for potential province-wide factors affecting the spread of COVID-19 such as income support policies or adaptation to the pandemic over time (so-called COVID fatigue), we also estimate (1) with a cubic time trend in days from the beginning of the sample, in columns (3) and (4) of Table 1, and with week fixed effects, in columns (5) and (6). Columns (3)-(6) show that our estimates of the mask mandate policy remain robust to the inclusion of a cubic time trend or week fixed effects. The results indicate that, depending on the specification, mask mandates are associated with a reduction of up to 38 log points in weekly case growth or, equivalently, a 31% reduction in weekly cases. The magnitude of the mask policy estimate is not very sensitive to whether lagged province-level data are included as additional information.

The results in Table 1 suggest that indoor mask mandates can be a powerful preventative measure in the COVID-19 context. Our estimates of the mask mandate impact across Ontario's PHUs are equivalent to a 25–31% reduction in weekly cases. This estimate is larger than the 9–10% reduction estimated by CKS (2020) for the U.S. One possible explanation is that Ontario's mask policy is more comprehensive: we evaluate the effect of *universal* indoor mask-wearing for the public rather than the effect of mask wearing for *employees only* in CKS (2020). Differences in the compliance rate may also contribute to this difference; we discuss this potential channel in Section 4.4.

The results in Table 1 also show a statistically significant negative association between information (log of past cases, log(ΔC)_14) and current weekly case growth ($p < 0.01$ in all specifications), indicating that a higher level of cases two weeks prior is correlated with lower current case growth. While B_{it} allows for behavioural responses to information, the negative estimate on log(ΔC)_14 in Table 1 suggests that our location-based proxy does not capture

bootstrap standard errors clustered by both PHU and date. Our results are robust to alternative ways of calculating standard errors.

[24] Using equation (3), a coefficient of x translates into a $1-\exp(x)$ reduction in weekly cases $\Delta C_{it}/\Delta C_{it-7}$.

Notes: The sample time period is May 15 to August 13, 2020. P-values from wild bootstrap (cgmwildboot) standard errors clustered by public health unit (PHU) with 5000 repetitions are reported in the square brackets. Mask_14, Business/gathering_14, Behaviour_14, $\Delta\log(\Delta C)$_14, and $\log(\Delta C)$_14 are measured at the PHU level, while Long-term care_14, $\Delta\log(\Delta PC)$_14, $\log(\Delta PC)$_14, and $\Delta\log(\Delta T)$ are measured at the province level. PC denotes provincial total cases. ***, ** and * denote 10%, 5% and 1% significance level respectively. Missing values (1.3% of all observations) for Behaviour proxy_14 are imputed via linear interpolation.

important aspects of behaviour, such as frequent hand-washing or physical distancing. In fact, our coefficient estimate on the behavioral proxy B_{it} is very close to zero (both in Table

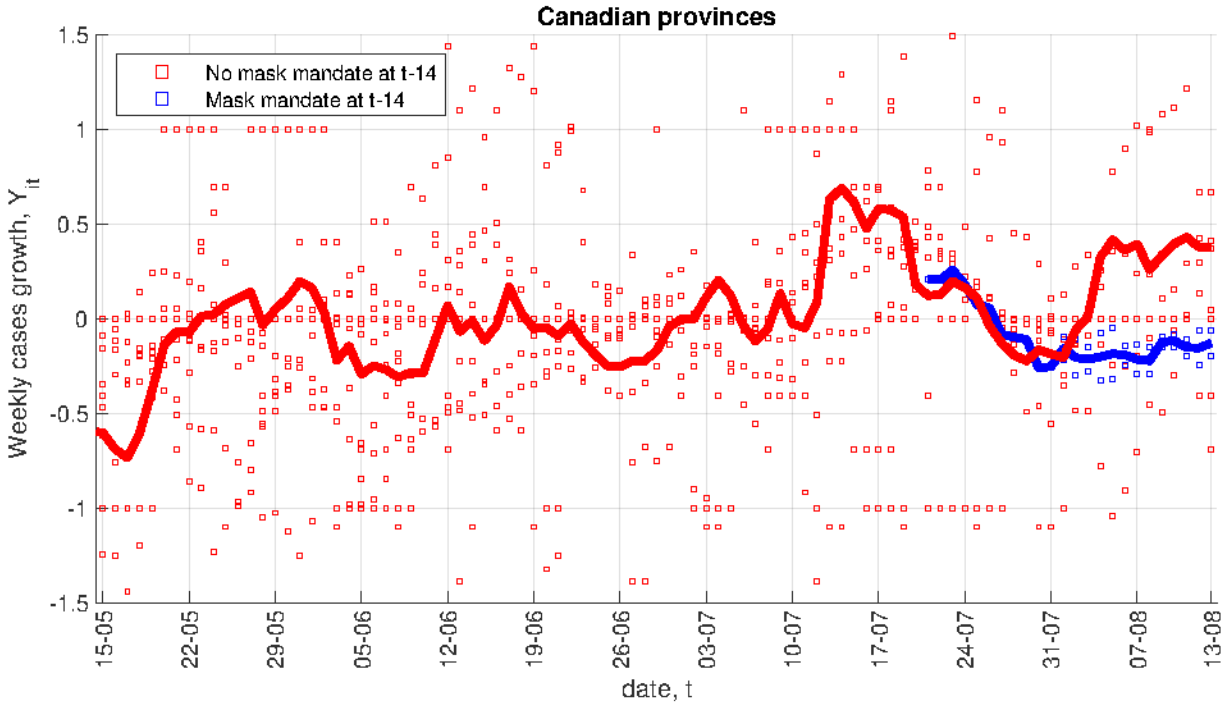
MS-DOH-21-1816-A-000337

1 and in Section 4.2's province-level results), unlike in CKS (2020).[25] In Appendix Table A18, we find strong contemporaneous correlations between the policy measures, log cases, and the Google mobility behavioral proxy from estimating equation (2). This suggests that the information (lagged cases) and the lagged policy variables included in equation (1) may absorb lagged behavioral responses proxied by B_{it-l} or other latent behavioral changes not captured by B_{it-l}.

4.2 Province-level results

We next evaluate the impact of NPIs on COVID-19 cases growth in Canada as a whole by exploiting variation in the timing of policies across the 10 provinces. Here, we examine NPIs for which there is no variation across Ontario's PHUs (i.e., schooling, travel, and LTC) in addition to mask mandates. Also, provincial data contain variation in the timing of policy changes in both the closing and re-opening phases, allowing us to study both the imposition and relaxation of restrictions.

Figure 4: Canada - mask mandates and weekly case growth



Notes: The figure plots the average weekly case growth $\Delta \log(\Delta C)$ in the provinces with mask mandate (blue) vs. without mask mandate (red) 14 days prior.

[25] We also tried including each location change measure separately and the results are similar (not shown).

As in the Ontario analysis, we begin with a graphical illustration of mask mandates and COVID-19 case growth across Canadian provinces, in the period March 11 to August 13, 2020. Figure 4 plots the average log weekly case growth in the provinces with vs. without mask mandates. While mask mandates are implemented relatively late in our sample period, average case growth in the provinces with a mask mandate (Ontario and Quebec) diverged from the average case growth in the provinces without a mandate begin roughly four weeks after the mandates are imposed.[26]

Table 2 displays the estimates of equation (1) for weekly case growth, along with wild bootstrap p-values, clustered at the province level (see Table A9 for other methods of computing the standard errors). The odd-numbered columns use lagged cases and lagged case growth at the provincial level as information while the even-numbered columns include in addition lagged cases and case growth at the national level as additional information variables.

As in the Ontario analysis, we present in Table 2 estimates from three specifications: no time trend (columns (1)-(2)), including cubic time trend in days (columns (3)-(4)) and including week fixed effects (columns (5)-(6)). The most robust result is the estimated effect of mask mandates: they are associated with a large reduction in weekly case growth of 45 to 62 log points, which is equivalent to a 36 to 46% reduction in weekly cases across the different specifications. The estimates are statistically significantly different from zero in all cases, with a p-value of less than 0.001 in columns (1)-(4). It is reassuring that these results regarding mask mandates are consistent with the Ontario analysis in the previous section.

Table 2 further shows that restrictions on businesses and gatherings are associated with a reduction in the weekly case growth of 65 to 85 log points or, vice versa, that relaxing business/gathering restrictions is associated with higher case growth. The estimate is equivalent to a 48 to 57% decrease in weekly cases in our sample period. The business/gathering estimates are, however, more noisy than our estimates for mask mandates and do not retain statistical significance in the specifications with week fixed effects ($p = 0.15$ and 0.14). Tables A8 and A15 further suggest that the results on business and gathering NPIs are driven by the smaller provinces and the re-opening period (May to August). Still, these results suggest that lowered restrictions and the associated increase in business/workplace activity or gatherings can be an important offsetting factor for the estimated effect of mask mandates on COVID-19 case growth, both in our sample and in the future.

We also find that school closures (the School_14 variable in Table 2) can be negatively

[26]Figure 4 assumes a July 7 mask mandate implementation date for Ontario (when its most populous PHU, Toronto, adopted a mask mandate, along with Ottawa), and July 18 for Quebec (province-wide mandate).

Notes: The time period is March 11 to August 13, 2020. P-values from wild bootstrap (cgmwildboot) standard errors clustered by province with 5000 repetitions are reported in the square brackets. ***, ** and * denote 10%, 5% and 1% significance level respectively. NC denotes national total cases.

associated with case growth. However, the estimates are statistically significant from zero only in the specifications with cubic time trend (columns (3) and (4)). As seen in Figure

MS-DOH-21-1816-A-000340

2, provincial school closures occurred in a very short time interval during March, so we may lack statistical power to separately identify its effect from other NPIs (especially the travel-related). Hence, we interpret this result with caution.

As in Table 1, the level of past cases, $\log(\Delta C)$, is negatively and statistically significantly associated with current weekly case growth in columns (1)-(4).

Since the specification with cubic time trend in Tables 1 and 2 allows for possible non-monotonic aggregate time trends in case growth in a parsimonious way, we choose it as our baseline specification with which to perform robustness checks in the next section. Robustness checks with the other specifications are available upon request.

4.3 Robustness

Policy collinearity

A possible concern about our data for the national analysis is that some NPIs (e.g. international travel restrictions or closing of schools) were implemented within a very short time interval.[27] Thus, we may lack enough regional variation to distinguish and identify the separate effect of each policy.[28] Collinearity could also affect the standard errors and the signs of the estimated coefficients.

To check robustness with respect to potential collinearity in the NPI policies, Tables A7 and A10 report estimates from our baseline specification, omitting one policy at a time, for Ontario and Canada respectively. First, it is reassuring that the mask mandate estimates are hardly affected by omitting any of the other policies. This is expected since mask mandates were imposed during a period where other NPIs changed little (see Figure 2). Similarly, the effects of business/gathering regulations and school closures in Table A10 are not sensitive to omitting other policies one at a time, which suggests that there is sufficient statistical power and variation to identify them in the national analysis.

Treatment of zero weekly cases

Another concern for our empirical strategy is that the usual formula for our dependent variable, $\Delta \log(\Delta C_{it})$, cannot be applied when the weekly case total ΔC_{it} is zero. We follow CKS (2020) and replace ln(0) with -1 in our baseline specifications in Tables 1 and 2. We now check the robustness of our estimates to alternative treatments of zero weekly cases.

For easier comparison, the first two columns in Table A5 repeat columns (3) and (4)

[27] For example, Table A4 shows a correlation of 0.61 between the Travel and School policy aggregates.

[28] Aggregating the 17 basic policy indicators into five groups mitigates this issue. Here, we test whether any remaining collinearity poses a problem.

MS-DOH-21-1816-A-000341

from Table 1 for Ontario.[29] Our main results on mask mandates across Ontario PHUs are robust to replacing log(0) with 0 and to adding 1 to all ΔC_{it} observations before taking logs, as shown in columns (3)-(6) of Table A5. Another way to mitigate the issue of PHUs with very few cases is to estimate a weighted least squares regression where PHUs are weighted by population. Columns (7) and (8) in Table A5 show that the resulting mask estimate has a slightly smaller magnitude and, due to the reduced effective sample size, weaker statistical significance.

Similarly, Table A8 shows that our province-level estimates, in particular for mask mandates, are also robust to the same manipulations as above.[30] In columns (9) and (10) of Table A8, we restrict the sample to only the largest 4 provinces (British Columbia, Ontario, Quebec and Alberta), which have only 0.3% (2 out of 624) zero observation cases. Again, the estimated mask effects are little changed.

Alternative dates

Figure B4 shows that our estimates and confidence intervals for the effect of mask mandates in the Ontario baseline regressions do not vary much by the initial date of the sample. Similarly, Figure B5 shows that, in the national analysis, our results about mask mandates and business/gathering restrictions are also robust to alternative sample start dates.

Alternative lags

We explore alternative time lags, either shorter or longer in duration, centered around the baseline value of 14 days. Figure B6 (with Ontario data) and Figure B7 (with province-level data) plot the estimates and confidence intervals from the baseline regressions and show that our mask effect estimates remain fairly consistent for different lags.

Omitted variables

Our behaviour proxy variable (Google geo-location trends) likely misses some aspects of behaviour relevant for COVID-19 transmission. One factor that may meaningfully impact behaviour is weather. For example, good weather could entice more people to spend time outside, lowering the chance of viral transmission. Columns (3) and (4) in Table A11 report national estimates with lagged weather variables (daily maximum and minimum temperatures and precipitation for the largest city in each province[31]) as additional regressors. Our NPI estimates, in particular mask mandates, are little changed from the baseline results in columns (1) and (2).

[29] 535 out of 3,094 observations (17%) had to be replaced.

[30] 230 out of 1,560 observations (15%) had to be replaced.

[31] Vancouver, BC; Calgary, AB; Saskatoon, SK; Winnipeg, MB; Toronto, ON; Montreal, QC; Moncton, NB; Halifax, NS; Charlottetown, PE; and St. John's, NL.

Another possible concern is that our information variables, lagged cases and lagged case growth, may not fully capture the information based on which people react or adjust their behaviour, possibly affecting the observed weekly case growth. Columns (5) and (6) in Table A11 add a national-level "news" variable to the baseline specification. The news variable is defined as the number of daily search results from a news aggregator website (*Proquest Canadian Newsstream*) for the terms "coronavirus" or "COVID-19" (see Appendix C for more details). In column (6), the lagged news variable approaches the 10% significance level ($p = 0.103$). Our estimates on masks and business/gathering remain very close to those in the baseline.

4.4 Self-reported mask usage

The effectiveness of any NPI or public policy crucially depends on whether it affects behaviour. In this section, we use self-reported data on mask usage to examine whether mask mandates indeed increase mask use in Canada ("first-stage" analysis).

We use data from the YouGov COVID-19 Public Monitor, which includes multiple waves of public opinion surveys fielded regularly since early April in many countries.[32] Here, we focus on inter-provincial comparison within Canada. Our variable of interest is based on responses to the question "Thinking about the last 7 days, how often have you worn a face mask outside your home (e.g. when on public transport, going to a supermarket, going to a main road)?" The answer choices are "Always", "Frequently", "Sometimes", "Rarely", and "Not at all". We create a binary variable taking value 1 if the response is "Always" and 0 otherwise, as well as another variable taking value of 1 if the respondent answered either "Always" or "Frequently" and 0 otherwise.

We begin with a simple illustration of self-reported mask usage in Canada from April to August 2020. Figure B2 plots the average self-reported mask usage (the response "Always") in the provinces with and without mask mandates.[33] The figure clearly shows that self-reported mask usage is higher, by up to 50 percentage points, in the provinces with a mask mandate than in the provinces without mask mandates. Since Figure B2 does not account for compositional changes in the data, we formally estimate equation (2), using self-reported mask usage as the behavioral outcome.[34]

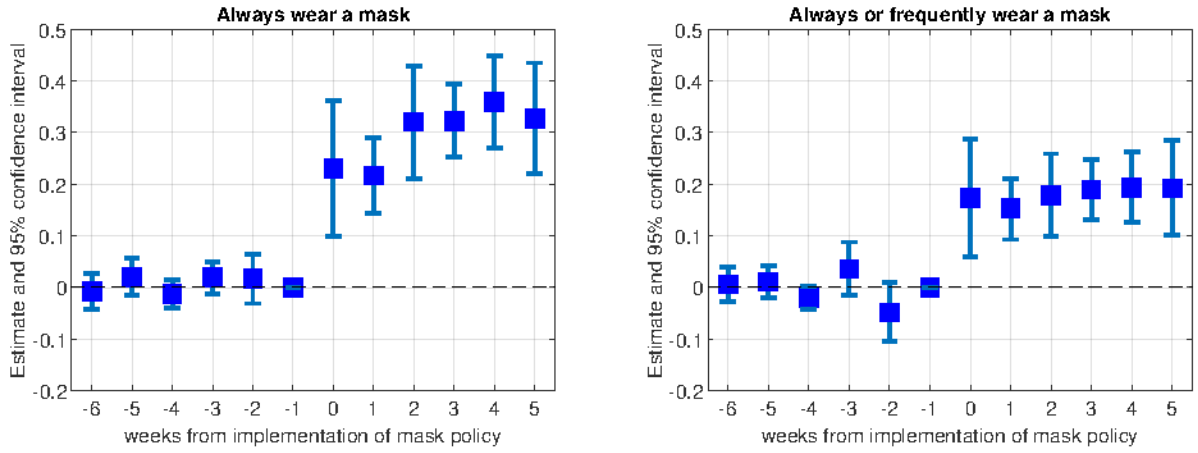
[32]The YouGov data can be accessed at: https://yougov.co.uk/covid-19.

[33]As on Figure 4, we use July 7 as the mask mandate implementation date in Ontario.

[34]Since mask usage is reported only for specific dates within each survey wave, we use our mask policy variable daily values for these same dates instead of the weekly moving average.

MS-DOH-21-1816-A-000343

Figure 5: Event Study of Self-reported Mask Usage – Canada



Notes: The data source is YouGov. The outcome is a binary variable taking value 1 if the respondent respectively answered "Always" (in the left panel) or "Always" or "Frequently" (in the right panel) to "Thinking about the last 7 days, how often have you worn a face mask outside your home?" The figure plots the estimates from a version of equation (2) where the mask policy variable is replaced by the interaction of the variables corresponding to being in the treatment group (imposed mask mandate) and a series of dummies for each week, ranging from 6 weeks before the mask mandate to 6 weeks after ($T = -6$ to $+5$, where $T = 0$ is the mandate implementation date). The reference point is 1 week before the implementation ($T = -1$). Wild bootstrap (cgmwildboot) standard errors clustered by province with 5000 repetitions are used to construct the confidence intervals. Sample weights are used.

Figure 5 shows a graphical event study analysis on mask mandates and changes in mask usage. The event study approach is appropriate for the mask usage outcome variable, since the policy impact is expected to be immediate, unlike the other outcomes we study, for which any impact is expected to occur with a lag and we use weekly totals or moving averages. We replace the mask policy variable in equation (2) by the interaction of variables corresponding to being in the treatment group (i.e. under a mask mandate), and a series of dummies for each week, ranging from 6 weeks before the mask mandate to 5 weeks after the mask mandate ($T = -6$ to $+5$, where $T = 0$ is the implementation date of the mask mandate). The reference point is one week before the implementation of the mask mandate ($T = -1$), and we use the same y-axis scale on both panels.

The left and right panels of Figure 5 present the results from the event study analysis for the "Always" and "Always" or "Frequently" mask usage answers, respectively. We make several observations. First, neither panel shows a pre-trend – the estimates are close to zero before the mask mandates. This addresses the potential concern that provinces that implemented mask mandates may have had a different trend in mask usage than provinces that did not. Second, the effect of mask mandates on mask usage is immediate: an increase

MS-DOH-21-1816-A-000344

of roughly 20 percentage points as soon as the mask policy is implemented at ($T = 0$). Third, the effect appears persistent rather than transitory, since mask usage after $T = 0$ does not revert to its level before $T = 0$.

cubic time trend (days)			X	X		
week fixed effects					X	X
† average mask usage rate without mask mandate = 0.298						

Notes: The time period is April 2 to August 13, 2020. P-values from wild bootstrap (cgmwildboot) standard errors clustered by province with 5000 repetitions are reported in the square brackets. NC denotes national total cases. The data source is YouGov. The outcome is a dummy which takes value 1 if the respondent answered "Always" to the survey question "Thinking about the last 7 days, how often have you worn a face mask outside your home?" Sample weights are used. Individual characteristics include a gender dummy, age dummy (in years), dummies for each household size, dummies for each number of children, and dummies for each employment status. ***, ** and * denote 10%, 5% and 1% significance level respectively.

Table 3 displays the estimates on self-reported mask usage (answer "Always") in equation (2) along with wild bootstrap p-values clustered at the province level. The odd-numbered columns use lagged cases and lagged case growth at the provincial level as information while the even-numbered columns include in addition lagged cases and case growth at the national level as additional information variables. As in Table 1 and Table 2, we present estimates

without time trend, including cubic time trend (in days), and including week fixed effects. Our preferred specification with cubic time trend, column (4) of Table 3, shows that mask mandates are associated with 31.5 percentage point increase in self-reported mask usage ($p < 0.001$), from a base of self-reported mask usage without mask mandate of 29.8%.[35,36]

These "first-stage" results show that mask mandates exhibit significant compliance in Canada and establish a basis for the significant impact of mask mandates on the spread of COVID-19 that we find. That said, given that mask mandates do not change everyone's behaviour, our estimates in Tables 1 and 2 represent intent-to-treat effects. The full effect of the entire population shifting from not wearing to wearing masks is likely significantly larger.[37]

There is a heated debate on whether community use of masks may create a false sense of security that reduces adherence to other preventive measures. We also investigate this question using YouGov survey data. As Tables A13 and A14 indicate, we find no evidence that mask mandates in Canada have had an offsetting effect on other preventive measures such as hand washing, using sanitizer, avoiding gatherings, and avoiding touching objects in public during the period we study. On the contrary, mask mandates may slightly increase social distancing in one out of the eight precaution categories (avoiding crowded areas) ($p < 0.10$).[38]

4.5 Counterfactuals

We evaluate several counterfactuals corresponding to replacing the actual mask policy in a province or Canada-wide with a counterfactual policy, including absence of mask mandate.

Letting t_0 be the implementation date of a counterfactual policy, we set the counterfactual weekly case count, ΔC_{it}^c, equal to ΔC_{it} for all $t < t_0$. For each date $t \geq t_0$, using the definition of Y_{it} from (3), we then compute the counterfactual weekly cases, ΔC_{it}^c and the counterfactual

[35]Similarly, in Table A12, column (4) shows that "Always" or "Frequent" mask usage increases by 21.5 percentage points. The finding that the increase in mask usage among the "Always" respondents is larger than among the "Always" or "Frequent" respondents is consistent with some people switching from wearing masks "frequently" to "always."

[36]Hatzius et al. (2020) document that state mask mandates in the US increased mask usage roughly by 25 percentage points in 30 days. The compliance with mask mandates may differ across countries or regions based on social norms, peer effects, political reasons or the consequences of noncompliance (e.g., fines).

[37]If we take the increase of about 30 percentage points in reported mask usage induced by mask mandates at face value, the full effect of mask wearing (treatment-on-the-treated effect) would be roughly triple our estimates. It could be larger still if there is desirability bias in answering the mask usage survey question, so that the actual increase in mask use may be smaller than our estimate.

[38]Consistent with this result, Seres et al. (2020) find that wearing masks increased physical distancing based on a randomized field experiment in stores in Germany.

MS-DOH-21-1816-A-000346

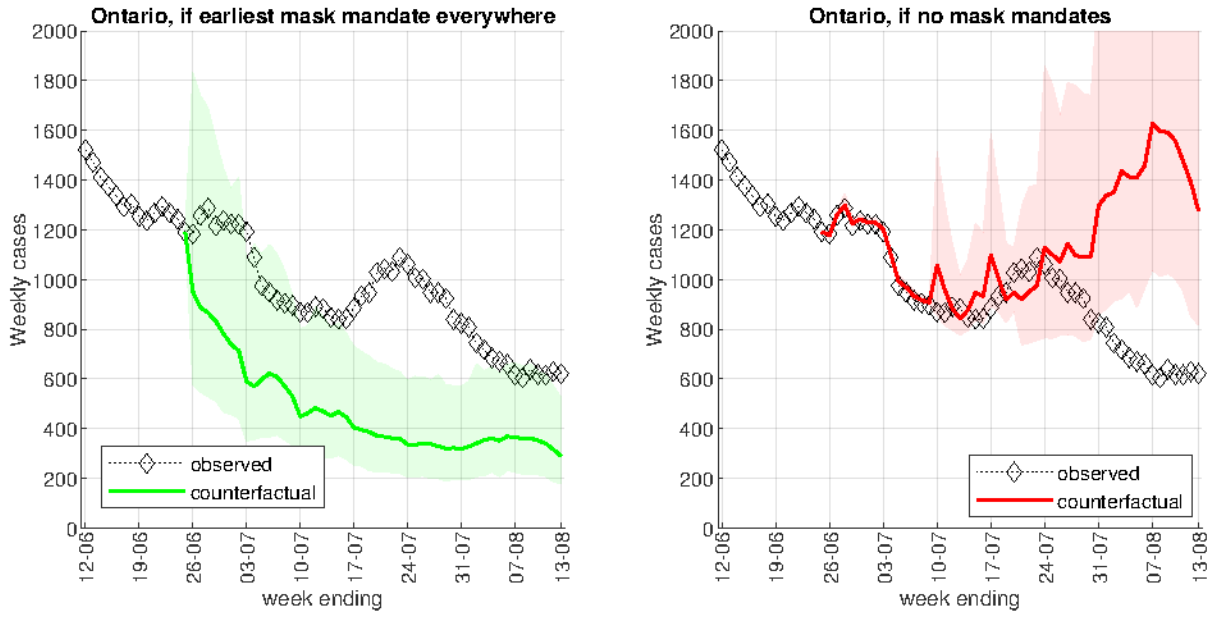
case growth rate, Y_{it}^c, as follows:

$$\Delta C_{it}^c = \exp(Y_{it}^c)\left(\Delta C_{it-7}^c\right) \text{ and}$$

$$Y_{it}^c = \hat{Y}_{it} + \beta_{Mask_14}\left(\text{Mask}^c_14 - \text{Mask}_14\right) + \beta_{log_dC_14}\left(\ln(\Delta C_{it-14}^c) - \ln(\Delta C_{it-14})\right),$$

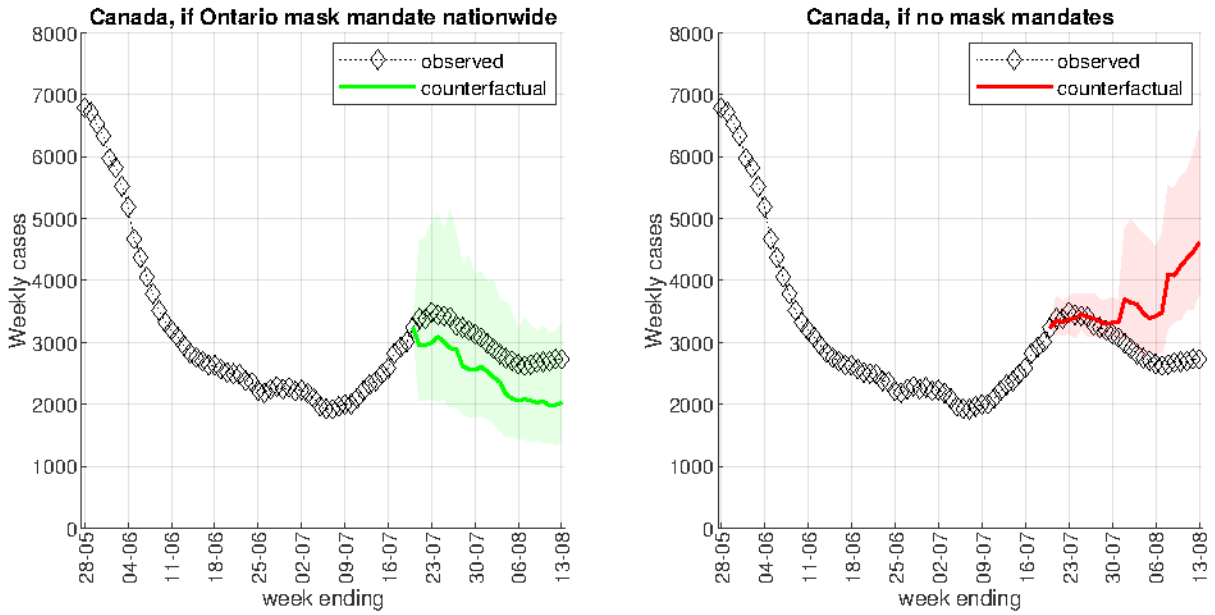
where $\hat{Y}_{it}$ is the regression-fitted value of weekly case growth; β_{Mask_14} is the coefficient estimate on the mask mandate variable Mask_14 in baseline specification (4) in Table 1 or 2, depending on the counterfactual; Mask^c_14 is the counterfactual mask policy (e.g. different implementation date, wider geographic coverage or absence of mask mandate); and $\beta_{log\Delta C_14}$ is the coefficient estimate (-0.227 or -0.209) on lagged cases log(ΔC)_14 in Table 1 or 2, column 4. The coefficient $\beta_{log\Delta C_14}$ adjusts the counterfactual case growth rate for the negative statistically significant association between the weekly case total two weeks prior and time-t case growth. This effect may be due to people being more careful when they perceive the risk of infection to be higher or less careful vice versa.

Figure 6: Counterfactuals - Ontario public health regions



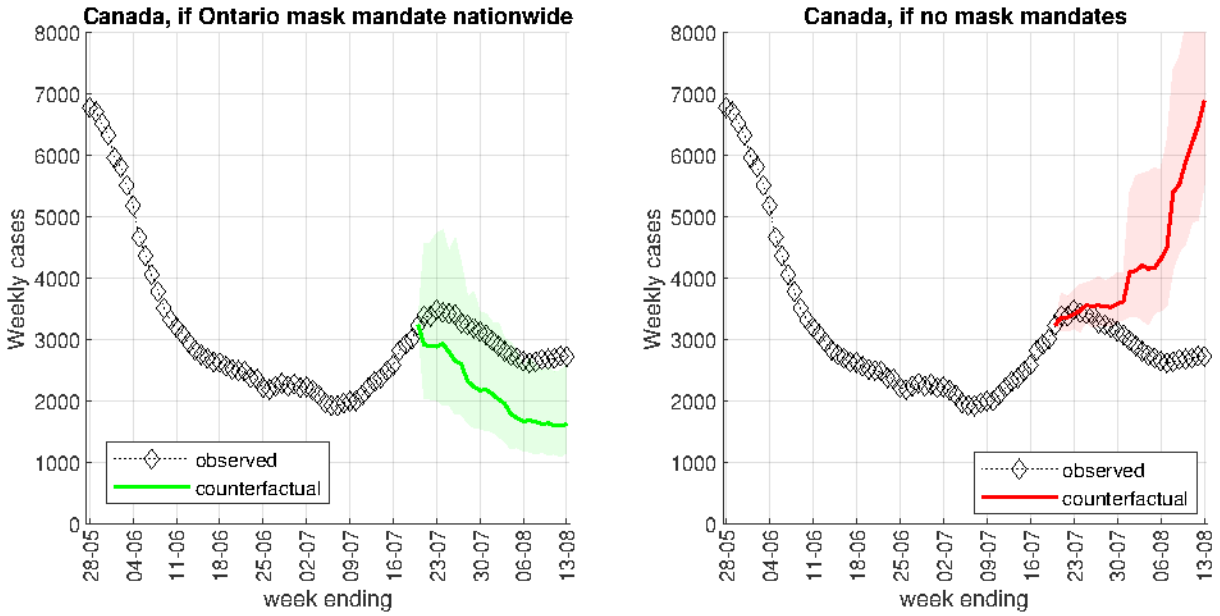
Notes: The left panel assumes that mask mandates were adopted in all PHUs on June 12 (date of the first mask mandate in ON). The right panel assumes that mask mandates were not adopted in any PHU. We use the mask estimate (-0.376) from column (4) of Table 1.

Figure 7: Counterfactuals – Canada (Table 1 mask estimate)



Notes: The left panel assumes that mask mandates were adopted in all provinces on July 7 (the adoption date in Toronto and Ottawa). The right panel assumes that mask mandates were not adopted in any province. We use the mask estimate (-0.376) from column (4) of Table 1.

Figure 8: Counterfactuals – Canada (Table 2 mask estimate)



Notes: The left panel assumes that mask mandates were adopted in all provinces on July 7 (the adoption date in Toronto and Ottawa). The right panel assumes that mask mandates were not adopted in any province. We use the mask estimate (-0.613) from column (4) of Table 2.

MS-DOH-21-1816-A-000348

Figures 6, 7 and 8 show results from two counterfactual policy evaluations. The first exercise, depicted in the left-hand side panel of the figures, assumes that masks are adopted everywhere at the earliest date observed in the data. Specifically, Figure 6 considers the counterfactual of all Ontario PHUs adopting mask mandates on June 12, while Figures 7 and 8 assume that all provinces adopt a mask mandate on July 7.[39]

Using our mask policy estimate from Table 1, Figure 6 shows that an earlier face mask mandate across Ontario PHUs could have lead to an average reduction of about 300 cases per week as of August 13, holding all else equal. For Canada as a whole, a nation-wide adoption of mask mandates in early July is predicted to reduce total cases per week in the country by 700 to 1,100 cases on average as of August 13, depending on whether we use the more conservative mask estimate (-0.376) from column (4) of Table 1 (see Figure 7) or the larger estimate (-0.613) from column (4) of Table 2 (see Figure 8). In all cases, the indirect feedback effect via $\beta_{log\Delta C_14}$ (lagged cases as information) starts moderating the decrease in cases two weeks after the start of the counterfactual mask policy.

In the right-hand side panel of Figures 6, 7 and 8, we perform the opposite exercise, namely assuming instead that mask mandates were *not* adopted in any Ontario PHU or any Canadian province. Our estimates imply that the counterfactual absence of mask mandates would have led to a large increase in new cases, both in Ontario and Canada-wide, especially when using the larger mask coefficient estimate from Table 2 (see Figure 8).

Finally, in Figure B11 in the Appendix, we also evaluate the counterfactual in which British Columbia and Alberta, the third and fourth largest Canadian provinces by population, adopt province-wide mask mandates on July 15. The results, using the Mask_14 estimate from Table 2, suggest a reduction of about 300 cases per week in each province by mid-August.

The counterfactual simulations assume that all other variables, behaviour and policies (except the mask policy and $t-14$ cases) remain fixed, as observed in the data. This is a strong assumption, but it may be plausible over the relatively short time period that we analyze. Moreover, the counterfactuals assume that regions without a mask mandate would react in the same way, on average, as the regions that imposed a mandate. Therefore, these results should be interpreted with caution and only offer a rough illustration and projection of the estimated effect of mask mandates on COVID-19 cases.

[39] June 12 is the date of the earliest mask mandate in Ontario. For the national analysis, July 7, the effective date for Toronto and Ottawa, is considered Ontario's first significant date of mask mandate enactment: PHUs with earlier mandates account for less than 10% of Ontario's population.

MS-DOH-21-1816-A-000349

4.6 Additional analysis

Closing and re-opening sub-periods

We investigate whether policy impact varied in different phases of the pandemic by splitting the full sample period into two sub-periods: "closing" (March 11 to May 14) and "re-opening" (May 15 to August 13). The dividing date of May 15 (referring to the NPIs in place around May 1) was chosen because very few policies were relaxed before May 1, and very few non-mask policies were tightened after May 1 in our sample period (see Figure 2).

In Table A15, we report estimates and wild bootstrap standard errors using our baseline specification with cubic time trend, separately for the closing and re-opening periods. We find that the imposition of school closures and travel restrictions early in the closing period is associated with a very large subsequent reduction in weekly case growth, as can be also seen on Figure B8 – the average observed log growth rate of cases $\Delta \log(\Delta \text{C})$ falls from 2.4 (ten-fold growth in weekly cases) to -0.4 (33% decrease in weekly cases) between March 15 and April 5. Long-term care restrictions are also associated with reduced case growth two weeks later during the March to May closing period. We interpret these results with caution, however, since many of these policy measures and restrictions were enacted in a brief time interval during March and there is not much inter-provincial variation (see Figure 2). No mask mandates were present in the closing period.

In the re-opening period, our results in Table A15 are in line with our full-sample results for mask mandates and business/gathering regulations (Table 2), with slightly larger coefficient estimates and less statistically significant p-values, possibly due to the smaller sample. Travel and school closures are not statistically significant in the re-opening period. This is unsurprising: relaxation of travel policies was minor and endogenous (only re-open to safe areas within Canada), and the schools that re-opened (in parts of Quebec and, on a part-time basis, in British Columbia) did so on voluntary attendance basis, yielding smaller class sizes.

Deaths

We also examine the weekly death growth as an outcome. We only have access to disaggregated deaths data at the province level (not at PHU levels in Ontario). We thus estimate regression equation (1) using $Y_{it} = \Delta \log(\Delta D_{it})$ for each province i as the dependent variable. In addition, we use a 28-day lag for the policy, behaviour proxy, and information variables to reflect the fact that deaths occur on average about two weeks after case detection; see Appendix D for details and references.[40]

[40] In Table 4, *Variable*_28 denotes the *Variable* lagged by 28 days.

Table 4 reports the estimates from the same specifications as those for case growth in Table 2. In all specifications, mask mandates are associated with a large reduction in the observed weekly deaths growth rate four weeks later (more than 90 log points, or equivalently more than 60% reduction in weekly deaths). These results are larger than our case growth results, but consistent with them given the substantial uncertainty. See also Figure B12, which plots the average weekly death growth in the provinces without a mask mandate four weeks prior vs. that for Ontario, the only province with mask mandate four weeks prior in our sample period.

The robustness checks in Table A16, however, show that, unlike for case growth, the mask mandate estimates in Table 4 are not robust to weighing by population or to restricting the sample to the largest 4 provinces. This suggests that the estimated effect is largely driven by observations from the small provinces, which have a disproportionately larger number of zero or small weekly death totals.[41] Furthermore, given the 28-day lag, there are only 9 days with observations (from Ontario only) for which the mask mandate variable takes value of 1. Due to these serious data limitations, the relation between mask mandates and COVID-19 deaths in Table 4 is suggestive at best, and we urge caution in interpreting or extrapolating from these results.

That said, our main findings about the growth in cases may have implications about future growth in deaths, particularly if the affected demographics become less skewed toward the young in later periods.

[41] 205 out of the 1,470 observations (14%) had log(0) replaced by -1.

5 Conclusion

The wearing of face masks by the general public has been a very contentious policy issue during the COVID-19 pandemic, with health authorities in many countries and the World Health Organization giving inconsistent or contradictory recommendations over time. "Conspiracy theories" and misinformation surrounding mask wear abound in social media, fuelled by some individuals' perception that mask mandates constitute significant restrictions on individual freedoms. Given the absence of large-scale randomized controlled trials or other direct evidence on mask effectiveness in preventing the spread of COVID-19, quantitative observational studies like ours are essential for informing both public policy and the public opinion.

We estimate the impact of mask mandates and other public policy measures on the spread of COVID-19 in Canada. We use both within-province and cross-province variation in the timing of mask mandates and find a robust and significantly negative association between mask mandates and subsequent COVID-19 case growth – 25 to 46% average reduction in weekly cases in the first several weeks after adoption, depending on the data sample and empirical specification used. These results are supported by our analysis of survey data on compliance with the mask mandates, which show that the mandates increase the proportion of reporting as always wearing a mask in public by around 30 percentage points. However, our sample period does not allow us to determine whether their effect lasts beyond the first few weeks after implementation. We conclude that mask mandates can be a powerful policy tool for at least temporarily reducing the spread of COVID-19.

Mask mandates were introduced in Canada during a period where other policy measures were relaxed, as part of the economy's re-opening. Specifically, we find that relaxed restrictions on businesses or gatherings are positively associated with subsequent COVID-19 case growth – a factor that could offset and obscure the health benefits of mask mandates. Past case totals were also found to matter for subsequent COVID-19 outcomes, suggesting that riskier behaviour based on favourable lagged information may limit how low mask mandates and other restrictions – short of a lockdown – can push the number of new cases.

We have deliberately abstained from studying the direct economic impacts of COVID-19, focusing instead on the unique features of the Canadian data for identifying the effect of NPIs, in particular mask mandates, on COVID-19 case growth. Future research combining epidemiological finding with the economic benefits and costs of various public policies or restrictions would enrich the ongoing policy debate and provide further guidance.

Notes: The time period is April 2 to August 13, 2020. P-values from wild bootstrap (cgmwildboot) standard errors clustered by province with 5000 repetitions are reported in the square brackets. NC denotes national total cases. The data source is YouGov. The outcome is a dummy which takes one for the respondent who answers "Always" or "Frequently" to the survey question "Thinking about the last 7 days, how often have you worn a face mask outside your home?" Sample weights are used. Individual characteristics include a gender dummy, dummies for each age (in years), dummies for each household size, dummies for each number of children, and dummies for each employment status. ***, ** and * denote 10%, 5% and 1% significance level respectively.

Notes: The time period is April 2 to August 13, 2020. P-values from wild bootstrap (cgmwildboot) standard errors clustered by province with 5000 repetitions are reported in the square brackets. NC denotes national total cases. The data source is YouGov. The outcome is a dummy which takes value 1 if the respondent answered "Always" to each survey question listed in Table C4. Sample weights are used. Individual characteristics include a gender dummy, age dummy (in years), dummies for each household size, dummies for each number of children, and dummies for each employment status. ***, ** and * denote 10%, 5% and 1% significance level respectively.

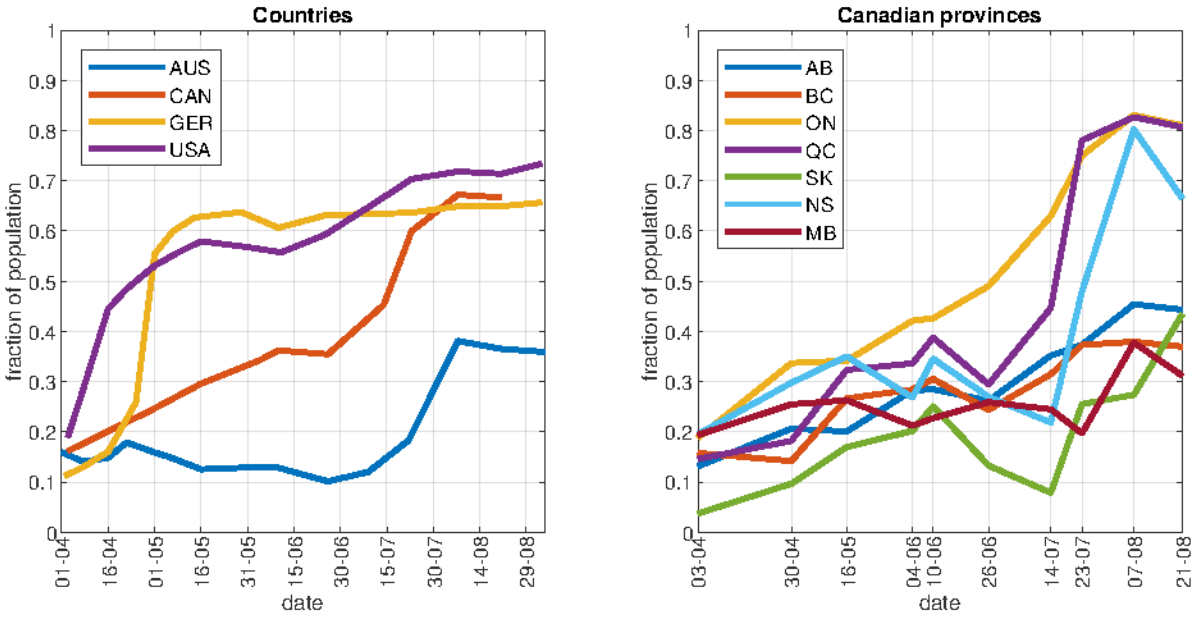
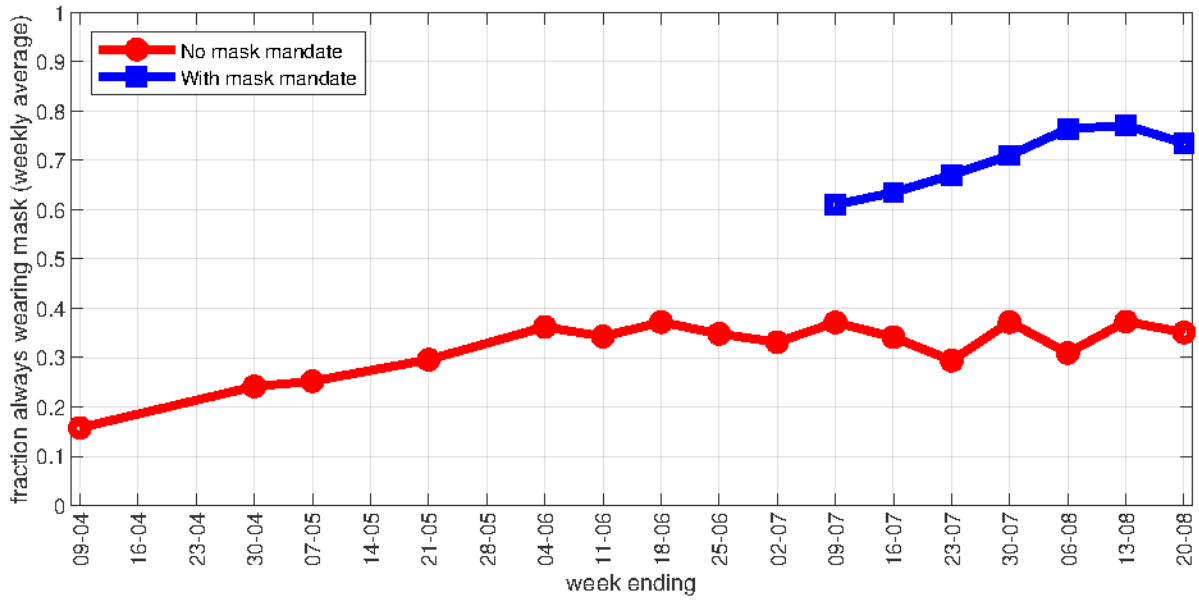
Appendix B. Additional Figures

Figure B1: Self-reported mask usage in selected countries and Canadian provinces



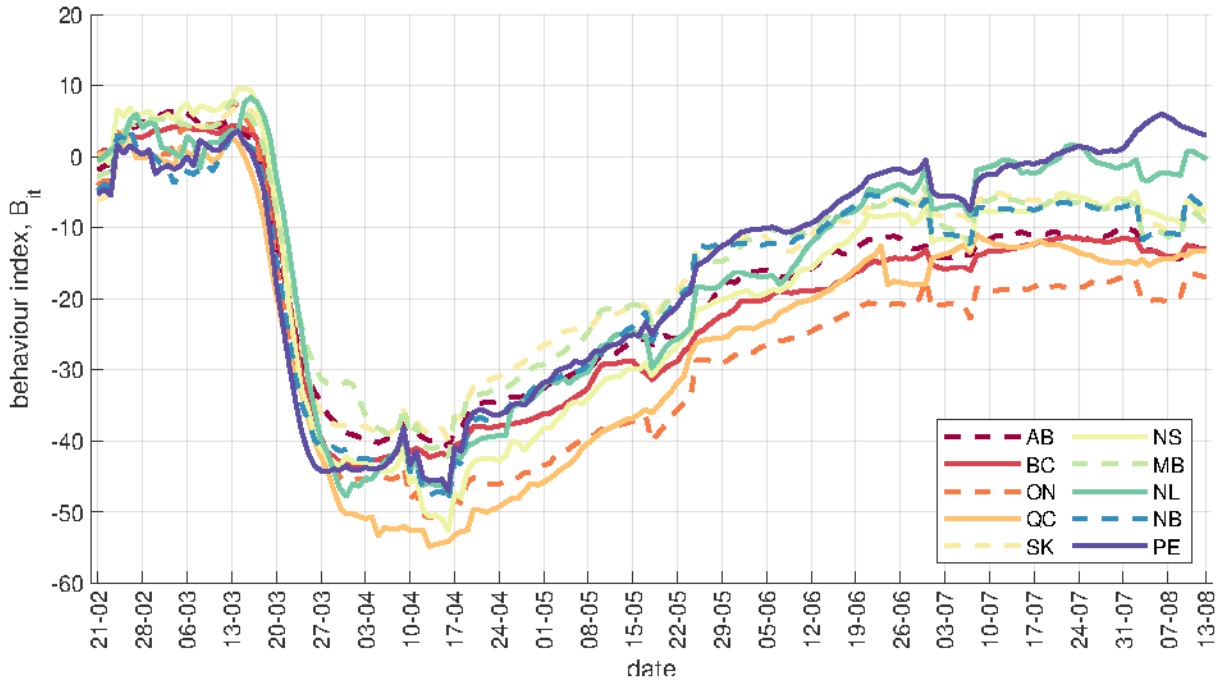
Notes: The data source is YouGov. The outcome equals 1 if the respondent answered "Always" to the question "Worn a face mask outside your home" and 0 otherwise. The sample weights are used to construct the country and provincial averages.

Figure B2: Canada - mask mandates and self-reported mask usage



Notes: The data source is YouGov. The figure plots the average self-reported mask usage by week (the fraction of respondents who answered "Always" to the survey question "Worn a face mask outside your home") in the provinces with vs. without mask mandates. Sample weights used to compute the averages.

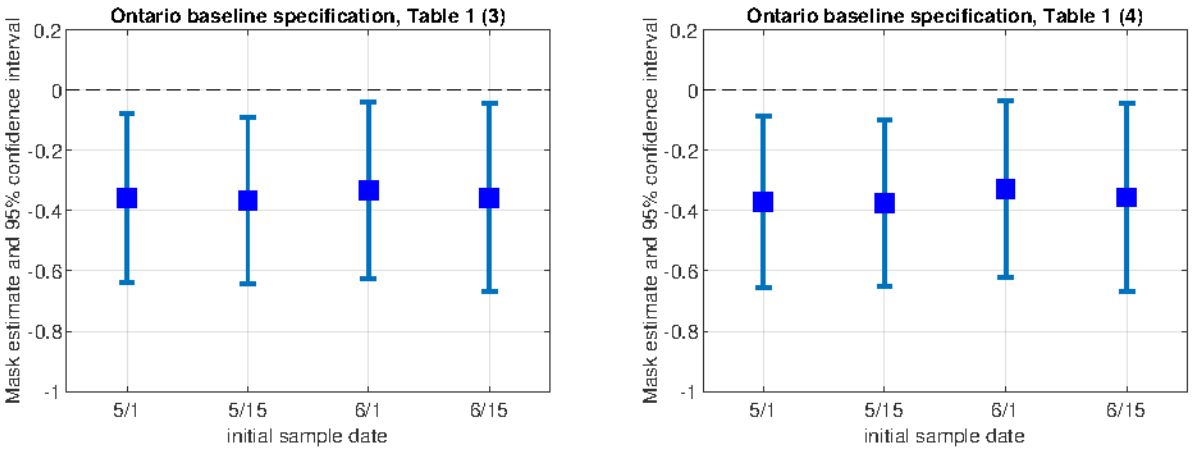
Figure B3: Canada - Behaviour proxy, B_{it}



Notes: The Behaviour proxy B_{it} is the average of the "retail", "grocery and pharmacy", and "workplaces" Google mobility indicators. Province-level 7-day moving averages are plotted.

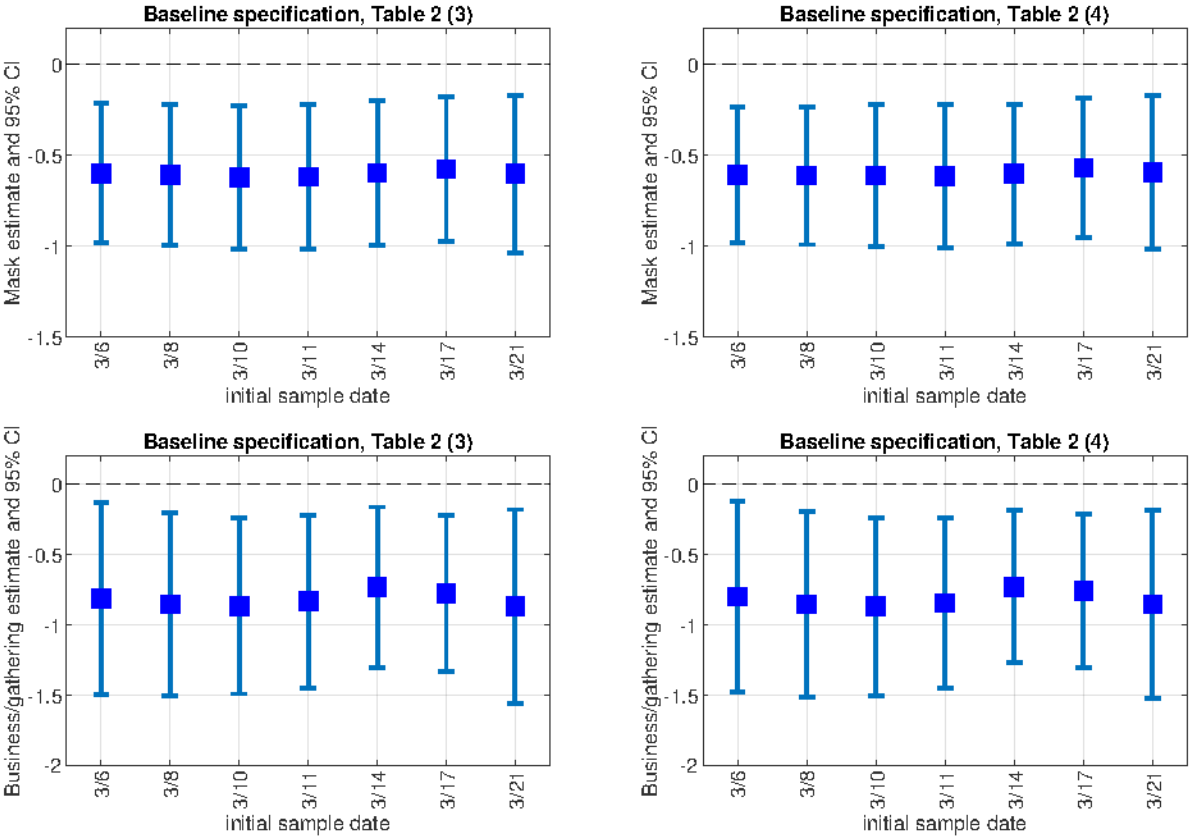
MS-DOH-21-1816-A-000376

Figure B4: Ontario - different initial dates



Notes: We plot the coefficient estimates on mask policy, with 95% confidence intervals, from equation (1), for different initial dates of the sample. The initial sample date in the baseline specifications reported in Table 1 is May 15. The left panel corresponds to baseline column (3) in Table 1, the right column corresponds to column (4) in Table 1.

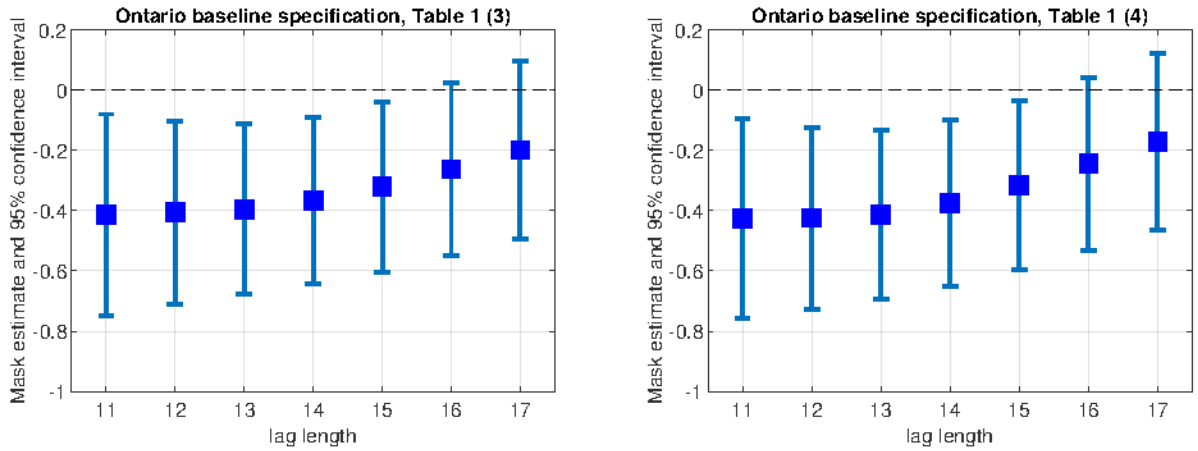
Figure B5: Canada - different initial dates



Notes: We plot the coefficient estimates on mask policy, with 95% confidence intervals, in the upper panel and the estimates on business/gathering policy in the lower panel, from equation (1) for different initial dates of the sample. The initial date in our baseline specification (Table 2) is March 11. The left panels correspond to column (3) in Table 2; the right panels correspond to column (4) in Table 2.

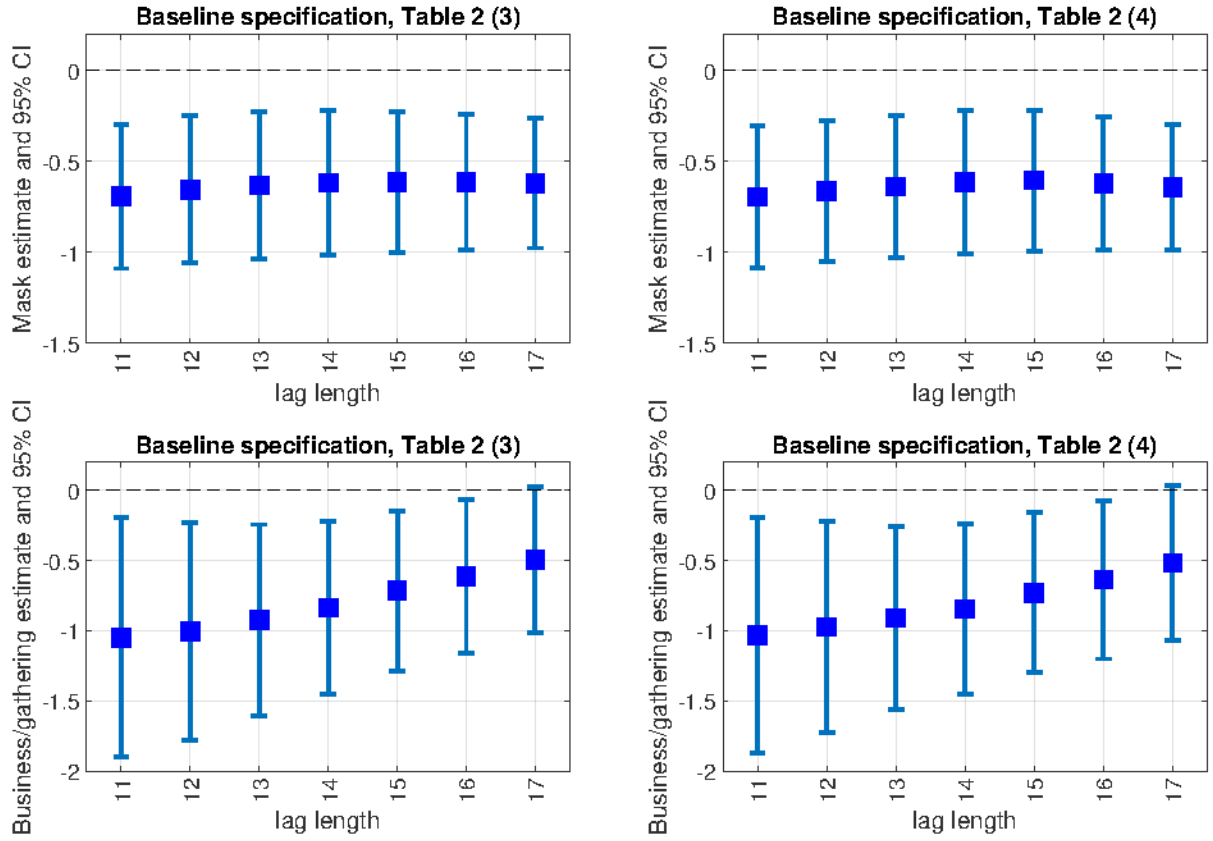
MS-DOH-21-1816-A-000377

Figure B6: Ontario - different lags



Notes: We plot the coefficient estimates on mask policy, with 95% confidence intervals, in equation (1) for different lag values. The lag used in the baseline specifications in Table 1 is 14 days. The left panel corresponds to column (3) in Table 1, the right column corresponds to column (4) in Table 1.

Figure B7: Canada - different lags



Notes: We plot the estimates on mask policy in the upper panel and the business/gathering policy in the lower panel, in equation (1) for different lag values. The lag in our baseline specification (Table 2) is 14 days. The left panels correspond to column (3) in Table 2; the right panels correspond to column (4) in Table 2.

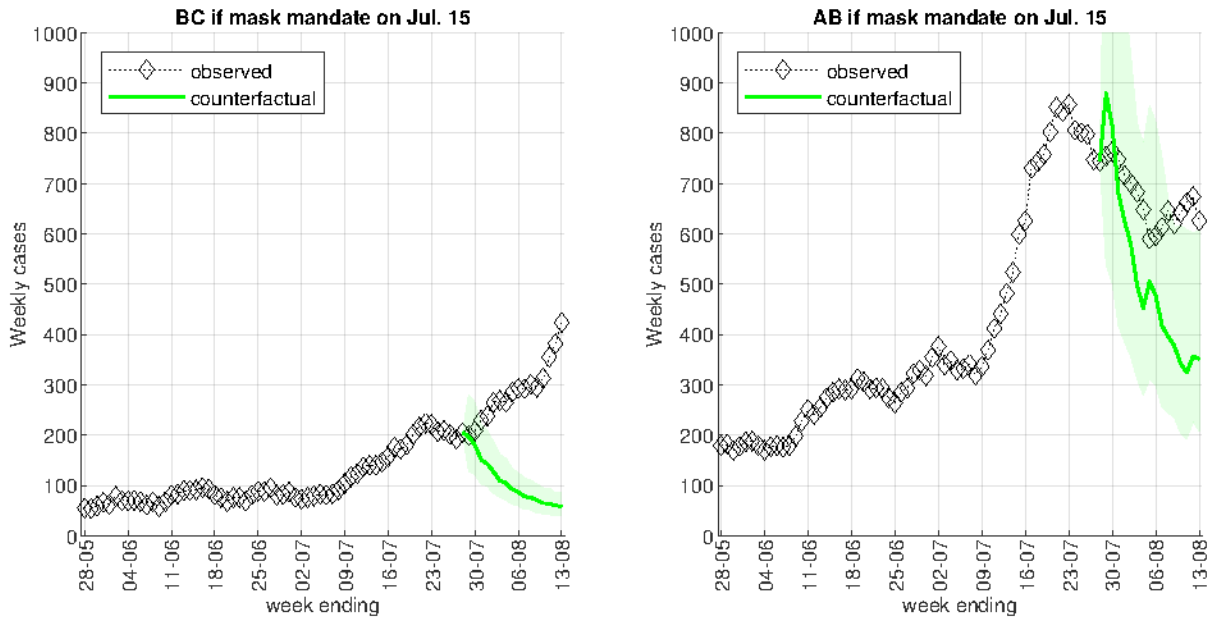
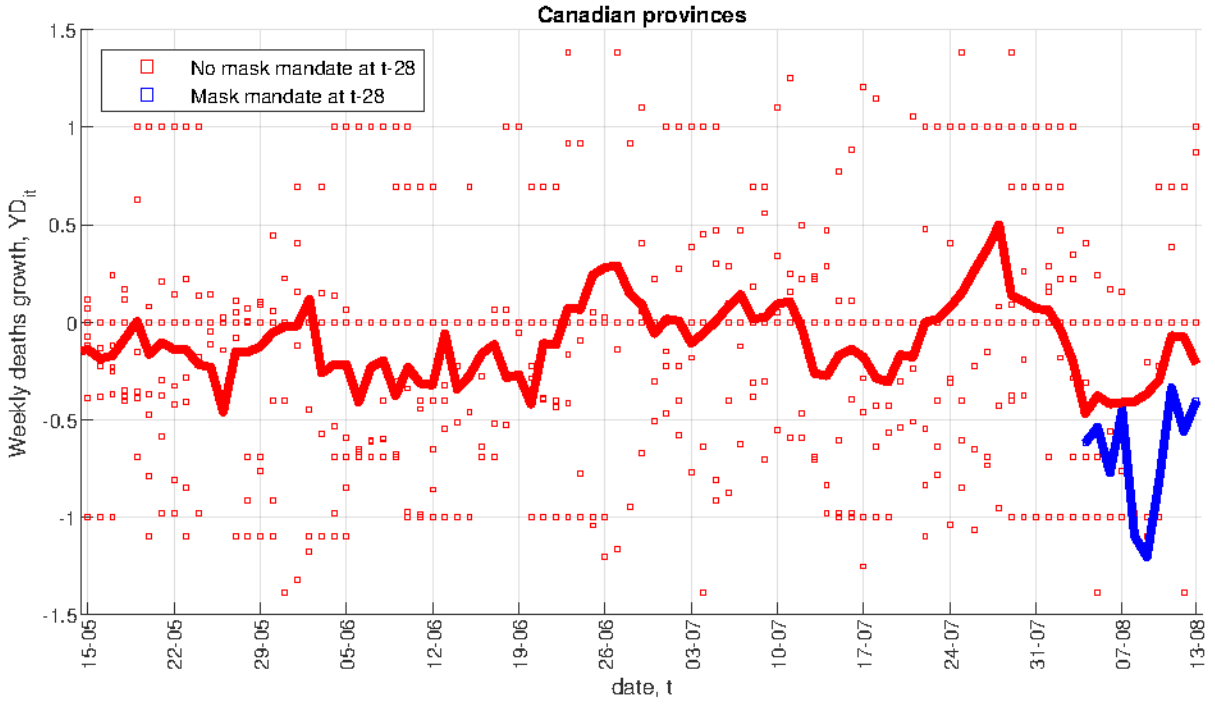
Figure B11: Counterfactuals – Mask mandates in Alberta and British Columbia



Notes: The figure assumes mask adoption on July 15 for two provinces that have not yet adopted mask mandates, specifically British Columbia (BC, left panel) and Alberta (AB, right panel). The counterfactual uses the mask mandate estimate -0.613 from Table 2, column (4).

Figure B12: Canada - mask mandates and weekly deaths growth



Notes: Average log weekly death growth in provinces with vs. without mask mandates 28 days prior.

Appendix C. Definitions and data sources

Table C1: Policy indicators and aggregates

Non-Essential Travel	
restrictions - international	1: travelers that are neither citizens nor residents 0.5: same as 1, but US citizens allowed
restrictions - inter-provincial	1: residents of all other provinces 0.5: residents of some other provinces
self-isolation - international	1: required (by provincial or federal government) 0.5: recommended (by provincial or federal government)
self-isolation - inter-provincial	1: required of residents of all other provinces 0.5: required of residents of some other provinces, or recommended
Primary and Secondary Schools	
schools closed	1: no classes (includes Spring and Summer breaks) 0.5: part-time classes; 0: classes in session
Business and Gathering Regulations	
non-essential and retail business personal services business restaurants bars and nightclubs places of worship events and gatherings recreation, gyms and parks	0: no or lowest restrictions; 1: strictest restrictions; values between 0 and 1: partial restrictions
indoor gatherings maximum	1: no gathering allowed; $x \in [0.5, 1]$: limit of $100(1-x)$ $x \in [0, 0.5]$: limit of $25/x$
Long-Term Care (LTC) Regulations	
visiting restrictions	1: no visits (with limited exceptions such as end of life) 0.5: number of visitors restricted
single-site work requirement[1]	1: requirement in effect 0.5: requirement with explicit later implementation deadline
Mandatory Masks	
indoor public places[2]	1: mask mandate in effect; 0: no mandate
provincial declaration of emergency	1: in effect; 0: not in effect

Notes: 1. We do not consider recommendations or requirements limited to outbreak facilities. 2. We do not consider limited mask mandates such as applying only to transit or personal service establishments.

Table C3: Canada COVID-19 official data sources

Province	Cases	Deaths	Tests
Alberta (AB)	link	link	link
British Columbia (BC)	link	link	link
Ontario (ON)	link	link	link
Quebec (QC)	link	link	link
Saskatchewan (SK)	link[1]	link	link
Nova Scotia (NS)	link	link	link
Manitoba (MB)	link	link	link[2]
Newfoundland and Labrador (NL)	link[1]	link	link
New Brunswick (NB)	link	link	link
Prince Edward Island (PE)	link	link	link

Notes: 1. Saskatchewan and Newfoundland and Labrador do not revise their posted data series. We made data adjustments based on subsequent revisions announced in government bulletins; 2. The Manitoba tests numbers were manually collected from the COVID-19 provincial government bulletins.

Weather – we downloaded historical weather data for the largest city in each province from the Weather Canada website. The data provide daily information on 11 variables: maximum temperature (C), minimum temperature (C), mean temperature (C), heating degree-days, cooling degree-days, total rain (mm), total snow (cm), total precipitation (mm), snow on the ground (cm), direction of maximum wind gust (tens of degrees), and speed of maximum wind gust (km/h). We only use the temperature and precipitation data in Table A11 as possible factors determining outside vs. inside activity.

News – we collected data from *Proquest Canadian Newsstream*, a subscription service to all major and small-market daily or weekly Canadian news sources. We recorded the number of search results for each day from Feb 1, 2020 to Aug 20, 2020 by searching the database for the keywords "Coronavirus" or "COVID-19". We only counted the results with source listed as "newspaper" since other sources, such as blogs or podcasts, tend to duplicate the same original content.

MS-DOH-21-1816-A-000385

Table C4: YouGov Survey Questions

Survey item	Question
i12_health_2	Washed hands with soap and water
i12_health_3	Used hand sanitiser
i12_health_6	Avoided going out in general
i12_health_12	Avoided small social gatherings (not more than 2 people)
i12_health_13	Avoided medium-sized social gatherings (between 3 and 10 people)
i12_health_14	Avoided large-sized social gatherings (more than 10 people)
i12_health_15	Avoided crowded areas
i12_health_20	Avoided touching objects in public (e.g. elevator buttons or doors)

Notes: the data source is YouGov. Possible responses to each survey item are "Always", "Frequently", "Sometimes", "Rarely", and "Not at all". For Table A13, we create a binary variable taking value 1 if the response is "Always" and 0 otherwise. For Table A14, we create a binary variable taking value of 1 if the respondent answered either "Always" or "Frequently" and 0 otherwise.

All data used in the paper are available at https://github.com/C19-SFU-Econ/data.

Appendix D. Lags Determination

As discussed in Section 3.1, we assume a lag of 14 days between a change in policy or behaviour and its hypothesized effect on weekly case growth, and a lag of 28 days between such a change and its effect on weekly death growth.

First, we consider the lag between infection and a case being reported. As most identified cases of COVID-19 in Canada are symptomatic, we focus on symptomatic individuals. For most provinces cases are listed according to the date of report to public health. In provinces where the dates instead refer to the public announcement, we shifted them back by one day, as announcements typically contain the cases reported to public health on the previous day. The relevant lag therefore has two components:

1. Incubation period: Most studies suggest an average incubation period of 5-6 days (e.g. 5.2 days in Li et al. (2020), 5.5 days in Lauer et al. (2020), 5.6 days in Linton et al. (2020), 6.4 days in Backer et al. (2020)).

2. Time between symptoms onset and reporting of the case to public health: the Ontario data contain an estimate of the symptom onset date ("episode date") for each case. For our sample period the average difference between the date of report and the episode date is 4.8 days (median: 4 days) including only values from 1 to 14 days, and 6.3

MS-DOH-21-1816-A-000386

days (median: 5 days) including only values from 2 to 28 days. We assume that the lags in Ontario and in other provinces are similar, and use a value of 5-6 days between symptom onset and report to public health authorities.

Adding these together implies that the typical lag between infection and a positive case being reported to public health is around 11 days.

Second, we consider the effect of weekly averaging on the appropriate lag for our analysis. Suppose a policy or behavioural change starts on date t, impacting the daily growth in infections between dates $t-1$ and t and in each subsequent day. Then, assuming a lag of 11 days between infection and case reporting, case counts C are affected from date $t+11$ onward. Our outcome variable $\Delta \log(\Delta \mathrm{C})$ thus would react to the original policy or behavioral change on date $t+11$. The change is complete on $t+23$, when the week from $t+17$ to $t+23$ is compared to the week from $t+10$ to $t+16$. The midpoint of the change is $t+17$.

Choosing a lag of l days implies that the policy/behaviour variable phases in from $t+l$ to $t+l+6$. To match the midpoint of this phase-in to the midpoint of the change in the outcome variable, we set $l=14$. The chosen lag matches the lag used by other authors who study COVID-19 policy interventions, e.g., CKS (2020). We explore sensitivity to alternative lags in Section 4.3.

With respect to deaths, our data are, in most cases, backdated (revised by the authorities ex-post) to the actual date of death. The medical literature suggests that the mean time from symptom onset to death is around 19 days (20 days in Wu et al. (2020), 17.8 days in Verity et al. (2020), 20.2 days when accounting for right truncation in Linton et al. (2020), 16.1 days in Sanche et al. (2020), etc.), that is, two weeks longer than our estimate of the time from symptom onset to reporting of a positive test result. We correspondingly set the lag used in our analysis of the death growth rate (Section 4.5) to 28 days.

Community Use Of Face Masks And COVID-19: Evidence From A Natural Experiment Of State Mandates In The US

DOI: 10.1377/hlthaff.2020.00818
HEALTH AFFAIRS 39,
NO. 8 (2020): 1419–1425

Foundation, Inc.

ABSTRACT **State policies mandating public or community use of face masks or covers in mitigating the spread of coronavirus disease 2019 (COVID-19) are hotly contested. This study provides evidence from a natural experiment on the effects of state government mandates for face mask use in public issued by fifteen states plus Washington, D.C., between April 8 and May 15, 2020. The research design is an event study examining changes in the daily county-level COVID-19 growth rates between March 31 and May 22, 2020. Mandating face mask use in public is associated with a decline in the daily COVID-19 growth rate by 0.9, 1.1, 1.4, 1.7, and 2.0 percentage points in 1–5, 6–10, 11–15, 16–20, and 21 or more days after state face mask orders were signed, respectively. Estimates suggest that as a result of the implementation of these mandates, more than 200,000 COVID-19 cases were averted by May 22, 2020. The findings suggest that requiring face mask use in public could help in mitigating the spread of COVID-19.**

Wei Lyu is a research associate in the Department of Health Management and Policy, College of Public Health, University of Iowa, in Iowa City, Iowa.

George L. Wehby (george-wehby@uiowa.edu) is a professor in the Department of Health Management and Policy, College of Public Health, at the University of Iowa, and a research associate at the National Bureau of Economic Research.

One of the most contentious issues being debated worldwide in the response to the coronavirus disease 2019 (COVID-19) pandemic is the value of wearing masks or face coverings in public settings.[1] A key factor fueling the debate is the limited direct evidence thus far on how much widespread community use would affect COVID-19 spread. However, there is now substantial evidence of asymptomatic transmission of COVID-19.[2,3] For example, a recent study of antibodies in a sample of customers in grocery stores in New York State reported an infection rate of 14.0 percent by March 29 (projected to represent more than 2.1 million cases), which substantially exceeds the number of confirmed COVID-19 cases.[4] Moreover, all public health authorities call on symptomatic people to wear masks to reduce transmission risk. Even organizations that at the time of our study had not yet recommended widespread community use of face masks for COVID-19 mitigation (that is, everyone without symptoms should use a face mask outside of their home), such as the World Health Organization, strongly recommend that symptomatic individuals wear them.[5] Because mask wearing by infected people can reduce transmission risk, and because of the high proportion of asymptomatic infected individuals and transmissions, there appears to be a strong case for the effectiveness of widespread use of face masks in reducing the spread of COVID-19. However, there is no direct evidence thus far on the magnitude of such effects, especially at a population level.

Researchers have been reviewing evidence from previous randomized controlled trials for other respiratory illnesses, examining mask use and types among people at higher risk of contracting infections (such as health care workers or people in infected households). Systematic reviews and meta-analyses of such studies have provided suggestive, although generally weak, evidence.[6] The estimates from the meta-analyses

based on randomized controlled trials suggest declines in transmission risk for influenza or influenza-like illnesses to mask wearers, although estimates are mostly statistically insignificant possibly because of small sample sizes or design limitations, especially those related to assessing compliance.[7–9] There is also a relationship between increased adherence to mask use, specifically, and effectiveness of reducing transmission to mask wearers: In one randomized study of influenza transmission in infected households in Australia, transmission risk for mask wearers was lower with greater adherence.[10] Further, the evidence is mixed from randomized studies on types of masks and risk for influenza-like illness transmission to mask wearers; for example, a recent systematic review and meta-analysis comparing N-95 respirators versus surgical masks found a statistically insignificant decline in influenza risk with N-95 respirators.[11]

Positions on widespread face mask use have differed worldwide but are changing over time. In the US, public health authorities did not recommend widespread face mask use in public at the start of the pandemic. The initially limited evidence on asymptomatic transmission and concern about mask shortages for the health care workforce and people caring for patients contributed to that initial decision. On April 3, 2020, the Centers for Disease Control and Prevention (CDC) issued new guidance advising everyone to wear cloth face covers in public areas where close contact with others is unavoidable, citing new evidence on virus transmission from asymptomatic or presymptomatic people.[12] Guidelines differ between countries, and some, including Germany, France, Italy, Spain, China, and South Korea, have mandated the use of face masks in public.[13–16]

This study adds complementary evidence to the literature on the impacts of widespread community use of face masks on COVID-19 spread from a natural experiment based on whether or not US states had mandated the use of face masks in public for COVID-19 mitigation as of May 2020. Fifteen states plus Washington, D.C., issued mandates for face mask use in public between April 8 and May 15.

We identified the effects of state mandates for the use of face masks in public on the daily COVID-19 growth rate, using an event study that examined the effects over different periods. We considered the impact of mandates for mask use targeted only to employees in some work settings, as opposed to communitywide mandates. This evidence is critical, as states and countries worldwide begin to shift to "reopening" their economies and as foot traffic increases. Mandating the public use of masks has become a socially and politically contentious issue, with multiple protests and even acts of violence directed against masked employees and those asking customers to wear face masks.[17] Face cover recommendations and mandates are part of the current set of measures, following earlier social distancing measures such as school and nonessential business closures, bans on large gatherings, and shelter-in-place orders being considered by states and local governments, especially as regions of the country reopen. For example, during Virginia's phase one reopening, begun May 22, 2020, everyone in the state was required to wear a face mask in public where people congregate.[18] Even though more states have issued such orders since the study was completed, it is critical to provide direct evidence on this question not only for public health authorities and governments but also for educating the public.

Study Data And Methods

DATA We collected information on statewide face cover mandate orders from public data sets on such policies and from searching and reviewing all state orders issued between April 1 and May 21, 2020. Our study focused on state executive orders or directives signed by governors that mandate use. Recommendations or guidelines from state departments of public health were not included, as these largely follow the CDC guidelines and might not necessarily add further information or impact. See online appendix A for a more detailed description of the data sources and measuring of the mandates.[19]

States differ in whether or not they require their citizens to wear face masks (covers) to limit COVID-19 spread. Between April 8 and May 15, governors of fifteen states and the mayor of Washington, D.C., signed orders mandating all individuals who can medically tolerate the wearing of a face mask do so in public settings (for example, public transportation, grocery stores, pharmacies, or other retail stores) where maintaining six feet of "social distance" might not always be practicable. These sixteen jurisdictions also have specific mandates requiring employees in certain professions to wear masks at all times while working.

In addition to these sixteen jurisdictions, twenty additional states have employee-only mandates (but no community mandate) requiring that some employees (for example, close-contact service providers such as in barber shops and nail salons) wear a face mask at all times while providing services. The face mask defined in these orders primarily refers to cloth face coverings or nonmedical masks. The state orders

MS-DOH-21-1816-A-000389

strongly discourage the use of any medical or surgical masks and N-95 respirators, which should be reserved for health care workers and first responders. The orders also clearly specify that the face masks are not a replacement for any other social distancing protocols. More information on dates and links to these state orders are in appendix exhibit A1 and appendices D and E.[19] Fifteen states had not yet issued community or employee mandates when we performed the study.

The main model used publicly available daily county-level data of confirmed COVID-19 cases from March 25 through May 21.[20] The data covered all states plus Washington, D.C., and the analytical sample included 2,930 unique counties plus New York City (five boroughs combined). See appendix A for a more detailed description of COVID-19 data.[19]

STATISTICAL ANALYSIS We employed an event study, which is generally similar to a difference-in-differences design, to examine whether statewide mandates to wear face masks in public affect the spread of COVID-19 based on the state variations noted earlier. This design allowed us to estimate the effects in the context of a natural experiment, comparing the pre-post mandate changes in COVID-19 spread in the states with mandates versus changes in COVID-19 spread in the states that did not pass these mandates, over time. The model also tested whether states issuing these mandates had differential pre-event trends in COVID-19 rates before they were issued. This is a critical assumption of the validity of an event study that must be upheld under testing. In addition, the model allowed us to control for a wide range of time-invariant differences between states and counties, such as population density and socioeconomic and demographic factors, plus time-variant differences between states and counties, such as other mitigation and social distancing policies, in addition to state-level COVID-19 testing rates.

We estimated the effects of face cover mandates on the daily county-level COVID-19 growth rate, which is the difference in the natural log of cumulative COVID-19 cases on a given day minus the natural log of cumulative cases in the prior day, multiplied by 100.[21] This measure gives the daily growth rate in percentage points.

The reference period for estimating the face cover mandate effects was 1–5 days before signing the order. We examined how effects change over five post-event periods: 1–5, 6–10, 11–15, 16–20, and 21 or more days. The model also tested for pre-event trends over the course of 6–10, 11–15, and 16 or more days before signing the mandate. For all counties in the analytical sample, the main model included daily data from March 31 (seven days before the first state signed a face cover mandate) through May 22. The models were estimated by least squares weighted by the county's 2019 population with heteroscedasticity-robust and state-clustered standard errors.

As noted earlier, all of the fifteen states plus Washington, D.C., that mandated face cover use in public also mandated employee mask use. To assess the effects of employee face cover mandates, we employed another event study model that focused solely on the employee face cover mandate as the policy intervention. In this analysis, we excluded the sixteen jurisdictions that enacted both public and employee face cover mandates and focused on the twenty states that enacted an employee-only mandate and the fifteen states with neither a public nor an employee mandate.

LIMITATIONS We were unable to measure face cover use in the community (that is, compliance with the mandate). As such, the estimates represent the intent-to-treat effects of these mandates—that is, their effects as passed and not the individual-level effect of wearing a face mask in public on one's own COVID-19 risk. Related, we did not measure enforcement of the mandates, which might affect compliance. We also did not have data on county-level mandates for wearing face masks in public. In some states without state-level mandates at the time of our study, such as California,[22] Texas,[23] and Colorado,[24] multiple counties had enacted such mandates. These county-level mandates did not bias the intent-to-treat estimates of effects of state-level mandates as actually passed, but they added local-level heterogeneity not directly accounted for in the model. We did examine the robustness of estimates to the exclusion of some of these states. Finally, we were able to examine only confirmed COVID-19 cases. However, there is evidence of a higher infection rate in the community than is reflected in the number of confirmed cases.[25]

Study Results

EFFECTS OF MANDATES FOR FACE COVERING IN PUBLIC Exhibit 1 plots the event study estimates of effects of state mandates for community face covering in public on the county-level daily growth rate of COVID-19 cases, with 95 percent confidence intervals, obtained from the main regression model (in appendix B),[19] using county-level daily data from March 31 through May22; appendix exhibit C1 (column 1) reports the exact estimates. The effects are shown over the course of five periods after signing the orders, relative to the five days before signing (which is the reference period). Also shown

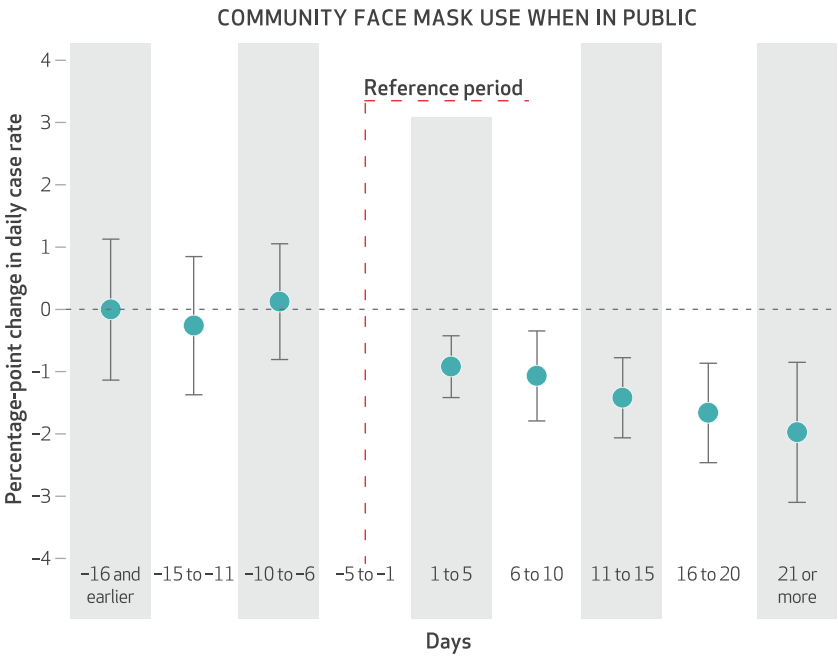
EXHIBIT 1

Event study estimates of the effects of states mandating community face mask use in public on the daily county-level growth rate of COVID-19 cases, 2020



SOURCE Authors' analysis of US county-level COVID-19 case data between March 31 and May 22, 2020. **NOTES** Event study estimates (dots) and 95% confidence intervals (bars) of the effects of states mandating community use of face covers or masks when people are in public on the county-level daily growth rate of COVID-19 cases over different periods before and after the mandate order was signed. The reference period was the first five days before the mandate order was signed. The model controlled for major COVID-19 mitigation policies as time-varying (closure of K–12 schools, county-level or statewide shelter-in-place orders, nonessential business closure, closure of restaurants for dining in, closure of gyms or movie theaters), COVID-19 tests per 100,000 people, county fixed effects, and day fixed effects. The model was estimated by least squares weighted by the county 2019 population, and the standard errors were robust to heteroscedasticity and clustered at the state level.

are estimated differences in daily COVID-19 growth rates between states with and without the mandates over the course of three periods before the reference period.

There was a significant decline in daily COVID-19 growth rate after the mandating of face covers in public, with the effect increasing over time after the orders were signed. Specifically, the daily case rate declined by 0.9, 1.1, 1.4, 1.7, and 2.0 percentage points within 1–5, 6–10, 11–15, 16–20, and 21 or more days after signing, respectively. All of these declines were statistically significant ($p < 0.05$ or less). In contrast, the pre-event trends in COVID-19 case growth rates were small and statistically insignificant.

We also projected the number of averted COVID-19 cases with the mandates for face mask use in public by comparing actual cumulative daily cases with daily cases predicted by the model if none of the states had enacted the public face cover mandate at the time they did (see details in appendix B).[19] The main model estimates suggested that because of these mandates, 230,000–450,000 cases may have been averted by May 22. Estimates of averted cases should be viewed cautiously and only as general approximations.

ROBUSTNESS CHECKS We estimated multiple extensions of the main event study model to assess the robustness of estimates to different model specifications and sample choices. These checks started the event study on March 26; added flexible controls for social distancing measures, state reopening measures, employee face mask use mandates, and county-specific time trends; and allowed time trends to vary by sociodemographic indicators. Other checks used the mandate effective date instead of the signing date, used hyperbolic sine transformation to account for zero cases, included states as the unit instead of counties, included only urban counties, and excluded some states without state-level mandates but with multiple counties having local mandates. The detailed description and results of these robustness checks are in appendix C.[19] The results were robust across these checks; effects were smaller when we used the effective dates instead of the signing dates, which differ by about two to three days, on average, suggesting earlier compliance, and when we used states as the unit of analysis. But the estimates remained meaningful and statistically significant in all checks.

EFFECTS OF EMPLOYEE-ONLY FACE COVER MANDATES As noted earlier, we also directly assessed the effects of states mandating only that certain employees wear face masks. Twenty states issued employee use mandates but not community use mandates. We reestimated the event study model described earlier for an employee-only mandate including those twenty states (issued between April 17 and May 9) and the fifteen states without mandates, and excluding the sixteen jurisdictions that issued both public and employee use mandates. Exhibit 2 plots the event study estimates of changes in county-level daily COVID-19 growth rates with the employee-only face cover mandates and their 95 percent confidence intervals. All pre- and postmandate estimates were small and insignificant. Overall, these results indicate no evidence of declines in daily COVID-19 growth rates with employee-only mandates.

Discussion

Around the world, governments have been fighting COVID-19 spread through a mix of policies and mitigation measures such as school and nonessential business closures and shelter-in-place orders. Some countries have also recommended or mandated widespread community use of face

Downloaded from HealthAffairs.org on September 15, 2020.

masks as a mitigation measure. However, the effectiveness of this measure is highly debated. The debate and uncertainty are fueled by the limited direct empirical evidence available on the magnitude of the effects of widespread face mask use in public on COVID-19 mitigation. There is a critical need for empirical evidence on the magnitude of these effects from natural experiments.[8] This evidence is especially relevant as governments reopen their economies and loosen social distancing restrictions while new infections continue to occur and while there is no vaccine or widely accessible or effective treatments in sight.

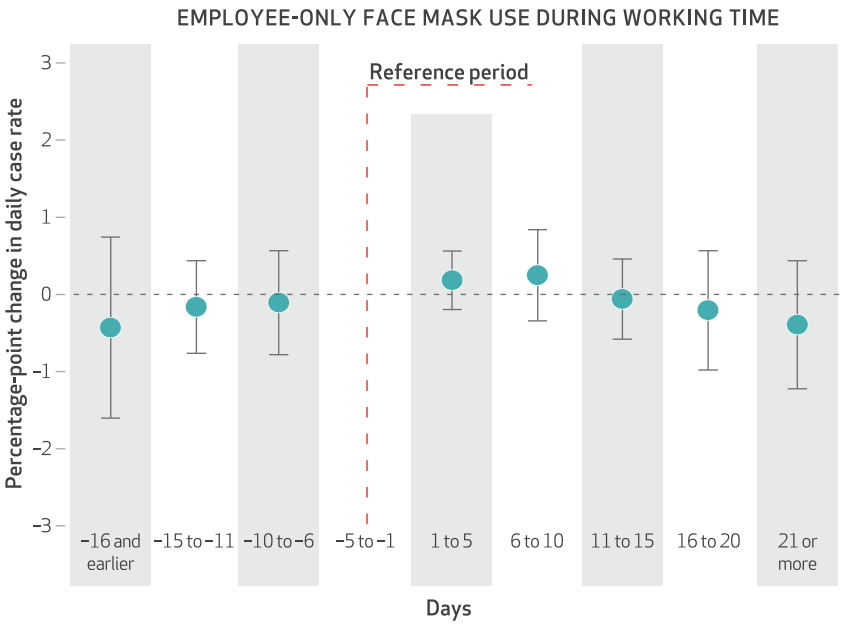
The study provides direct evidence on the effectiveness of widespread community use of face masks from a natural experiment that evaluated the effects of state government mandates in the US for face mask use in public on COVID-19 spread. Fifteen states plus Washington, D.C., mandated face mask use between April 8 and May 15. Using an event study that examined daily changes in county-level COVID-19 growth rates, the study found that mandating public use of face masks was associated with a reduction in the COVID-19 daily growth rate. Specifically, we found that the average daily county-level growth rate decreases by 0.9, 1.1, 1.4, 1.7, and 2.0 percentage points in 1–5, 6–10, 11–15, 16–20, and 21 or more days after signing, respectively.

These estimates are not small; they represent nearly 16 percent to 19 percent of the effects of other social distancing measures (school closures; bans on large gatherings; shelter-in-place orders; and closures of restaurants, bars, and entertainment venues) after similar periods from their enactment.[21] The estimates suggest that the effectiveness of and benefits from these mandates increase over time. By May 22, 2020, the estimates suggest that 230,000–450,000 COVID-19 cases may have been averted on the basis of when states passed these mandates. Again, the estimates of averted cases should be viewed cautiously, as they are sensitive to assumptions and different approaches to transforming the changes in the daily growth rate estimates to cases.

The early declines in the daily growth rate over the course of five days after signing the order are broadly consistent with the timing of the effects of other social distancing measures such as business closures.[21] Although the median incubation period is estimated to be around five days,[26] there is a wide range from 2.2 days (2.5th percentile) to 11.5 days (97.5th percentile), which suggests that for many people, symptoms may appear relatively early. Further, people may become aware of the mandates early through governors' briefings and related media reports, or they may be anticipating them.

EXHIBIT 2

Event study estimates of effects of states mandating only employee use of face masks during working time on daily county-level growth rate of COVID-19 cases



SOURCE Authors' analysis of US county-level COVID-19 case data between March 31 and May 22, 2020. **NOTES** Event study estimates (dots) and 95% confidence intervals (bars) of the effects of states mandating employee use of face covers or masks on the county-level daily growth rate of COVID-19 cases over different periods before and after the mandate order was signed. This model excluded fifteen states plus Washington, D.C., that made the use of face covering mandatory for both the general public and employees. The reference period was the first five days before the mandate order was signed. The model controlled for major COVID-19 mitigation policies as time-varying (closure of K–12 schools, county-level or statewide shelter-in-place orders, nonessential business closure, closure of restaurants for dining in, and closure of gyms or movie theaters), COVID-19 tests per 100,000 people, county fixed effects, and day fixed effects. The model was estimated by least squares weighted by the county 2019 population, and the standard errors were robust to heteroscedasticity and clustered at state level.

There is no evidence of differential pre-mandate COVID-19 trends with respect to issuing these mandates. The estimates represent the intent-to-treat effects of the statewide face cover mandates as passed, conditional on other national and local measures. In that way, the effects are independent of the CDC national guidance to wear face masks that was issued April 3, 2020.[12] These effects were robust to several model checks. The study provides evidence from a natural experiment on the effectiveness of mandating public use of face masks in mitigating the spread of COVID-19. We found no evidence for effects of states mandating employee face mask use, perhaps because many businesses themselves already required their employees to wear masks.[27,28] In that case, mandating employee mask use reinforce what many businesses already choose to do on their own.

Although the intent-to-treat estimates are of interest for understanding the effectiveness of

these policies in limiting COVID-19 spread at the community and population levels, understanding how their effects change with compliance and enforcement strategies is important for designing effective policies. Our study has built the first step in estimating the overall effect of these policies as enacted. However, these policies vary in their strictness and the consequences of noncompliance. The mandates generally require wearing a face mask in public whenever the social distance cannot be maintained. States such as Delaware, Maryland, Massachusetts, and Maine clarify what "public" areas are (for example, indoor space in retail establishments, outdoor space in busy parking lots and waiting areas for take-out services, semi-enclosed areas such as at public transportation stops, and enclosed spaces such as in taxis and other public transportation). The language on enforcement and penalties for noncompliance also vary. In states such as Delaware, Hawaii, Maryland, and Massachusetts, the face mask orders state that they have the force and effect of law, with a willful violation subject to a criminal offense with penalties. For example, the order in Maryland states that "a person who knowingly and willfully violates this order is guilty of a misdemeanor and on conviction is subject to imprisonment not exceeding one year or a fine not exceeding $5,000 or both."[29] In contrast, the orders of other states such as Connecticut, Maine, and Pennsylvania, although clearly mandating the wearing of a face mask in public, do not appear to clearly specify that violations of the order are subject to criminal offense or penalties. Future work should examine whether and how differences in strictness and enforcement modify the effects of these mandates.

Compliance and enforcement may also differ across contextual factors (such as other social distancing measures, workforce distribution, population demographics, and socioeconomic and cultural factors). In that regard, it is important to clarify that the suggested benefits from mandating face mask use are not substitutes for other social distancing measures; the effects are conditional on the other enacted social distancing measures and how communities are complying with them. It is also important to extend the evidence into additional measures of exposure to the virus in the community as data become available, such as from serological testing for antibodies. Finally, future work can examine effects on deaths, which lag cases and change not only with the number of cases but also with case severity.

Conclusion

The study provides evidence that US states mandating the use of face masks in public had a greater decline in daily COVID-19 growth rates after issuing these mandates compared with states that did not issue mandates. These effects were observed conditional on other existing social distancing measures and were independent of the CDC recommendation to wear face covers issued April 3, 2020. As international and state governments begin to relax social distancing restrictions, and considering the high likelihood of a second COVID-19 wave in the fall and winter of 2020,[30] requiring the use of face masks in public could help in reducing COVID-19 spread. ■

ABSTRACT

Face Masks Considerably Reduce COVID-19 Cases in Germany: A Synthetic Control Method Approach[1]

We use the synthetic control method to analyze the effect of face masks on the spread of Covid-19 in Germany. Our identification approach exploits regional variation in the point in time when face masks became compulsory. Depending on the region we analyse, we find that face masks reduced the cumulative number of registered Covid-19 cases between 2.3% and 13% over a period of 10 days after they became compulsory. Assessing the credibility of the various estimates, we conclude that face masks reduce the daily growth rate of reported infections by around 40%.

1 Introduction

Many countries have experimented with several public health measures to mitigate the spread of Covid-19. One particular measure that has been introduced are face masks. It is of obvious interest to understand the contribution made by such a measure to reducing infections.

The effect of face masks on the spread of infections has been studied for a long time. The usefulness in the clinical context is beyond dispute. There is also considerable evidence that they helped in mitigating the spread of epidemics such as SARS 2003 or influenza (see below). The effect of face masks worn in public on the spread of Covid-19 has not been systematically analyzed so far. This is the objective of this paper.

There is a general perception in Germany that public wearing of face masks reduces incidences considerably. This perception comes mainly from the city of Jena. After face masks were introduced on 6 April 2020, the number of new infections fell almost to zero. Jena is not the only city or region in Germany, however, that introduced face masks. Face masks became compulsory in all federal states between 20 April and 29 April 2020. Six regions made masks compulsory before the introduction at the federal level. These dates lay between 6 April and 25 April (see appendix A and Kleyer et al., 2020, for a detailed overview of regulations in Germany). This leads to a lag between individual regions and the corresponding federal states of between two and 18 days.

We derive findings by employing synthetic control methods (SCM, Abadie and Gardeazabal, 2003, Abadie et al., 2010, Abadie, 2019). Our identification approach exploits the previously mentioned regional variation in the point in time when face masks became compulsory in public transport and sales shops. We use data for 401 German regions to estimate the effect of this public health measure on the development of registered infections with Covid-19. We consider the timing of mandatory face masks as an exogenous event to the local population. Masks were imposed by local authorities and were not the outcome of some process in which the population was involved.[2] We compare the Covid-19 development in various regions to their synthetic counterparts. The latter are constructed as a weighted average of control regions that are similar to the regions of interest. Structural dimensions taken into account include prior Covid-19 cases, their demographic structure and the local health care system.

We indeed find strong and convincing statistical support for the general perception that public wearing of face masks in Jena strongly reduced the number of incidences. We obtain a synthetic control group that closely follows the Covid-19 trend before introduction of mandatory masks in Jena and the difference between Jena and this group is very large after 6 April. Our findings indicate that the early introduction of face masks in Jena has resulted in a reduction of almost 25% in the cumulative number of reported Covid-19 cases after 20 days. The drop is greatest, larger than 50%, for the age group 60 years and above. Our results are robust when we conduct sensitivity checks and apply several placebo tests, e.g. tests for pseudo-treatment effects in similarly sized cities in the federal state of Thuringia and for pseudo-treatment effects in Jena before the treatment actually started. We also test for announcement effects.

Constructing control groups for other single regions is not always as straightforward as for Jena. As a consequence, it is harder to identify the effect of face masks in these regions. When we

[2] This is similar to the setup in Abadie et al. (2010), who study the effect of an increase in the tobacco tax in California. The tobacco tax was decided upon by the state government.

move from single to multiple treatment effects, we find smaller effects. They are still sufficiently large, however, to support our point that wearing face masks is a very cost-efficient measure for fighting Covid-19. When we summarize all of our findings in one single measure (we compare all measures in appendix B.4), we conclude that the daily growth rate of Covid-19 cases in the synthetic control group falls by around 40% due to mandatory mask-wearing relative to the control group.[3]

Concerning the literature (see appendix D for a more detailed overview), the effects of face masks have been surveyed by Howard et al. (2020) and Greenhalgh et al. (2020). Greenhalgh et al. (2020) mainly presents evidence on the effect of face masks during non-Covid epidemics (influenza and SARS). Marasinghe (2020) reports that they "*did not find any studies that investigated the effectiveness of face mask use in limiting the spread of COVID-19 among those who are not medically diagnosed with COVID-19 to support current public health recommendations*".

In addition to medical aspects (like transmission characteristics of Covid-19 and filtering capabilities of masks), Howard et al. (2020) survey evidence on mask efficiency and on the effect of a population. They first stress that "*no randomized control trials on the use of masks <…> has been published*". The study which is "*the most relevant paper*" for Howard et al. (2020) is one that analyzed *"exhaled breath and coughs of children and adults with acute respiratory illness*" (Leung et al., 2020, p. 676), i.e. used a clinical setting. Concerning the effect of masks on community transmissions, the survey needs to rely on pre-Covid-19 studies. We conclude from this literature review that our paper is the first analysis that provides field evidence on the effect of masks on mitigating the spread of Covid-19.

2 Identification, data and implementation

Identification. Our identification approach exploits the regional variation in the point in time when face masks became mandatory in public transport and sales shops. Given the federal structure of Germany, decisions are made by municipal districts (regions in what follows) and federal states. We can exploit differences by, first, identifying six regions (equivalent to the EU nomenclature of territorial units for statistics, NUTS, level 3) which made wearing face masks compulsory before their respective federal states. For all other regions, mandatory mask-wearing followed the decision of the corresponding federal state. Second, as Figure 1 shows, variation across federal states also implies variations across regions.

To identify possible treatment effects from introducing face masks, we apply SCM for single and multiple treated units. Our methodical choice is motivated as follows: First, the original goal of SCM to "*estimate the effects of <…> interventions that are implemented at an aggregate level affecting a small number of large units (such as cities, regions, or countries)*" (Abadie, 2019, p.3) clearly matches with our empirical setup. Compared to standard regression analyses, SCM is particularly well suited for comparative case study analyses with only one treated unit or a very small number thereof (Abadie and Gardeazabal, 2003, Becker et al., 2018). Second, the method is flexible, transparent and has become a widely utilized tool in the policy evaluation literature (Athey and Imbens, 2017) and for causal analyses in related disciplines

[3] The main channel through which masks reduce transmission of SARS-CoV-2 is the reduction in aerosols and droplets, as argued by Prather et al. (2020).

(see, e.g., Kreif et al., 2015, for an overview of SCM in health economics, Pieters et al., 2017, for a biomedical application).[4]

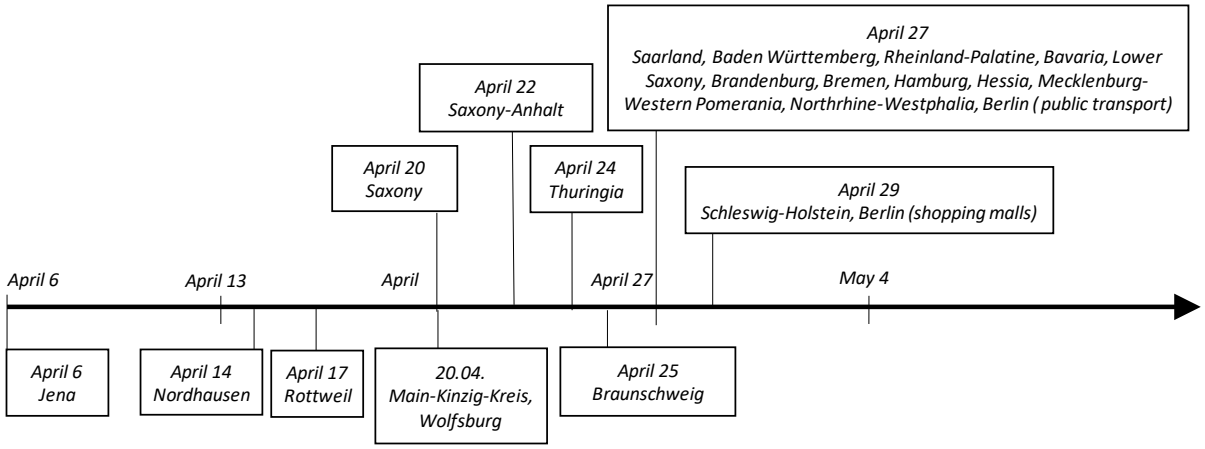

Figure 1: The timing of mandatory mask wearing in federal states (top) and individual regions (below)

SCM identifies synthetic control groups for the treated unit(s) to build a counterfactual. In our case, we need to find a group of regions that have followed the same Covid-19 trend as treated units before mandatory masks in the latter. This control group would then most likely have had the same behavior as treated unit(s) in the absence of the mask obligation. We can then use this group to 'synthesize' the treated unit and conduct causal inference. The synthetic control group is thereby constructed as an estimated weighted average of all regions in which masks did not become compulsory earlier on. Historical realizations of the outcome variable and several other predictor variables that are relevant in determining outcome levels allow us to generate the associated weights, which result from minimizing a pre-treatment prediction error function (see Abadie and Gardeazabal, 2003, Abadie et al., 2010 and Abadie, 2019 for methodical details).

Data. We use the official German statistics on reported Covid-19 cases from the Robert Koch Institute (RKI, 2020). The RKI collects the data from local health authorities and provides updates on a daily basis. Using these data (available via API), we build a balanced panel for 401 NUTS Level 3 regions and 95 days spanning the period from January 28 to May 1, 2020 (38,095 observations). We use the cumulative number of registered Covid-19 cases in each district as main outcome variable.[5] We estimate overall effects for this variable together with disaggregated effects by age groups (persons aged 15-34 years, 35-59 years and 60+ years). As an alternative outcome variable, we also use the cumulative incidence rate. Table 1 shows summary statistics for both variables for our sample period.

Table 1 also presents our other predictor variables. We focus on factors that are likely to describe the regional number and dynamics of reported Covid-19 cases. Obviously, past values

[4] Friedson et al. (2020) employ the SCM to estimate the effect of the shelter-in-place order for California in the development of Covid-19. The authors find *inter alia* that around 1600 deaths from Covid-19 were avoided by this measure during the first four weeks.

[5] We are aware of the existence of hidden infections. As it appears plausible to assume that they are proportional to observed infections across regions, we do not believe that they affect our results. We chose the date of reporting (as opposed to date of infections) because not all reported infections include information about the date of infection.

of (newly) registered Covid-19 cases are important to predict the regional evolution of Covid-19 cases over time in an autoregressive manner. In addition, we argue that a region's demographic structure, such as the overall population density and age structure, and its basic health care system, such as the regional endowment with physicians and pharmacies per population, are important factors for characterizing the local context of Covid-19. Predictor variables are obtained from the INKAR online database of the Federal Institute for Research on Building, Urban Affairs and Spatial Development. We use the latest year available in the database (2017). We consider it likely that regional demographic structures only gradually vary over time such that they can be used to measure regional differences during the spread of Covid-19 in early 2020.

Table 1: Summary Statistics of Covid-19 indicators (outcome variables) and predictors characterizing the regional demographic structure and basic health care system

	Mean	**S.D.**	**Min.**	**Max.**
PANEL A: Data on registered Covid-19 cases				
[1] Newly registered cases per day	4.13	10.66	0	310
[2] Cumulative number of cases	120.86	289.07	0	5795
[3] Cum. cases [2] per 100,000 inhabitants	59.87	106.80	0	1,530.32
PANEL B: Regional demographic structure and local health care system				
Population density (inhabitants/km^2)	534.79	702.40	36.13	4,686.17
Population share of highly educated* individuals (in %)	13.07	6.20	5.59	42.93
Share of females in population (in %)	50.59	0.64	48.39	52.74
Average age of females in population (in years)	45.86	2.11	40.70	52.12
Average age of males in population (in years)	43.17	1.83	38.80	48.20
Old-age dependency ratio (persons aged 65 years and above per 100 of population age 15-64)	34.34	5.46	22.40	53.98
Young-age dependency ratio (persons aged 14 years and below per 100 of population age 15-64)	20.54	1.44	15.08	24.68
Physicians per 10,000 of population	14.58	4.41	7.33	30.48
Pharmacies per 100,000 of population	27.01	4.90	18.15	51.68
Settlement type (categorial variable$^{\$}$)	2.59	1.04	1	4

Notes: * = International Standard Classification of Education (ISCED) Level 6 and above; $ = categories are based on population shares and comprise 1) district-free cities *(kreisfreie Großstädte)*, 2) urban districts *(städtische Kreise)*, 3) rural districts *(ländliche Kreise mit Verdichtungsansätzen)*, 4) sparsely populated rural districts *(dünn besiedelte ländliche Kreise)*.

Implementation. The implementation of the SCM is organized as follows: As baseline analysis, we focus on the single treatment case for the city of Jena for three reasons. First, as shown in Figure 1, Jena was the first region to introduce face masks in public transport and sales shops on April 6. This results in a lead time of 18 days relative to mandatory face masks in the surrounding federal state Thuringia on April 24. By April 29, all German regions had introduced face masks (exact dates are provided in appendix A). A sufficiently long lag between mandatory face masks in the treated unit vis-à-vis the sample of control regions is important for effect identification.

Second, the timing of the introduction of face masks in Jena is -by and large- not affected by other overlapping public health measures related to the Covid-19 spread. Since March 22 the German economy had been in a general "lock down" coordinated among all federal states. Only from April 20 onwards has the economy been gradually reopening. Third, Jena is in various ways a representative case for studying the Covid-19 development: On April 5, which is one day before face masks became compulsory in Jena, the cumulative number of registered Covid-19 cases in Jena was 144. This is very close to the median of 155 for Germany. Similarly, the cumulative number of Covid-19 incidences per 100,000 inhabitants was 126.9 in Jena compared to a mean of 119.3 in Germany (compare Figure A1).

In our baseline configuration of the SCM, we construct the synthetic Jena by including the number of cumulative Covid-19 cases (measured one and seven days before the start of the treatment) and the number of newly registered Covid-19 cases (in the last seven days prior to the start of the treatment) as autoregressive predictor variables. The chosen period shall ensure that the highly non-linear short-run dynamics of regional Covid-19 cases are properly captured. We use cross-validation tests to check the sensitivity of the SCM results when we allow for a shorter training period in the pre-treatment phase by imposing longer lags. The autoregressive predictors are complemented by the cross-sectional data on the region's demographic and basic health care structure.

Although the case study of Jena can be framed in a clear identification strategy, the Covid-19 spread in a single municipality may still be driven by certain particularities and random events that may prevent a generalization of estimated effects. We therefore also test for treatment effect in districts that introduced face masks after Jena but still before they became compulsory in the corresponding federal state. More importantly, however, we apply a multiple treatment approach that takes all regions as treated units which introduced face masks by April 22. This results in 32 regions from Saxony and Saxony-Anhalt. All other regions apart from Thuringia introduced face masks on April 27. We employ this delay to study the effects of mandatory masks up to May 1st. We end on May 1st as we would expect that differences across treated and non-treated regions should disappear 5-7 days after April 27. This delay results from a median incubation time of 5.2 days (Linton et al., 2020 and Lauer et al., 2020) and around 2 days accounting for reporting to authorities (as assumed e.g. in Donsimoni et al., 2020a, b).

Although SCM appears to be a natural choice for our empirical identification strategy, we are well aware of the fact that its validity crucially depends on important practical requirements including the availability of a proper comparison group, the absence of early anticipation effects or interference from other events (Cavallo et al., 2013, Abadie, 2019). In the implementation of the single and multiple treatment SCM we check for these pitfalls through sensitivity and placebo tests. We deal with these issues in our baseline case study for Jena as follows:

1. We have screened the introduction and easing of public health measures, as documented in Kleyer et al. (2020), to ensure that no interference takes place during our period of study. This is the case at least until April 20 when exit strategies from public health measures started.
2. We make sure that the regions used to create the synthetic control, i.e. the donor pool, are not affected by the treatment (Campos et al., 2015). We eliminate the two immediate geographical neighbors of Jena from the donor pool to rule out spillover effects. We also exclude those regions for which anticipation effects may have taken place because face masks became compulsory in quick succession to Jena.

3. We account for early anticipation effects in Jena. Specifically, we take the announcement that face masks will become compulsory one week before their introduction as an alternative start of the treatment period.
4. We apply cross-validation tests to check for sensitivities related to changes in historical values in the outcome variables used as predictors. We also run placebo-in-time tests to check whether effects actually occurred even before the start of the treatment.
5. We test for the sensitivity of the results when changing the donor pool and run comprehensive placebo-in-space tests as a mode of inference in the SCM framework.

Inference thereby relies on permutation tests and follows the procedures suggested by Cavallo et al. (2013) and applied, for example, by Eliason and Lutz (2018) or Hu et al. (2018). For both the single and multiple treatment applications we estimate placebo-treatment effects for each district in which masks did not become compulsory early on. These placebo treatments should be small, relative to the treated regions. We calculate significance levels for the test of the hypothesis that the mask obligation did not significantly affect reported Covid-19 cases. This provides us with *p*–values for each day, which capture the estimated treatment effect on reported Covid-19 cases from placebo regions. The *p*-values are derived from a ranking of the actual treatment effect within the distribution of placebo treatment effects. We follow the suggestion in Galiani and Quistorff (2017) and compute adjusted *p*-values taking the pre-treatment match quality of the placebo treatments into account.[6]

3 The effects of face masks on Covid-19

Baseline results for Jena. Panel A in Figure 2 shows the SCM results for the introduction of face masks in Jena on April 6. The visual inspection of the development of cumulative Covid-19 cases shows that the fit of the synthetic control group is very similar to Jena before the treatment.[7] The difference in the cumulated registered Covid-19 cases between Jena and its corresponding synthetic control unit after the start of the treatment can be interpreted as the treatment effect on the treated.

The figure clearly shows a gradually widening gap in the cumulative number of Covid-19 cases between Jena and the synthetic control unit. The size of the effect 20 days after the start of the treatment (April 26) amounts to a decrease in the number of cumulative Covid-19 cases of 23%. For the first 10 days, the decrease amounts to 13%. Expressed differently, the daily growth rate of the number of infections decreases by 1.32 percentage points per day (see appendix B.4 for computational details and an overview of all measures). If we look at the estimated differences by age groups, Table A2 in the appendix indicates that the largest effects are due to the age group of persons aged 60 years and above. Here the reduction in the number of registered cases is even larger than 50%. For the other two age groups we find a decrease between 10 and 20%.

[6] We conduct all estimations in STATA using "Synth" and "Synth Runner" packages (Abadie at al., 2020, Galiani and Quistorff, 2017). Data and estimation files can be obtained from the authors upon request.

[7] The pre-treatment root mean square prediction error (RMSPE) of 3.145 is significantly below a benchmark RMSPE of 6.669, which has been calculated as the average RMSPE for all 401 regions in the pre-treatment period until April 6. This points to the relatively good fit of the synthetic control group for Jena in this period.

If we consider a median incubation of 5.2 days plus a potential testing and reporting lag of 2-3 days, the occurrence of a gradually widening gap between Jena and its synthetic control three to four days after the mandatory face masks seems fast. One might conjecture that an announcement effect played a role. As shown in appendix B.7, online searches for (purchasing) face masks peaked on April 22, when it was announced that face masks would become compulsory in all German federal states.[8] A smaller peak (70% of the April 22 peak) of online searches appeared on March 31. This is one day after Jena announced that masks would become compulsory on April 6. The announcement was accompanied by a campaign "Jena zeigt Maske" to communicate the necessity to wear face masks in public[9] and was widely discussed all over Germany.

Panel B in Figure 2 therefore plots the results when we set the start of the treatment period to the day of the announcement on 30 March. The visual inspection of the figure shows the existence of a small anticipation effect (which is mainly driven by the relative development of Covid-19 age group 15-34 years (Panel B in Figure A2). Yet, the gap to the synthetic control significantly widens only approximately 10 days after the announcement. As this temporal transmission channel appears plausible against the background of incubation times and given that no other intervention took place around this time in Jena or the regions in the synthetic control group, we take this as first evidence for a face mask-effect in the reduction of Covid-19 infections. Appendix B.6 shows similar SCM results for the incidence rate (overall and by age groups). We find a reduction of approximately 30 cases per 100,000 of population.

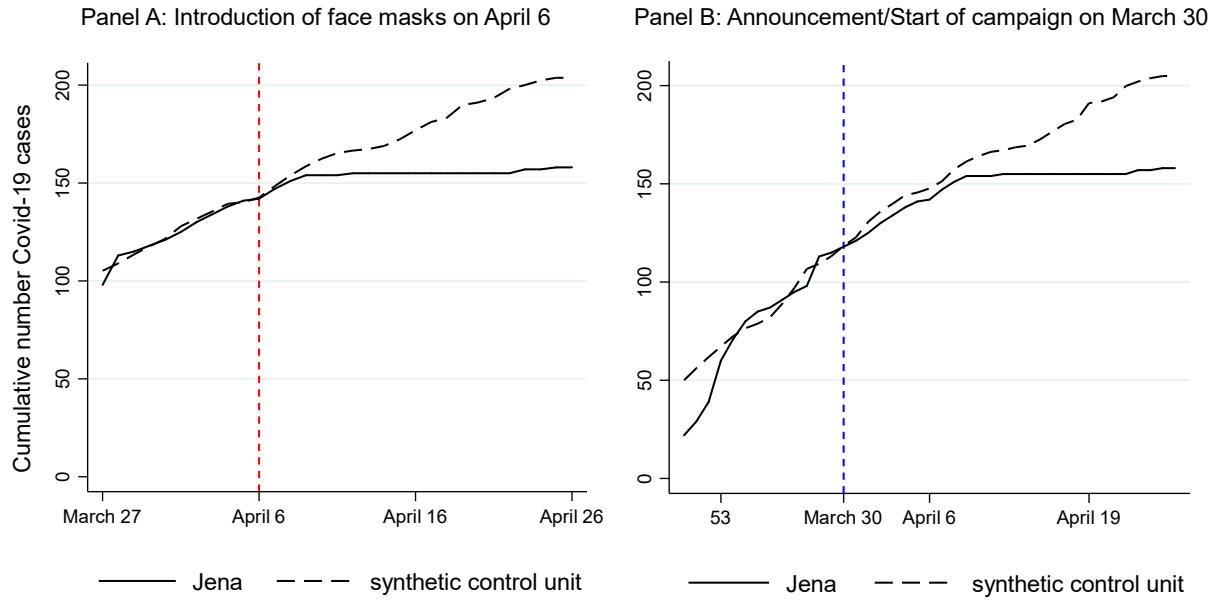

Figure 2: Treatment effects of mandatory face masks in Jena on April 6 and start of campaign on March 30 (see Table A3 and appendix B.2 for details)

Obviously, the estimated differences in the development of Jena vis-à-vis the synthetic Jena is only consistently estimated if our SCM approach delivers robust results. Accordingly, we have applied several tests to check for the sensitivity of our findings.

Cross-validation and placebo-in-time test. One important factor is that our results are not sensitive to changes in predictor variables. We therefore perform cross-validation checks by modifying the length of the training and validation periods before the start of the treatment. Panel A in Figure 3 shows that lagging the autoregressive predictor variables further in time only slightly changes our results. Importantly, we do not find a systematic downward bias of our baseline specification (cumulative number of reported Covid-19 cases: one and seven days before start of treatment; number of newly registered Covid-19 cases: last seven days before start of treatment) compared to an alternative specification. The latter trains the synthetic control on the basis of information on cumulative Covid-19 cases 7 and 14 days prior to the treatment together with the development of newly register cases between day 7 and 14 prior to the treatment. Given that regional Covid-19 cases developed very dynamically and non-linearly in this period, this is an important finding in terms of the robustness of our results.

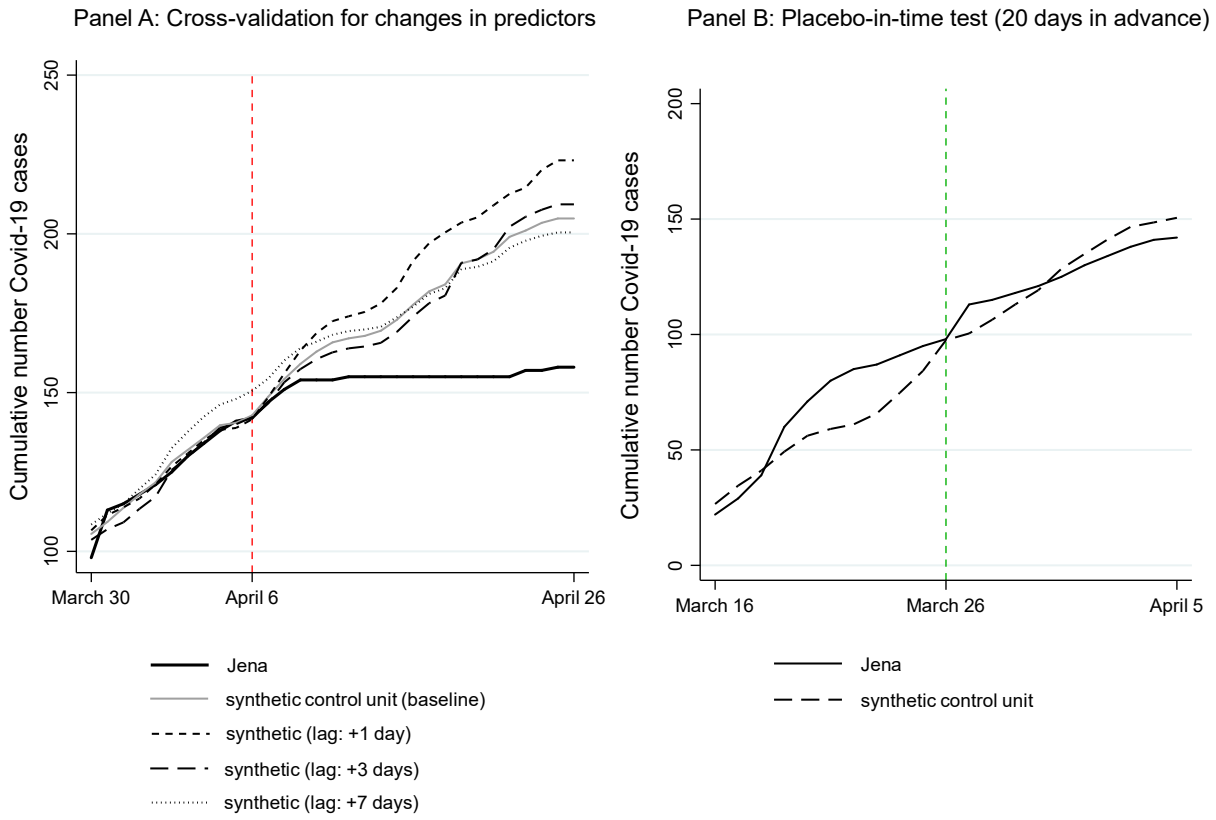

Figure 3: Cross-validation for changes in predictor variables and placebo-in-time test

Notes: In Panel A the baseline specification for the synthetic control group uses historical values of the outcome variable in the following way: i) number of cumulative Covid-19 cases (measured one and seven days before the start of the treatment), ii) the number of newly registered Covid-19 cases (in the last seven days prior to the start of the treatment); the alternative specifications lag these values by 1, 3 and 7 days.

Another important factor for the validity of the results is that we do not observe an anticipation effect for Jena prior to the announcement day. We test for a pseudo-treatment in Jena over a period of 20 days before the introduction of face masks. This period is equally split into a pre-

and pseudo post-treatment period. As Panel B in Figure 3 shows, there is no strong deviation from the path of the synthetic control group. This result needs to be interpreted with some care as the regional variation of Covid-19 cases in Germany is very heterogeneous the longer we go back in time. This is indicated by the generally lower fit of the synthetic control group in matching the development in Jena in mid-March when the absolute number of Covid-19 cases was still low.

Changing the donor pool. In addition, we also check for the sensitivity of the results when changing the donor pool. This may be important as our baseline specification includes the region of Heinsberg in the donor pool used to construct the synthetic Jena (with a weight of 4.6%; compare Table A3). As Heinsberg is one of the German regions which was significantly affected by the Covid-19 pandemic during the Carnival season, this may lead to an overestimation of the effects of face masks. Accordingly, appendix B.8 presents estimates for alternative donor pools. Again, we do not find evidence for a significant bias in our baseline specification. By tendency, the treatment effect becomes larger, particularly if we compare Jena only to other regions in Thuringia (to rule out macro-regional trends) and to a subsample of larger cities (*kreisfreie Städte*). Both subsamples exclude Heinsberg. We also run SCM for subsamples excluding Thuringia (to rule out spillover effects) and for East and West Germany (again in search for specific macro regional trends). Generally, these sensitivity tests underline the robustness of the estimated treatment effect for Jena.

Placebo-in-space tests. A placebo test in space checks whether other cities that did not introduce face masks on April 6 have nonetheless experienced a decline in the number of registered Covid-19 cases. If this had been the case, the treatment effect may be driven by other latent factors rather than face masks. Such latent factors may, for instance, be related to the macro-regional dynamics of Covid-19 in Germany. Therefore, appendix B.9 reports pseudo-treatment effects for similarly sized cities in Thuringia assuming that they have introduced face masks on April 6 although –in fact– they did not. As the figure shows, these cities show either a significantly higher or similar development of registered Covid-19 compared to their synthetic controls. This result provides further empirical support for a relevant effect in the case of Jena.

As a more comprehensive test, we also ran placebo-in-space tests for all other regions that did not introduce face masks on April 6 or closely afterwards. Again, we estimate the same model on each untreated region, assuming it was treated at the same time as Jena. The empirical results in Figure 4 indicate that the reduction in the reported number of Covid-19 cases in Jena clearly exceeds the trend in most other regions – both for the overall sample in Panel A and the subsample of large cities (*kreisfreie Städte*) in Panel B.

As outlined above, one advantage of this type of placebo-in-space-test is allows us to conduct inference. Accordingly, Panel C and Panel D report adjusted *p*-values that indicate the probability if the treatment effect for Jena was observed by chance given the distribution of pseudo-treatment effects in the other German regions (see Galiani and Quistorff, 2017). For both samples, the reported *p*-values indicate that the reduction in the number of Covid-19 cases in Jena did not happen by chance but can be attributed to the introduction of face masks, at the latest - roughly two weeks after the start of the treatment. This timing is again in line with our above argument that a sufficiently long incubation time and testing lags need to be considered in the evaluation of treatment effects.

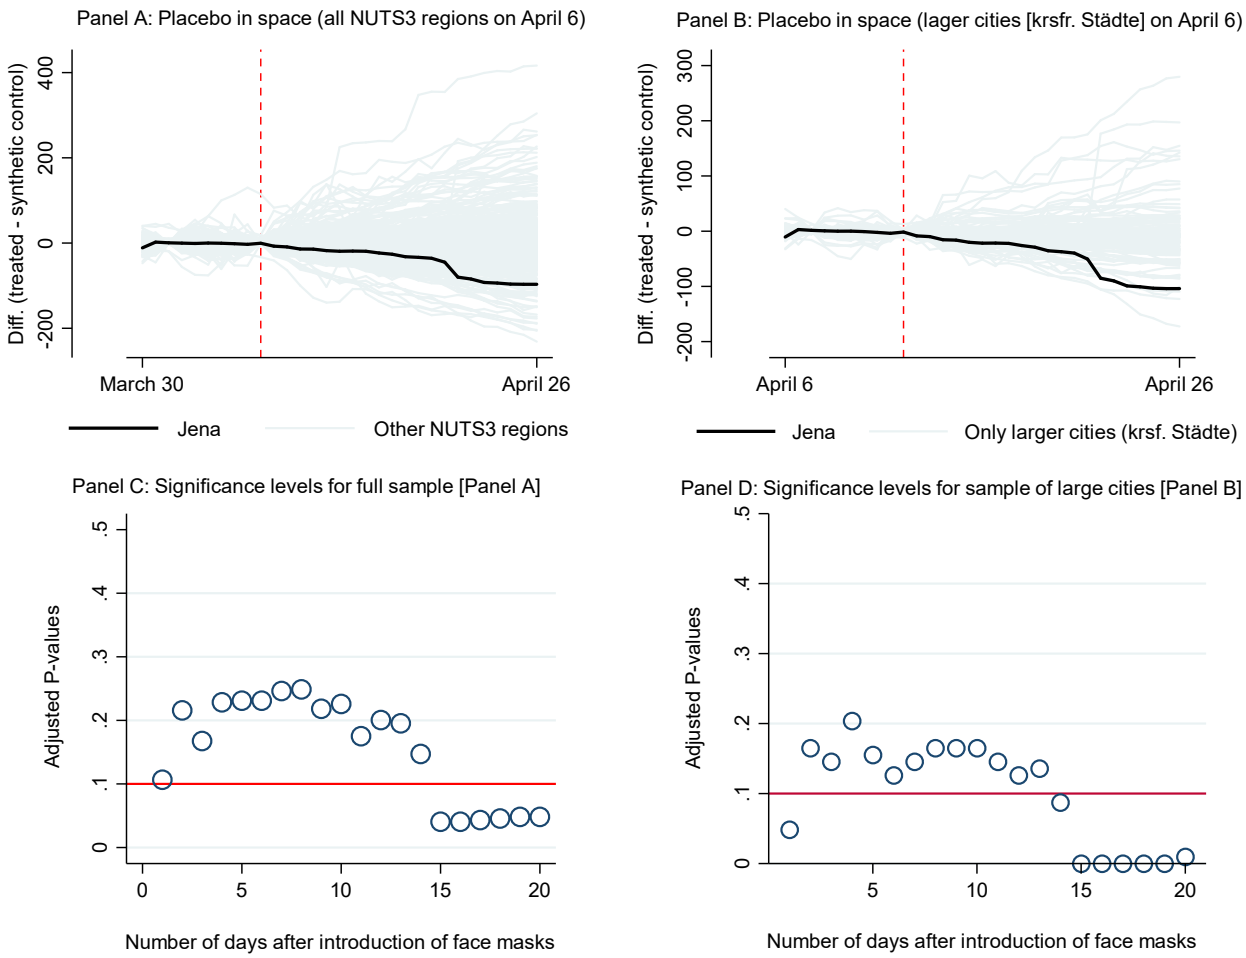

Figure 4: Comprehensive placebo-in-space tests for the effect of face masks on Covid-19 cases

Notes: Graphs exclude the following regions with a very large number of registered Covid-19 cases: Hamburg (2000), Berlin (11000), Munich (9162), Cologne (5315) and Heinsberg (5370). In line with Abadie et al. (2010), we only include placebo effects in the pool for inference if the match quality (pre-treatment RMSPE) of the specific control regions is smaller than 20 times the match quality of the treated unit. *P*-values are adjusted for the quality of the pre-treatment matches (see Galiani and Quistorff, 2017).

Treatment in other districts. Jena may be a unique case. We therefore also study treatment effects for other regions that have antedated the general introduction of face masks in Germany. Further single unit treatment analyses are shown in appendix C. Multiple unit treatments are studied in two ways. The first sample covers all 401 regions and 32 treated units. The second focused on the subsample of 105 larger cities (*kreisfreie Städte*), of which 8 are treated units. Treated regions introduced face masks by April 22. The multiple treatment approach, visible in Figure 5, points to a significant face mask-effect in the reduction of Covid-19 infections. The adjusted *p*-values indicate that the estimated treatment effects are not random.

Face masks may have made a particular difference in the spread of Covid-19, particularly in larger cities with higher population density and accordingly higher intensity of social interaction.[10] Over a period of 10 days, we observe an average reduction of 12.3 cases between treated and control regions. Relative to the average number of cumulative Covid-19 cases on May 1 in control regions (295.6), this amounts to a reduction of 4.2% of cases. The daily growth

[10] This is perfectly in line with Prather et al. (2020) given the reduction in aerosols and droplets via using masks.

rate of the number of infections correspondingly shrinks by 0.42 percentage points. For the entire sample, the reduction in the daily growth rate is estimated to be 0.23 percentage points (see again appendix B.4 for an overview of all measures).

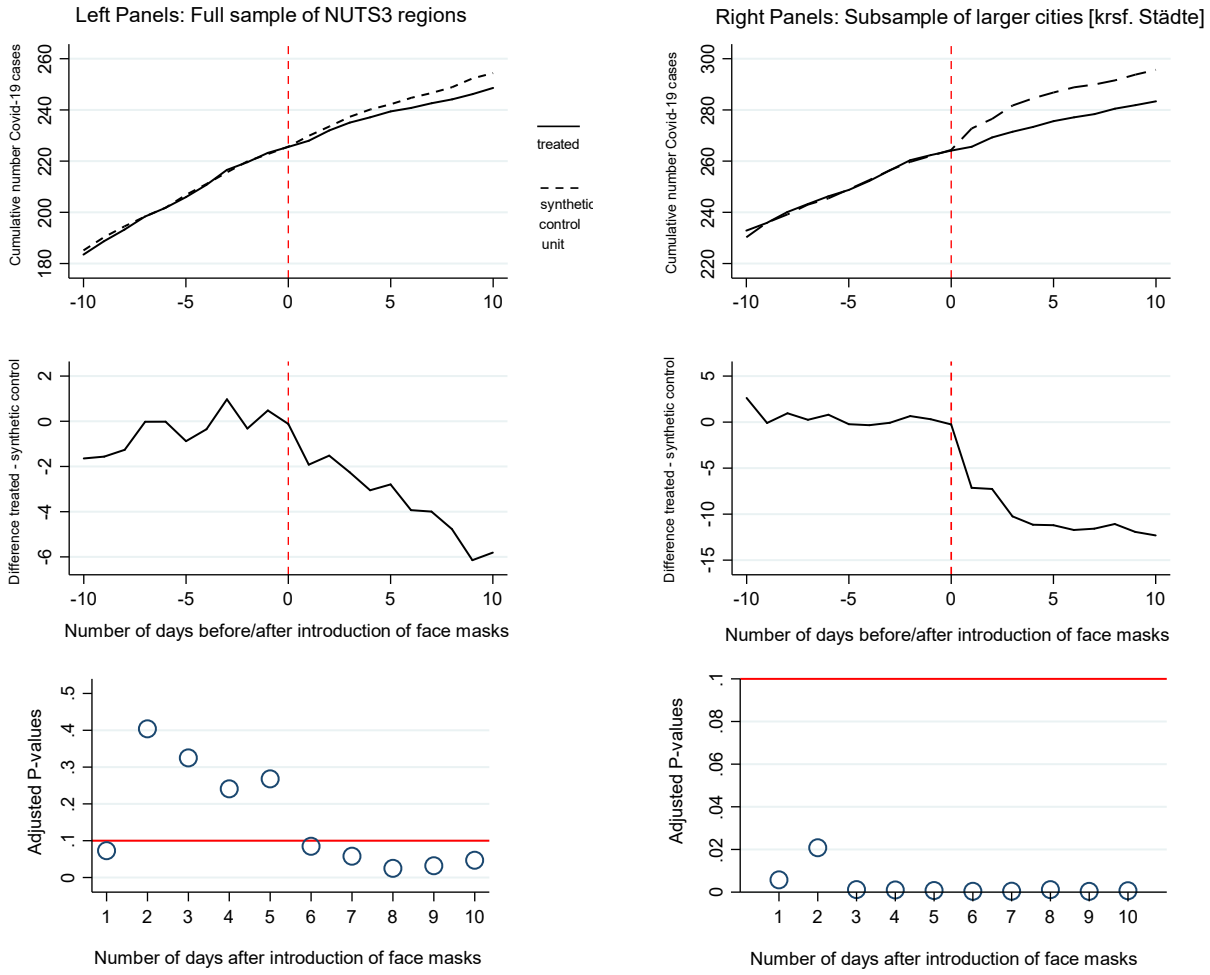

Figure 5: Average treatment effects for introduction of face masks (multiple treated units)

Notes Statistical inference for adjusted *p*-values has been conducted on the basis of a random sample of 1,000,000 placebo averages.

4 Conclusion

We set out by analyzing the city of Jena. The introduction of face masks on 6 April reduced the number of new infections over the next 20 days by almost 25% relative to the synthetic control group. This corresponds to a reduction in the average daily growth rate of the total number of reported infections by 1.32 percentage points. Comparing the daily growth rate in the synthetic control group with the observed daily growth rate in Jena, the latter shrinks by around 60% due to the introduction of face masks. This is a sizeable effect. Wearing face masks apparently helped considerably in reducing the spread of Covid-19. Looking at single treatment effects for all other regions puts this result in some perspective. The reduction in the growth rate of infections amounts to 20% only. By contrast, when we take the multiple treatment effect for larger cities into account, we find a reduction in the growth rate of infections by around 40%.

What would we reply if we were asked what the effect of introducing face masks would have been if they had been made compulsory all over Germany? The answer depends, first, on which of the three percentage measures we found above is the most convincing and, second, on the point in time when face masks are made compulsory. The second aspect is definitely not only of academic interest but would play a major role in the case of a second wave.

We believe that the reduction in the growth rates of infections by 40% to 60% is our best estimate of the effects of face masks. The most convincing argument stresses that Jena introduced face masks before any other region did so. It announced face masks as the first region in Germany while in our post-treatment period no other public health measures were introduced or eased. Hence, it provides the most clear-cut experiment of its effects. Second, as stated above, Jena is a fairly representative region of Germany in terms of Covid-19 cases. Third, the smaller effects observed in the multiple treatment analysis may also result from the fact that –by the time that other regions followed the example of Jena– behavioral adjustments in Germany's population had also taken place. Wearing face masks gradually became more common and more and more people started to adopt their usage even when it was not yet required.

We should also stress that 40 to 60% might still be a lower bound. The daily growth rates in the number of infections when face masks were introduced was around 2 to 3%. These are very low growth rates compared to the early days of the epidemic in Germany, where daily growth rates also lay above 50% (Wälde, 2020). One might therefore conjecture that the effects might have been even greater if masks had been introduced earlier.

We simultaneously stress the need for more detailed analyses. First, Germany is only one country. Different norms or climatic conditions might change the picture for other countries. Second, we have ignored spatial dependencies in the epidemic diffusion of Covid-19. This might play a role. Third, there are various types of face masks. We cannot identify differential effects since mask regulations in German regions do not require a certain type. This calls for further systematic causal analyses of the different health measure implemented to fight the spread of Covid-19. Our results provide some initial empirical evidence on this important matter.

A. Timing of introduction of mandatory face masks

Table A1: Overview of dates when masks became compulsory in federal states and districts

Federal State	Public transport	Sales shops	Individual NUTS3 region	Introduction of face masks	Difference in days to state
Baden-Wurttemberg	27.04.2020	27.04.2020	LK Rottweil	17.04.2020	10
Bavaria	27.04.2020	27.04.2020			
Berlin	27.04.2020	29.04.2020			
Brandenburg	27.04.2020	27.04.2020			
Bremen	27.04.2020	27.04.2020			
Hamburg	27.04.2020	27.04.2020			
Hesse	27.04.2020	27.04.2020	Main-Kinzig-Kreis	20.04.2020	7
Mecklenburg-West Pomer.	27.04.2020	27.04.2020			
Lower Saxony	27.04.2020	27.04.2020	Wolfsburg	20.04.2020	7
			Braunschweig	25.04.2020	2
North Rhine-Westphalia	27.04.2020	27.04.2020			
Rheinland-Pfalz	27.04.2020	27.04.2020			
Saarland	27.04.2020	27.04.2020			
Saxony	20.04.2020	20.04.2020			
Saxony-Anhalt	22.04.2020	22.04.2020			
Schleswig-Holstein	29.04.2020	29.04.2020			
Thuringia	24.04.2020	24.04.2020	Jena	06.04.2020	18
			Nordhausen	14.04.2020	10

Notes: A comprehensive overview of all public health measures introduced in German federal states and individual regions is given in Kleyer et al. (2020).

B. Background and additional estimates for SCM application to Jena

This appendix presents supporting findings for the comparative case study of Jena.

B.1. Covid-19 cases and cumulative incidence rate in Jena and Germany on April 5

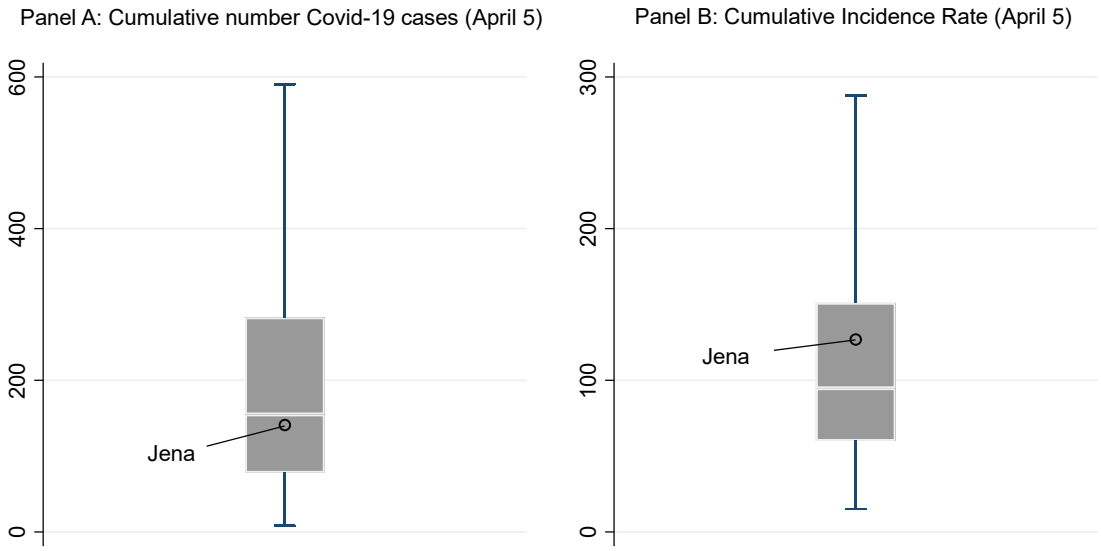

Figure A1: Box plots for distribution of Covid-19 cases across German NUTS3 regions (April 5)

B.2. Evaluation of pre-treatment predictor balance and prediction error (RMSPE)

This appendix shows the balancing properties of the SCM approach together with the root mean square percentage error (RMSPE) as a measure for the quality of the pre-treatment prediction.

Table A2: Pre-treatment predictor balance and RMSPE for SCM in Figure 2

Treatment:	**Introduction of face masks**		**Announcement/ start of campaign**	
	Jena	Synthetic control group	Jena	Synthetic control group
Cumulative number of registered Covid-19 cases (one and seven days before start of treatment, average)	129.5	129.2	93	92.7
Number of newly registered Covid-19 cases (last seven days before the start of the treatment, average)	3.7	3.8	5	5.2
Population density (Population/km^2)	38.4	22.8	968.1	947.9
Share of highly educated population (in %)	968.1	1074.3	38.4	26.3
Share of female in population (in %)	50.1	50.1	50.1	50.1
Average age of female population (in years)	43.5	43.7	43.5	43.9
Average age of male population (in years)	40.5	40.6	40.5	40.8
Old-age dependency ratio (in %)	32.1	29.3	32.1	29.8
Young-age dependency ratio (in %)	20.3	19.6	20.3	19.5
Physicians per 10,000 of population	20.5	19.8	20.5	20.8
Pharmacies per 100,000 of population	28.8	28.7	28.8	28.6
Settlement type (categorial variable)	1	1.3	1	1.9
RMSPE (pre-treatment)	**3.145**		**4.796**	

Notes: Donor pool includes all other German NUTS3 regions except the two immediate neighboring regions of Jena (Weimarer Land, Saale-Holzland-Kreis) as well as the regions Nordhausen and Rottweil since the latter regions introduced face masks in short succession to Jen on April 14 and April 17.

B.3. Selected control regions and their associated sample weights

Table A3: Distribution of sample weights in donor pool for synthetic Jena

Introduction of face masks (Panel A in Figure 2)		
ID	**NUTS 3 region**	**Weight**
13003	Rostock	0.326
6411	Darmstadt	0.311
3453	Cloppenburg	0.118
7211	Trier	0.117
6611	Kassel	0.082
5370	Heinsberg	0.046

Note: Donor pools corresponds to SCM estimation in Panel A of Figure 2. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

B.4. Growth rates

Jena has 142 registered cases on April 6 compared to an estimated number of 143 cases in the synthetic control group. On April 26 Jena counts 158 cases and the synthetic control group reports 205 (again estimated) cases. The daily growth rate in Jena is denoted by x_{Jena} and can be computed from $142\ [1+x_{Jena}]^{20} = 158$. The daily growth rate in the control group is denoted by $x_{control}$ and can be computed from $143\ [1+x_{control}]^{20} = 205$. Hence, the introduction of the face mask is associated with a decrease in the number of infections of $x_{control} - x_{Jena}$ percentage points per day.

Table A4: Summary of treatment effects of face mask introduction in Germany

	Single Treatment (Jena)	Multiple treatments (all districts)	Multiple treatments (cities)
Percentage change in cumulative number of Covid-19 cases over 20 days	-22.9%	n.a.	n.a.
Absolute change in cumulative number of Covid-19 cases over 10 days	-23	-5.8	-12.3
Percentage change in cumulative number of Covid-19 cases over 10 days	-12.8%	-2.3%	-4.2%
Difference in daily growth rates of Covid-19 cases in percentage points	-1.32%	-0.23%	-0.42%
Reduction in daily growth rates of Covid-19 cases in percent	60.1%	18.94%	37.28%

These numbers are computed in an Excel-file available on the web pages of the authors.

B.5. SCM results by age groups

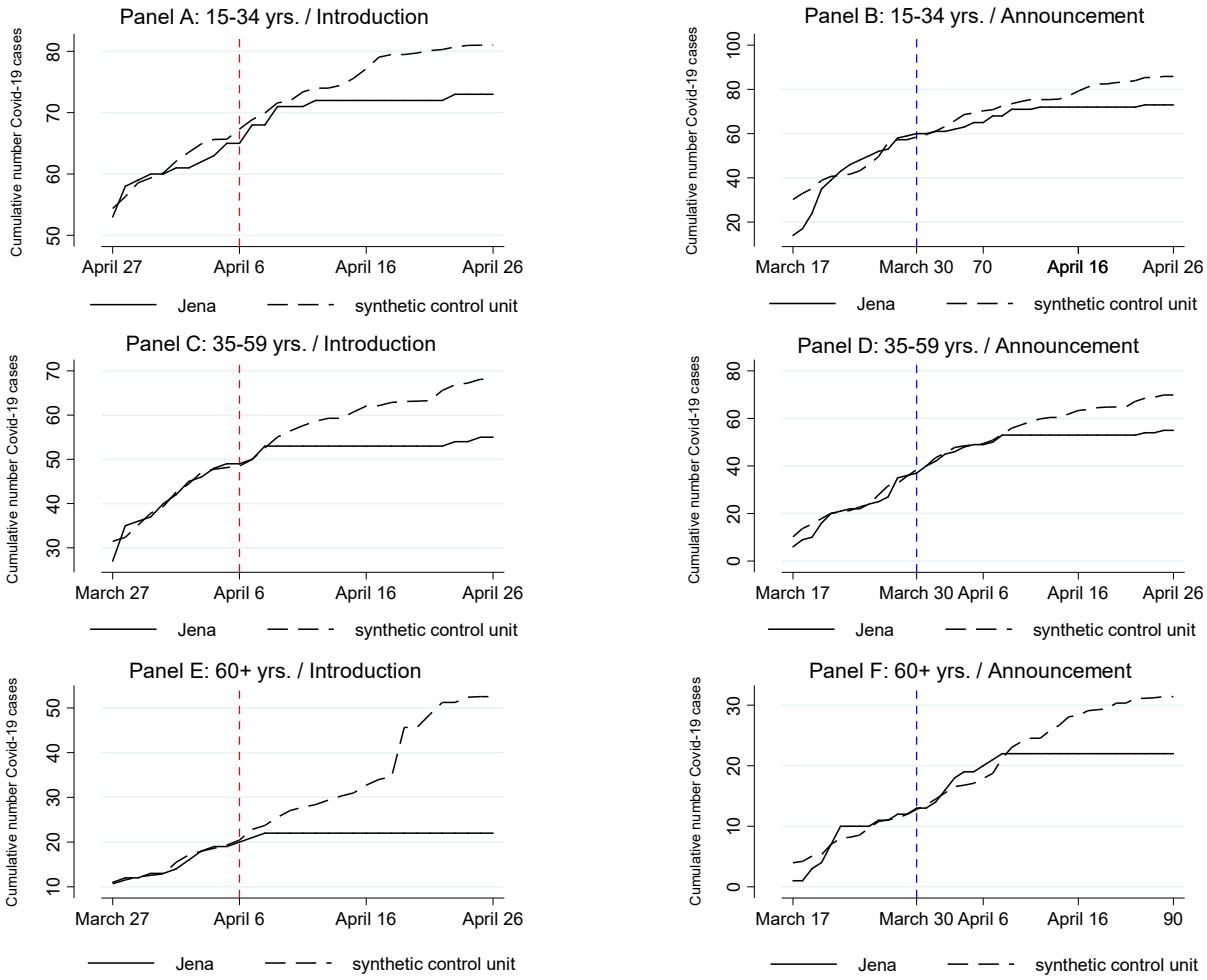

Figure A2: Treatment effects for introduction and announcement of face masks in Jena

Notes: Predictor variables are chosen as for overall specification shown in Figure 2.

Table A5: Sample weights in donor pool for synthetic Jena (cumulative Covid-19 cases; by age groups)

Age Group 15-34 years			**Age Group 35-59 years**			**Age Group 60 years and above**		
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
1001	Flensburg	0.323	6411	Darmstadt	0.528	6411	Darmstadt	0.522
7211	Trier	0.207	16055	Weimar	0.16	16055	Weimar	0.244
13003	Rostock	0.184	14511	Chemnitz	0.15	7316	Neustadt a.d. Weinstraße	0.068
5370	Heinsberg	0.142	8221	Baden-Baden	0.07	9562	Erlangen	0.06
3453	Cloppenburg	0.107	6434	Hochtaunus-kreis	0.062	3356	Osterholz	0.056
6413	Offenbach am Main	0.038	8435	Bodenseekreis	0.029	5515	Münster	0.027
			5370	Heinsberg	0.001	9188	Starnberg	0.022

Note: Donor pools corresponds to SCM estimations in Figure A2. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

B.6. Effects on cumulative number of infections per 100,000 inhabitants

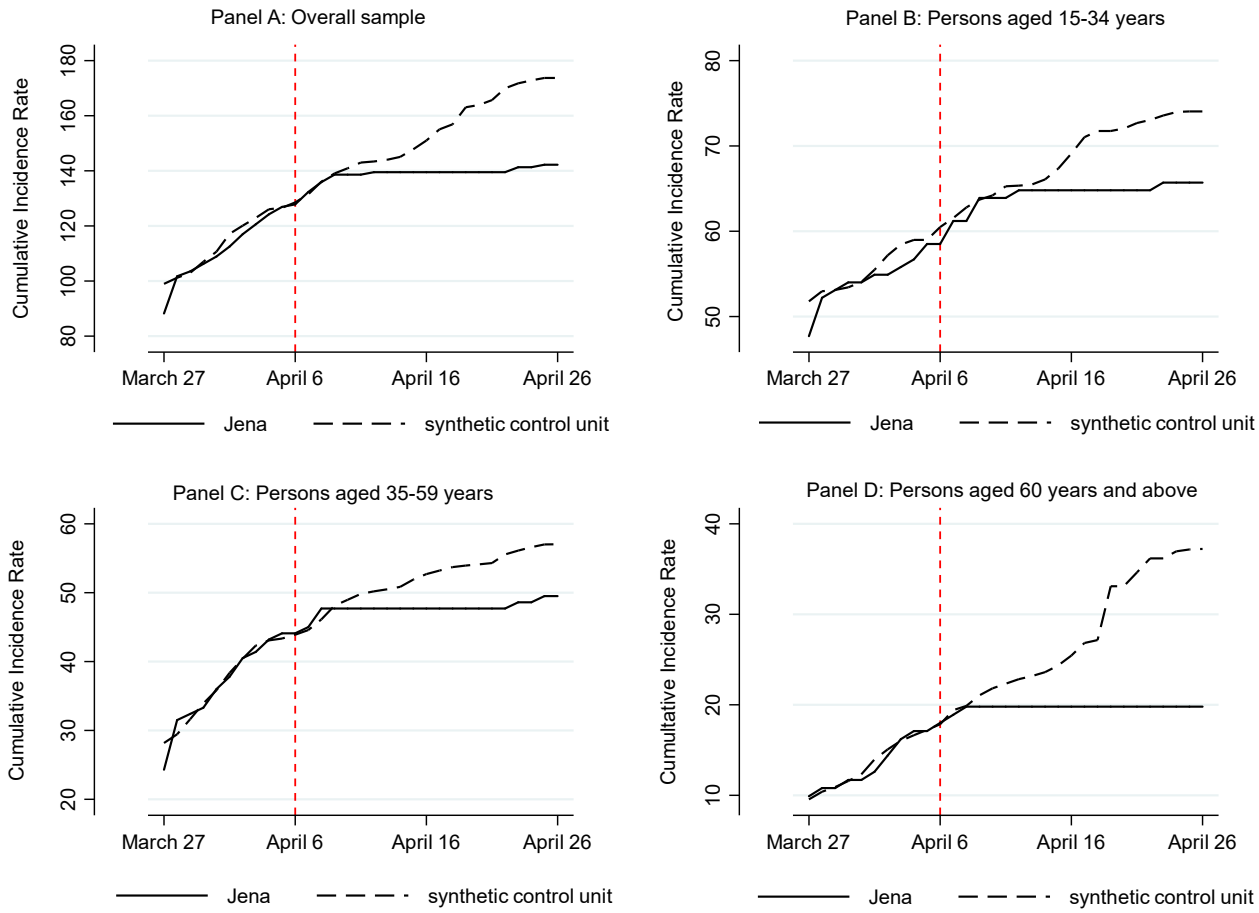

Figure A3: Treatment effects for introduction of face masks on cumulative incidence rate

Notes: See Table 1 for a definition of the incidence rate. Predictor variables are chosen as for overall specification shown in Figure 2.

Table A6: Sample weights in donor pool for synthetic Jena (cumulative incidence rate)

ID	NUTS 3 region	Weight
6411	Darmstadt	0.46
15003	Magdeburg	0.171
5370	Heinsberg	0.133
13003	Rostock	0.093
5515	Münster	0.066
11000	Berlin	0.035
12052	Cottbus	0.032
6611	Kassel	0.011

Note: Donor pools corresponds to SCM estimation in Figure A3. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

Table A7: Sample weights in donor pool for synthetic Jena (cumulative incidence rate; by age groups)

Age Group 15-34 years			Age Group 35-59 years			Age Group 60 years and above		
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
5370	Heinsberg	0.377	6411	Darmstadt	0.419	6411	Darmstadt	0.448
13003	Rostock	0.288	14511	Chemnitz	0.184	14612	Dresden	0.313
1001	Flensburg	0.14	14612	Dresden	0.154	9188	Starnberg	0.071
6611	Kassel	0.138	8221	Heidelberg	0.138	16054	Suhl	0.069
11000	Berlin	0.058	9188	Starnberg	0.088	5515	Münster	0.06
			5370	Heinsberg	0.016	8221	Heidelberg	0.039

Note: Donor pools corresponds to SCM estimations in Figure A3. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

B.7. Google trends and announcement effects

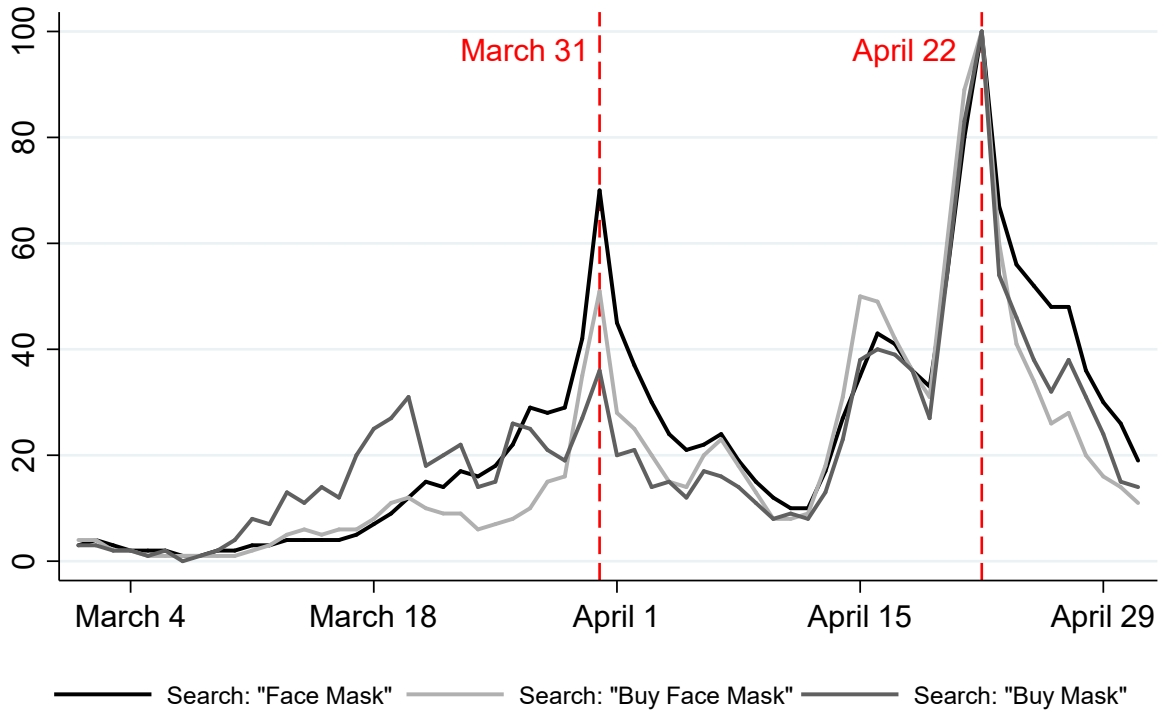

Figure A4: Online search for face masks and purchase options according to Google Trends

Note: Online search for keywords (in German) as shown in the legend as Face Mask ("Mund.-Nasen-Schutz"), Buy Face Mask ("Mundschutz kaufen") and Buy mask ("Maske kaufen"); alternative keywords show similar peaks but with a lower number of hits; based on data from Google Trends (2020).

B.8. Changes in donor pool for synthetic Jena

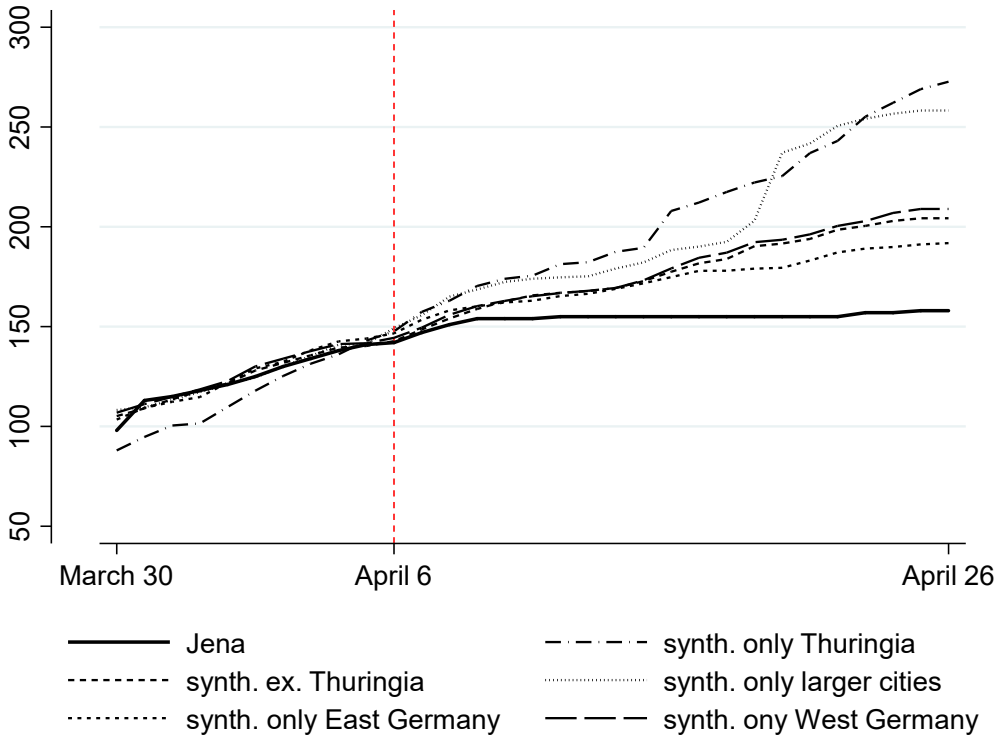

Figure A5: Treatment effects for changes in donor pool used to construct synthetic Jena

Notes: See main text for a detailed definition of the respective donor pools. Predictor variables are chosen as for overall specification shown in Figure 2.

Table A8: Sample weights for alternative donor pools used to construct synthetic Jena

Only Thuringia			**Excluding Thuringia**			**Only larger cities**		
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
16076	Greiz	0.533	13003	Rostock	0.318	6411	Darmstadt	0.504

11000	Berlin	0.011	6611	Kassel	0.169			
			7211	Trier	0.168			
			4012	Bremerhaven	0.167			
			5370	Heinsberg	0.057			

Note: Donor pools corresponds to SCM estimations in Figure A5. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

B.9. Place-in-space tests for other major cities in Thuringia

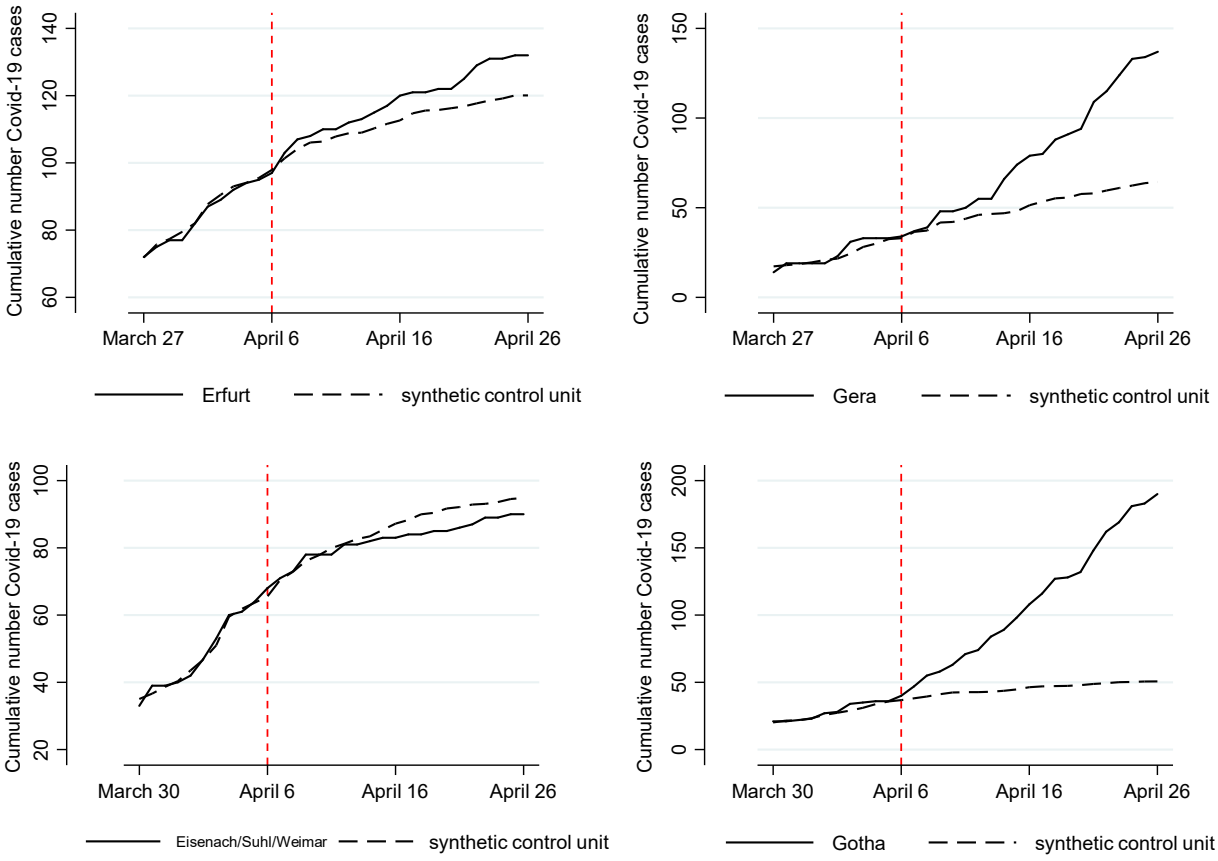

Figure A6: Placebo tests for the effect of face masks in other cities in Thuringia on April 6.

Notes: For the placebo tests in the other cities in Thuringia the same set of predictors as for Jena (Figure 2) has been applied. The reported regions cover all *kreisfreie Städte* plus Gotha (*Landkreis*). The cities Weimar, Suhl and Eisenach have been aggregated since the number of reported Covid-19 is low in these cities.

Table A9: Sample weights in donor pool for synthetic control groups (other cities in Thuringia)

Erfurt			Gera		
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
13003	Rostock	0.28	15001	Dessau-Roßlau	0.501
16055	Weimar	0.244	16054	Suhl	0.222
3356	Osterholz	0.212	7318	Speyer	0.162
7313	Landau in der Pfalz	0.154	8231	Pforzheim	0.061
6413	Offenbach am Main	0.078	7311	Frankenthal (Pfalz)	0.046
5370	Heinsberg	0.029	8211	Baden-Baden	0.005
5515	Münster	0.004	9662	Schweinfurt	0.003
			14521	Erzgebirgskreis	0.001
Weimar/Suhl/Eisenach			**Gotha**		
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
15001	Dessau-Roßlau	0.263	15081	Altmarkkreis	0.23
12052	Cottbus	0.236	16077	Altenburger Land	0.164
13004	Schwerin	0.202	15086	Jerichower	0.161
9361	Amberg	0.177	3402	Emden	0.111
14626	Görlitz	0.069	16071	Weimarer Land	0.108
9363	Weiden i.d. Opf.	0.036	16074	Saale-Holzland-Kreis	0.063
14521	Erzgebirgskreis	0.008	16061	Eichsfeld	0.058

6411	Darmstadt	0.005	3453	Cloppenburg	0.027
			15003	Magdeburg	0.017
			4012	Bremerhaven	0.007

Note: Donor pools corresponds to SCM estimations in Figure A6. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

C. The effect in other German cities and regions (single treatment analyses)

In addition to Jena, we test for treatment effects in Nordhausen, Rottweil, Main-Kinzig-Kreis, and Wolfsburg (compare Figure 1). We ignore Braunschweig here as the introduction became effective only two days in advance of its federal state.

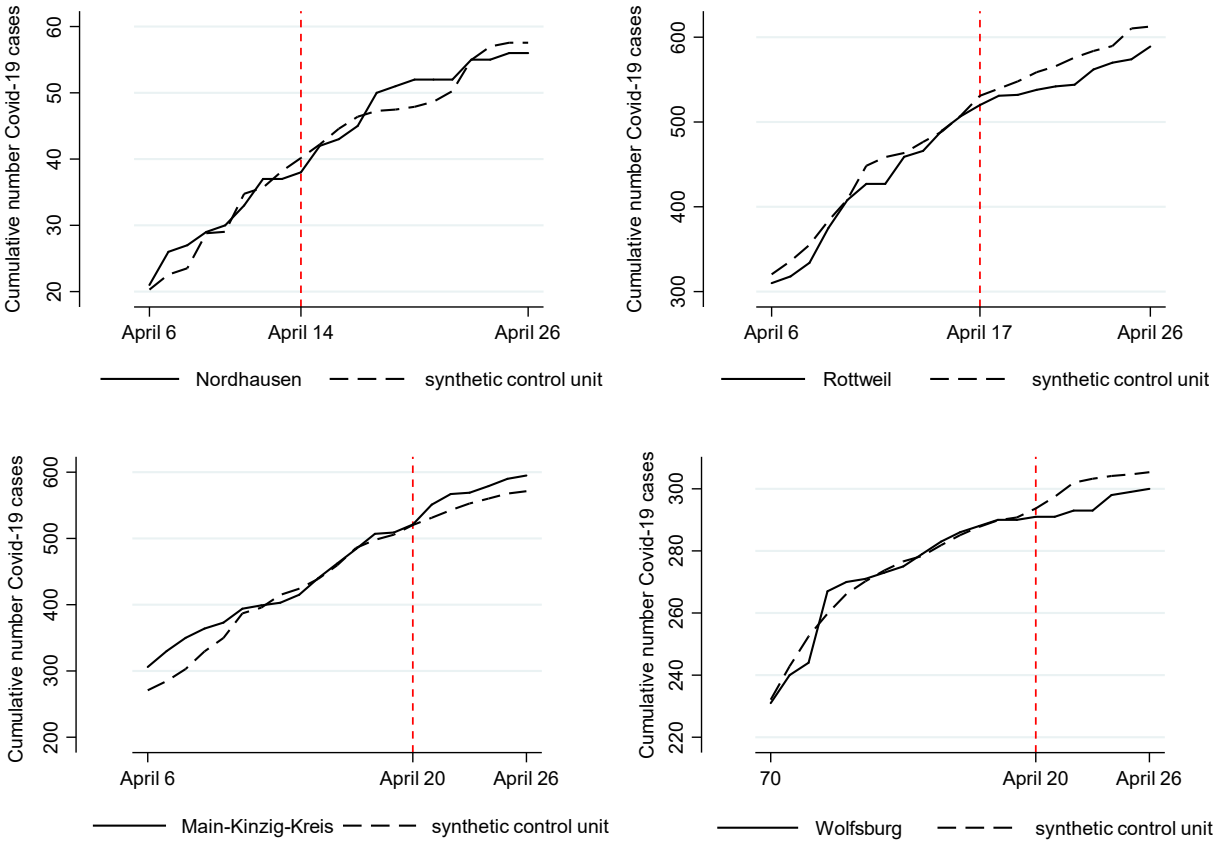

Figure A7: Treatment effects for introduction of face masks in other cities

Notes: Nordhausen (Thuringia, April 14, top left), Rottweil (Baden Württemberg, April 17, top right), Wolfsburg (Lower Saxony, April 20, middle left), Main-Kinzig-Kreis (Hessia, April 20, middle right). Predictor variables are chosen as for overall specification shown in Figure 2.

As the figure shows, the result is 2:1:1. Rottweil and Wolfsburg display a positive effect of mandatory mask wearing, just as Jena. The results in Nordhausen are very small or unclear. In the region of Main-Kinzig, it even seems to be the case that masks increased the number of cases relative to the synthetic control group. As all of these regions introduced masks after Jena, the time period available to identify effects is smaller than for Jena. The effects of mandatory face masks could also be underestimated as announcement effects and learning from Jena might have induced individuals to wear masks already before they became mandatory. Finally, the average pre-treatment RMSPE for these four regions (7.150) is larger than for the case of Jena (3.145). For instance, in the case of the region of Main-Kinzig it is more than three times as high (9.719), which indicates a lower pre-treatment fit. The obtained treatment effects should then be interpreted with some care as the pre-sample error could also translate into the treatment period. In order to minimize the influence of a poor pre-treatment fit for some individual regions, the main text therefore compares the results in Jena mainly with a multiple unit treatment approach.

Table A10: Sample weights in donor pool for synthetic controls (other treated NUTS3 regions)

	Nordhausen			**Rottweil**	
ID	**NUTS 3 region**	**Weight**	**ID**	**NUTS 3 region**	**Weight**
16069	Hildburghausen	0.228	8327	Tuttlingen	0.324

8236	Enzkreis	0.041			
3159	Göttingen	0.023			

Note: Donor pools corresponds to SCM estimations in Figure A7. Sample weights are chosen to minimize the RMSPE ten days prior to the start of the treatment.

D. A brief survey of public health measures against Covid-19

Our approach goes in line with various studies that have already tried to better understand the effect of public health measures on the spread of Covid-19 (Barbarossa et al., 2020, Hartl et al., 2020, Donsimoni et al., 2020, Dehning et al., 2020, Gros et al., 2020, Adamik et al, 2020). However, these earlier studies all take an aggregate approach in the sense that they look at implementation dates for a certain measure and search for subsequent changes in the national incidence. There are some prior analyses that take a regional focus (Khailaie et al. 2020) but no attention is paid to the effect of policy measures.[11]

There are also many cross-country analyses, both in a structural SIR (susceptible, infectious and removed) sense (Chen and Qiu, 2020) and with an econometric focus on forecasting the end of the pandemic (Ritschl, 2020). Others draw parallels between earlier pandemics and Covid-19 (Barro et al., 2020). These studies do not explicitly take public health measures into account. Some studies discuss potential effects of public health measures and survey general findings (Wilder-Smith et al. 2020, Anderson et al., 2020, Ferguson et al, 2020) but do not provide direct statistical evidence on specific measures.

The synthetic control method (SCM) has been applied by Friedson et al. (2020) to estimate the effect of the shelter-in-place order for California, USA, in the development of Covid-19. The authors find *inter alia* that around 1600 deaths from Covid-19 have been avoided by this measure during the first four weeks. The effects of face masks have been surveyed by Howard et al. (2020) and Greenhalgh et al. (2020). Greenhalgh et al. (2020) mainly presents evidence on the effect of face masks during non-Covid epidemics (influenza and SARS). Marasinghe (2020) reports that they "*did not find any studies that investigated the effectiveness of face mask use in limiting the spread of COVID-19 among those who are not medically diagnosed with COVID-19 to support current public health recommendations*".

In addition to medical aspects (like transmission characteristics of Covid-19 and filtering capabilities of masks), Howard et al. (2020) survey evidence on mask efficiency and on the effect of a population. They first stress that "*no randomized control trials on the use of masks <…> has been published*". The study which is "*the most relevant paper*" for Howard et al. (2020) is one that analyzed *"exhaled breath and coughs of children and adults with acute respiratory illness*" (Leung et al., 2020, p. 676), i.e. used a clinical setting. Concerning the effect of masks on community transmissions, the survey needs to rely on pre-Covid-19 studies.

We conclude from this literature review that our paper is the first analysis that provides field evidence on the effect of masks on mitigating the spread of Covid-19.

[11] In a short note, Hartl and Weber (2020) apply panel methods based on time dummies to understand the relative importance of various public health measures. They employ data at the federal state level and not at the regional level. As a detailed model description is not available, an appreciation of results is difficult at this point.

- "Mask Mandate Effectiveness" via *Resolve to Save Lives* Weekly Science Review: https://preventepidemics.org/covid19/science/weekly-science-review/october-3-9/
    - **Main message:** Enforceable policies and mandates to promote health behaviors can be highly effective when they are evidence-based and implemented with the health of the population and the greater good in mind. Mask mandates to mitigate spread of the virus that causes COVID-19 have been enacted differently across and within countries. Although the magnitude of the effect can be difficult to measure, comparisons between settings with and without mandates suggest that mask mandates, together with other mitigation measures, contribute to control the COVID-19 pandemic. Enforceable mask mandates are one strategy leaders can use to reduce the spread of COVID-19 and protect the health of their residents.

RESEARCH LETTER

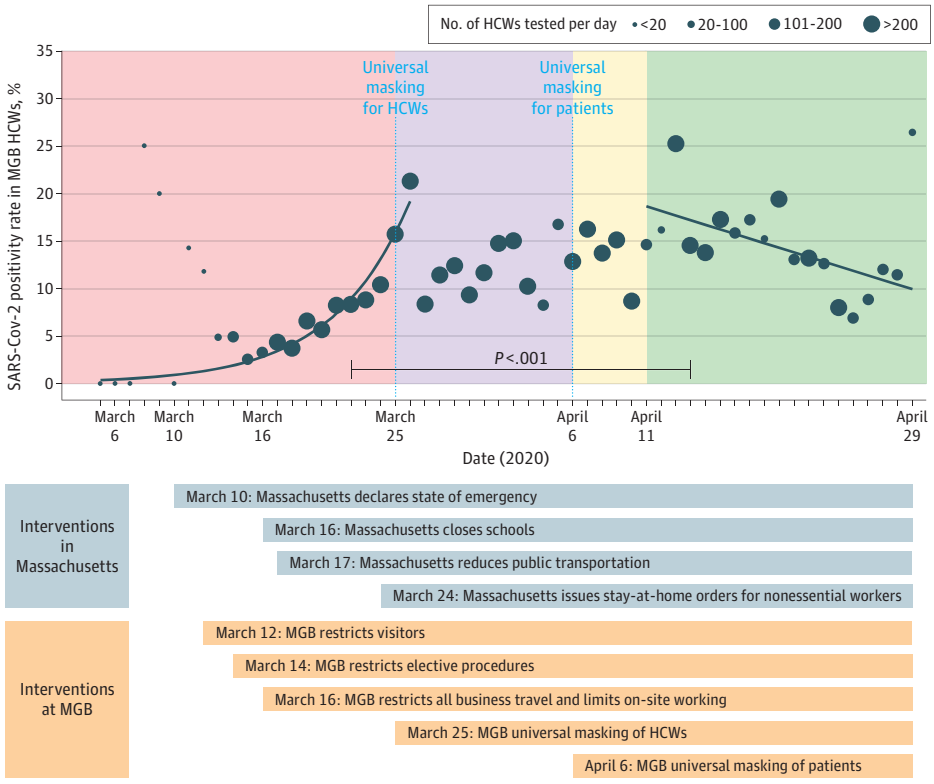
Association Between Universal Masking in a Health Care System and SARS-CoV-2 Positivity Among Health Care Workers

The coronavirus disease 2019 (COVID-19) pandemic, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has severely affected health care workers (HCWs).[1] As a result, hospital systems began testing HCWs[2] and implementing infection control measures to mitigate workforce depletion and prevent disease spread.[3] Mass General Brigham (MGB) is the largest health care system in Massachusetts, with 12 hospitals and more than 75 000 employees. In March 2020, MGB implemented a multipronged infection reduction strategy involving systematic testing of symptomatic HCWs and universal masking of all HCWs and patients with surgical masks.[4] This study assessed the association of hospital masking policies with the SARS-CoV-2 infection rate among HCWs.

Editorial

Methods | The institutional review board of MGB approved the study and waived informed consent. Using electronic medical records, we identified HCWs providing direct and indirect patient care who were tested for SARS-CoV-2 with reverse transcriptase–polymerase chain reaction between March 1 and April 30, 2020. The primary criterion for testing HCWs in our health care system was having symptoms consistent with SARS-CoV-2 infection. Information on the job description of each HCW was obtained by linking their record to the MGB Occupational Health Services and Human Resources databases.

Figure. Temporal Trend in Percentage Positivity of SARS-CoV-2 Testing Among HCWs



HCW indicates health care worker; MGB, Mass General Brigham; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2. All dates given are for the year 2020. The size of each data marker is proportional to the total number of SARS-CoV-2 tests performed each day over the time of the study period (x-axis), while the position of each data marker along the y-axis shows the percentage of daily test results that were positive among HCWs. The horizontal bars below the x-axis represent the timing of key interventions implemented in the state of Massachusetts and at MGB. The dotted lines represent the implementation dates of hospital policies. The study period is divided into 3 phases: a preintervention period before implementation of universal masking of HCWs (pink), which includes March 26, the day after implementation of universal masking for HCWs, to account for HCWs who became symptomatic after business hours on March 25 and were tested on March 26; a transition period until implementation of universal masking of patients (purple) plus an additional lag period (yellow); and the intervention period (green). For the preintervention and intervention periods, daily tests were fitted by weighted nonlinear regression (curves). The change in overall slope was compared between the 2 curves to determine any statistically significant changes in trend (as shown by the *P* value).

Downloaded From: https://jamanetwork.com/ by a Boston University User on 07/14/2020

We identified 3 phases during the study period: a preintervention period before implementation of universal masking of HCWs (March 1-24, 2020); a transition period until implementation of universal masking of patients (March 25-April 5, 2020) plus an additional lag period to allow for manifestations of symptoms (April 6-10, 2020), as previously defined[5]; and an intervention period (April 11-30, 2020). Positivity rates included the first positive test result for all HCWs in the numerator and HCWs who never tested positive plus those who tested positive that day in the denominator. For each HCW, any tests subsequent to their first positive test result were excluded. Using weighted nonlinear regression, we fit the best curve for the preintervention and intervention periods (based on R^2 value). The number of daily tests was used as the weight such that days with more tests had more weight in determining the curve. The overall slope of each period was calculated using linear regression to estimate the mean trend, regardless of curve shape. The change in overall slope between the preintervention and intervention periods was compared to determine any statistically significant change in mean trend, using a 2-sided $\alpha = .05$. The analysis was conducted using R version 4.0 (R Foundation).

Results | Of 9850 tested HCWs, 1271 (12.9%) had positive results for SARS-CoV-2 (median age, 39 years; 73% female; 7.4% physicians or trainees, 26.5% nurses or physician assistants, 17.8% technologists or nursing support, and 48.3% other). During the preintervention period, the SARS-CoV-2 positivity rate increased exponentially from 0% to 21.32%, with a weighted mean increase of 1.16% per day and a case doubling time of 3.6 days (95% CI, 3.0-4.5 days). During the intervention period, the positivity rate decreased linearly from 14.65% to 11.46%, with a weighted mean decline of 0.49% per day and a net slope change of 1.65% (95% CI, 1.13%-2.15%; $P < .001$) more decline per day compared with the preintervention period (**Figure**).

Discussion | Universal masking at MGB was associated with a significantly lower rate of SARS-CoV-2 positivity among HCWs. This association may be related to a decrease in transmission between patients and HCWs and among HCWs. The decrease in HCW infections could be confounded by other interventions inside and outside of the health care system (Figure), such as restrictions on elective procedures, social distancing measures, and increased masking in public spaces, which are limitations of this study. Despite these local and statewide measures, the case number continued to increase in Massachusetts throughout the study period,[6] suggesting that the decrease in the SARS-CoV-2 positivity rate in MGB HCWs took place before the decrease in the general public. Randomized trials of universal masking of HCWs during a pandemic are likely not feasible. Nonetheless, these results support universal masking as part of a multipronged infection reduction strategy in health care settings.

Science Agenda Development and Update

Greg Armstrong
Chris Braden
Mary Chamberland
Joanne Cono
Rita Helfand
Brandi Limbago
Sam Posner
Henry Walke

October 19, 2020

Background and Current Status

- Request to develop a Science Agenda
  - Build on what had been previously done
  - Other research agendas (NIAID, DHS, WHO, Published Literature)
  - 1-3 year time horizon
- Related products in development
  - Internal document for internal decision making
  - Project tracking and reporting
  - Priority Questions

Status and Purpose of the Internal Document

- Review
  - Agency Leadership
  - Team B
  - IM Leadership
  - Task Forces
- Purpose
  - Support internal decision making
  - Document and prioritize emerging issues
  - Identify priority areas

Document Structure

- Six Priority Areas
  - COVID-19 disease detection, burden and impact
  - Transmission of SARS-CoV-2
  - Natural history of SARS-CoV-2 infection
  - Protection in healthcare and non-healthcare work settings
  - Prevention, mitigation, and intervention strategies
  - Social, behavioral, and communication science
- Objectives for each Priority Area
- Specific Activities

PRIORITY AREA I. COVID-19 DISEASE DETECTION, BURDEN, AND IMPACT

- Objective 1. Develop new, or modify existing, methods of epidemiologic surveillance for COVID-19
- Objective 2. Develop and optimize testing for SARS-CoV-2
- Objective 3. Utilize viral genomics to advance understanding of COVID-19 and mitigate its impact
- Objective 4. Use mathematical modeling and other technological tools to forecast COVID-19 trends and measure the impact of interventions across a range of populations
- Objective 5. Assess and limit the impact of COVID-19 on healthcare services and public health programs in domestic and international settings

PRIORITY AREA II. TRANSMISSION OF SARS-CoV-2

- **Objective 1. Refine understanding of SARS-CoV-2 transmission modes**
- **Objective 2. Identify host and virus factors associated with person-to-person transmission**
- **Objective 3. Assess and characterize transmission of SARS-CoV-2 across a spectrum of healthcare settings**
- **Objective 4. Evaluate transmission of SARS-CoV-2 in non-healthcare workplace and community settings/populations**
- **Objective 5. Evaluate zoonotic and reverse zoonotic transmission of SARS-CoV-2**

PRIORITY AREA III. NATURAL HISTORY OF SARS-CoV-2 INFECTION

- **Objective 1. Define the spectrum and clinical course of SARS-CoV-2 infection**
- **Objective 2. Characterize the immune response in infected persons**

PRIORITY AREA IV. PROTECTION IN HEALTHCARE AND NON-HEALTHCARE WORK SETTINGS

- **Objective 1. Improve and assess the effectiveness of personal protective equipment**
- **Objective 2. Assess strategies to reduce transmission of SARS-CoV-2 in healthcare and non-healthcare work settings**

PRIORITY AREA V. PREVENTION, MITIGATION, AND INTERVENTION STRATEGIES

- Objective 1. Evaluate individual- and community-level strategies to limit infection with SARS-CoV-2
- Objective 2. Evaluate strategies to limit infection with SARS-CoV-2 in specialized settings or select populations
- Objective 3. Develop methods to detect SARS-CoV-2 in the environment
- Objective 4. Identify the most effective methods for contact tracing, testing, and monitoring
- Objective 5. Evaluate travel-related interventions
- Objective 6. Optimize the acceptability, coverage, safety, and effectiveness of COVID-19 vaccines

PRIORITY AREA VI. SOCIAL, BEHAVIORAL, AND COMMUNICATION SCIENCE

- Objective 1. Understand where people receive information about the pandemic
- Objective 2. Optimize uptake of recommended behaviors and actions
- Objective 3. Enhance CDC communication products and information tools
- Objective 4. Assess the social, behavioral, and mental health impacts of the pandemic

Proposed list of priority questions that need to be answered by October 2020

- How can schools mitigate risks when reopening?
- How can workplaces mitigate risks when reopening?
- How to prevent and control COVID-19 in congregate and critical infrastructure settings?
- How can racial/ethnic disparities in COVID-19 impact be addressed?
- What are the best practices for contact tracing?
- What are the relative roles of aerosol vs. droplet vs. fomite transmission in COVID-19?
- Can the effectiveness of face coverings be documented and improved?
- How effective are other non-pharmaceutical interventions?
- What is the role of superspreaders and superspreading events?
- What is the extent of protection afforded by immune response to infection?

New questions to be addressed by January 2021

- How well are prevention and control strategies performing in schools, congregate settings, and critical infrastructure settings?
- Can the effectiveness of masks worn in community settings, for source control or protection, be documented and improved?
- How can adherence to mitigation recommendations (masks, social distancing, hand hygiene) be improved?
- How can racial/ethnic disparities in COVID-19 be assessed and addressed?
- What are best practices for increasing vaccine confidence in the general population, and what strategies are needed to ensure early vaccine uptake in groups that may be prioritized for vaccination, such as healthcare personnel and essential workers, and in racial and ethnic minority communities?
- How can we ensure we are actively monitoring the safety and effectiveness of vaccines in a consistent manner across different vaccines ?

New questions to be addressed by January 2021

- How do antigen assays antigen perform relative to presence of transmissible virus, including in asymptomatic individuals? How should these tests be complemented by other testing strategies?
- Is there enough evidence to support reducing the quarantine period, with or without testing? With or without a mask?
- What are the health impacts of infection with special consideration for long-term sequelae, pediatric populations, and persons with co-morbidities?
- What is the duration of protection afforded by immune response to infection and immunization and can we identify correlates of protection?
- Can the relationship of duration, distance, mask use, and environmental factors (ventilation, temperature, humidity) on risk of transmission be better defined to inform public health practice (e.g. whom to quarantine and test or how to prioritize various prevention approaches)?

Thank you for your interest

Trends in COVID-19 Incidence After Implementation of Mitigation Measures — Arizona, January 22–August 7, 2020

M. Shayne Gallaway, PhD[1,2]; Jessica Rigler, MPH[1]; Susan Robinson, MPH[1]; Kristen Herrick, MPH[1]; Eugene Livar, MD[1]; Kenneth K. Komatsu, MPH[1]; Shane Brady, MPH[1]; Jennifer Cunico[1]; Cara M. Christ, MD[1]

Mitigating the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), requires individual, community, and state public health actions to prevent person-to-person transmission. Community mitigation measures can help slow the spread of COVID-19; these measures include wearing masks, social distancing, reducing the number and size of large gatherings, pausing operation of businesses where maintaining social distancing is challenging, working from or staying at home, and implementing certain workplace and educational institution controls (*1*–*4*). The Arizona Department of Health Services' (ADHS) recommendations for mitigating exposure to SARS-CoV-2 were informed by continual monitoring of patient demographics, SARS-CoV-2 community spread, and the pandemic's impacts on hospitals. To assess the effect of mitigation strategies in Arizona, the numbers of daily COVID-19 cases and 7-day moving averages during January 22–August 7, 2020, relative to implementation of enhanced community mitigation measures, were examined. The average number of daily cases increased approximately 151%, from 808 on June 1, 2020 to 2,026 on June 15, 2020 (after stay-at-home order lifted), necessitating increased preventive measures. On June 17, local officials began implementing and enforcing mask wearing (via county and city mandates),* affecting approximately 85% of the state population. Statewide mitigation measures included limitation of public events; closures of bars, gyms, movie theaters, and water parks; reduced restaurant dine-in capacity; and voluntary resident action to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases in Arizona peaked during June 29–July 2, stabilized during July 3–July 12, and further declined by approximately 75% during July 13–August 7. Widespread implementation and enforcement of sustained community mitigation measures informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

ADHS supports surveillance and investigation efforts of local public health departments, compiles surveillance and investigation information across counties, and provides infrastructure statewide to support infectious disease surveillance. Data on laboratory-confirmed and probable (*5*) COVID-19 cases (based on the Council of State and Territorial Epidemiologists case definitions)† were collected in the centralized Medical Electronic Disease Surveillance Intelligence System (MEDSIS),§ which is used by state, tribal, and county public health agencies to report human-based diseases in Arizona. Information was submitted to or entered into MEDSIS by health care providers, laboratories, local health departments, tribal entities, and ADHS. Multiple laboratory tests submitted for a single patient were combined into a single record. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

Temporal trends were examined by comparing the number of daily COVID-19 cases (as of September 1)¶ and 7-day moving averages before, during, and after implementation of enhanced community mitigation measures, defined as the following: limitations on persons' time away from their place of residence

*Mandates and ordinances varied and were county- and city-specific. Enforcement types included educating persons on the dangers of COVID-19 spread, issuing fines to persons and businesses who refused to comply with mandates, and loss of licenses for businesses not enforcing rules or mandates.

except for essential activities; certain business closures and service limitations (e.g., occupancy limitations, curbside pickup, and delivery of goods); enhanced sanitation practices**; social distancing, employee mask wearing, and symptom screenings for all businesses operating a physical location; limitations on the occurrence and size of public events; and local mandates enforcing mask use. The 7-day moving average was calculated after the cumulative case count exceeded 20 cases and is presented to describe COVID-19 trends.

On March 11, 2020, Arizona declared a public health state of emergency to prepare for, prevent, respond to, and mitigate the spread of SARS-CoV-2. Additional guidance was provided to local officials, businesses, communities, and individual persons to implement social distancing and close schools statewide (March 15); postpone and limit large gatherings to fewer than 50 persons; recommend telework options; restrict access to congregate settings; require restaurants to provide dine-out options only; and close all bars, gyms, and movie theaters in counties with confirmed COVID-19 cases (March 19) (Table). Based on Arizona data and CDC guidance (*1*,*2*), ADHS also recommended limiting persons' time away from their place of residence except for essential activities (i.e., stay-at-home order, "Stay Home, Stay Healthy, Stay Connected")†† (March 31).

During April 1–May 15, the 7-day moving average of daily cases ranged from 154 to 443 (Figure). During April 29–May 11, Arizona initiated a phased approach for retail shops and stores, cosmetologists, and barbers to reopen and operate, and for restaurants to resume dine-in services; the stay-at-home order ended May 15.

Average daily cases increased 151% from June 1 (808) to June 15 (2,026), necessitating an increased focus on preventive measures by businesses, communities, and individual persons. Updated guidance from state officials provided local governments the authority to implement mask policies (June 17) and enforcement measures tailored to local public health needs (local policies were applicable to approximately 85% of the total Arizona population). Before June 17, mask wearing had not been widely mandated or enforced. Arizona limited organized public events to fewer than 50 persons (with some exceptions); closed bars, gyms, movie theaters, and water parks and recreational tubing facilities (June 29); and limited restaurants' indoor dining to <50% capacity, with at least 6 feet of separation between patrons (July 9). The 7-day moving average of daily cases peaked during

** Based on guidance from ADHS, CDC, and the Department of Labor, and Occupational Safety and Health Administration to limit and mitigate the spread of COVID-19, including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

TABLE. Public policies to implement and enforce COVID-19 community mitigation measures and dates of issue/reissue* — Arizona, March 11–August 7, 2020

Mitigation measure	Date of issue/reissue
Declaration of emergency	Mar 11
School closure (on-site learning)	Mar 15
Limits on senior living facilities visitation	Mar 19
Expanded availability and coverage for telemedicine for persons, pets, and animals	Mar 25, Apr 1
Deferred requirements to renew driver license	Mar 20
Stay-at-home order	Mar 30–May 15
Business/Service closures	
Bars	Mar 19, Jun 29, Jul 23
Movie theaters	Mar 19, Jun 29, Jul 23
Indoor gyms and fitness clubs	Mar 19, Jun 29, Jul 23
Restaurants, on-site dining	Mar 19
Pools	Mar 19
Water parks and recreational tubing facilities	Jun 29, Jul 23
Business/Service limits (requirements)	
All businesses operating a physical location (enhanced sanitation,† social distancing, employee mask wearing, symptom screenings)	Jun 17
Retail (limited capacity, social distancing, enhanced sanitation)	Apr 29
Barbers and cosmetologists (employee mask wearing, spaced appointments, enhanced sanitation)	May 4
Restaurants (social distancing, limited capacity, employee mask wearing, patron mask wearing [when not eating or drinking], employee screening, enhanced sanitation)	May 4, Jul 9
Public pools (e.g., at hotels; limited capacity)	Jun 29, Jul 23
Private pools in public areas (e.g., multihousing complexes; limited capacity)	Jun 29, Jul 23
Public events (<50 persons)	Mar 15, Jun 29, Jul 23
Wearing masks (mandatory)	
Local officials able to mandate and enforce wearing masks	Jun 17
Yuma County	Jun 18
Maricopa County	Jun 19
Pima County	Jun 19
Santa Cruz County	Jun 19
Coconino County	Jun 20
>40 other cities/tribal communities	Jun 17–25§

Abbreviation: COVID-19 = coronavirus disease 2019.

* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† Based on guidance from the Arizona Department of Health Services, CDC, Department of Labor, and Occupational Safety and Health Administration (OSHA) to limit and mitigate the spread of COVID-19 including promoting healthy hygiene practices; and intensifying cleaning, disinfection and ventilation practices.

§ Other tribal communities with mask mandates (issued June 18–23) included Fort McDowell Yavapai Nation, Gila River Indian Community, Navajo Nation, Salt-River Pima-Maricopa Indian Community, Tohono O'Odham Nation. Other cities with mask mandates (issued June 17–25) included Avondale, Bisbee, Buckeye, Carefree, Casa Grande, Chandler, Clarkdale, Clifton, Coolidge, Cottonwood, Douglas, Flagstaff, Fountain Hills, Gila Bend, Gilbert, Glendale, Globe, Goodyear, Guadalupe, Jerome, Kingman, Litchfield Park, Mammoth, Mesa, Miami, Nogales, Oro Valley, Paradise Valley, Payson, Peoria, Phoenix, San Luis, Sedona, Scottsdale, Somerton, Superior, Surprise, Tempe, Tolleson, Tucson, Youngtown, Yuma. Several other tribal communities and cities encouraged but did not mandate wearing masks.

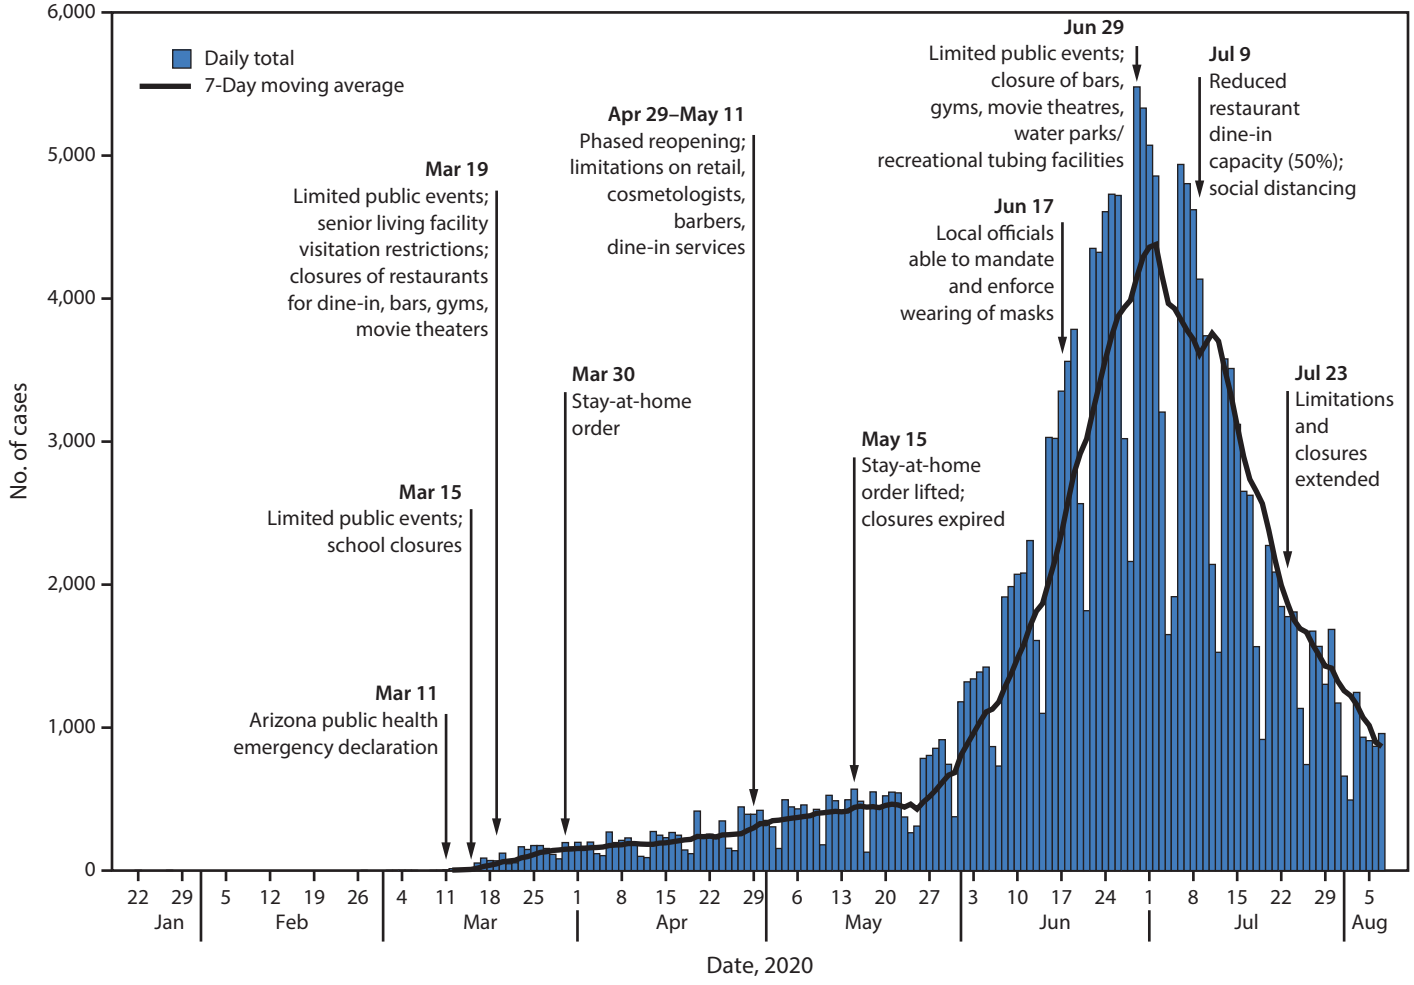
FIGURE. Selected community mitigation measures* and COVID-19 case counts† and 7-day moving averages§ — Arizona, January 22–August 7, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Issue dates are the dates the issuing official signed the order implementing the mandatory mitigation measure. In some instances, mitigation measures were effective either immediately or within 1 to 3 days of issue. https://www.azdhs.gov/preparedness/epidemiology-disease-control/infectious-disease-epidemiology/index.php#novel-coronavirus-admin-orders; https://azgovernor.gov/executive-orders.

† As of September 1, 2020. Specimen collection date was used for confirmed cases, and symptom onset date was used for probable cases.

§ Plotting of 7-day moving average began when cumulative case count exceeded 20 cases.

June 29–July 2 (range = 4,148–4,377), stabilized during July 3–12 (range = 3,609–4,160), and subsequently decreased 75% from July 13 (3,506) to August 7 (867). Mitigation measures put in place in June were extended through August to further limit transmission.

Discussion

Quantitative data on the effectiveness of community mitigation measures at suppressing the spread of COVID-19 are limited. The primary goal of implementing widespread enhanced mitigation measures in Arizona was to protect and save lives and maintain capacity in the health care system. A combination of voluntary and enforceable measures is more effective than any single measure (*6*). Mitigation measures mandated through public policy can effectively increase social distancing (*7*), and wearing masks has prevented transmission of SARS-CoV-2 (*8*). In Arizona, decreases in daily COVID-19 cases were observed after widespread sustained community mitigation measures that promoted social distancing, limited large gatherings, paused operations of businesses where mask use and social distancing were difficult to maintain, mandated and enforced mask wearing, and promoted voluntary resident actions to stay at home and wear masks (when and where not mandated). The number of COVID-19 cases stabilized and began to decrease approximately 2 weeks after local officials began mandating mask wearing (throughout several counties

MS-DOH-21-1816-A-000449

and cities) and enhanced sanitation practices. Additional declines in case counts were associated with implementation of statewide limitations and closures sustained throughout July and extended into August.

The findings in this report are subject to at least four limitations. First, the relationship between mitigation measures and changes in case counts are temporal correlations and should not be interpreted to infer causality. Other factors that might have influenced the rate of change (e.g., travel restrictions, neighboring state mitigation measures, and individual choices to reduce movement before implementation of mandates) cannot be ruled out. Second, health centers run by tribal entities and federal health facilities (i.e., Indian Health Service, Veteran's Administration, and Department of Defense) in the state are requested but not required to comply with state reporting rules. Many of these health centers and federal health facilities complied with reporting, but the completeness of reporting by these entities is unknown. Third, adherence to mitigation measures was not assessed, nor could the extent to which each individual measure affected the number of incident COVID-19 cases be established. Finally, Arizona might not be representative of other U.S. states, and community mitigation measures might have a different impact in more populous or densely populated states; thus, these findings are not necessarily generalizable to other settings.

Enhanced mitigation measures should be implemented by communities and persons to slow COVID-19 spread, particularly before a vaccine or therapeutic treatment becomes widely available. State, local, and tribal officials are best positioned to continually monitor data and collaborate to determine the level and types of enhanced mitigation required. Mitigation measures, including mask mandates, that are implemented and enforced statewide appear to have been effective in decreasing the spread of COVID-19 in Arizona.

Summary

What is already known about this topic?

Community mitigation measures can help slow the spread of COVID-19.

What is added by this report?

The number of COVID-19 cases in Arizona stabilized and then decreased after sustained implementation and enforcement of statewide and locally enhanced mitigation measures, beginning approximately 2 weeks after implementation and enforcement of mask mandates and enhanced sanitations practices began on June 17; further decreases were observed during July 13–August 7, after statewide limitations and closures of certain services and businesses.

What are the implications for public health practice?

Widespread implementation and enforcement of sustained community mitigation measures, including mask wearing, informed by state and local officials' continual data monitoring and collaboration can help prevent transmission of SARS-CoV-2 and decrease the numbers of COVID-19 cases.

Field Notes

King County Monitors the Ongoing Economic, Social, and Health Effects of COVID-19

Community mitigation strategies used to slow pandemics—such as physical distancing policies, mask mandates, avoiding crowds, hand washing or using hand sanitizers, business and school closures, and travel restrictions—can reduce the spread of disease but have other effects on individual health and community well-being. As the local health jurisdiction tasked with protecting the health of its residents, Public Health—Seattle & King County (PHSKC) needed to quickly develop ways to monitor and evaluate the ongoing social and economic impacts of the COVID-19 mitigation response. The first COVID-19 case diagnosed in the United States came through the international airport in King County, Washington, in January 2020, with additional community-acquired cases

diagnosed among King County residents in February 2020. As cases began to increase, state and local governments enacted strategies designed to prevent person-to-person spread of the novel coronavirus.

In population health assessments, King County often performs better than the US average but continues to face stark health disparities by race/ethnicity, location, and income. COVID-19 is no exception. With support from CDC, PHSKC incorporated aspects of CDC's approach to evaluating COVID-19 community mitigation strategies to track various social, emotional, and economic impacts on the King County community since April 2020.

Attachments:	image001.png IDPC Meeting Notes_11.22.2021.docx DRAFT - Public Health Authority Policy Statement.002.docx

Good afternoon,

Thank you for participation in last week's IDPC call. Attached please see notes from the call and an updated draft of the *Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease* policy statement.

- Since we met last week, we have been fortunate to gain a new IDPC member! **Dr. Manisha Juthani (SHO-CT)** has agreed to serve on the IDPC and plans to join us on our next call. Please join me in welcoming her to our group.
- *Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease* policy statement: Andy incorporated edits from our call in the attached draft. **If you are interested in meeting with Andy as a small group to wordsmith the draft, please let me know and I'll work to propose a few dates and times for that conversation.**
- As I mentioned during the call, Alyssa Boyea from our staff will be also be sending a request for your feedback to the questionnaire to assess public opinion on rebuilding trust and confidence in public health after the Thanksgiving holiday.
- Additionally, CDC's National Center for HIV, Viral Hepatitis, STD, and TB Prevention (NCHHSTP) will soon be updating its Data Security and Confidentiality Guidelines. The purpose of the document is to recommend standards for all NCHHSTP programs that, when adopted, will facilitate the secure collection, storage, and use of data while maintaining confidentiality. NCHHSTP has requested that ASTHO provide concrete examples and feedback on what needs to be updated in these guidelines. Please share anything you think should be added, removed, or reframed within these guidelines with me by **December 15.**

Lastly, the next IDPC call is scheduled for **February 15, 2022 at 12PM ET**. An agenda and call-in information will be sent closer to the call. Please send any suggested agenda topics to me.

Thank you all for your continued support of the IDPC and have a wonderful Thanksgiving.

PUBLIC HEALTH AUTHORITY TO PREVENT AND CONTROL THE SPREAD OF COMMUNICABLE AND INFECTIOUS DISEASE

POSITION

The Association of State and Territorial Health Officials (ASTHO) supports the establishment of robust public health legal authorities to facilitate the timely and adequate response to communicable and infectious disease outbreaks. These legal authorities are often exercised without the need of an emergency declaration and may allow, among other things, the abatement of nuisances, investigation of the causes of disease, institution of quarantine measures, ordering individuals or groups to isolate, conducting contact tracing and case investigations, collecting data, temporarily limiting or canceling public events, temporarily restricting or closing venues, and requiring vaccination verification for certain conduct and activities (e.g., school attendance). Beyond their use in the response to the historic pandemic caused by the novel coronavirus, in the past, these powers have been routinely exercised for more commonly experienced disease outbreaks, such as mumps and measles. Additionally, other societal sectors, such as business, education, cultural, and religion often depend on public health to stop the spread of infectious disease, prevent widespread disruptions, and quell public anxiety and fear. Maintaining these state and territorial legal authorities are key to being prepared for communicable and infectious disease outbreaks both now and in the future.

Summary of Recommendations:

- Ensure public health authority that can respond to future disease outbreaks without undue delay.
- Support public health authority that is guided by data and science.
- Ensure public health authority that protects the public's interest and well-being.

BACKGROUND

Establishing and using legal authority to control the spread of infectious disease dates to before the founding of the country. For example, colonial governments implemented isolation and quarantine precautions for incoming ships to prevent the introduction and spread of smallpox and other contagions.[1] These powers and activities were seen not only as a way of protecting the health of the local communities but also protective of trade and commerce.[2] As the scientific understanding of communicable and infectious disease grew, new tools such as contact tracing, disease investigation, data collection, and vaccines were added to public health's legal authority and practice. During the current pandemic public health authority has been used, with evidenced benefit, to slow the spread of the coronavirus by limiting the size of gatherings, encouraging social distancing, temporarily closing high-risk venues, and requiring the use of face coverings in certain places.[3,4,5,6,7,8,9]

Despite the successes in exercising public health authority, grave questions and negative perceptions about the role and use of public health powers in response to the pandemic and, by implication, future infectious disease outbreaks have arisen. Over the last year, the critical attitude toward the pandemic response has led to the rolling back of public health authority in several jurisdictions.[10] The reductions in public health legal authority will conceivably make it more difficult to respond to future disease outbreaks. As state and territorial policy makers continue to address the many issues related to the current pandemic, they are encouraged to consider these potential impacts and costs.

RECOMMENDATIONS

With regards to state and territorial public health authority to prevent and control the spread of communicable and infectious disease, ASTHO recommends:

- Ensuring public health legal authority that is appropriate and necessary for the prevention and control of future communicable and infectious disease outbreaks. Highly contagious illnesses, like measles, can be effectively contained through the public health measures and activities that are being questioned and criticized during the COVID-19 pandemic. We are unsure how the next major disease outbreak will spread and public health authority must be ready and able to respond to future diseases. Public health authority to implement non-medical and medical interventions swiftly and adeptly must be maintained and the creation of administrative burdens that delay public health action, endangers the public well-being, and leaves communities vulnerable to infectious disease outbreaks, should be avoided.
- Supporting evidence-based laws and policies for the identification, prevention, and control of communicable and infectious diseases. Public health authority should align with present and future diseases that public health agencies are obligated and required to confront and the authority should also be exercised in a manner that addresses the identifiable, known characteristics of the disease outbreak.
- Ensuring that public health legal authority properly and adequately balances a public health agency's obligations and requirements to protect the public's health and well-being with the rights of individuals. Laws and policies that undermine and encumber a public health agency's obligations or arbitrarily limit the agency's authority, impede disease prevention and control. Public health authority that is reasonable and aligned with the preventing and controlling the spread of infectious disease should be established and maintained.

APPROVAL DATES

Prevention Policy Committee Approval:
Board of Directors Approval:
Policy Expires:

ASTHO membership supported the development of this policy, which was subsequently approved by the ASTHO Board of Directors. Be advised that the statements are approved as a general framework on the issue at a point in time. Any given state or territorial health official must interpret the issue within the current context of his/her jurisdiction and therefore may not adhere to all aspects of this Policy Statement.

IDPC Meeting

Attending

- Jose Romero
- Scott Harris
- Thomas Dobbs
- Randy Mayer
- Joe McLaughlin
- Kris Ehresmann
- Jeff Stover
- Carolyn McCoy
- Kate Heyer
- Grace Lee
- Andy Baker-White
- Meredith Allen
- Ericka McGown
- Marcus Plescia

Meeting Notes

- Carolyn McCoy (ASTHO) provided an update on her discussion between staff in Rep. Rosa De Lauro's office from the Appropriations Committee with Dr. Dobbs on flexible funding.
    - ASTHO has been tracking three key issues:
        - Bipartisan Infrastructure Bill was signed into law.
        - Build Back Better Act, which is awaiting a score from the Congressional Budget Office (CBO) before being sent to members of Congress who will move on a vote.
            - The House may take it to the floor this week, despite parts of the CBO scoring estimates not coming out until the end of this week.
            - ASTHO is keeping track of this proposal because 7.5 billion is allocated for PH preparedness in the proposal.
        - The Fiscal Year 2022 Fiscal Appropriations process is underway.
            - Dr. Dobbs spoke to Senate Appropriations y staff. There is $1 billion proposed in the House, $600 million proposed in the Senate for flexible funding for PH infrastructure.
    - Federal funding runs out on Dec 3rd, and it is largely acknowledged that there is a need for a short-term continuing resolution. There is a question on how long this funding will last and if it will go into the 2022 election year. Likely fiscal fallout from not raising the debt ceiling would be catastrophic.

Andy Baker-White (ASTHO) shared the draft of the ***Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease*** policy statement

- IDPC members discussed some edits that could be made on the list of recommendations.
    - State health officials shared that they have gotten far less resistance on isolation/quarantine mandates directed towards individuals compared to broader

PH-based population-based interventions (mask and vaccine mandates, school closures, etc.)

- Members emphasized the need to make sure that the recommendations section needs to be concise as some may not read the rest of the statement.
- Members expressed appreciation for the statement striking a balance between protecting individual rights and ensuring the public wellbeing. Many people do not recognize their obligation to protecting community health, so making this statement stronger would be a suggestion.
    - Joe McLaughlin said that CSTE has a public health law subcommittee, and it be helpful to reach out to them for some collaboration.
        - ASTHO has a steering committee of attorneys to who can also provide feedback.
    - Dr. Dobbs said many people don't respect the individual liberties of people who want to be safe during the pandemic. The pandemic has allowed those who are reckless to rob freedoms from people who want to live safely.

- The ***Preparing for the Next Pandemic/Public Health Crisis*** white paper was presented to the IDPC to gather feedback and edits.
    - The pandemic has highlighted how the PH sector has received a lot of funding, but that it is not always at the right time or for the right activities. Action-based flexible funding is necessary.
    - Members expressed a need for an all-hazards preparedness and response plan that is more nimble, more useful, less cumbersome, and easy for all those in the workforce to access and execute a pandemic response plan.
        - The white paper should acknowledge the role of misinformation during a pandemic response. Communications have been a challenge, especially for those whose first language was English. It's important to think about non-English speaking populations when planning for and throughout a response.
        - Ensuring judicious use of FEMA funds, proposing requiring a 100% federal match, and increasing surveillance capacity were all discussed as additional recommendations to the white paper.
    - Depoliticization of public health is vital in future pandemic responses. State leaders should be trained to be prepared to navigate political environments early and frequently in their work at a health agency. Legislators must support state health departments and the science.
    - There is a critical need to instill and boost trust in public health.
        - Mandates are challenging to explain when you're trying to increase trust in public health because they further emphasize and exacerbate public health fears of government overreach.
        - Emphasizing that PH is prevalent in everyday life, not just during a pandemic, is crucial for boosting the public's education on the role of PH.
            - State health agencies should emphasize that we train for PH responses through everyday PH initiatives.

- Another white paper is currently being drafted by MIT. It may be useful to reference this document, specifically on using technology for surveillance. Having an IT infrastructure is part of the PH infrastructure.
- Members emphasized that now, during the COVID-19 pandemic, is the most important time to get ahead of PH fear and mistrust.
- Members discussed ways to build back trust in public health. Members discussed whether the IDPC believes that a year from now there is going to be this level of mistrust. He wanted more perspective on trust as an issue going into the future, or if mistrust is just an issue now.
    - Dr. Dobbs said that they are using their roles as leaders to promote other important PH topics, because PH is broader than a pandemic.
    - Jeff Stover said VA is doing some marketing on a "PH Reality Campaign". Using the environment of the COVID-19 pandemic right now serves as platform to educate people on what PH really is.

- Next topics for future IDPC calls:
    - Trust in public health institutions.
    - Negative test reporting, contact tracing (for conditions outside of COVID such as STDs and TB), frequency of case reporting, and what the markers are for COVID becoming endemic.

Action Items

- Andy Baker-White will incorporate the IDPC's suggested edits in the draft of the policy statement. Any members who wish to send proposed edits via e-mail can e-mail kheyer@astho.org or reach out to set up a time for a call with Andy
- ASTHO will incorporate the IDPC's suggestions into the white paper and consider whether to engage public health attorneys to review. The ASTHO team will also solicit feedback from the ASTHO Preparedness Policy Committee and provide a draft back for IDPC review.

Hello, IDPC members,

Attached are the notes and suggested action items from the August IDPC call. I ask that you please not distribute the notes outside of this group.

I will send a draft of the *Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease* policy statement when it is ready.

Given the preference for a quarterly meeting, we will plan to hold the next call on **November 16 at 12PM ET**. An Outlook invitation is forthcoming.

Thank you again and please do not hesitate to reach out with any questions or discussion items for the next call.

IDPC Meeting – August 17, 2021

Attendees: Thomas Dobbs (MS, IDPC Chair), Scott Harris (AL), Jose Romero (AR), Terry Dwelle (Alumni-ND), David Lakey (Alumni-TX), Randy Mayer (NASTAD Rep – IA), Joe McLaughlin (CSTE Rep - AK)

Key Takeaways:

- State legislatures are receiving a lot of pushback on issuing policies relating to vaccine mandates, mask mandates, school reopening, and other public health measures. There has been conflict and confusion between the roles of state legislative bodies and state health officials on authority to implement public health measures in many states.
- Communication remains a barrier between national, state, and local levels, which further elevates confusion amidst the pandemic.
- There is a dire need to critically think about and reevaluate the future of pandemic response. The COVID-19 pandemic has been a heavily politicized topic in public health. Public health must move towards working with politicians, and state legislatures must publicly show support for state health officials, striving to reach a compromise between both parties.
- Misbeliefs on the COVID-19 pandemic are far entrenched in many communities across the country. It is important to utilize both horizontal and vertical communicators to transform communities. Joining forces with healthcare providers (especially private physicians), increasing transparency within the CDC, ensuring continued healthcare access, engaging academic medical centers, and utilizing community healthcare workers are all ways to bridge gaps. It is vital to engage all stakeholders to ensure no one is working within a silo.
- ***Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease policy statement*** discussion**:** ASTHO supports state and territorial frameworks that establish a robust authority on the response to disease outbreak.
    - Recommendations:
        - Public health powers should be such that they facilitate timely, flexible responses to disease outbreak.
            - Legislative oversight must allow for timely and flexible responses
        - Legal frameworks must be reliable and reasonable so that they can be aligned with the disease(s) that need to be prevented or managed.
        - Any sort of public health authority to direct the mitigation of the disease is to be guided by data and science.
        - This legal framework is to prepare and respond to future unknown outbreaks.
    - SHOs had some thoughts on the policy statement and recommendations. The state legislature should be involved in these conversations. This policy statement should separate the daily activities that stop daily outbreaks from historic events that have tremendous economic impacts on the state. SHOs would also like to hear something about the balance of individual rights and the importance on why states have an interest in preventing disease.

Action Items:

- ASTHO will develop the first draft of the policy statement to disseminate for review and comment.
- ASTHO staff will reach out to invite Dr. Jay Butler (CDC) and/or Dr. John Auerbach (CDC) for a discussion with the IDPC on a future call about bridging science and politics in public health to generate consistent messages across the political spectrum.
- ASTHO's ID Guiding Principles need to be updated, approved, and in a policy statement format by September 2022. ASTHO staff will add detail about delineating federal vs. state responsibilities for pandemic response for committee review.

Proposed Activities for Future IDPC Engagement:

- Continue discussing options for SHOs to take more proactive action with governors when they propose or implement actions that do not support public health goals. Strategies should include advance relationship-building before a pandemic emerges. Additional efforts should also be focused on engaging private physicians—to assist with depoliticizing future responses. Included in this is reiterating the role of the SHO: SHOs *should* be a bridge between politics and science.
- Consider sharing state public health leaders' experiences working to increase the credibility of public health during the COVID response via ASTHO's *Public Health Review Morning Edition* podcast. Note: this is an outlet we can use to share innovative ideas or to discuss public health priorities across any public health topic area.

Hi Dr. Dobbs,

Attached please see the high-level notes and proposed action items from the August IDPC call. I have 2 comments in the document that I would appreciate your thoughts on before I distribute to the committee. Please let me know if you approve of the notes and any thoughts about the proposed action items.

Also, would you like to plan for the next IDPC call to be held on November 16 at 11AM CT/12PM ET? That would fit the quarterly cadence the members requested and is in the same time block as our August call. If that does not work, I will send a Doodle poll for scheduling.

Best, Kate

    - SHOs had some thoughts on the policy statement and recommendations. The state legislature should be involved in these conversations. This policy statement should separate the daily activities that stop daily outbreaks from historic events that have tremendous economic impacts on the state. SHOs would also like to

hear something about the balance of individual rights and the importance on why states have an interest in preventing disease.

Action Items:

- ASTHO will develop the first draft of the policy statement to disseminate for review and comment.
- ASTHO staff will reach out to invite Dr. Jay Butler (CDC) and/or Dr. John Auerbach (CDC) for a discussion with the IDPC on a future call about bridging science and politics in public health.

Commented [KH1]: Dr. Dobbs, can you provide any additional detail about this request to help me frame my outreach?

Proposed Activities for Future IDPC Engagement:

- Consider options for SHOs to take more proactive action with governors when they propose or implement actions that do not support public health goals. Would include advance relationship-building before a pandemic emerges. Additional efforts should also be focused on engaging private physicians—to assist with depoliticizing future responses. Included in this is reiterating the role of the SHO: SHOs *should* be a bridge between politics and science.
- Develop a framework for future pandemic response, delineating federal vs. state responsibilities.
- Consider sharing described by Joe McLaughlin to increase the credibility of public health by reaching out via routine ECHOs with healthcare providers, scientists, and the media during the COVID response via Public Health Review Morning Edition podcast. Note: this is an outlet we can use to share innovative ideas or to discuss public health priorities across any public health topic area.

Commented [KH2]: Since the ID Guiding Principles need to be updated, approved, and in the policy statement format by September 2022, this could be the best place to address this.

Updates on the Federal Retail Pharmacy Program for COVID-19 Vaccination

The initial phased implementation of the program will begin with select retail pharmacies administering COVID-19 vaccine across the country as early as Thursday, February 11. The program will be implemented incrementally, based on the available supply of COVID-19 vaccines. As the vaccine supply increases, the program aims to expand the number of participating pharmacy locations ultimately providing COVID-19 vaccines in all 40,000 retail pharmacy locations nationwide. Allocations to support the Federal Retail Pharmacy Program are separate from weekly allocations provided to jurisdictions. What jurisdictions see in their weekly allocation will remain stable.

Eligibility Criteria for Vaccination

The Federal pharmacy partners will administer vaccine to individuals according to state-selected eligibility criteria. Pharmacy partners have developed screening questionnaires specific to each jurisdiction's criteria and will finalize them based on the survey results to help ensure eligibility prior to vaccination. After launch, immunization program managers will be able to update eligibility criteria weekly using an application in Tiberius, the centralized system used by the federal government to support vaccine distribution efforts. Information about how to use this new Tiberius application will be sent to immunization programs this week.

Program Data and Monitoring

By Friday, CDC will provide a list of the retail locations that will be providing COVID-19 vaccine in each jurisdiction as part of the initial phased implementation of the program.

All pharmacy partners enrolled in the Federal Retail Pharmacy Program are required to report inventory daily to VaccineFinder and patient administration information to the jurisdiction's IIS as

well as directly to CDC's Data Clearing House. Jurisdictions will have access to patient administration data submitted by all pharmacies in their jurisdiction. Jurisdictions will also have access to information in Tiberius-specific to pharmacy programs.

Information will include details on stores that will be receiving vaccine, store-level supply information, and administration/uptake information as it becomes available. Jurisdictions will also be provided points of contacts for pharmacy partners to facilitate coordination with partners.

Communications Support
CDC has developed a **toolkit of materials** to help jurisdictions and partners describe and communicate about the implementation of the Federal Retail Pharmacy Program. We hope these materials will assist in providing clear and consistent information about the program goals and parameters.

The toolkit includes the attached materials for your use and reference:

- Frequently Asked Questions about the Program for Jurisdictions and Pharmacy Partners
- Key communication messages for jurisdictions and pharmacy partners
- A One-Page Fact Sheet on the Federal Retail Pharmacy Program (to share with partners or members of the community)

Upcoming Trainings/Webinars/Jurisdictional Calls

- Below is a link to a series of accredited education about COVID-19 vaccine in general, safety, and administration considerations.
    - Vaccine Courses, Broadcasts, Webcasts and Self Study Training | CDC
- Tiberius users can access the training video on submitting transfer requests at the following link: https://protect-ows.hhs.gov/workspace/compass/view/ri.compass.main.folder.c95b290c-2561-4cd1-85f7-e31dac51d34b [protect-ows.hhs.gov

- Live webcast link and agenda found here

COVID-19 Resources

- Vaccine Confidence Consultations from Vaccine Task Force
  - This email serves as an entry point to many vaccine confidence consultation options offered by CDC. Vaccine confidence and communications experts will receive emails from providers and public health professionals and then set up brief calls to understand needs, tailor support, and provide further technical assistance in data collection, creation of communication products and more to promote community vaccine confidence for COVID-19 vaccines. They can be contacted at confidenceconsults@cdc.gov
- ELC Enhancing Detection Expansion FAQ (attached)
  - Developed by the ELC Team, this FAQ answers common questions about Enhancing Detection Expansion funding for jurisdictions. More information can be found on the ELC Website.
- Factsheet: 12 Things Jurisdictions Need to Know about VAERS (attached)
  - A factsheet developed by VTF on how to report adverse events following vaccination to the Vaccine Adverse Events Reporting System (VAERS)
- The COVID State-Profiles Report (aka Governors Report) is now posted publicly at COVID Data Tracker, and will be updated weekly. As a reminder, Community Profile Report has been posted publicly since December, and is updated daily. There is also a public facing version of the **T**herapeutics Distribution Location Tool**.**
- COVID-19 Vaccination Communication Toolkits for Community- Based Organizations and Essential Workers
  - COVID-19 vaccines will be available to essential workers and other community members soon. CDC has designed two toolkits to help build confidence in this new vaccine. The toolkits will help community-based organizations (CBOs) and employers to educate community members and workers about COVID-19 vaccines, raise awareness about the benefits of vaccination, and address common questions and concerns.

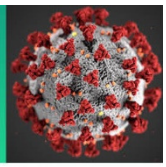
COVID-19 Science Update



From the Office of the Chief Medical Officer, CDC COVID-19 Response, and the CDC Library, Atlanta, GA.
Intended for use by public health professionals responding to the COVID-19 pandemic.

***** Available on-line at https://www.cdc.gov/library/covid19 *****

Section headings in the COVID-19 Science Update align with the CDC Science Agenda for COVID-19.

Detection, Burden, and Impact

PEER-REVIEWED

Antigen-based testing but not real-time polymerase chain reaction correlates with severe acute respiratory syndrome coronavirus 2 viral culture. Pekosz *et al.* Clinical Infectious Diseases (January 20, 2021).

Key findings:

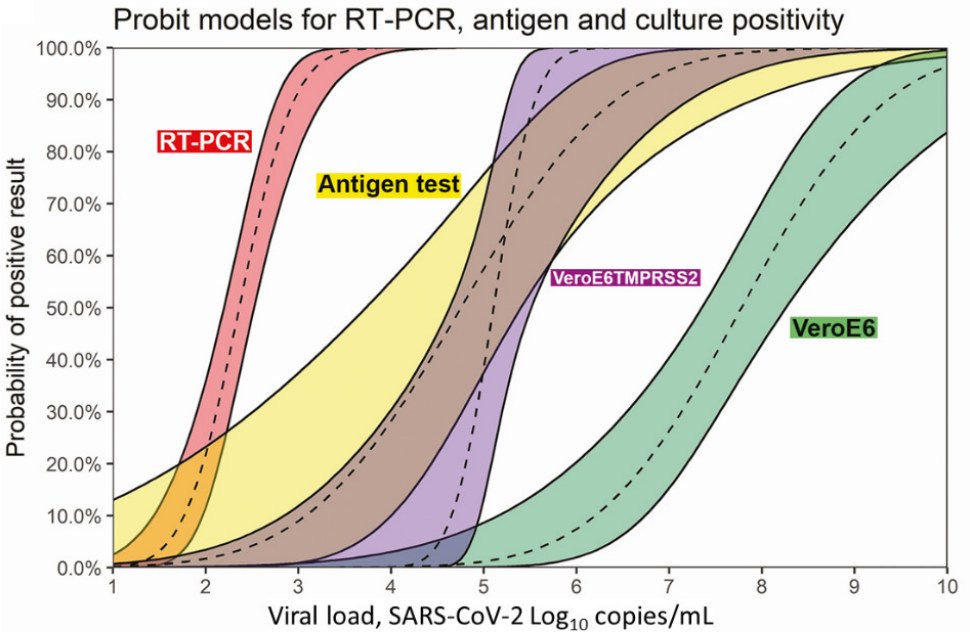
- The BD Veritor antigen test had a higher positive predictive value (PPV) (90.0%, 95% CI 76.3%-97.6%) than the Quidel Lyra RT-PCR SARS-CoV-2 test (73.7%, 95% CI 60.8%-85.3%) relative to positive viral culture.
- Viral culture using VeroE6TMPRSS2 cells, which are susceptible to infection by influenza and coronaviruses, correlated better with antigen tests compared with VeroE6 cells (Figure).

Methods: RT-PCR and antigen tests were compared with SARS-CoV-2 viral cultures from 38 adult patients sampled within 7 days of symptom onset across 21 US localities in June 2020. Probability of positivity and viral loads were fit with probit models for each testing method. *Limitations*: Correlations may be valid only for samples taken within 7 days from symptom onset; small sample of symptomatic adults.

Implications: Point-of-care antigen tests might minimize the spread of SARS-CoV-2 by identifying infectious adults in areas of high community transmission.

MS-DOH-21-1816-A-000479

Figure.



Note: Adapted from Pekosz *et al.* Modelled probability distributions of each SARS-CoV-2 test type, **RT-PCR**, **antigen**, and viral cultures (**VeroE6TMPRSS2** and **VeroE6**), across log-transformed viral load. As viral load increases, the probability of any test producing a positive result increases. Licensed under CC BY-NC-ND 4.0.

PREPRINT (NOT PEER-REVIEWED)

Predictive power of SARS-CoV-2 wastewater surveillance for diverse populations across a large geographical range. Melvin *et al.* medRxiv (January 25, 2021).

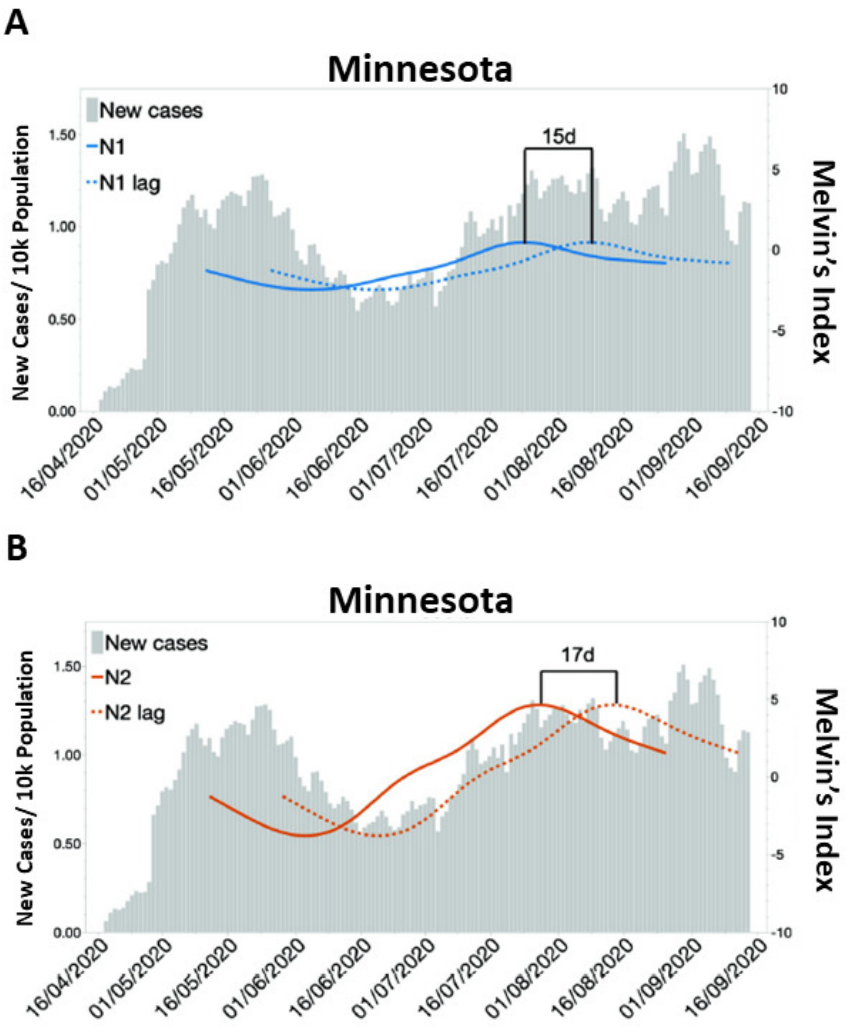
Key findings:

- In Minnesota, wastewater SARS-CoV-2 RNA levels, using RT-PCR to amplify 2 nucleocapsid gene targets (N1 and N2), predicted new clinical cases with a lag of 15 days for N1 ($r = 0.73$, $p < 0.001$) and 17 days for N2 ($r = 0.77$, $p < 0.001$) (Figure).

Methods: Compared Minnesota Department of Health COVID-19 case data with indexed SARS-CoV-2 RNA levels in municipal wastewater from 19 Minnesota cities in summer 2020. Developed a novel index (Melvin's Index) of wastewater SARS-CoV-2 viral load, standardized based on a plant virus that is abundant in human feces, to control for factors such as treatment facility capacity, flow rate, and population size. Successively lagged Melvin's Index values in 1-day increments to find the lag time (between observing an increase in SARS-CoV-2 RNA in wastewater and the appearance of confirmed new COVID-19 positive tests) that maximized correlation (r) between Melvin's Index and new confirmed cases. *Limitations*: Variations in clinical SARS-CoV-2 testing might affect correlation with population wastewater viral load.

Implications: Wastewater surveillance for SARS-CoV-2 might allow early detection of local outbreaks, especially where access to healthcare services is limited. A study in Barcelona found SARS-CoV-2 was detected in sewage collected 41 days before the first COVID-19 case.

Figure.



Note: Adapted from Melvin *et al*. Correlation and lag analysis of wastewater SARS-CoV-2 levels with new COVID-19 clinical cases in Minnesota. **A)** Indexed **N1 levels in real time** and **transposed (dotted line)** to show lag (15 days) to clinical case reports **B)** **N2 levels in real time** and **transposed (dotted line)** to show lag (17 days) to clinical case reports. Licensed under CC BY-ND 4.0.

Transmission

PEER-REVIEWED

Resurgence of COVID-19 in Manaus, Brazil, despite high seroprevalence. Sabino *et al.* Lancet (January 27, 2021).

Key findings:

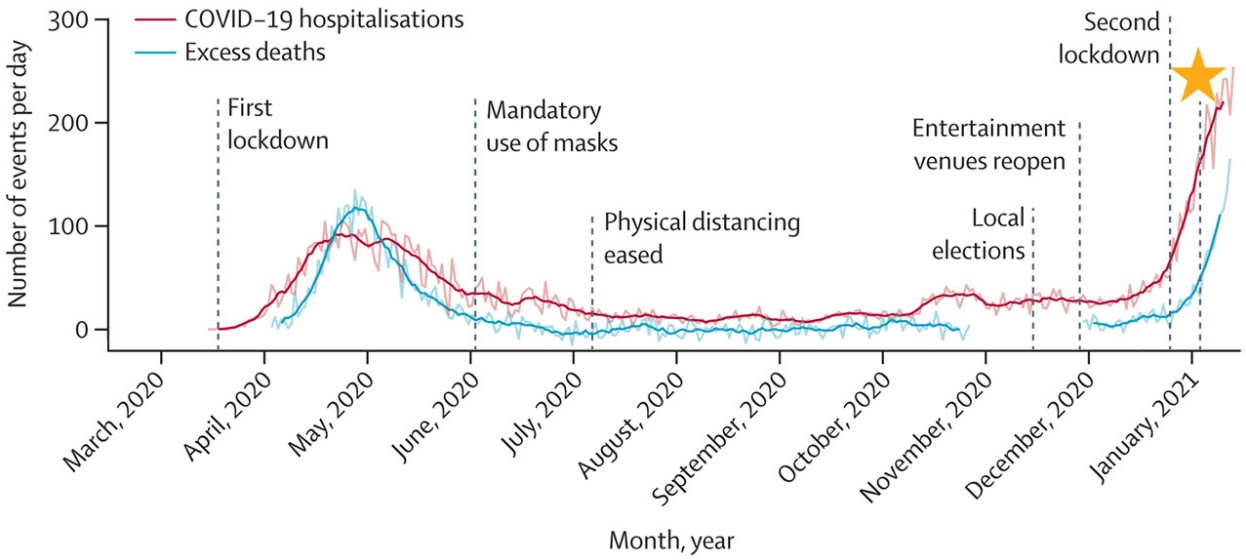
- Manaus, Brazil experienced a sharp rise in COVID-19 hospitalizations in January 2021 despite extensive transmission earlier in the pandemic and rates that had been stable and low for 7 months during relaxed COVID-19 mitigation (Figure).
- There are 4 possible explanations for the surge.
    - Greater mixing of susceptible and infected persons in December 2020.

- Waning immunity in the population.
- Circulating variants, specifically B.1.1.7 (501Y.V1) and P.1 with the E484K mutation, evading immunity.
- New variants being more transmissible.

Methods: COVID-19 hospitalizations, excess deaths, and real-time effective reproductive numbers were assessed from the literature and qualitatively compared monthly from March 2020 to January 2021 in Manaus, Brazil. *Limitations*: Associations were not directly estimated.

Implications: New variants of SARS-CoV-2 might demonstrate changes in transmissibility and/or virulence and could lead to a resurgence of COVID-19 despite high reported seroprevalence. In Rio Grande do Sul, another state in Brazil, da Silva Francisco *et al.* found wide circulation of the B.1.1.28 variant, with the E484K mutation, co-infection of variants, and new emerging variants. These findings stress the importance of tracking circulating viruses and of reaffirming COVID-19 mitigation measures.

Figure.



Note: Adapted from Sabino *et al.* Smoothed COVID-19 **hospitalizations** and **excess deaths** since March 2020 in Manaus, Brazil. Key mitigation events are marked with dotted lines. The gold star indicates the first detection of P.1 variant. Reprinted from The Lancet, Vol. 397 number 10273, Sabino *et al*, Resurgence of COVID-19 in Manaus, Brazil, despite high seroprevalence., Pages 452– 455, Copyright (2021), with permission from Elsevier.

Natural History of SARS-CoV-2 Infection

PREPRINTS (NOT PEER-REVIEWED)

SARS-CoV-2 seropositivity and subsequent infection risk in healthy young adults: a prospective cohort study. Letizia *et al.* medRxiv (January 29, 2021).

Key findings:

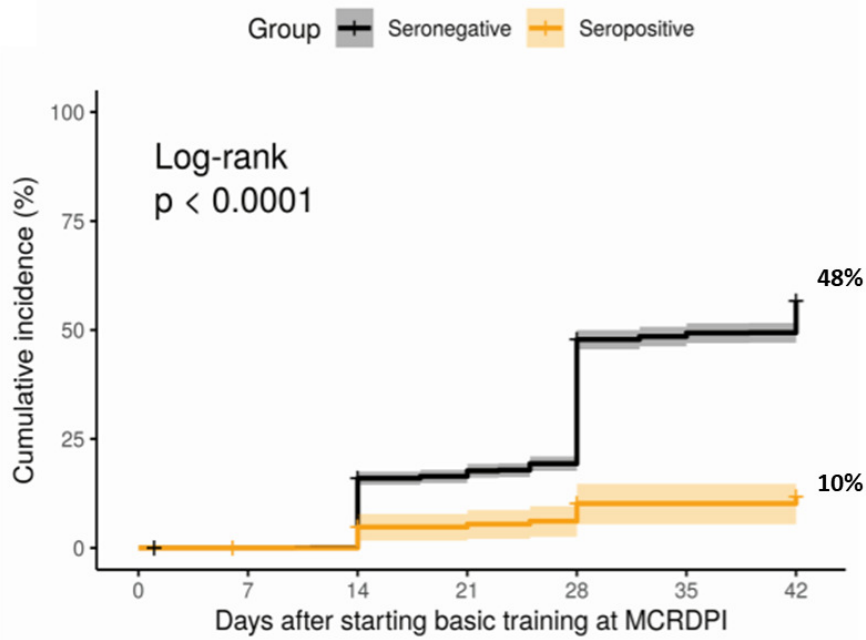
- Although seropositivity conferred an 82% reduced incidence rate, 10.1% of 189 seropositive participants had ≥1 positive RT-PCR test for SARS-CoV-2 (compared with 48.0% of 2,247 seronegative participants) (Figure).

    - Among those infected, seropositive participants had only a modest, approximately 10-fold decrease in nares virus load compared with seronegative participants.
- Among seropositive participants
    - New infection was associated with significantly lower baseline full-length spike protein IgG titers.
    - Baseline neutralizing titers were detected in 83.3% of the first 54 participants who never became PCR positive compared with 31.6% of the 19 infected participants.

Methods: Prospective 6-week observational study of 3,249 predominantly male, 18–20-year-old Marine recruits, who underwent baseline 2-week supervised quarantine and SARS-CoV-2 RT-PCR and IgG antibody testing. Serial RT-PCR testing was conducted and questionnaires on development of symptoms were completed during and after quarantine. *Limitations*: Overall high attack rate might not be generalizable to other populations and settings; unknown when seropositive participants were initially infected.

Implications: Although persons with SARS-CoV-2 antibodies are largely protected, subsequent infection is possible for some persons due to lack of sterilizing immunity. Some re-infected individuals could have a similar capacity to transmit virus as those infected for the first time.

Figure.



Note: Adapted from Letizia *et al*. SARS-CoV-2 PCR positive incidence curves during the six-week follow-up period among baseline **seropositive** and **seronegative** groups. Licensed under CC BY 4.0.

Kinetics and correlates of the neutralizing antibody response to SARS-CoV-2. Vanshylla *et al.* bioRxiv (January 26, 2021).

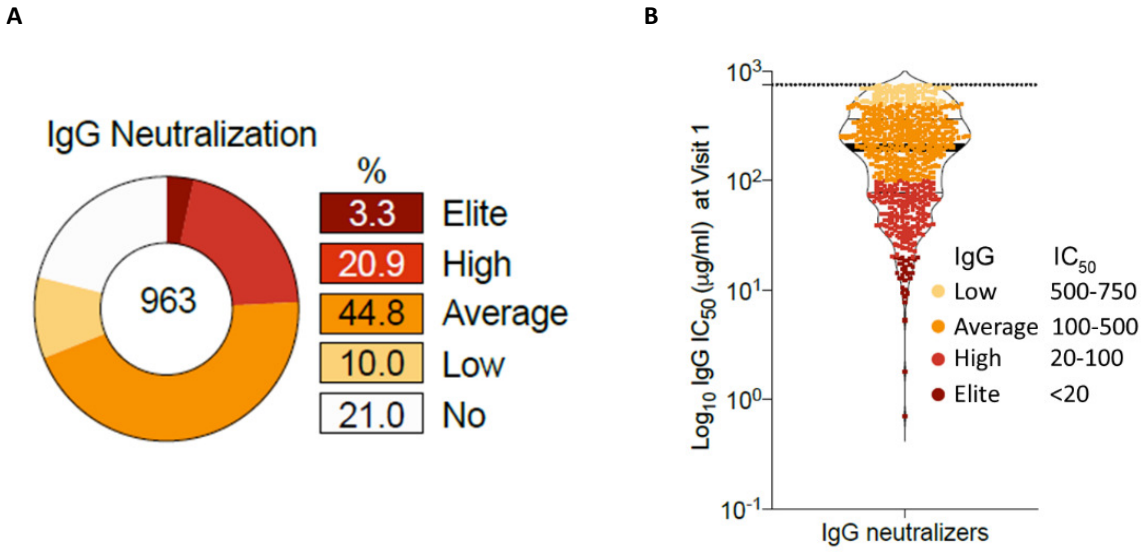
Key findings:

- 82% of individuals developed serum, and 79% IgG, neutralizing antibodies (NAb) to SARS-CoV-2.
- Neutralizing activity was highly variable, ranging from 3% who were initially 'elite' neutralizers, with a 50% Inhibitory Concentration [IC_{50}] of <20 µg/ml of IgG, to 21% who had no neutralizing activity (Figure).
- Higher anti-spike IgG levels, older age, time since disease onset, and fever during acute infection were predictors of SARS-CoV-2 neutralizing activity in mild courses of COVID-19.
- NAb had an initial half-life of 7 weeks in serum and 31 weeks in IgG titer samples.

Methods: NAb responses to SARS-CoV-2 were examined in 963 persons recently recovered from (mostly) mild COVID-19, during up to 4 follow-up visits between April 6 and December 17, 2020. Statistical modeling was used to infer antibody decay rates and to build a prediction model to evaluate how clinical features correlate with NAb titers. *Limitations:* Loss to follow up may bias results.

Implications: Although NAb can persist for up to 10 months after infection, persons who recover from mild COVID-19 illness have a broad spectrum of neutralizing activity which might affect protective immunity at a population level.

Figure.



Note: Adapted from Vanshylla *et al*. **(A)** Donut chart depicts the initial fraction of persons who developed NAb at study visit 1. **(B)** Violin plot depicts IgG IC_{50} values for the persons who developed neutralizing antibodies (n=760), categorized by IgG IC_{50}: **low** (IC_{50} >500-750 µg/ml), **average** (IC_{50} >100-500 µg/ml), **high** (IC_{50} 20-100 µg/ml), **and elite** (IC_{50} <20 µg/ml). Dotted line represents the limit of detection of the assay. Used by permission of authors.

Protection in Healthcare and Non-Healthcare Work Settings

PREPRINT (NOT PEER-REVIEWED)

Strategies to minimize SARS-CoV-2 transmission in classroom settings: combined impacts of ventilation and mask effective filtration efficiency. Rothamer *et al.* medRxiv. (January 4, 2021).

Key findings:

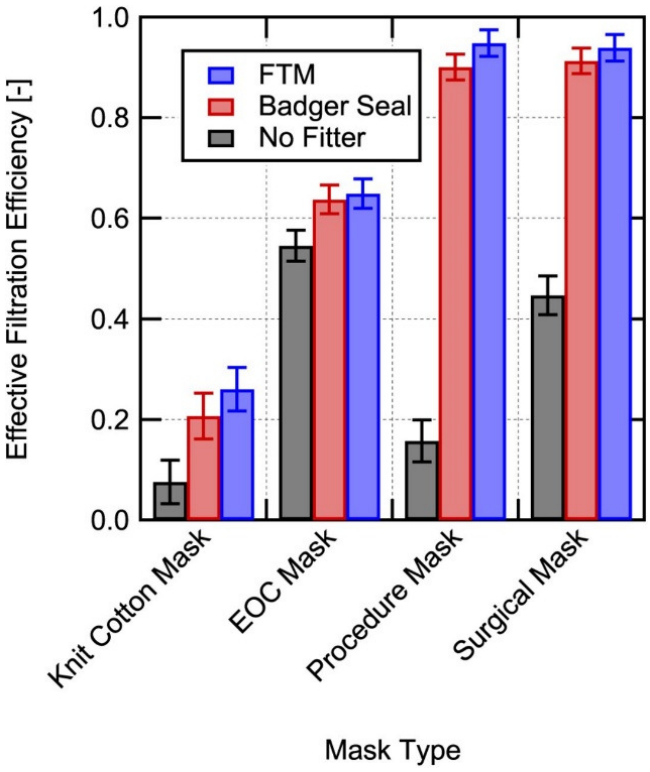
- Filtration efficiencies of four masks tested ranged from 7.5% to 54.5%.
- The addition of mask fitters, devices to improve the seal of a mask, increased filtration efficiency from 20.6% to 91.3% (Figure).
- Ventilation alone did not substantially reduce infection risk.

Methods: A simulation study to evaluate ventilation and mask filtration efficiency of non-medical grade masks, with and without mask fitters, on aerosol transmission in a classroom setting using CPR manikins fitted with aerosol-releasing tubing. Two mask fitters were tested, Badger Seal and Fit the Mask (FTM), using 4 masks: 1) a commercial 4-ply knit cotton mask, 2) a 3-ply polypropylene mask, 3) a 3-ply disposable procedure mask, and 4) a

surgical mask. *Limitations*: Potential overestimation of mask efficacy because manikins were fitted to minimize leakage; simulation might not represent real-world settings.

Implications: All non-medical grade masks are prone to leakage; however, the use of mask fitters can significantly reduce aerosol transmission of SARS-CoV-2 in a classroom setting. Gandhi *et al.* hypothesized that the use of multi-layered, well-fitting masks could achieve >90% efficiency at reducing aerosol transmission.

Figure.



Note: Adapted from Rothamer *et al*. Overall effective filtration efficiency for inhalation for 4 masks by fitter status (with **no mask fitter**, with the **Badger Seal mask fitter**, with the **Fit the Mask (FTM) mask brace**). Licensed under CC BY-ND 4.0.

Prevention, Mitigation and Intervention Strategies

PEER-REVIEWED

Model-informed COVID-19 vaccine prioritization strategies by age and serostatus. Bubar *et al.* Science (January 21, 2021).

Key findings:

- Prioritizing adults ≥60 years old shows the greatest reduction in mortality and years of life lost (YLL) after accounting for country-specific age structure, age-contact structure, infection fatality rates, seroprevalence, and age-varying efficacy of vaccine.
- Prioritizing adults aged 20–49 years old minimizes cumulative incidence but is only superior at minimizing deaths when R_0 = 1.15 and vaccine efficacy is ≥80% or vaccine rollout is ≤0.2%, or when vaccine efficacy is lower in older adults (≥60 years old) compared to individuals <60 years.
- Prioritizing seronegative individuals provides the greatest benefit where seroprevalence is high.

Methods: A mathematical model quantified the impact of five age-stratified COVID-19 vaccine prioritization strategies on cumulative incidence, mortality and YLL. *Limitations*: Model assumptions limit generalizability; disease severity is considered by age only.

Implications: Pairing vaccination with serological testing of individuals may be a useful strategy for prioritization of limited vaccine supplies and to reach vulnerable populations.

PREPRINTS (NOT PEER-REVIEWED)

mRNA-1273 vaccine induces neutralizing antibodies against spike mutants from global SARS-CoV-2 variants. Wu *et al.* bioRxiv (January 25, 2021).

Key findings:

- Moderna mRNA-1273 vaccine was able to neutralize all known strains of SARS-CoV-2.
    - Full neutralization was still achieved despite diminished neutralizing responses against the B.1.351 (South Africa) variant, with the E484K mutation, because neutralizing titers remained relatively high (1:290).
    - No significant differences in neutralizing antibody titers against B.1.1.7 (UK), 20E, 20A.EU2, DG614-N439K, or mink cluster 5, variants were detected.

Methods: Neutralization assays using pseudovirus expressing SARS-CoV-2 spike protein mutations found in major current variants were used to determine the neutralizing capacity of sera from 8 human subjects and 12 non-human primates vaccinated with the Moderna mRNA-1273 vaccine. Neutralization was compared to the neutralization observed against D614G, the dominant strain of 2020. *Limitations*: Small sample size; P.1 variant was not included.

Implications: Moderna mRNA-1273 vaccine appears to be effective against both the UK and South African SARS CoV-2 variants. However, further studies are warranted to substantiate these findings.

The effectiveness of the first dose of BNT162b2 vaccine in reducing SARS-CoV-2 infection 13-24 days after immunization: real-world evidence. Chodick *et al.* medRxiv (January 29, 2021).

Key findings:

- The cumulative incidence of SARS-CoV-2 infection was 0.57% (n=2,484) during days 1-12 and 0.27% (n=614) during days 13-24 following the first dose of the BNT162b2 mRNA COVID-19 vaccine.
- There was a 51.4% reduction in the weighted average daily incidence of SARS-CoV-2 infection at days 13–24 after the first dose (21.8 per 100,000 population), compared to days 1–12 (43.41 per 100,000 population).

Methods: A retrospective cohort study of 503,875 individuals aged ≥16 years old in Israel estimated the effectiveness of the first dose of the BNT162b2 vaccine administered from December 19, 2020 to January 15, 2021. Daily and cumulative infection rates during days 13-14 were compared to days 1-12 after the first dose using generalized linear models. *Limitations*: Unreported vaccinations might bias results.

Implications: Based upon temporal incidence, the BNT162b2 vaccine (Pfizer-BioNTech) is approximately 51% effective at reducing the risk of SARS-CoV-2 infection at 13 to 24 days following the first dose.

In Brief

Detection, Burden, and Impact

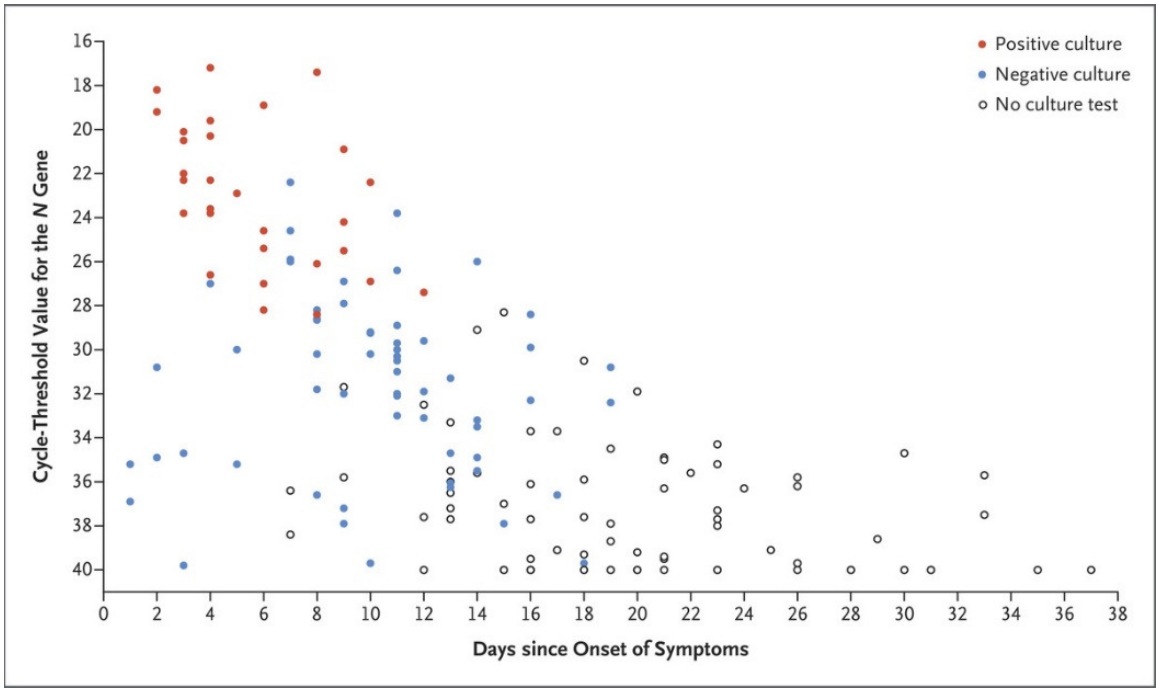
- Lowe *et al.* **Association of smoking and cumulative pack-year exposure with COVID-19 outcomes in the Cleveland Clinic COVID-19 registry.** JAMA Internal Medicine. (January 25, 2021). Of 7,102 adults with COVID-19 in the Cleveland Clinic COVID-19 registry between March 8 and August 25, 2020, 341 persons who smoked >30 pack-years had higher odds of hospitalization and death, although the odds were attenuated with inclusion of comorbidities; these data demonstrate an apparent dose-dependent relationship between smoking and adverse COVID-19 outcomes.

- Ehrenberg *et al.* **Launching a saliva-based SARS-CoV-2 surveillance testing program on a university campus.** medRxiv (Preprint, January 26, 2021). Describes a successful university-based surveillance system using saliva-based testing for SARS-CoV-2 among 3,653 persons to identify asymptomatic and pre-symptomatic cases and prevent outbreaks.

Natural History of SARS-CoV-2 Infection

- Kim *et al.* **Duration of culturable SARS-CoV-2 in hospitalized patients with COVID-19.** NEJM (January 27, 2021). Based on all 2-day RT-PCRs and viral cultures among 21 hospitalized patients with COVID-19, the median duration of shedding of viable virus was approximately 7 days (95% CI 5-10).

Figure.



Adapted from Kim *et al.* Timing of presence or absence of viable SARS-CoV-2 on viral culture and Ct values for 165 serial samples. Viral loads were determined with the Ct value for the *N* gene of SARS-CoV-2. Each circle represents a sample obtained on the specified day. Viral culture was either **positive** or **negative**. DOI: 10.1056/NEJMc2027040. Copyright © (2021) Massachusetts Medical Society. Reprinted with permission from Massachusetts Medical Society.

- Al-Samkari et al. **Thrombosis, bleeding, and the observational effect of early therapeutic anticoagulation on survival in critically ill patients with COVID-19.** Annals of Internal Medicine (January 26, 2021). In a multi-center, observational cohort study of 3,239 critically ill patients admitted between March 4 and April 11, 2020, early therapeutic anticoagulation did not affect in-hospital survival.

- Starr *et al.* **Prospective mapping of viral mutations that escape antibodies used to treat COVID-19.** Science (January 25, 2021). Mapping of viral mutations to SARS-CoV-2 receptor binding domain showed that a single amino acid mutation (E406W) escapes the two monoclonal antibody REGN-CoV2 cocktail.

- Rappazzo *et al.* **Broad and potent activity against SARS-like viruses by an engineered human monoclonal antibody.** Science (January 25, 2021). An engineered human monoclonal antibody demonstrated neutralization potency similar to neutralizing antibodies currently in clinical use providing significant protection against COVID-19 in mouse models.

- Nemani *et al.* **Association of psychiatric disorders with mortality among patients with COVID-19.** JAMA (January 27, 2021). In a retrospective cohort study of 7,348 patients with confirmed COVID-19 at 4 acute care hospitals in New York City from March 3 to May 31, 2020, persons with schizophrenia had significantly increased odds of 45-day mortality.

- Alam *et al.* **An interactive COVID-19 virus mutation tracker (CovMT) with a particular focus on critical mutations in the receptor binding domain (RBD) region of the spike protein.** medRxiv (Preprint, January 25, 2021). As new SARS-CoV-2 variants emerge with increased transmissibility and potential immune escape, it is important to monitor sequencing efforts and evolution of mutations. These authors developed a global mutation tracker that is updated daily and includes clinical data.

Protection in Healthcare and Non-Healthcare Work Settings

- Moghadas *et al.* **Evaluation of COVID-19 vaccination strategies with a delayed second dose.** medRxiv (Preprint, January 29, 2021). Based on an assumed 80% efficacy after the first dose, modelling showed that delaying the second dose of the Moderna vaccine by 9-12 weeks could reduce infections, hospitalizations, and deaths. However, for the Pfizer-BioNTech COVID-19 vaccine, with an assumed 52% efficacy after the first dose, there was no clear advantage to delaying the second dose due to waning immunity.

Prevention, Mitigation, and Intervention Strategies

- Crane *et al.* **Change in reported adherence to nonpharmaceutical interventions during the COVID-19 pandemic, April-November 2020.** JAMA (January 22, 2021). National survey responses from 7,705 participants between April 1 and November 24, 2020, showed a decrease in adherence to nonpharmacological interventions indicating "pandemic fatigue; however, there was in increase in self-reported mask-wearing which may reflect improved public health messaging.

Social, Behavioral, and Communication Science

- Ayers *et al.* **Suicide-related internet searches during the early stages of the COVID-19 pandemic in the US.** JAMA Network Open (January 21, 2021). Google searches related to suicide between January 1 and July 5, 2020, showed a decline after a national emergency was declared in March 2020. This decline was likely due to increased social support, called the "pulling together" phenomenon, often associated with catastrophes.

Disclaimer: The purpose of the CDC COVID-19 Science Update is to share public health articles with public health agencies and departments for informational and educational purposes. Materials listed in this Science Update are selected to provide awareness of relevant public health literature. A material's inclusion and the material itself provided here in full or in part, does not necessarily represent the views of the U.S. Department of Health and Human Services or the CDC, nor does it necessarily imply endorsement of methods or findings. While much of the COVID-19 literature is open access or otherwise freely available, it is the responsibility of the third-party user to determine whether any intellectual property rights govern the use of materials in this Science Update prior to use or distribution. Findings are based on research available at the time of this publication and may be subject to change.

ELC Enhancing Detection Expansion

Questions & Answers

As of February 2, 2021

All questions are hyperlinked to their respective answers below; click on a question to be brought to its answer. Click on 'ELC Enhancing Detection Expansion' at the bottom of each page to be brought back to the start of the document. Appendices available at the end which include allowable expense comparisons between ELC Enhancing Detection Expansion and Immunization VFC Supplemental Funding.

Budget and Allowable Costs

1. Is there a budget template?
2. What are examples of some costs not allowed in Enhancing Detection (ED) Expansion?
3. Can we use the funds to pay for activities done in months before the grant was awarded?
4. Can funding be used to support providers with Electronic Laboratory Reporting (ELR) or telemedicine technology to enhance testing?
5. Can funding be used to purchase vaccines?
6. When submitting a revised budget as an amendment, do you have to submit other forms?
7. Can resources be used for quarantine/isolation-related costs?
8. When setting up and operating pop-up testing sites, what types of expenses are allowable through ED Expansion?
9. If a recipient's partners and community providers meet the testing goal and need to provide additional supplies/resources for expanded testing, what costs are allowable through ELC Enhancing Detection Expansion?
10. Are funds intended to support activities for the duration of the 30-month period? For example, if a jurisdiction liquidates all their funds prior to the end of the 30 months, are they still required to continue activities in the guidance until the end of the 30 months?
11. If a jurisdiction liquidates most or all funds towards supporting a few activities in the workplan, are they still required to complete the remaining activities?
12. Can ELC ED Expansion funds be used to cover the costs of COVID-19 testing?
13. When reporting the monthly expenses in the REDCap Financial Reporting page, what are 'unliquidated obligations' and how do they differ from expenses?
14. Am I required to have prior approval (redirection/contract approval) before I can use the funds that were placed in the "Other" cost category of my ELC ED Expansion Notice of Award (NOA) for COVID-19 response activities?
15. The Notice of Award for ELC ED Expansion has a budget period from August 1, 2020, to July 31, 2023; does this mean that contracts and other acquisitions using ELC ED Expansion funds cannot go past July 31, 2021?
16. How does expanded authority work for the supplemental COVID-19 funds?
17. May social services be supported with ED Expansion funds?
18. Can ELC ED Expansion funding be used to purchase vehicles, including mobile testing vans?
19. Can ELC ED Expansion funding be used for renovations and minor construction costs?
20. Can recipients request more than the recommended "1 program manager, 1 budget staff" in the budget?
21. With this new funding opportunity, and the allowance of covering existing core staff's percent of work redirected to COVID-19 activities, what happens to our (base) core ELC funding?
22. Are recipients able to start spending funds, before revised budgets are approved?
23. Now that workplans are being combined into ED Expansion for ELC CARES and Enhancing Detection, will financial reporting be bundled as well?

Workforce Capacity:

24. If the health department has previously reached the personnel/hiring cap in their jurisdiction, should this be addressed or acknowledged in the budget?

ELC Enhancing Detection Expansion Testing & Testing Plan Template:

25. Can you confirm that the target coverage for our testing projections is 2% of population each month?

26. What level of continued federal support can recipients expect for laboratory testing (e.g., provision of specimen collection and testing kits) as the COVID-19 response evolves?
27. Is the laboratory test order and reporting activity required?

Advance Electronic Data Exchange at Public Health Labs:

28. Is the laboratory test order and reporting activity required?
29. I cannot find the ED Expansion performance measures, where are they located?
30. What elements are needed in the line level testing data reporting to CDC?
31. Will these expectations for lab test reporting affect current reporting feeds from labs to health departments? If the state feed changes, does the originating reporting feed at the lab have to change?
32. Our jurisdiction is having difficulty with ensuring all laboratories are reporting line-level test data (including negatives); how important is this element to our ELC activities?
33. Can CDC provide additional clarity on what specific activities under "Improve Surveillance and Reporting of Electronic Health Data" are considered to "enable comprehensive, automated, daily reporting to the CDC and others in a machine-readable format"?

Activities:

34. Could you elaborate on what activities are allowable under contact tracing?
35. Are we able to obligate subcontracts before our revised budgets are submitted?
36. If ED Expansion is a copy of ED in REDCap, do we still report milestones and progress updates for ED?

Coordinate and Engage with Partners:

37. If a jurisdiction is largely de-centralized, to what extent is the State Health Department expected to partner at the local level?
38. What are examples of partners to consider funding when addressing health equity needs?

Other projects:

39. We attended the webinar presented by the United States Digital Service (USDS) and are interested in participating. Can the ELC facilitate this?
40. For ELC COVID performance measures, where are measures E23, E24 and E25 located in the REDCap portal?

Appendices

A: Basic Comparison & Examples of Allowable
B: Costs Allowable Expenses At-A-Glance

ELC Enhancing Detection Expansion Answers

Budget & Expenses:

1. Is there a budget template?
   - Yes, the ELC budget workbook (Excel) was provided in a Grant Note in GrantSolutions (GMM). You can also contact your ELC Project Officer. Recipients must complete the budget revision using the Excel budget workbook and adhere to the CDC guidelines (https://www.cdc.gov/grants/documents/Budget-Preparation-Guidance.pdf). The revised budget must then be sent back to CDC through a budget revision amendment in GrantSolutions, along with a cover letter signed by the Authorized Organizational Representative (AOR) of record in GrantSolutions.
2. What are examples of some costs not allowed in Enhancing Detection (ED) Expansion?
   - Research, lobbying, and clinical care (except as may be allowed by law) cannot be supported with funds awarded under ELC Enhancing Detection (ED) Expansion. However, all questions should be submitted as a Grant Note in GMM for review by your Grants Management Specialist (GMS) at CDC's Office of Grant Services (OGS) and your ELC Project Officer.
3. Can we use the funds to pay for activities done in months before the grant was awarded?
   - Legislative language was not included in this appropriation to permit retroactive charges; therefore, only costs associated with activities from time of award issuance are allowable.
4. Can funding be used to support providers with Electronic Laboratory Reporting (ELR) or telemedicine technology to enhance testing?
   - Certain costs not associated with the delivery of clinical care may be allowable. Please email your ELC Project Officer for a more individualized consult to discuss the specifics of your situation.
5. Can funding be used to purchase vaccines?
   - Per OGS, the purchase of vaccines is not permissible using ED Expansion funds. However, certain vaccine related costs may be allowable using ED Expansion funds. This includes storage and administration costs (i.e., injection cost if not covered in question #12). Recipients are encouraged to coordinate with PHEP and Immunization partners within the jurisdiction to effectively plan necessary activities and optimize use of resources.
6. When submitting a revised budget as an amendment, do you have to submit other forms?
   - The following must be part of the submission:
     i. The workplan completed in REDCap (and exported as a PDF);
     ii. The revised ELC budget workbook, using the Excel workbook provided at the time of award issuance;
     iii. A cover letter which is on agency/recipient stationary and signed by the Authorizing Official of record in GrantSolutions;
     iv. The State Testing and Case Investigation & Contact Tracing Plan completed in REDCap (and exported as a PDF); and
     v. The ELC Governance Team support letter.
7. Can resources be used for quarantine/isolation-related costs?
   - Costs associated with quarantine and isolation may be allowable as they relate to one or more activities in the workplan. For example, resources necessary to support testing and monitoring of individuals traveling from high-risk areas (within or outside of the U.S.) may be allowable and within scope of this project (this includes wrap- around services). Resources necessary for quarantine under a legal order (hotel, wraparound services, etc.) may also be allowable; recipients should simply tie these requests to their ELC workplan. ELC Project Officers should be contacted to discuss the specifics of such a request.
8. When setting up and operating pop-up testing sites, what types of expenses are allowable through ED Expansion?
   - Most costs associated with setting up and operating alternate testing sites are allowable under ED Expansion if the workplan reflects these sites in one or more of the activities. Please see question #12 for additional details pertaining to insurance.

9. If a recipient's partners and community providers meet the testing goal and need to provide additional supplies/resources for expanded testing, what costs are allowable through ELC Enhancing Detection Expansion?
    - Most costs, in particular supplies and resources, are allowable so long as they relate to one or more of the activities in the workplan. However, testing costs, even for the uninsured would not be allowable when any/all of the associated costs are being reimbursed in any fashion. Please see question #12 for additional details pertaining to insurance.
10. Are funds intended to support activities for the duration of the 30-month period? For example, if a jurisdiction liquidates all their funds prior to the end of the 30 months, are they still required to continue activities in the guidance until the end of the 30 months?
    - The expected timeframe for completion of all required activities under ELC ED Expansion is 30 ½ months. It is possible that certain activities may be completed in a shorter period (e.g., 24 months); however, the overall project period is 30 ½ months to allow sufficient time to conduct the range of activities. As this award builds on the ELC ED award, it is important to gauge progress based on the achievement of the required expansion of activities, not the spending of funds. Expenditures that are not aligned with the commensurate level of completion of the approved activities will be scrutinized. Should it be found that resources were not utilized in the manner consistent with grant regulations, the award terms and conditions and/or approved work plans and budget submissions, the jurisdiction may be found to be noncompliant and could be required to reimburse the federal government. Additionally, as indicated in the Guidance associated with this award (https://www.cdc.gov/ncezid/dpei/elc/resources.html), if required tasks and activities in the Guidance are not addressed, funds may be restricted in the Payment Management System (PMS). It is highly recommended that recipients continue to engage their ELC Project Officer and the OGS GMS as funds are activities are undertaken and funds are expended to ensure appropriate progress during the ED Expansion project period.
11. If a jurisdiction liquidates most or all funds towards supporting a few activities in the workplan, are they still required to complete the remaining activities?
    - The ELC ED Expansion Guidance sets out the required activities in furtherance of the purpose and use of the funds and the award. Budgets should align to the workplans and are intended to support the breadth of all required activities.
12. Can ELC ED Expansion funds be used to cover the costs of COVID-19 testing?
    - Yes, COVID-19 testing can be covered using ELC Enhancing Detection Expansion funds in the following ways:
        i. Uninsured: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing for the uninsured.
        ii. Unable to bill: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing when billing is not feasible. While not an exhaustive list, some examples are the following: mobile testing sites; non-traditional testing sites; state/local laboratories not having the authority or ability to bill insurance; etc.
        iii. Billing serves as a real or perceived barrier to timely test delivery: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing when establishing billing services (directly or through a contractual agreement) would delay testing and/or reduce the jurisdiction's ability to rapidly increase testing capacity to meet needs.
        iv. Payor of last resort when billing insurance: In situations where COVID-19 testing is billed to insurance and is either not covered or partially covered by a third-party payor (e.g., private insurance, CMS, etc.), after the claim is rejected or partial reimbursement occurs, the outstanding balance can be covered by ELC Enhancing Detection Expansion funds.
13. When reporting the monthly expenses in the REDCap Financial Reporting page, what are 'unliquidated obligations' and how do they differ from expenses?
    - The funds awarded fall into one of three categories:
        i. Unobligated: Funds in a budget or spend plan that are available for use, but not yet encumbered or committed.

ii. Unliquidated obligations (ULOs): Funds that have been encumbered/committed but have not yet been paid out. Examples include: (1) executing a $100K contract and having to pay 10% upfront would result in $10K in 'expenditures' and $90K in 'unliquidated obligations'; (2) using a purchase order to acquire a piece of equipment for $50K would result in $50K in 'unliquidated obligations' until the equipment is delivered, the agency is invoiced, and the invoiced is paid.
iii. Expenditures: Funds that have been drawn down from the account and paid out.

- Note: It is important to remember that once an unliquidated obligation is paid, the following monthly reporting should transfer the amount paid from 'unliquidated obligations' to 'expenditures' as the obligation has now been liquidated.

14. Am I required to have prior approval (redirection/contract approval) before I can use the funds that were placed in the "Other" cost category of my ELC ED Expansion Notice of Award (NOA) for COVID-19 response activities?
    - All awarded funds were placed in the 'Other' cost category as an initial means to obligate and award funding. This action allowed CDC to expedite your award and facilitate your emergency response. Based on the emergency, you have been authorized to use these funds consistent with the issued Guidance and terms of the award set out therein, including entering into contracts as required to address the needs of COVID-19. Please ensure that such funds are expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75. All costs must also be reflected in the budget and workplan you are preparing for submission by March 18, 2021. You are not required to wait until your budget is submitted and approved to execute any needed contracts or other obligations. We do however require that this information is incorporated in the budget and that the contract(s) are in alignment with the issued CDC Guidance, applicable terms and conditions, and your internal procurement policies. This ability to use the funds prior to the budget submission and approval is an exception that applies solely to COVID-19 awards within ELC.
15. The Notice of Award for ELC ED Expansion has a budget period from August 1, 2020, to July 31, 2023; does this mean that contracts and other acquisitions using ELC ED Expansion funds cannot go past July 31, 2021?
    - The ELC ED Expansion awards were issued in ELC Budget Period 2. There was specific guidance in the Terms and Conditions of the Notice of Award that provided an extended fiscal period (i.e., extending past the end of the budget period in which funds were awarded) for these special COVID-19 funds. The 30 ½ -month fiscal period for the ELC Enhancing Detection Expansion awards means that contracts can extend past the July 31, 2021, end of Budget Period 2, by exercising option years. Additionally, other costs (e.g., purchasing equipment, supplies, etc.) can also occur after July 31, 2021, in accordance with the terms and conditions of this award.
16. How does expanded authority work for the supplemental COVID-19 funds?
    - Unlike funding in ELC (base) core awards, the supplemental ELC ED Expansion COVID-19 awards are issued with an expanded budget period; therefore, expanded authority is not needed to extend use of COVID supplemental funds from one ELC budget period to the next.
    - During the regular ELC budget period closeout (i.e., October 30), when submitting the annual FFRs, one FFR will need to be submitted for each document number that ELC awards were made on. The special COVID-19 document numbers will be reported on separate FFRs from the (base) core ELC award for Budget Periods 1 & 2. For base (core) funding only, whatever funds remain unobligated at time of submitting the annual FFR should be noted in Section #12 along with the intended use of Expanded Authority.
    - Given the ELC ED Expansion award has an extended fiscal period, the account will continue to be active in the Payment Management System (PMS) and can have funds drawn down to cover expenses through the end of the ED Expansion award budget period.
17. May social services be supported with ED Expansion funds?
    - Social services that are critical to facilitating the detection, prevention, and control of COVID-19 may be allowable. For example, those services that help facilitate compliance with isolation and quarantine and/or case investigation and contact tracing efforts may be allowable expenses and may be a part of recipient workplans (e.g., health educators, counselors, etc.). ELC Project Officers should be contacted to

discuss the specifics of such a request. Recipients are reminded that funds are to be expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.

18. Can ELC ED Expansion funding be used to purchase vehicles, including mobile testing vans?
    - Yes, but recipients must include three (3) quotes and/or a blanket purchasing agreement along with a justification for leasing/purchasing in the revised budgets that are due by March 18, 2021. For situations where the acquisition needs to occur before the revised NOA is issued, please submit the request and associated quotes in GrantSolutions via Grant Note. This information must also be included in the revised budget once submitted.
    - For redirecting funds to purchase vehicles, including mobile testing vans, that were not in the approved budgets, please work with your ELC Project Officer to submit a redirection request. The request will need to include a cost analysis between lease versus purchase options and quote. For mobile testing vans, due to the nature of having to customize the vehicle, it is understood that a lease versus purchase analysis might not be applicable.
19. Can ELC ED Expansion funding be used for renovations and minor construction costs?
    - Yes, but recipients must include the quotes and justification for renovations and/or minor construction in the revised budgets that are due by March 18, 2021. For situations where the alterations need to occur before the revised NOA is issued, please submit the request and associated quotes in GrantSolutions via Grant Note.
    - For redirecting funds to conduct renovations and/or minor construction that were not in the approved budgets, please work with your ELC Project Officer to submit a redirection request. The request will need to include:
        i. A description of the renovation or minor construction,
        ii. The justification of how the renovations or minor construction will relate to activities in the approved workplan, and
        iii. A quote or bid justifying the cost that is being requested in the redirection.
20. Can recipients request more than the recommended "1 program manager, 1 budget staff" in the budget?
    - Yes, this is a minimum recommendation for basic management of this project. Recipients may also need to increase overall administrative staff support to accommodate the demands of managing their portfolio.
21. With this new funding opportunity, and the allowance of covering existing core staff's percent of work redirected to COVID-19 activities, what happens to our (base) core ELC funding?
    - Recipients' (base) core dollars should be reserved for non-COVID programmatic activities. As numerous health department staff are working on COVID-19 currently, it is understandable if (base) core funding spending is lower than usual. These programmatic activities can be extended into Budget Period 3.
    - ELC staff who are typically supported through (base) core funding but are working all or a portion of their time on the COVID-19 response should have their associated personnel costs charged to the ELC CARES, ELC Enhancing Detection, and/or ELC ED Expansion COVID accounts as appropriate.
22. Are recipients able to start spending funds, before revised budgets are approved?
    - Yes, funds are available for use now. In the interim (before revised budgets are accepted), make sure your expenses align with activities described in the ELC Guidance (https://www.cdc.gov/ncezid/dpei/elc/resources.html). Also, please see response to #14 above. Also, recipients are reminded that funds are to be expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.
23. Now that workplans are being combined into ED Expansion for ELC CARES and Enhancing Detection, will financial reporting be bundled as well?
    - No, each COVID-19 supplemental award requires its own, monthly financial report due to the nature of being awarded on separate accounts in the Payment Management System (PMS) and the need to track and account for spending by each separate supplemental appropriation.

Workforce Capacity:

24. If the health department has previously reached the personnel/hiring cap in their jurisdiction, should this be addressed or acknowledged in the budget?
    - Increased staffing (e.g., contractual, temporary, term staff, etc.) may be essential to achieve the targets and requirements of this award, but we understand expanding human resources in your jurisdictions may not be in your control. If you anticipate insurmountable challenges with hiring or starting new contracts, please let your ELC Project Officer know immediately. Direct assistance and technical assistance can be discussed on a case-by-case basis, and major challenges will also be proactively communicated to the Department of Health and Human Services (HHS).

ELC Enhancing Detection Expansion Testing & Testing Plan Template:

25. Can you confirm that the target coverage for our testing projections is 2% of population each month?
    - Yes, and 2% is the minimum threshold as recommended by HHS/Office of the Assistant Secretary for Health (OASH).
26. What level of continued federal support can recipients expect for laboratory testing (e.g., provision of specimen collection and testing kits) as the COVID-19 response evolves?
    - The ELC can only speak to the funding that CDC administers. Questions regarding the monthly allocations of Viral Transport Medium (VTM) and swabs should be directed to your regional HHS/OASH representative. Of note: the published Jurisdictional Testing Plans may be found at: https://www.hhs.gov/coronavirus/testing-plans/index.html. Any questions should be directed to your HHS/OASH representative.

Advance Electronic Data Exchange at Public Health Labs:

27. Can recipients accelerate previously on-going activities to improve laboratory informatics, for example, more rapid interfacing diagnostic equipment to improve the automation of reporting?
    - Yes, ELC expects all funded jurisdictions will make measurable progress in improving the efficiency of laboratory management and operations, as well as improving the analytic capacity within the laboratory settings. This may include improving automation of reporting with increased test volumes to efficiently manage throughput and staffing, or new analytic capacity to better inform the jurisdictional response efforts.
28. Is the laboratory test order and reporting activity required?
    - Yes, all activities included in the Guidance document (https://www.cdc.gov/ncezid/dpei/elc/resources.html) should be considered required with the ELC ED Expansion award.
29. I cannot find the ED Expansion performance measures, where are they located?
    - At the time the Guidance was published, the performance measures were not yet finalized. Recipients should anticipate their performance under the ED Expansion award will continue to be measured by and monitored as was done with the ELC Enhancing Detection award. Once changes are finalized for the ELC ED Expansion award, information will be shared via the ELC mailbox and a webinar will be held.
30. What elements are needed in the line level testing data reporting to CDC?
    - This includes all RT-PCR, antigen, and antibody tests and results (positives, negatives, and indeterminants), patient demographics, as well as reporting, performing and ordering facilities. For more detailed guidance please refer to standard CSV file, which ELC will share.
    - Critical data elements should be the primary focus for lab data reporting to CDC for COVID-19:
        i. Test ordered – use harmonized LOINC codes provided by CDC
        ii. Device Identifier – use if LOINC codes do not indicate device/test kit
        iii. Test result
        iv. Test Result date
        v. Accession #/Specimen ID
        vi. Age (or DOB)
        vii. Patient race

viii. Patient ethnicity
ix. Patient gender
x. Patient residence zip code
xi. Patient residence county
xii. Ordering provider name and NPI or CLIA (as applicable)
xiii. Ordering provider zip
xiv. Performing Lab name and CLIA number, if known
xv. Performing Lab zip code
xvi. Specimen Source - use appropriate LOINC, SNOMED-CT, SPM4 codes, or equivalently detailed alternative codes
xvii. Date test ordered (date format)
xviii. Date specimen collected (date format)

- "Ask On Order" questions that are highly desired are shown below. These are secondary in importance to the critical data elements above:
  i. First test (Y/N/U)
  ii. Employed in healthcare? (Y/N/U)
  iii. Symptomatic? Y/N/U and then Date of Symptom Onset (mm/dd/yy)
  iv. Hospitalized? (Y/N/U)
  v. ICU? (Y/N/U)
  vi. Resident in a long-term care facility (including skilled nursing facilities, nursing homes, long-term care for the developmentally disabled, and assisted living homes): (Y/N/U)
  vii. Pregnant? (Y/N/U)

31. Will these expectations for lab test reporting affect current reporting feeds from labs to health departments? If the state feed changes, does the originating reporting feed at the lab have to change?
    - It is possible reporting fields or feeds will be expanded to accommodate for this reporting, but please defer to your local and state health department guidance. It should result in laboratories collecting and sending more complete data, though laboratories should continue to report the most complete data they have to their jurisdictional health departments. States should include the more complete data they receive to CDC. Any changes with reporting to CDC will be handled and managed through the epidemiology and informatics sections of your health departments.
32. Our jurisdiction is having difficulty with ensuring all laboratories are reporting line-level test data (including negatives); how important is this element to our ELC activities?
    - The public health response to COVID-19 depends on having comprehensive laboratory testing data - at scale, in near real-time, and including critical geographic and demographic information, to the fullest extent as feasible and with sufficient granularity. These data will contribute to understanding disease incidence and testing coverage and may contribute to the identification of testing issues and/or supply shortages. Additionally, the ELC has several performance measures that rely on the reporting of these data. The ELC has elected to reduce the burden placed on recipients by utilizing data sources and elements where states/jurisdictions are already reporting. Without the successful line-level test data reported (see: https://www.cdc.gov/coronavirus/2019-ncov/lab/reporting-lab-data.html), the ELC would need to institute a separate reporting process for laboratory data.
33. Can CDC provide additional clarity on what specific activities under "Improve Surveillance and Reporting of Electronic Health Data" are considered to "enable comprehensive, automated, daily reporting to the CDC and others in a machine-readable format"?
    - This suite of activities is intended to improve the health department's access to and interoperability of many relevant data sources for visibility on the spread of disease and to increase the usefulness of all data sources. Health departments should be able to receive all data message types and have the systems, processing ability, and staffing to consume and analyze new feeds alongside existing data, such as: increased testing volumes from new sites, death registry reports, and ADT data feeds from emergency departments and urgent care clinics. Linked data should be accessible to local public health

(and the public, where possible), in a format that can be easily uploaded into commonly used analysis and visualization tools, such as ESRI, Tableau, and PowerBI.

Activities:

34. Could you elaborate on what activities are allowable under contact tracing?
    - Activities allowable under contact tracing may include:
        i. Temporary staff used for incremental tracing
        ii. Public education/awareness campaign
        iii. Contracted vendor for contact tracers and monitors
        iv. Management and supervision of trainers, as well as the conducting of training
        v. Data and software platforms needed to support the training programs
35. Are we able to obligate subcontracts before our revised budgets are submitted?
    - Yes, you are able to grant subawards at this time, so long as the activity is undertaken consistent with the Guidance and the terms of the award. Please see response to #14 above.
36. If ED Expansion is a copy of ED in REDCap, do we still report milestones and progress updates for ED?
    - We are in the midst of Quarter 2 workplan milestone progress reporting for ED. Once that ends, we will close the ED workplan monitoring portal. Starting with Quarter 3 reporting, the Community-based Surveillance, ELC CARES, and ELC Enhancing Detection workplan milestone progress reporting will cease. Recipients will only be required to report the workplan milestone progress for ELC ED Expansion as these activities cover the other prior COVID awards.

Coordinate and Engage with Partners:

37. If a jurisdiction is largely de-centralized, to what extent is the State Health Department expected to partner at the local level?
    - CDC encourages State Health Departments to continue working collaboratively with city, county, and local health departments, and other partners (e.g., academic, regional organizations) to improve capacity for addressing gaps in addressing COVID-19 within their communities (e.g., testing, outbreak investigation, infection prevention and control (IPC) practices, etc.). Providing financial resources to local health departments is strongly encouraged, where possible, to build local public health capacity.
38. What are examples of partners to consider funding when addressing health equity needs?
    - Examples of partners may include but are not limited to:
        i. Tribal affiliates and community-based organizations colleges and universities
        ii. Occupational health settings for large employers
        iii. Churches or religious or faith-based institutions
        iv. Federally Qualified Health Centers (FQHCs), including Community Health Centers (CHCs)
        v. Pharmacies
        vi. Long-term care facilities (LTCFs), including independent living facilities, assisted living centers, and nursing homes
        vii. Organizations and businesses that employ critical workforce
        viii. First responder organizations
        ix. Non-traditional providers and locations that serve high-risk populations
        x. Other partners that serve underserved populations

Other Projects:

39. We attended the webinar presented by the United States Digital Service (USDS) and are interested in participating. Can the ELC facilitate this?
    - The USDS webinar provided an overview of the three projects which will be piloted in interested jurisdictions to help with better, faster data to public health departments. The ELC is not directly involved with the projects or the decision-making process for pilot selection. It is ELC's understanding that any products developed through the pilots will be open source and available for all jurisdictions to

adopt. While you may utilize ELC resources to support a project, you will need to tie the project back to your workplan and ensure successful completion of all the required ELC Enhancing Detection Expansion activities. If you have any questions about USDS-CDC collaboration or any specific projects, please email USDS@cdc.gov.

40. For ELC COVID performance measures, where are measures E23, E24 and E25 located in the REDCap portal?
    - Measures E23, E24 and E25 are collected by the HAI/AR program via their performance measure REDCap site "HAI/AR Performance Measures 2019 - 2020 (BP1)". Recipients will be notified directly by the HAI/AR program when these measures are available on REDCap.

Appendices

A: Basic Comparison & Examples of Allowable
B: Costs Allowable Expenses At-A-Glance

ELC Enhancing Detection Expansion & Immunization CoAg COVID-19 Funding Supplementals

A: Basic Comparison & Examples of Allowable Costs

Please ensure that such funds are expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.

All costs must alignment to the workplan and the impact to the overall ability to complete required activities.

	ELC Enhancing Detection (ED) Expansion	Immunization & VFC Cooperative Agreement
Purpose	Provide critical resources to state, local, & territorial health departments in support of a broad range of COVID- 19/SARS-CoV-2 testing & epidemiologic surveillance related activities. Activities intended to complement activities covered through other ELC COVID resources and explicitly expand upon those strategies and activities in ELC Enhancing Detection Expansion.	Provide resources to support and strengthen critical COVID-19 immunization planning and implementation requirements and activities to ensure effective and efficient vaccination in phases 1 (a, b, and c), 2, and 3 for state, local, and territorial awardees.
Funding appropriation	Coronavirus Response and Relief Act, 2020 (P.L. 116-260)	Coronavirus Response and Relief Supplemental Appropriations Act of 2021 (P.L. 116-260)
Key Activities	All Activities are required: 1. Enhance Laboratory, Surveillance, Informatics, and other Workforce Capacity (5 Activities) 2. Strengthen Laboratory Testing (3 Activities) 3. Advance Electronic Data Exchange at Public Health Labs (1 Activity) 4. Improve Surveillance and Reporting of Electronic Health Data (6 Activities) 5. Use Laboratory Data to Enhance Investigation, Response, and Prevention (3 Activities) 6. Coordinate and Engage with Partners (2 Activities)	1. Increase COVID-19 vaccination capacity across the jurisdiction, including among high-risk and underserved populations 2. Ensure high-quality and safe administration of COVID-19 vaccines 3. Ensure equitable distribution and administration of COVID-19 vaccines 4. Increase vaccine confidence through education, outreach, and partnerships 5. Develop and implement community engagement strategies to promote COVID-19 vaccination efforts 6. Support high vaccination uptake in tribal nations 7. Use immunization information systems to support efficient COVID-19 vaccination
Amount	$19.11 billion	$3 billion
Previous COVID funding	Over $11 billion and 15 projects represented. Of this, $10.25 billion was for ELC Enhancing Detection—the guidance upon which ED Expansion builds	This is the 3rd IP19-1901 COVID supplement during budget year 2 (July 2020 - June 2021) and the 4th total IP19-1901 COVID supplement. In total between all the supplements, approximately $3.48 billion in COVID funding has been awarded to the 64 immunization jurisdictions.
Funding period	1/15/2021 - 7/31/2023	7/1/2020 - 6/30/2024
Number of recipients	64	64
Funding strategy	PHEP formula (per legislation)	PHEP formula (per legislation)
Project director	Project Directors largely from Epi and Lab	Immunization and VFC CoAg Principal Investigator which is largely the immunization program manager

	ELC Enhancing Detection (ED) Expansion	Immunization & VFC Cooperative Agreement
Engagement with local health departments	While no formula exists for the advisable level of funding to local health departments (LHD), LHD needs should be reflected within budgets. Workplans should indicate how LHD engagement will take place to successfully complete the activities. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.	Allowable and encouraged. LHD needs should be reflected within budgets. Workplans should indicate how LHD engagement will take place to successfully complete the activities. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.
Mandate to support local health departments at a specified level	No, however, budgets and workplans should reflect how LHD needs will be addressed through these resources. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.	No, however, LHD and partners work plans must include activities and deliverables to meet vaccination needs of their community.
Financial reporting	Monthly reporting via REDCap & GrantSolutions	Monthly reporting via REDCap & GrantSolutions
Progress on activities reporting	Quarterly reporting via REDCap. Includes updates to Jurisdictional Testing and Contact Tracing/Case Investigation plans	Quarterly through REDCap
Performance measure reporting	Quarterly, through REDCap, but reporting frequency may be adjusted	Quarterly, through REDCap, but reporting frequency may be adjusted
Reimbursement of allowable costs	Officially allowable but activities supported would largely fall upon award/post-award. Prior incurred costs would need to be associated with activities in the workplan. Charges not related to the workplan activities may result in the health department having to pay the money back.	Allowable
Restrictions	Research as defined by CDC, clinical care (except as may be allowed by law), purchasing vaccines, and major construction (e.g., new building, modification of more than 50% of structure, etc.) are not allowed. Renovations and minor construction (e.g., modification of less than 50% of structure, concrete slabs for modular labs/generators, etc.) are allowable.	Research as defined by CDC, clinical care (except as may be allowed by law), purchasing vaccines, and major construction (e.g., new building, modification of more than 50% of structure, etc.) are not allowed. Renovations and minor construction (e.g., modification of less than 50% of structure, concrete slabs for modular labs/generators, etc.) are allowable.
Of note: Allowable, allocable, reasonable; and consistent with the appropriation, grant regulations, grant terms and conditions	Resources to complement, but not duplicate, other CDC vaccine delivery efforts (e.g., those activities covered under IP19-1901). Costs can include infrastructure needs (e.g. staff, contractors, call centers, storage, space, etc.) that support testing as well as vaccination operations.	Resources to complement, but not duplicate, other CDC vaccine delivery efforts (e.g., those activities covered under IP19-1901). Costs can include infrastructure needs (e.g., staff, contractors, call centers, storage, space, etc.) that support testing as well as vaccination operations.

ELC Enhancing Detection Expansion & Immunization CoAg COVID-19 Funding Supplementals

B: Allowable Expenses At-A-Glance

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Personnel (term, temporary, students, overtime, contract staff, etc.)	**Laboratorians**	Yes	No
	Informaticians	Yes	Yes
	Epidemiologists	Yes	Yes
	Data Entry Clerks, managers/analysists	Yes	Yes
	Data Visualization Specialists	Yes	Yes
	Vaccine registry data manager	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Health Communicators (including those specializing in risk comms.)	Yes	Yes
	Health Educators	Yes	Yes
	Management, budget, & administrative support	Yes	Yes
	Infection Prevention & control staff	Yes	Yes, may be allowable if the position is responsible for vaccine-related work
	Community Health Workers & organizations working with populations at higher risk for COVID-19	Yes	Yes
	Security staff (for personnel and clinic settings)	Yes	Yes
	Nurses or other staff used to administer vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
Equipment	**Laboratory equipment & necessary maintenance contracts at PHL (includes state PHLs that are affiliated with clinical or academic institutions)**	Yes	May be allowable if support is not available through the ELC CoAg.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Equipment	**Laboratory equipment & necessary maintenance contracts at local or regional PHLs**	Yes, to the extent that equipment is necessary to successfully complete the Activities listed in the guidance, resources (e.g. equipment) may be purchased. Disposition of these items, including any reporting on their location/condition, is the responsibility of the prime recipient of funds & must be in accordance with grant regulations and OGS policies.	Yes, to the extent that equipment is necessary to successfully complete the Activities listed in the guidance, resources (e.g. equipment) may be purchased. Disposition of these items, including any reporting on their location/condition, is the responsibility of the prime recipient of funds and must be in accordance with grant regulations and OGS policies. Equipment may include items such as vaccine storage units.
	General equipment (generators, freezers, computers)	Yes	Yes, may be allowable as they support COVID- 19 vaccine administration & reporting
	Vaccine storage equipment & necessary maintenance contracts	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Hardware/software necessary for robust implementation of electronic laboratory & surveillance data exchange between recipient & other entities (e.g. healthcare entities, jurisdictional public health, & CDC)	Yes	Yes
	Hardware/software that may be used to assist with case investigation & contact tracing	Yes	No
	Equipment necessary to ensure safety of laboratory workers (e.g. BSCs, HVAC, etc.)	Yes	No
Supplies	**Collection supplies, test kits, reagents, consumables & other necessary supplies for existing testing or onboarding new platforms**	Yes	May be allowable if support is not available through the ELC CoAg.
	Collection supplies, test kits, reagents, consumables & other testing or onboarding new platforms at regional or local health departments	Yes	May be allowable if support is not available through the ELC CoAg.
	Ancillary supplies & consumables necessary to perform testing for SARS-CoV-2 within or outside of traditional PHL setting	Yes	May be allowable if support is not available through the ELC CoAg.
	PPE for laboratorians or other staff conducting sample collection or	Yes	May be allowable if support is not available through the ELC CoAg.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Supplies	**processing. Also includes PPE for general staff as needed & deemed necessary by the work conditions**		
	PPE for use during vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
Software	**Software or systems to assist with laboratory resource management (e.g. software for inventory management, temperature notifications, etc.), quality management, biosafety, or training needs**	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Software/hardware necessary for robust implementation of electronic laboratory and surveillance data exchange between recipients and other entities, jurisdictional public health & CDC	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Tools that assist in the rapid identification, electronic reporting, monitoring, analysis, & evaluation of control measures to reduce the spread of disease (e.g. GIS software, visualization dashboards, cloud services, etc.)	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Software or applications that allow for more efficient case investigation & contact tracing	Yes	No
	Software associated with vaccine registries or tracking of vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Vaccine Registry enhancements	Enhancements to registries already initiated with ELC resources may be completed if it does not interfere with the successful completion of all required activities; however, these should be considered one-time system improvements. The ELC will not be able to maintain the costs of these systems or upgrades.	Yes
Construction & Renovation	**Renovations & minor construction (e.g. alteration of less than 50% total square footage of an existing structure, installation of a concrete**	Yes, may be considered for unique cases where conditions do not currently allow for safe or effective testing and/or delivery of effective public health services.	Yes, on a case by case basis and as it relates to vaccines or vaccination activities.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
	slab for modular laboratory units, etc.)		
Vehicles	**Leasing/purchasing vehicles (e.g. mobile testing, providing public health services in underserved areas, etc.)**	Yes, recipients will need to submit quotes with their revised budgets that are due within 60 days of award issuance and receive prior approval from OGS. After the revised NOA is issued, any further request for leasing/purchasing must be made through GrantSolutions and include the necessary quotes. Vehicles already purchased or leased for the purpose of testing may also be utilized for vaccine delivery	Leasing and rentals allowable, however, purchase is not
Quarantine & Isolation	**Quarantine & isolation support necessary for preventing the spread of COVID-19 (including wraparound services such as hoteling, food, laundry, mental health services, etc.)**	Yes, and may include wraparound services but not medical costs associated with treatment.	No
	Medication & patient treatment	No	No
Outreach & Education	**Expenses associated with outreach & assistance (e.g. support provided through community-based organizations) for those at higher risk of COVID-19**	Yes, these may include but are not limited to organizations that work with tribes, individuals experiencing homelessness, and racial and ethnic minority populations.	Yes, these may include but are not limited to organizations that work with tribes, individuals experiencing homelessness, and racial and ethnic minority populations.
	Health communications materials & health education services to inform & protect communities	Yes, health communications materials & health education services to inform & protect communities are allowable, if they do not duplicate activities covered by other CDC funding mechanisms (e.g., IP21-2106, IP21-2107). Recipients are reminded to be cognizant of the statutory & policy requirements for acknowledging the HHS/CDC funding when issuing statements, press releases, publications, requests for proposal, bid solicitations & other documents. In accordance with CDC General Terms & Conditions for Non-research Awards - Acknowledgement of Federal Funding, in your base award.	Yes, health communications materials & health education services to inform & protect communities are allowable, if they do not duplicate activities covered by other CDC funding mechanisms (e.g., IP21-2106, IP21-2107). Recipients are reminded to be cognizant of the statutory & policy requirements for acknowledging the HHS/CDC funding when issuing statements, press releases, publications, requests for proposal, bid solicitations & other documents. In accordance with CDC General Terms & Conditions for Non-research Awards - Acknowledgement of Federal Funding, in your base award.
	Support for social services & health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts	Yes	Yes, as it relates to vaccination activities
	Mass vaccination campaigns	Aspects of this activity may be supported if not already covered by another source.	Yes

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Stipends & Incentives	**Incentives to encourage participation by individuals (e.g., have testing done) or by a facility (e.g., onboard ELR for timely reporting of results)**	Stipends/incentives may be considered to encourage participation in testing and/or vaccination coverage for those put at higher risk for COVID-19 (individual level) or for facilities/agencies to enroll and/or report data to the health department (institutional level). Recipients interested in exploring this option (individual and/or institutional) must submit a plan that covers all of the following elements: (a) justification, (b) cost savings [e.g., how it will defray costs or have a positive return on investment], (c) defined amount, (d) qualifications for issuance, & (e) method of tracking. When submitting the revised budget within 60 days of award issuance, stipend/incentive plans must be included in the 'budget justification' section of the ELC budget workbook and receive CDC approval before implementation. After the revised NOA is issued, any subsequent requests for using funds to support stipends/incentives must be made in GrantSolutions, including the stipend/incentive plan, and receive CDC approval before implementation.	No, but please also speak with your POB Project Officer.
Contracts	**Contracts with academic institutions, private laboratories, other non-commercial healthcare entities, and/or commercial entities**	Yes	Yes, as it relates to vaccines or vaccination activities
	Contracts (or mini grants) with local or regional health departments	Yes	Yes
	Courier service (new or expansion of existing agreements)	Yes	Yes
	Contracts to support testing at non-traditional testing sites or POC tests	Yes	No
	Contracts to support testing at clinical, private, or academic institutions	Yes	No
Social Services	**Support for social services and health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts**	Support for social services & health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts.	Support for social services & education efforts that support vaccination activities.

12 Things States Need to Know about the Vaccine Adverse Event Reporting System (VAERS)

The federal government takes all reports of vaccine adverse events seriously, and CDC and the U.S. Food and Drug Administration (FDA) are actively engaged in safety monitoring of COVID-19 vaccines. CDC uses numerous vaccine safety monitoring systems, including VAERS, to watch for adverse events (possible side effects) after vaccination.

Q. What is the Vaccine Adverse Event Reporting System?

After a vaccine has been authorized or approved by the FDA, post-approval monitoring using VAERS begins. VAERS is a national system used by FDA and CDC to collect reports of adverse events that happen after vaccination. VAERS can provide vaccine safety experts with valuable information to assess possible safety concerns. VAERS is especially useful for quickly detecting unusual or unexpected patterns of adverse event reporting that might signal a possible safety problem with a vaccine.

Q. Who can report post-vaccination adverse events to VAERS?

Anyone can submit a report to VAERS. Healthcare professionals, health departments, vaccine manufacturers, vaccine recipients, and parents or family members of people who have received a vaccine are encouraged to submit a VAERS form if they experience any adverse events after getting any vaccine.

Q. What do CDC and FDA do when a VAERS report is submitted?

Experts from CDC and FDA monitor VAERS reports to identify adverse events that need to be studied further. All serious reports are reviewed daily by vaccine safety experts. Scientists at CDC and FDA use statistical models to help understand whether there are any safety signals for a vaccine product and compare them with safety signals for other vaccines to determine if further investigation is needed.

Helpful Hints for States:

- Work with your communications team when considering developing statements about reporting adverse events after COVID-19 vaccination.
- Each state has a vaccine safety coordinator who can serve as a liaison with local health departments, providers, and partners on vaccine safety issues.
- CDC staff is available to provide state and local health departments with technical support and communications around adverse events after COVID-19 vaccination.
- Contact COVID19VaxSafety@cdc.gov to reach CDC for non-urgent matters. For urgent matters, call **(770) 488-7100** to reach the CDC Emergency Operations Center.

Q. When does CDC follow up on reports submitted to VAERS?

VAERS staff obtains follow-up medical records for reports classified as serious. A serious report describes an event that resulted in permanent disability, hospitalization, life-threatening illness, or death. VAERS staff may also obtain follow-up medical records for adverse events of interest, like anaphylaxis. Reviewing these records can help CDC and FDA medical staff better understand cases.

www.cdc.gov/coronavirus/vaccines

MS-DOH-21-1816-A-000507

CS322534-A 02/03/21

Q. Will CDC follow up with people who submit VAERS reports?

The person who submits a VAERS report will receive a confirmation that VAERS has received the report or a reminder if important information was left out of the initial report. If additional information is needed, CDC may reach out to healthcare providers relevant to the case.

Q. What happens when a death is reported to VAERS?

When a death is reported to VAERS, CDC obtains medical records about the person's death, including an autopsy report, if available. If no autopsy was performed, CDC will obtain a death certificate and other relevant medical records. VAERS scientists will **not** reach out to the person who submitted the report, unless the name of the hospital or vaccination provider is **not** included.

Q: Do CDC and FDA provide VAERS reporters with an assessment following reports of serious adverse events, including death?

No. One of the limitations of VAERS is that VAERS generally cannot assess causality. However, as a hypothesis-generating system, VAERS is valuable for identifying potential vaccine safety concerns that can be studied further.

Q. Who are vaccine safety coordinators?

Vaccine safety coordinators are public health officials at jurisdiction health departments that serve as CDC's "eyes and ears" on vaccine safety issues and coordinate with CDC on incident response. They also serve as primary educators for vaccine safety reporting at the state and local level and coordinate local efforts to report vaccine adverse events to VAERS.

Q. What information from VAERS does CDC make available to vaccine safety coordinators each week?

Each week, CDC makes available via Epi-X a summary of VAERS reports received within the jurisdiction in the last week and a summary of VAERS data from other jurisdictions. CDC also sends a daily email notification whenever VAERS receives death reports from the jurisdiction. These reports are available via Epi-X.

Q. Do we need to follow up on VAERS reports filed in our jurisdiction?

Public health jurisdiction staff does **not** need to follow up on VAERS reports. VAERS staff will routinely follow up to obtain medical records for all reports of serious adverse events or death.

Q. When should we consider contacting CDC about COVID-19 vaccine adverse event reports?

Vaccine safety coordinators, immunization program managers, and other health department staff are welcome to contact CDC about vaccine safety issues at any time. Consider contacting CDC about:

- Unusual or unexpected vaccine adverse event reports
- Clusters of adverse events
- Vaccine administration errors
- Events that may impact public confidence in vaccination programs
- CDC laboratory and/or pathology support
- Requests for investigation by high-ranking state or local health officials
- Adverse event reports that may generate an increased level of media attention

Q. How can we contact CDC if there is an emergency relating to COVID-19 vaccine safety?

For public health emergencies, jurisdictions and providers may call the CDC Emergency Operations Center at **(770) 488-7100**.
For non-urgent concerns, jurisdictions and providers may email covid19vaxsafety@cdc.gov. For medical emergencies call **911**.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC Partner Alert: N95 Effectiveness as Source Control [Attachments]
    - Today, **Tuesday, January 11**, CDC issued a partner update (attached) in response to numerous questions about N95 mask effectiveness as source control. The update shared two peer reviewed publications from National Institute for Occupational Safety and Health (NIOSH) researchers (both attached) on N95 mask effectiveness, including findings that a N95 respirator was 99% effective at blocking cough aerosols.

HHS Update: COVID-19 Allocation Projections for January [Attachments]

- On **Friday, January 7**, the U.S. Department of Health and Human Services (HHS) issued an update with a projected calendar of allocation amounts and cadence of COVID-19 therapeutics for the remainder of January (attached). Questions may be directed to us COVID19Therapetuics@hhs.gov.

- Partner Alert: CDC Expands Booster Shot Eligibility [Attachment, Link]
  - On **Saturday, January 6**, CDC issued a partner alert (attached) adjusting its recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months. CDC has extended this recommendation to recipients of a Moderna primary series. This means that people 12 years of age and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.
- CDC COCA Call: What Clinicians Need to Know About the New Oral Antiviral Medications for COVID-19 [Links]
  - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **tomorrow, Wednesday, January 12 at 2:00 pm EST** to discuss the recent emergency use authorizations (EUAs) for new oral antiviral medications intended to decrease hospitalizations, as well as prevent severe COVID-19 and death Call information is below:
    - Weblink: https://www.zoomgov.com/j/1612974214?pwd=VitYMEorako1YWhCaXpnaWdsc2Ixdz09
      Telephone: (660) 254-5252 or (646) 828-7666 or (669) 216-1590 or (551) 285-1373
      Webinar ID: 161 297 4214
      Passcode: 180866
      Post-Event Recording:
      https://emergency.cdc.gov/coca/calls/2021/callinfo_011222.asp
- Reminder: CDC Preventive Medicine Grand Rounds: "The Public Health System of the Future – Moving Ahead in Partnership with Health Care & Other Sectors" [Link]
  - CDC will host its monthly Preventive Medicine Grand Rounds **tomorrow, Wednesday, January 12** at **1:30 pm EST**. The session will focus on the public health system of the future and the speaker is John Auerbach, Director of Intergovernmental and Strategic Affairs for CDC. Continuing education (CE) is available at no cost. Registration information is available here.

Standing Updates

- CDC Partner Update – January 10 [Attachment]
  - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – January 10 [Link]
  - Please click here for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.

- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
  - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am ET**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC Resources

New & Updated

- CDC Recommends Moderna Booster at 5 Months: On January 4th, CDC made this recommendation for recipients of a Pfizer-BioNTech primary series. After FDA action on January 7th, we're extending this recommendation to recipients of a Moderna primary series. This means that people who initially received an mRNA vaccine series——two doses of Moderna or Pfizer-BioNTech —can now receive an mRNA booster shot 5 months after completing their initial series.
- Guidance for COVID-19 Prevention in K-12 Schools was recently updated to reflect new recommendations for isolation for people with COVID-19 and recommendations for people who have come into close contact with a person with COVID-19.
- CDC Expands Booster Shot Eligibility and Strengthens Recommendations for 12-17 Year Olds: CDC now recommends that adolescents age 12 to 17 years old should receive a booster shot 5 months after their initial Pfizer-BioNTech vaccination series.
- CDC Recommends Pfizer Booster at 5 Months, Additional Primary Dose for Certain Immunocompromised Children: On January 4th, CDC updated its recommendation for when many people can receive a booster shot, shortening the interval from 6 months to 5 months for people who received the Pfizer-BioNTech COVID-19 Vaccine.
- Stay Up to Date with Your Vaccines: To align with standard language CDC uses about other vaccinations, CDC is now using the phrase "up to date" when talking about COVID-19 vaccination. CDC recommends that individuals stay "up to date" by receiving any additional doses they are eligible for, according to CDC's recommendations, to ensure they have optimal protection against COVID-19. The technical definition of "fully vaccinated"—two doses of an mRNA vaccine or one dose of the J&J vaccine—has not changed.
- What We Know About Quarantine and Isolation provides information on why CDC shortened quarantine and isolation guidance for the general population.

DRAFT – PRE-DECISIONAL & DELIBERATIVE

Therapeutic Allocation

	Drug Class	Allocation Cadence	Sweep Schedule	Allocation Jan 3	Planned Allocation Jan 10	Planned Allocation Jan 17	Planned Allocation Jan 24	Planned Allocation Jan 31
Paxlovid *Pfizer*	Oral antiviral	Bi-Weekly	N/A	0	100,000	0	100,000	0
Molnupirivir *Merck*	Oral antiviral	Bi-Weekly	N/A	0	400,000	0	400,000	0
Evusheld *AstraZeneca*	Monoclonal for prevention	Weekly	N/A	50,000	75,000	75,000	75,000	75,000
Sotrovimab *GSK/Vir*	Monoclonal for treatment	Weekly	N/A	50,000	52,250	52,250	52,250	52,250
Bamlanivimab/ Etesevimab *Lilly*	Monoclonal; omicron resistance	Weekly	Weekly; Saturday	45,000	**45,000*	**45,000*	**45,000*	**45,000*
REGEN-COV *Regeneron*	Monoclonal, omicron resistance	Weekly	Weekly; Saturday	55,000	**55,000*	**55,000*	**55,000*	**55,000*
Remdesivir *Gilead*	IV antiviral	N/A; Commercial Market	N/A	N/A	N/A	N/A	N/A	N/A

** With the rise of the omicron variant, clinically appropriate use should be considered for bam/ete and REGEN-COV. Allocations of these products are subject to change based on omicron prevalence data.*

FOR OFFICIAL USE ONLY – NOT FOR FURTHER DISTRIBUTION

From: ASPR Stake Holder (OS/ASPR) <ASPRStakeholder@hhs.gov>
Sent: Friday, January 7, 2022 5:41:02 PM
Subject: HHS Update: COVID-19 allocation projections for January

Dear State and Territorial Health Officials,

Thank you for your continued partnership in this all-of-America approach to fighting the COVID-19 pandemic. It remains our goal to facilitate a fair and equitable process in the allocation of COVID-19 therapeutics, and we certainly couldn't do this without you. We know that providing a longer look ahead for expected allocation amounts will help further support your jurisdictional planning. As such, attached is a projected calendar of allocation amounts and cadence for the remainder of January. Of course, the COVID-19 environment is very dynamic; so, these projections could change based on daily analysis of related data.

Additionally, we wanted to provide you with an update regarding Gilead's product - VEKLURY(tm) (remdesivir), which is not allocated by the federal government but is available commercially. Following the recent statement from the National Institutes of Health (NIH) COVID-19 Treatment Guidelines Panel regarding therapies for the COVID-19 Omicron variant, CMS created HCPCS code J0248 for the VEKLURY(tm) (remdesivir) antiviral medication when administered in an outpatient setting. This code is available for use by all payers and is effective for dates of service on or after December 23, 2021:

* Long descriptor: Injection, remdesivir, 1 mg
* Short descriptor: Inj, remdesivir, 1 mg

Medicare Administrative Contractors (MACs) determine Medicare coverage when there is no national coverage determination, including in cases when providers use FDA-approved drugs for indications other than what is on the approved label. The MACs consider the major drug compendia, authoritative medical literature and accepted standards of medical practice to determine medical necessity when considering coverage. Therefore, the MACs will determine Medicare coverage for HCPCS code J0248 for VEKLURY(tm) (remdesivir) administered in an outpatient setting.

Thank you, again, and please contact us at COVID19Therapetuics@hhs.gov with any questions.

Regards,
HHS - Coordination Operations and Response Element (H-CORE)
Office of the Assistant Secretary for Preparedness and Response
U.S. Department of Health and Human Services

ABSTRACT

Universal mask wearing is recommended to help control the spread of COVID-19. Masks reduce the expulsion of aerosols of respiratory fluids into the environment (called source control) and offer some protection to the wearer. Masks are often characterized using filtration efficiency, airflow resistance, and manikin or human fit factors, which are standard metrics used for personal protective devices. However, none of these metrics are direct measurements of how effectively a mask blocks coughed and exhaled aerosols. We studied the source control performance of 15 cloth masks (face masks, neck gaiters, and bandanas), two medical masks, and two N95 filtering facepiece respirators by measuring their ability to block aerosols $\leq$7 µm expelled during simulated coughing and exhalation (called source control collection efficiency). These measurements were compared with filtration efficiencies, airflow resistances, and fit factors measured on manikin headforms and humans. Collection efficiencies for the cloth masks ranged from 17% to 71% for coughing and 35% to 66% for exhalation. Filtration efficiencies for the cloth masks ranged from 1.4% to 98%, while the fit factors were 1.3 to 7.4 on headforms and 1.0 to 4.0 on human subjects. The Spearman's rank correlation coefficients between the source control collection efficiencies and the standard metrics ranged from 0.03 to 0.68 and were significant in all but two cases. However, none of the standard metrics were strongly correlated with source control performance. A better understanding of the relationships between source control collection efficiency, filtration efficiency, airflow resistance, and fit factor is needed.

Introduction

Humans infected with SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can produce droplets and aerosols of respiratory fluids containing the virus when they cough, breathe, talk, sing and sneeze (Anderson et al. 2020; CDC 2020b; Hamner et al. 2020; Ma et al. 2020; Morawska and Milton 2020). To reduce the transmission of SARS-CoV-2, public health agencies have recommended that the general public wear cloth masks (CDC 2020c, 2020d, 2021; Edelstein and Ramakrishnan 2020; WHO 2020). The primary purpose of masks (which in this article includes face masks, neck gaiters, bandanas and other face coverings) is to block the expulsion of infectious droplets and aerosols from the wearer into the environment (called source control) and thereby reduce the exposure of other people to the virus (CDC 2020a). Laboratory studies using manikins and human subjects have shown that cloth face masks can partially block respiratory aerosols produced during coughing, breathing and talking (Asadi et al. 2020; Davies et al. 2013; Lindsley et al. 2021; Pan et al.

2021). Wearing medical face masks (i.e., "surgical masks" as defined by the U.S. Food and Drug Administration [FDA 2004]) reduces the dispersion of potentially infectious aerosols from patients with respiratory infections (Leung et al. 2020; Milton et al. 2013). Masks may also provide some personal protection to the wearer by reducing their exposure to infectious droplets and aerosols produced by others, although they are not as effective as a respiratory protective device such as a NIOSH-approved N95 filtering facepiece respirator (N95 respirator) (CDC 2020a; Lawrence et al. 2006; Oberg and Brosseau 2008; Pan et al. 2021). Several community level studies have shown that universal masking helps reduce the spread of COVID-19 (CDC 2020a). For example, a comparison of counties in the US state of Kansas found that mask mandates were associated with lower incidence rates of COVID-19 (Van Dyke et al. 2020). A study of 10 US states found that statewide mask mandates were associated with a decline in weekly COVID-19–associated hospitalization growth compared to states without such mandates (Joo et al. 2021).

In response to the need for source control devices for the general public, manufacturers worldwide have produced a broad array of masks. Unfortunately, because of the many different designs and construction materials, it is not possible to predict how well a particular mask will perform as a source control device without testing, which is rarely done for non-medical masks not intended for occupational use. Although general guidelines have been developed (CDC 2020d), it is very difficult for public health organizations, governments, medical facilities, and the general public to know which of the available devices are most effective.

Test methods and performance standards do exist for regulated medical face masks and respiratory protective devices (Rengasamy et al. 2017). In the United States, respiratory protective devices, which are devices such as N95 filtering facepiece respirators that are intended to protect the wearer from airborne particles, must be approved by the National Institute for Occupational Safety and Health (NIOSH) under 42 Code of Federal Regulations (CFR) Part 84 (NIOSH 1995). The approval process includes testing the filtration efficiency for the most-penetrating aerosol particle size and measuring the airflow resistance of the device (NIOSH 2019). Medical face masks that are not intended to be used as respiratory protective devices are cleared by the Food and Drug Administration (FDA), which reviews manufacturer-supplied information on filtration efficiency, airflow resistance, resistance to fluid penetration and flammability (FDA 2004). The FDA recommends that manufacturers use the ASTM standards F2299 for measuring particle filtration efficiency through the mask material using latex microspheres (ASTM 2003), and the F2101 Standard test method of evaluating the bacterial filtration efficiency (BFE) of medical face mask materials, using a biological aerosol of *Staphylococcus aureus* (ASTM 2019). Bacterial filtration efficiency can also be measured with the modified Greene and Vesley method using human test subjects (Greene and Vesley 1962; Quesnel 1975).

In addition to filtration performance, how well a respiratory protective device protects the wearer depends upon how well the device fits the face and whether the seal between the face and the device has gaps or leaks (Lawrence et al. 2006). ASTM Standard F3407-20 outlines procedures for testing respirators using a bivariate panel of human test subjects with different facial dimensions (ASTM 2020). The NIOSH approval test for respirators measures the filtration properties but does not include tests of how well the device fits faces of different shapes, although this has been proposed. Consequently, in the United States, when a worker is required to wear a respirator, the Occupational Safety and Health Administration (OSHA) requires that a respirator fit test be performed annually for each worker to determine how well the respirator protects the worker (OSHA 2020). Quantitative fit tests measure the aerosol particle concentration inside and outside the respirator during a series of exercises, and this information is used to calculate the fit factor (outside concentration/inside concentration) (Janssen and McKay 2017). The minimum acceptable fit factor for a respirator depends upon the exposure level and potential health consequences of the hazards to which the worker may be exposed (OSHA 2020).

The existing test methods for respirators and medical face masks provide a possible basis for developing standards for non-medical masks used as source control devices. The American Association of Textile Chemists and Colorists (AATCC) published guidelines for cloth face coverings that include the use of ASTM F2299 and other national and international performance standards (AATCC 2020). Leith, L'Orange, and Volckens (2021) proposed an estimated mask protection factor that is calculated based on tests of filtration efficiency and fit and on estimates of the average time spent speaking, inhaling, and exhaling. ASTM International has released a standard for testing barrier face coverings that includes tests of filtration efficiency and airflow resistance, and an assessment of leakage, which are standard metrics that are commonly used to test personal protective devices (ASTM 2021). The use of these standard performance metrics has many advantages, most notably that the equipment and procedures needed to conduct the tests are widely available. However, none of these metrics are

Table 1. Performance metrics used in this study. Outward mask airflow is in the direction of exhalation. Inward airflow is in the direction of inhalation.

Performance metric	**Parameter measured**	Mask airflow direction	Measurement instrument	**Measurement method**	Particle size	**Instrument airflow rate (liters/minute)**
Cough aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Outward	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Exhaled aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Cyclical	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Filtration efficiency	Aerosol mass concentration upstream & downstream of mask	Inward	TSI 8130 A	Photometer	75 nm count median diameter (GSD 1.86)	85
Airflow resistance	Pressure required for 85 lpm flow	Inward	TSI 8130 A	Manometer	n/a	85
Manikin fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode)	0.35
Human fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode) 0.02–1.0 μm (Class 100 mode)	0.35

direct measurements of the ability of a mask to block aerosols expelled during coughing and exhalation. To assist in the further development of these types of standards and guidelines, the relationship between the efficacy of masks as source control devices and their performance using standard metrics needs to be better understood. For example, it is possible to measure the filtration efficiency of the mask material, but it is not clear how that filtration efficiency translates to source control efficacy or what minimum performance level should be required.

The purpose of this study was to compare the performance of a variety of N95 respirators, medical masks, and cloth masks as source control devices with their filtration efficiencies, airflow resistances, fit factors measured using manikin headforms, and fit factors measured on humans. The results of these experiments will assist in the development of appropriate test methods and standardized performance metrics to evaluate the efficacy of cloth masks as source control devices for respiratory aerosols.

Materials and methods

Experimental design

A source control measurement system was used to assess the efficacy of N95 respirators, medical masks, and cloth masks as source control devices. The source control performance was determined by measuring the source control collection efficiency of the mask, which is the fraction of the mass of the coughed or exhaled test aerosol particles that were blocked by the mask from reaching the collection chamber. The filtration efficiencies and airflow resistance of the construction materials were measured using a modified version of the test method used for respirator approvals. Fit tests were performed both on a manikin headform with pliable skin and with human test subjects. The source control collection efficiencies were then compared with the fit factors, filtration efficiencies and airflow resistances measured on the same devices. A summary of the performance metrics used in the study is shown in Table 1.

Respiratory aerosol source control measurement system

The efficacy of respirators, medical masks, and cloth masks as source control devices for aerosols produced during coughing and exhalation was determined using a respiratory aerosol source control measurement system described previously (Lindsley et al. 2021). The system includes a coughing and breathing aerosol simulator, a manikin headform, an 136 L aerosol collection chamber, and a cascade impactor (Figure 1). The manikin headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each source control device would fit a human face (Bergman et al. 2014).

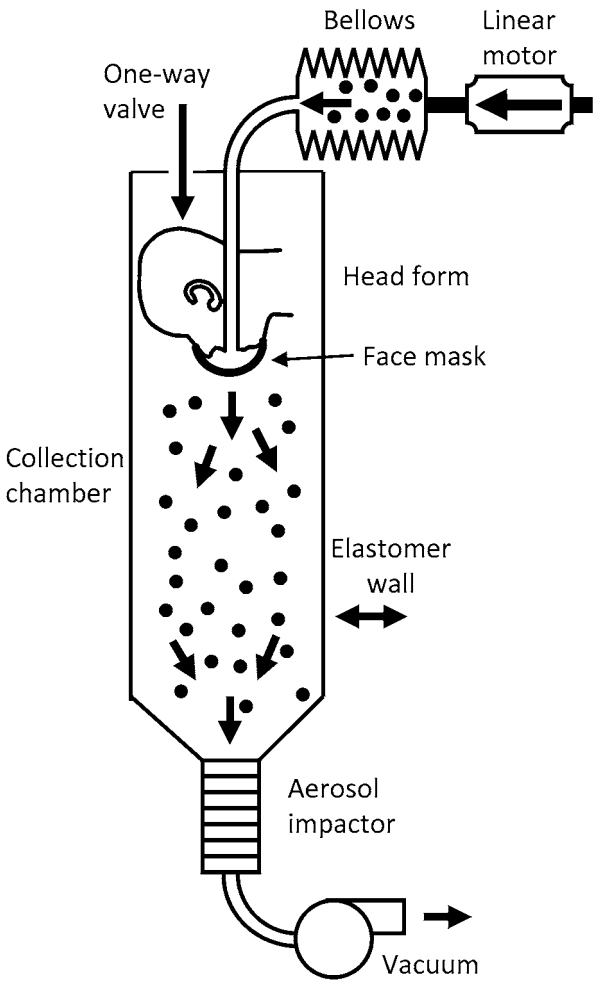

Figure 1. Source control measurement system. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated coughing and breathing, a pliable skin headform on which the source control device is placed, a 136 liter collection chamber into which the aerosol is coughed or exhaled, and a cascade impactor to separate the aerosol particles by size and collect them. The system is oriented vertically as shown to minimize the loss of aerosol particles due to settling before collection. The system is described in more detail in Lindsley et al. (2021).

The test aerosol was produced using a solution of 14% potassium chloride (KCl) and 0.4% sodium fluorescein in a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2). The aerosol passed through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), mixed with dry filtered air flowing at 10 L/min for the cough tests and 15 L/min for the breathing tests, and neutralized using a bipolar ionizer (Model HPX-1, Electrostatics). An elastomeric bellows driven by a computer-controlled linear motor produced the coughing or breathing airflow.

For cough tests, the test aerosol was loaded into the elastomeric bellows and then coughed out using a single cough with a volume of 4.2 L and a peak flow rate of 11 L/s (Lindsley et al. 2013). An Andersen cascade impactor (Model TE-10-830, Tisch Environmental) collected all aerosol particles that traveled through or around the device for 20 min after each cough. For breathing tests, the system used a ventilation rate of 15 L/min with a breathing rate of 12 breathes/min and a tidal volume of 1.25 liters, which corresponds to the ISO standard for a female performing light work (ISO 2015). The test aerosol was only generated for the first 30 s of breathing to avoid overloading the impactor. The breathing continued for 20 min total. The impactor collected the aerosol particles in the chamber during the 20-minute breathing period followed by an additional five minutes of collection after the breathing had stopped.

The impactor operated at a flow rate of 28.3 liters/minute and had six collection stages and a filter that separated the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm; 4.7–7.0 µm; and >7 µm. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). Because the amount of aerosol in the largest size fraction was small (<0.7% of total aerosol mass) and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction were not included in the analysis. After aerosol collection was completed, the aerosol particles were eluted from the impactor plates using a 0.1 M Tris solution and the fluorescence of the solution was read using a spectrofluorometer (SpectraMax M4, Molecular Devices).

To control for variations in the amount of aerosol in each experiment, a sample of each test aerosol was collected from the bellows prior to coughing or breathing using a 47 mm 5 µm PVC filter. The aerosol was eluted from the filter using 0.1 M Tris. An adjustment factor for the experiment (A) was calculated as:

$$A = \frac{Mass\ of\ aerosol\ on\ filter}{Mean\ (mass\ of\ aerosol\ on\ filter\ for\ all\ control\ experiments)} \quad (1)$$

The adjusted mass of aerosol on each impactor stage for the experiment was then calculated as:

$$M_{stage,\ adjusted} = \frac{M_{stage,\ unadjusted}}{A} \quad (2)$$

The adjusted masses were used for all subsequent calculations. The adjusted aerosol masses collected by the cascade impactor during the experiments are

Table 2. Source control devices used in experiments.

Type	Manufacturer	Product	Fastener	Material
Medical masks & respirators	3M	Model 1860 N95 respirator and surgical mask (TC-84A-0006)	Two elastic straps around head	Polypropylene and polyethylene composition

In this article, the reusable cloth face masks, neck gaiters and bandanas are referred to collectively as "cloth masks". IL is inner layer, ML is middle layer, and OL is outer layer. Photographs are shown in Figures S3–S5 (SI).

shown in Tables S1 and S2 in the supplemental information (SI).

The source control performance, or source control collection efficiency, of a face covering is defined as the fraction of the mass of the respiratory aerosol that is blocked from entering the environment around the wearer. For example, if 80% of the mass of the aerosol from a cough is blocked by a face mask and 20% of the aerosol mass is able to flow through or around the mask into the air around the wearer, then the mask is said to have a collection efficiency of 80%. The performance of each source control device was evaluated by calculating the collection efficiency as:

$$Collection\ efficiency = 1 - \frac{M_{mask}}{M_{control}} \qquad (3)$$

where:

M_{mask} = adjusted total mass of the aerosol particles that passed through or around the source control device and was collected by the impactor.

$M_{control}$ = adjusted total mass of the aerosol particles collected by the impactor while not wearing a source control device.

Note that the collection efficiency is based on the mass of the aerosol rather than a measure such as particle counts. Also, the aerosol is flowing from the inside of the mask toward the outside; that is, in our test system the aerosol flows in the same direction as it would flow during a cough or exhalation by a person wearing the mask.

Respirators, medical masks, and cloth masks

In our study, the term "cloth mask" refers to a cloth face mask, neck gaiter or bandana constructed from textiles or fabrics (both natural and synthetic) that is not a surgical mask or N95 respirator and is not intended for use as personal protective equipment. The term "medical masks" in this article refers to non-woven disposable masks that are held on the face with elastic ear loops. These masks are loose-fitting and are not expected to provide the wearer with as reliable a level of protection against airborne or aerosolized particles as N95 respirators regulated by NIOSH. Commercial manufacturers often refer to

masks held on by ear loops as procedure masks and masks that tie behind the head as surgical masks. However, the U.S. Food and Drug Administration uses the term "surgical mask" to describe commercially produced masks regulated by the under 21 CFR 878.4040 for performing medical procedures (FDA 2004). The FDA definition applies to all masks that cover the user's nose and mouth and provides a physical barrier to fluids and particulate materials, and includes masks that are labeled as surgical, laser, isolation, dental or medical procedure masks with or without a face shield.

Nineteen commercially available N95 respirators, medical masks, and cloth masks were selected to provide a broad cross-section of the different types of source control devices that are available (Table 2). For the source control tests, each device was placed on the headform as it would normally be worn by a person. Three of the neck gaiters were tested both as a single layer of fabric and folded over to provide two layers of fabric. Before the source control test, the manikin fit factor (Janssen and McKay 2017) was measured by performing a respirator fit test (Bergman et al. 2015) for each device using a PortaCount® Pro + respirator fit tester (Model 8038, TSI, Shoreview, MN) in N95 mode with the system breathing at 36 L/min but not producing an aerosol. Each device was used for two consecutive tests. Photographs of the source control devices on the headform are shown in the SI (SI; Figures S1–S3).

Filtration efficiency and airflow resistance measurements

The filtration efficiency of the face covering is the fraction of the test aerosol that is collected as the aerosol passes through the mask material. For example, if 70% of the test aerosol is collected by the mask material and 30% of the aerosol passes through it, then the filtration efficiency is 70%. Note that the filtration efficiency tests are performed by fastening the mask to a holder so that all the aerosol flows through the mask material, and none can escape through face seal leaks. Thus, the filtration efficiency is a property of the mask material.

The filtration efficiency and airflow resistance of the construction materials were measured using automated filter testers (Models 8130 and 8130 A, TSI). Material samples were secured to a test plate using beeswax as shown in Figure S4 in the SI. Measurements were made using a modified version of the NIOSH standard testing procedure (STP) (NIOSH 2019). Under the modified STP, samples were tested at ambient temperature and humidity but were not subjected to conditioning at 38°C and 85% relative humidity for 25 h, and sample testing was limited to 10 min. The device to be tested was oriented in the filter tester so that the air and aerosol flowed from the exterior of the device toward the interior (that is, as if the wearer were inhaling, which is the same direction as when testing a respirator as a personal protective device). The challenge aerosol was generated using a 2% sodium chloride (NaCl) solution in distilled water, conditioned to 25 °C and 30% relative humidity and neutralized to the Boltzmann equilibrium state. The challenge aerosol had a count median diameter of 75 nm ± 20 nm, a mass mean diameter of 260 nm and a geometric standard deviation (GSD) $\leq$ 1.86 (TSI 8130 A specifications). The automated filter tester compares particle mass concentration readings from upstream and downstream light-scattering laser photometers to calculate the material filtration efficiency. An electronic pressure transducer measures the pressure difference across the material sample to indicate airflow resistance. Tests were performed with an airflow of 85 L/minute.

Fit tests on human subjects

A convenience sample of eleven subjects (six males and five females) participated in fit testing. Subjects complied with CDC/NIOSH guidelines for facial hair styles intended for workers who wear tight-fitting respirators (CDC 2017). Fit testing was performed with a PortaCount® fit tester (model 8038, TSI) using OSHA's modified ambient aerosol condensation nuclei counter (CNC) protocol for filtering facepiece respirators (OSHA 2019). Because only fit factors were measured and no identifiable private information was collected, the West Virginia University Office of Human Research Protections determined that Institutional Review Board approval was not required. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy (see e.g., 45 C.F.R. part 46; 21 C.F.R. part 56; 42 U.S.C. §241(d), 5 U.S.C. §552a, 44 U.S.C. §3501 et seq.). All measurements were performed in a room with volume of 43.4 m^3 (1531 ft^3) at 19 °C (67 °F).

An NaCl aerosol generator (Model 8026, TI) was used to supplement the naturally occurring particles in the air. The particle generator was placed 10 feet away from all sampling apparatus and fit testing equipment. The generator was turned on ten minutes prior to testing to seed aerosols and turned off while

a triplicate series of fit tests were performed (around 7 min). As the aerosol concentration in the room had started to slightly decline at this point, the generator was turned on between tests (around 7 min) and then turned off during subsequent tests. This process was repeated until testing for the day was completed.

To verify that suitable aerosol concentrations were present during testing, particle concentrations were measured with a condensation particle counter (CPC Model 3775, TSI) for 25 min beginning at 2 min prior to the nebulizer being initially turned on. Particle size distributions were measured for 20 min with a scanning mobility particle sizer (SMPS Model 3938, TSI) and an electrical low-pressure impactor (ELPI+, Dakati). Information on the aerosol particle size distribution and concentration are shown in the SI (Figures S5 and S6).

Each source control device was tested by three subjects; for each subject three replicate measurements were made using each of the two protocols described below. One individual administered all fit tests. Subjects were instructed in the proper donning of medical masks and respirators, and they were asked to don cloth masks in the manner that they ordinarily don similar coverings for public use. If a cloth mask was too large, it was modified using materials that would be accessible to most lay individuals: tape was used to shorten mask ear loops or head straps, and a binder clip was used to decrease the circumference of neck gaiters. These adjustments were made so that the covering was held flush to the face, but the materials were not under tension.

Two particle measurement protocols were performed on all source control devices: the PortaCount® N95 Companion protocol (referred to here as N95 mode), which counts negatively charged particles 40–70 nm (mean 55 nm) in diameter; and the PortaCount® standard protocol (referred to here as Class 100 mode), which counts all particles from 0.02–1.0 µm (TSI 2010). The "Class 100 mode" is also called "N99 mode". For both modes, the fit factor (FF) was calculated by the PortaCount® software as (Janssen and McKay 2017; TSI 2015):

$$FF = \frac{C_B + C_A}{2C_R} \quad (4)$$

where:

C_B = ambient particle concentration measured before the particle concentration is measured inside the respirator.

C_A = ambient particle concentration measured after the particle concentration is measured inside the respirator.

C_R = particle concentration measured inside the respirator.

Note that the TSI PortaCount instrument used in our experiments measures the aerosol concentration based on the number of aerosol particles rather than the particle mass.

Data analysis

The source control results were compared with the filtration efficiencies, airflow resistances, and fit factor measurements by calculating the Spearman's rank correlation coefficients (ρ) between the metrics. Fit factors were transformed into fit efficiencies (= 1-1/fit factor) to allow for a direct comparison with the other parameters. For example, a fit factor of 5 corresponds to a fit efficiency of 80%, indicating that the mask blocked 80% of the ambient aerosol from being inhaled by the wearer. Because the replicate numbers were different for the different performance metrics, the correlations were calculated based on the mean results for each device. When analyzing the human fit factor results, we did not attempt to account for differences among test subjects. The p-value was calculated based on ρ and the number of types of devices that were tested (22 for all source control devices and 18 for the cloth masks alone, with the 1-layer and 2-layer gaiter tests counted separately). Correlations were considered significant if $p \leq 0.05$.

Results

Efficacy of N95 respirators, medical masks, and cloth masks as source control devices for respiratory aerosols

Twenty-six cough experiments were performed without a source control device to measure the cough aerosol output from the source control measurement system. The cough aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 525 µg (standard deviation [SD] 65; Figure 2 and SI Figure S7). Thirty-five breathing aerosol experiments were performed without a source control device to measure the exhaled aerosol output. The exhaled aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 495 µg (SD 68; Figure 2 and SI Figure S8). The experiments without source control devices were used as control experiments when evaluating performance of the devices.

The collection efficiencies of the 19 source control devices are shown in Figure 3 and Table 3. The mean

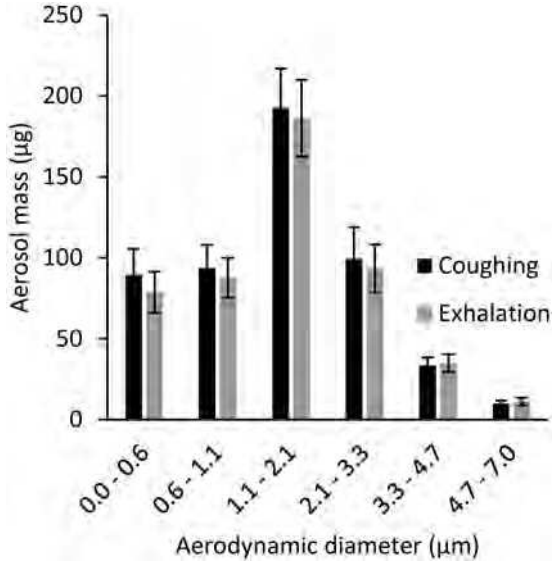

Figure 2. Mass of aerosol expelled by the source control measurement system during coughs and exhalations. The size bins correspond to the stages of the Andersen impactor. The size distribution is shown in units of µg/µm in Figures S7 and S8 in the SI.

collection efficiencies of the N95 respirators and the surgical mask ranged from 83% to 99% for aerosol particles during coughing and exhalation. For the procedure and cloth masks, the mean collection efficiencies ranged from 35% to 71% for coughing (except for the bandana at 17%) and 35% to 66% for exhalation. The collection efficiencies for the coughing and breathing source control experiments were correlated, with a Spearman's correlation coefficient (ρ) of 0.76 ($p < 0.001$; Table 4) when considering all the devices and 0.67 ($p = 0.003$; Table 4) when considering only the cloth face masks, gaiters and bandanas. The amounts of aerosol collected on each stage of the impactor are shown in Tables S1 and S2 in the SI.

Filtration efficiencies and inhalation airflow resistance

The mean material filtration efficiencies were >99% for the respirators, 80% to 93% for the medical masks, and 1.4% to 36% for the cloth face masks, neck gaiters, and bandanas, except for the Besungo sports mask at 98% (Figure 4 and Table 3). The inhalation

Manikin fit factors were measured with the fit tester in N95 mode only (as described in the Discussion). Human fit factors were measured using both the N95 mode and Class 100 mode.

Table 4. Correlations between different performance metrics for all source control devices.

		All source control devices		Cloth face masks, gaiters, and bandanas only	
Correlation parameter #1	Correlation parameter #2	ρ	*p*-value	ρ	*p*-value
Cough aerosol collection efficiency	Exhaled aerosol collection efficiency	0.76	<0.001	0.67	0.003
	Filtration efficiency of material	0.69	0.001	0.51	0.032
	Airflow resistance of material	0.55	0.009	0.54	0.020
	Human subject fit (N95 mode)	0.57	0.005	0.30	0.208
	Human subject fit (Class 100 mode)	0.68	<0.001	0.48	0.035
	Manikin fit before coughing	0.39	0.076	0.03	0.890
Exhaled aerosol collection efficiency	Filtration efficiency of material	0.60	0.004	0.54	0.023
	Airflow resistance of material	0.51	0.016	0.58	0.012
	Human subject fit (N95 mode)	0.60	0.003	0.51	0.024
	Human subject fit (Class 100 mode)	0.71	<0.001	0.63	0.003
	Manikin fit before breathing	0.72	<0.001	0.68	0.002
Manikin fit before coughing	Manikin fit before breathing	0.61	0.003	0.38	0.112
Filtration efficiency of material	Airflow resistance of material	0.78	<0.001	0.78	<0.001

Each Spearman's rank coefficient (ρ) was calculated based on data from 22 experiments for all source control devices and 18 experiments for cloth masks (cloth face masks, gaiters, and bandanas). A correlogram of the ρ values in shown in Figure S9 in the SI.

airflow resistances were from 5.2 to 154 Pa (Table 3). When comparing the data for all devices, the filtration efficiencies were correlated with cough aerosol collection efficiency ($\rho = 0.69$, $p = 0.001$) and exhaled aerosol collection efficiency ($\rho = 0.60$, $p = 0.004$; Table 4). For the group of cloth masks, the correlations were not as strong; the cough aerosol collection efficiency and filtration efficiency had an ρ of 0.51 ($p = 0.032$) while the exhaled aerosol collection efficiency and filtration efficiency had an ρ of 0.54 ($p = 0.023$; Table 4). The airflow resistance did not correlate as well as the filtration efficiency when all devices were considered ($\rho = 0.55$ and $p = 0.009$ for coughing; $\rho = 0.51$ and $p = 0.016$ for exhalation). However, when examining the cloth masks alone, the airflow resistance was slightly better correlated than filtration efficiency ($\rho = 0.54$ and $p = 0.020$ for coughing; $\rho = 0.58$ and $p = 0.012$ for exhalation).

Human fit tests

The fit factors measured on the human test subjects are shown in Table 3 and Figure 5. The mean fit factors for the two N95 respirators were 148 and 164

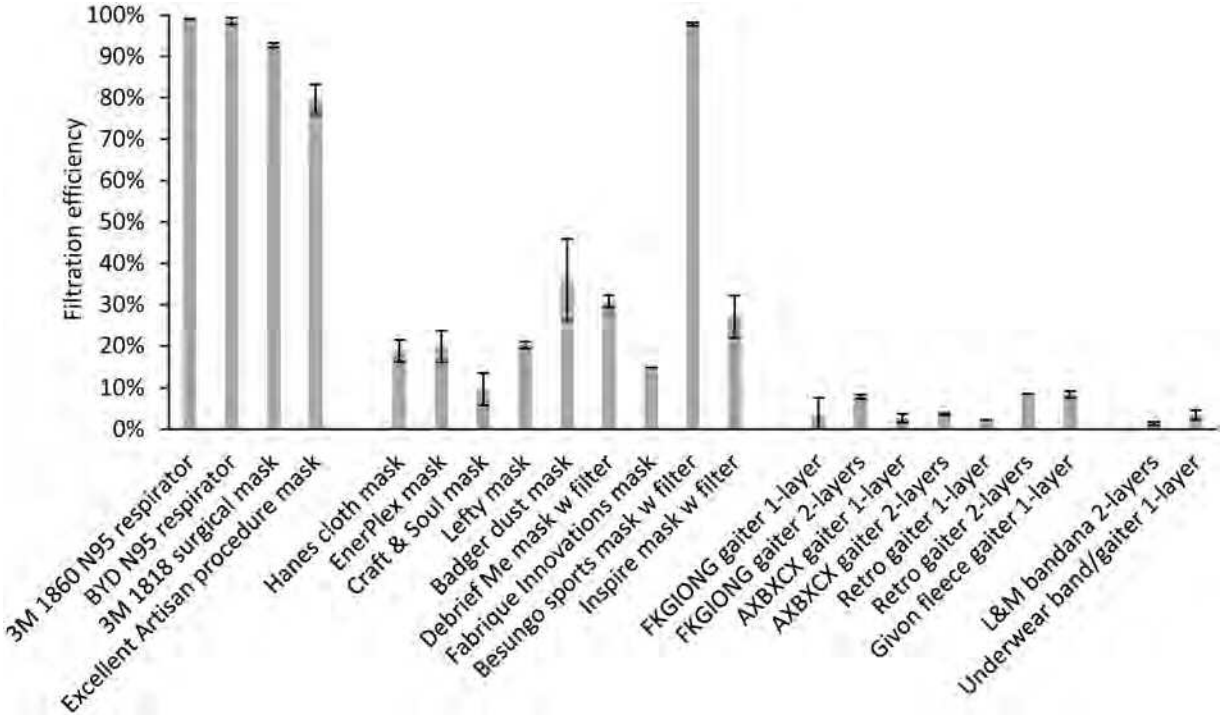

Figure 4. Filtration efficiencies for the source control devices used in the study. Three samples of each device were tested, except for the 3 M 1860 N95 respirator and Hanes cloth mask (10 samples each) and the Fabrique Innovations mask, Retro gaiter 1-layer, and Retro gaiter 2-layers (one sample each). Error bars show the standard deviation.

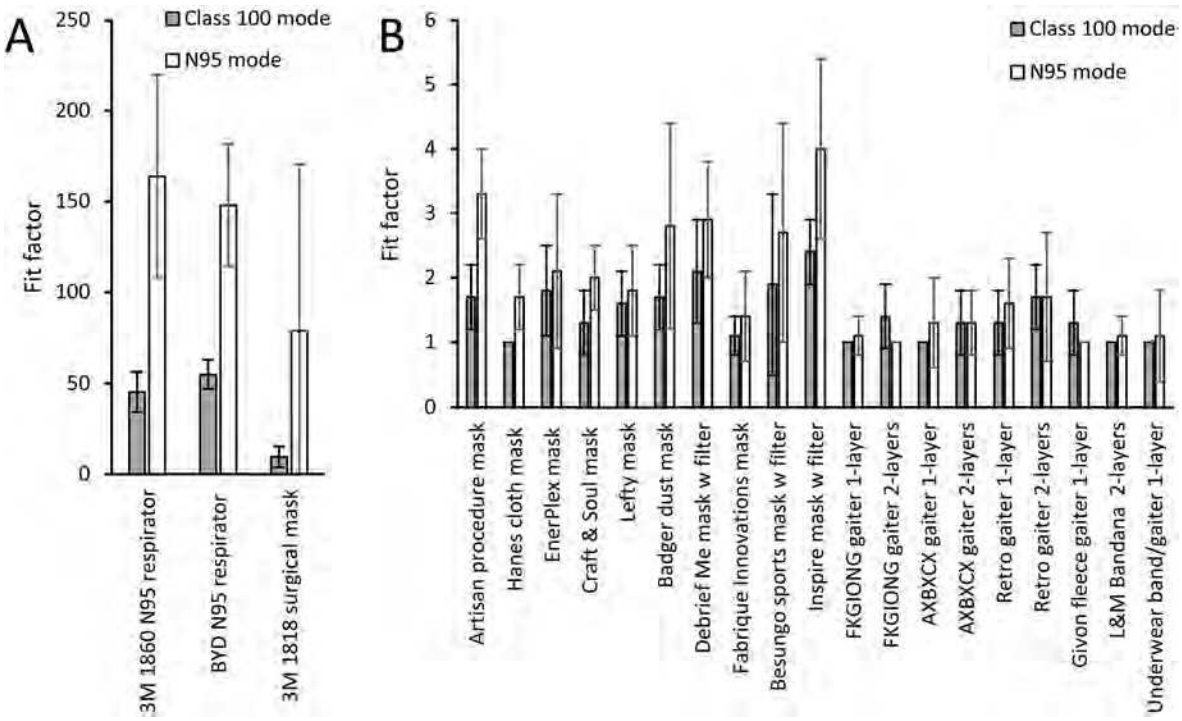

Figure 5. Fit factors measured with human subjects for (a) N95 respirators and surgical mask and (b) procedure mask, cloth face masks, gaiters and bandanas. The plot shows the means and standard deviations. Results for all human fit tests are given in Table S3 in the SI.

when using the N95 mode on the fit tester and 55 and 45 with the Class 100 mode. The surgical mask provided a mean N95 mode fit factor of 79 and a much lower mean fit factor of 9.6 in Class 100 mode. The mean N95 mode fit factor of the reusable cloth face masks ranged from 1.4 to 4.0, and the all sizes

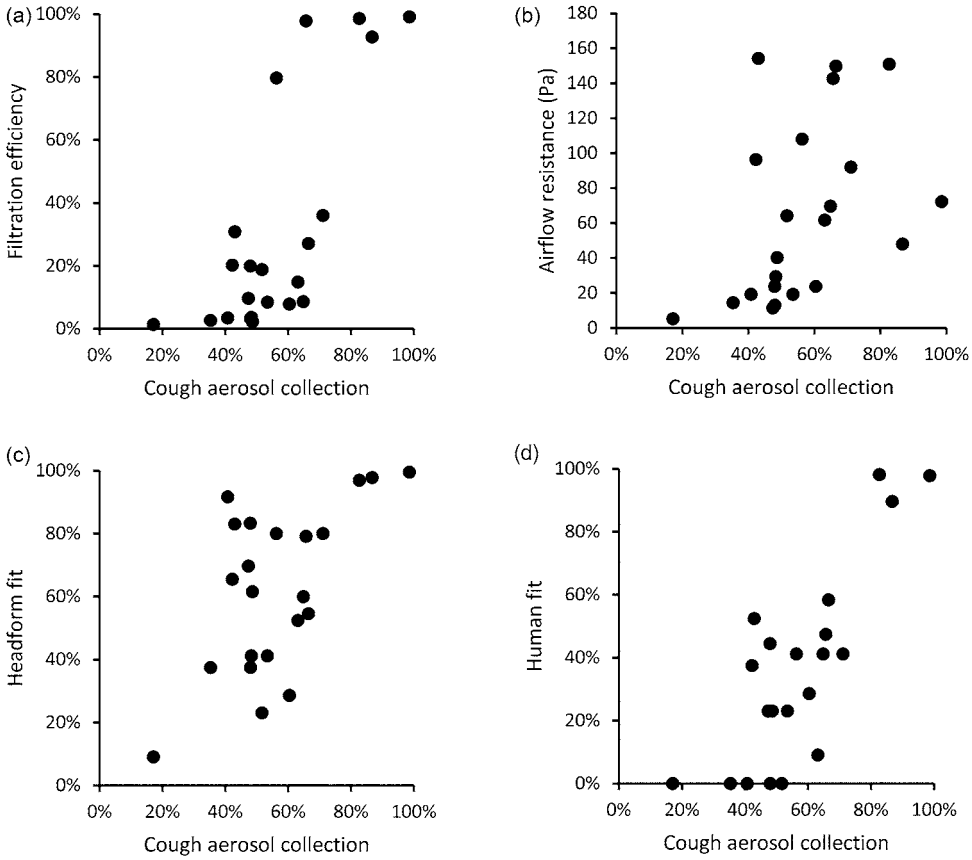

Figure 6. Comparison of collection efficiencies for aerosols from coughs to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot corresponds to the mean result for one type of source control device.

mode mean fit factors ranged from 1.0 to 2.4. Neck gaiters and bandanas demonstrated N95 mode fit factors ranging from 1.0 to 1.7 and all particle size mode mean fit factors from 1.0 to 1.7. The performance of cloth masks sometimes varied considerably when worn by different subjects. The fit test results for individual subjects are shown in Table S3 in the SI.

The cough and exhalation aerosol collection efficiencies for all devices were well correlated with the fit factors when measured using the Class 100 mode ($\rho = 0.68$ and $p < 0.001$ for coughing, $\rho = 0.71$ and $p < 0.001$ for exhalation, Table 4). When looking at the results for the cloth masks, gaiters, and bandanas in the all sizes mode, the correlations were not as strong, with $\rho = 0.48$ for coughing ($p = 0.035$), and $\rho = 0.63$ for exhalation ($p = 0.003$; Table 4). In all cases, the correlation coefficients were higher when the fit tester was in the Class 100 mode than when the tester was in N95 mode.

Manikin fit tests

The manikin fit factor measurements found using the source control measurement system before the cough tests were 25 to 198 for the N95 respirators and the surgical mask and 1.3 to 7.4 for the procedure mask and cloth masks (Table 3). Before the breathing tests, the manikin fit factors were 28 to 133 for the N95 respirators and the surgical mask and 1.4 to 6.1 for the procedure mask and cloth masks. The cough aerosol collection efficiencies and the pre-cough manikin fit factors were not significantly correlated, with a ρ of 0.39 ($p = 0.076$) for all devices (Table 4 and Figure 6) and a ρ of only 0.03 ($p = 0.890$) for the cloth masks (Table 4). The correlation was better between the exhaled aerosol collection efficiency and pre-breathing manikin fit factors, with a ρ of 0.72 ($p < 0.001$) for all devices (Table 4 and Figure 7) and 0.68 ($p = 0.002$) for the cloth masks (Table 4).

Discussion

The COVID-19 pandemic has resulted in considerable interest in the performance characteristics of masks and respirators as a means of reducing the person-to-person transmission of SARS-CoV-2. Some studies have looked at the emission of particles from human volunteers wearing different face coverings, which has

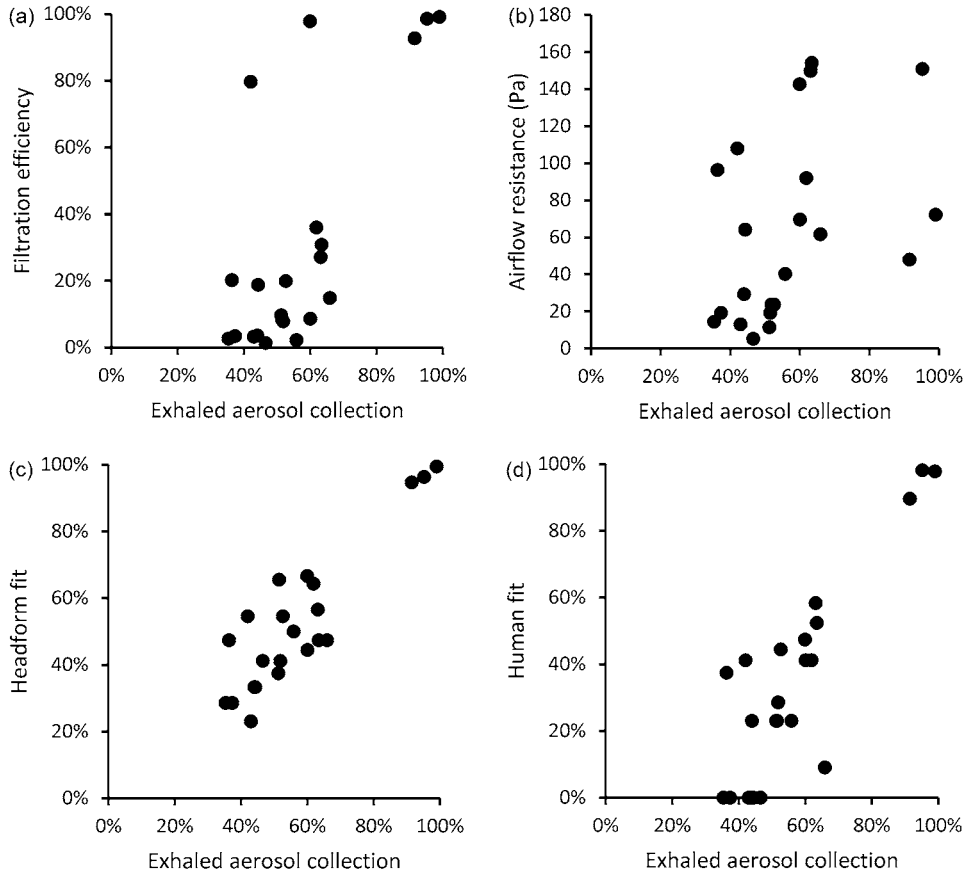

Figure 7. Comparison of collection efficiencies for exhaled aerosols from simulated breathing to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot shows the mean result for one type of source control device.

the advantage of directly examining the expulsion of aerosols into the environment by people (Asadi et al. 2020; Davies et al. 2013; Leung et al. 2020; Li, Niu, and Zhu 2021). However, the collection and measurement of human-generated respiratory aerosols is challenging and can be hazardous when the subject has a contagious respiratory infection. In addition, the amount and size distribution of aerosol particles produced by people during coughing, breathing and other respiratory activities varies tremendously from person to person and even for a particular person over time, which makes it difficult to compare results (Asadi et al. 2019; Fennelly 2020; Gralton et al. 2011; Lindsley et al. 2012). Consequently, lab-based surrogate techniques are more frequently used to study source control devices. The most commonly reported methods have been tests of filtration efficiencies and fit factors (Clapp et al. 2021; Guha et al. 2021; Konda et al. 2020; Wang et al. 2020; Zhao et al. 2020). Other studies have used manikins in a chamber or room to assess the efficacy of medical masks and cloth masks both as source control devices and as personal protective equipment (Pan et al. 2021; Patel et al. 2016; Rothamer et al. 2021). Experimental data have also been used to develop computational fluid dynamics models of medical and cloth masks performance (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020). These studies have provided valuable information about the properties of masks and respirators. However, it is unclear how the various metrics used in these studies are related to source control performance.

The source control measurement system used in this study allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough and exhaled breath aerosol particles into the environment (Lindsley et al. 2021). However, the system is complex and requires expertise to operate, and it is neither commercially sold nor easily constructed. In contrast, filtration measurement systems and respirator fit testers are widely available. If a methodology could be developed to gauge source control performance using existing commercially available equipment, it could be rapidly expanded and adopted by manufacturers and public health entities.

The filtration efficiency of a mask or respirator is a measurement of the ability of the mask material to remove aerosol particles from an airstream traveling through the fabric. Filtration efficiency tests typically use aerosol particles at or near the most-penetrating aerosol particle size, which is around 300 nm for an uncharged filter at low air velocities but shifts to smaller sizes at higher velocities and when the filter and particles are electrostatically charged (Martin and Moyer 2000; Rengasamy, BerryAnn, and Szalajda 2013; Rengasamy et al. 2017). The mechanisms by which filters collect aerosol particles are strongly dependent upon the size of the particles; for example, large particles are more likely to be collected by impaction or interception while small particles are more likely to be collected by diffusion (Lindsley 2016). Although the SARS-CoV-2 virus is about 100 nm in diameter, contagious humans do not shed bare viral particles. Instead, they expel aerosols and droplets of respiratory fluids that contain respiratory virus, and the size of these virus-laden aerosols and droplets can range from hundreds of nanometers to visible droplets of 1 mm or more (Fennelly 2020; Gralton et al. 2011). Thus, the collection efficiencies for 100-300 nm particles may not predict the performance for larger particles (Drewnick et al. 2021). In our experiments, the coughing and exhalation source control collection efficiencies increased as the particle size increased (Tables S1 and S2 in the SI) and in most cases were higher than the filtration efficiencies, likely because our coughing and exhalation test aerosols were much larger than the 75 nm aerosol used for filtration tests.

The fit factor is normally used to determine how well a respiratory protective device fits the wearer by measuring the degree to which aerosol particles can enter through gaps between the wearer's face and the respirator (face seal leaks). It is determined by placing the device on a person or on a manikin headform and measuring the ratio of the aerosol concentration outside the respirator to the aerosol concentration inside the respirator (Janssen and McKay 2017). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the respirator. Fit factor measurements are not intended to test the filtration efficiency of the device itself. In fact, the calculation of the fit factor for a respirator assumes that any ambient aerosol particles passing through respirator material are filtered out and that any particles detected inside the respirator are due to face seal leaks, not penetration of particles through the filter material (Halvorsen 1998). For example, a fit factor of 10 is interpreted as indicating that 90% of the air inside the respirator has passed through the respirator filtration media (with aerosol particles being completely removed) and that 10% of the air bypassed the media and entered through face seal leaks.

For high efficiency filters such as P100 respirator filters, which filter out 99.97% of airborne particles, a respirator fit test is performed by measuring the concentrations of aerosol particles of all sizes inside and outside the respirator (referred to here as Class 100 mode). However, N95 respirators can allow up to 5% of aerosol particles of the most penetrating size to pass through the filtration media. These particles would reduce the apparent fit factor if they were included in the calculation. Thus, when fit testing N95 respirators, the respirator fit tester used in our experiments has a size classifier to count only negatively charged aerosol particles near 55 nm in size (referred to here as N95 mode). For an N95 respirator, these charged 55 nm particles are almost entirely filtered out by the filtration media, and thus any particles detected inside the respirator can then be assumed to have entered through face seal leaks and not through the respirator (Halvorsen 1998; Han and Prell 2010).

It is important to note, however, that this assumption is not correct when using the fit tester with cloth masks. As can be seen in Table 3, the filtration efficiencies of most cloth masks are much lower than those of respirators, and ambient particles therefore can penetrate more easily through the cloth material. Thus, the fit factor for a cloth mask is not a true measurement of face seal leakage alone; instead, it represents a combination of face seal leakage and particle penetration through the mask material.

Our findings suggest that the results from filtration efficiency, airflow resistance and fit factor tests are correlated with measurements made using our source control measurement system. For the cloth masks, all but two of the standard performance metrics were significantly correlated with the cough and exhaled aerosol collection efficiencies, which suggests that these other measures could be useful as part of a method for testing the performance of cloth masks. However, none of the standard metrics were strong predictors of source control performance, and no metric was clearly superior to the others.

The limited correlations between the different test methods in our study likely have several explanations. First, filtration efficiency and airflow resistance measurements do not account for how well the devices fit the wearer or for face seal leaks around the edges of

the device. Thus, for example, the Artisan procedure mask had an 80% filtration efficiency but a 56% collection efficiency for cough aerosols and a 42% collection efficiency for exhaled aerosols. The most likely explanation is that this mask's material is an efficient filter but that aerosol particles were able to travel around the mask through face seal leaks because the Artisan mask fits loosely on the headform. On the other hand, the Hanes Defender cloth mask had only a 19% filtration efficiency but had similar aerosol collection efficiencies of 52% for coughs and 44% for exhalations. In this case, the cloth mask was not an effective filter for the 75 nm aerosol used in filtration testing, but the Hanes mask fit the manikin headform more tightly. Thus, much of the aerosol then flowed through the mask rather than around it during coughing and breathing tests and the larger aerosol particles that were used in the coughing and breathing tests were filtered out more effectively than the 75 nm particles used in filtration testing. The results presented here are consistent with a previous study by our group in which knotting the Artisan procedure mask to improve the fit increased the cough aerosol collection efficiency to 77%, while wearing a Hanes Defender cloth mask on top of an Artisan procedure mask increased the cough collection efficiency to 85% (Brooks et al. 2021). Together, these results also support the recommendation by Gandhi and Marr that members of the public wear a high-quality mask that fits tightly or wear a tight-fitting cloth mask over a surgical mask in order to reduce face seal leaks and improve the source control performance and protection offered by the masks (Gandhi and Marr 2021).

Fit tests are designed to measure the effects of face seal leaks but have their own limitations when applied to cloth masks. As noted above, fit factor measurements for cloth masks reflect some combination of particle penetration through the media and face seal leakage which will likely vary from mask to mask. Thus, it is neither clear how to interpret fit factor measurements for cloth masks nor is it clear how this relates to the effectiveness of the mask as a source control device. In addition, fit test results can vary greatly from person to person and even somewhat for the same person during repeated tests (Lawrence et al. 2006). Similarly, a comparison of fit tests between humans and a pliable skin manikin headform found significant differences (Bergman et al. 2015). Much of this discrepancy is likely due to facial variations and differences in how the mask is placed on the person or manikin headform. It is possible to shift, stretch, tighten, loosen, or adjust the masks in many ways,

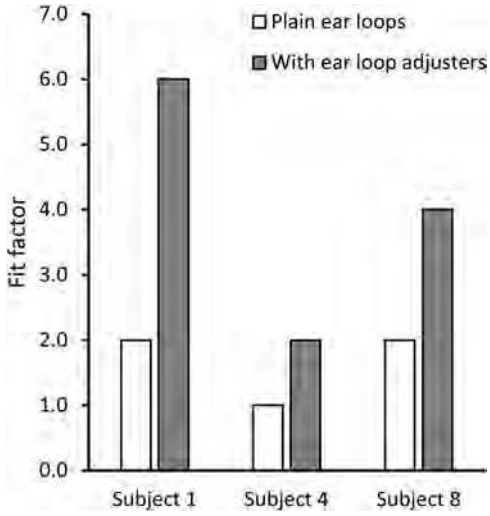

Figure 8. Effect on mask fit factor of adding ear loop adjusters to tighten the mask fit. Subjects were wearing the Excellent Artisan procedure mask. Tests were conducted with the fit tester in Class 100 mode. Each bar is the mean of three trials. All standard deviations were zero.

and small differences in how the mask is worn may have substantial effects on the fit test results. For example, in tests with three subjects using the Artisan procedure mask, we found that tightening the mask against the face by using silicone ear loop adjusters increased the mean fit factor from 1.7 to 4.0 (Figure 8). In experiments with cloth masks, the ρ value for the manikin headform fit tests done before coughing experiments compared with tests done before exhalation experiments was only 0.38, suggesting that differences were occurring even when the same model of mask was being placed on the same headform.

Finally, our study has several limitations. The source control measurement system produced a test aerosol with particles $\leq$7 µm in diameter, which is the size range of aerosol particles most likely to remain airborne and most difficult to block with source control devices. However, humans expel aerosol particles in a much broader range of sizes, particularly when coughing. We used a single cough flowrate profile and a single breathing ventilation rate for our studies; these parameters can vary greatly from person to person under different physiological conditions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We used representative examples of different types of source control devices, but many such devices are available with a wide range of shapes and compositions, which would be expected to affect their individual performance. As shown in Table 1, the instrumentation used for the

different performance metrics are based on different operating principles and thus caution should be used when comparing results; for example, the collection efficiency results from the impactors are based on aerosol mass, while the fit factor results from the PortaCount are based on particle counts. Lastly, because of the need to rapidly produce results in response to the COVID-19 pandemic, we only tested 2-3 samples of each source control device (each sample was used in two consecutive tests). By comparison, for example, the NIOSH procedure for evaluating N95 respirators calls for 20 samples to be tested (NIOSH 2019).

Current evidence indicates that masks like those tested in our experiments can substantially decrease the amount of respiratory aerosols released by the wearer, and also help reduce what the wearer breathes in (CDC 2020a). Both effects vary depending upon the material and construction of the mask, as well as how it is worn. In addition to consistent and correct mask use when in the company of others, other measures such as physical separation are important, particularly during brief exposures. In a room where someone sneezes, being six feet or further away is better than being closer. However, with prolonged exposure in the same space for more than a few minutes, the benefit of distance fades as exhaled respiratory aerosols drift, mix, and accumulate in the enclosed air space. Optimizing ventilation, air filtration, and the introduction of fresh air can help counter this effect, but at every distance, correct mask use reduces the risk for everyone.

Conclusions

The ongoing COVID-19 pandemic has created an urgent need for simple methods to evaluate cloth masks as respiratory aerosol source control devices and to produce meaningful performance metrics that can be used to determine the effectiveness of different materials and designs. Our results suggest that test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements on manikin headforms or human subjects have potential as ways to estimate the performance of masks as source control devices for respiratory aerosols. However, more research and improvements in the test methodologies are needed before such methods can be reliably implemented. Until the factors controlling the performance of source control devices are better understood and better testing methodologies are developed, results from test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements should be interpreted cautiously when used to evaluate source control devices for respiratory aerosols.

Efficacy of face masks, neck gaiters and face shields for reducing the expulsion of simulated cough-generated aerosols

William G. Lindsley, Francoise M. Blachere, Brandon F. Law, Donald H. Beezhold, and John D. Noti

Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Morgantown, West Virginia, USA

ABSTRACT

Face masks are recommended to reduce community transmission of SARS-CoV-2. One of the primary benefits of face masks and other coverings is as source control devices to reduce the expulsion of respiratory aerosols during coughing, breathing, and speaking. Face shields and neck gaiters have been proposed as an alternative to face masks, but information about face shields and neck gaiters as source control devices is limited. We used a cough aerosol simulator with a pliable skin headform to propel small aerosol particles (0 to 7 μm) into different face coverings. An N95 respirator blocked 99% (standard deviation (SD) 0.3%) of the cough aerosol, a medical grade procedure mask blocked 59% (SD 6.9%), a 3-ply cotton cloth face mask blocked 51% (SD 7.7%), and a polyester neck gaiter blocked 47% (SD 7.5%) as a single layer and 60% (SD 7.2%) when folded into a double layer. In contrast, the face shield blocked 2% (SD 15.3%) of the cough aerosol. Our results suggest that face masks and neck gaiters are preferable to face shields as source control devices for cough aerosols.

Introduction

SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can be transmitted from person-to-person by large respiratory aerosols (airborne liquid droplets and dried particles greater than about 10 μm in diameter) produced by people who are infectious while they are talking, singing, coughing, breathing or sneezing (CDC 2020a; Hamner et al. 2020). Smaller aerosols also are emitted by people during these activities, suggesting that short-range airborne transmission of SARS-CoV-2 might be possible under some circumstances (Anderson et al. 2020; CDC 2020a; Fennelly 2020; Ma et al. 2020; Morawska and Milton 2020).

To interrupt this potential transmission route, the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO), and other public health organizations recommend the wearing of face masks or other face coverings by the general public during the ongoing COVID-19 pandemic (CDC 2020b, 2020c; Edelstein and Ramakrishnan 2020; WHO 2020). One of the primary benefits of face coverings is to act as source control devices to reduce the expulsion of aerosols containing the virus from people who are infectious during coughing, breathing, and speaking. Source control devices are intended to protect other people from infectious aerosols emitted by the wearer, as compared with personal protective equipment such as N95 respirators which are primarily intended to protect the wearer. A face covering can provide source control in two ways (Diaz and Smaldone 2010). First, and most importantly, the covering may collect aerosol particles by filtration, impaction, or other mechanisms, and thus prevent infectious aerosols from entering the environment. Second, the face covering may change the direction of travel and the velocity of the aerosol stream and thus possibly divert the aerosol away from a potential recipient. However, deflection is more uncertain as a source control mechanism. For example, if large aerosols are deflected downward, they may settle to the floor or otherwise be unable to reach the breathing zones of other people. However, since exhaled breath is often warmer than the surrounding air, this

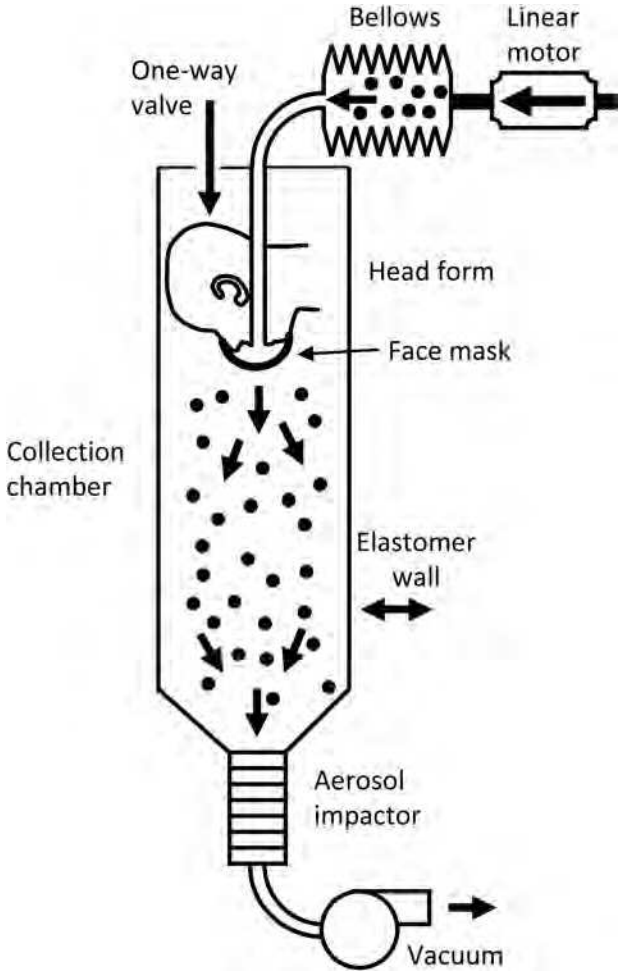

Figure 1. Cough aerosol simulator system for source control measurements. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated cough, a pliable skin head form on which the face mask, neck gaiter or face shield is placed, a 105 liter collection chamber into which the aerosol is coughed, and an Andersen impactor to separate the aerosol particles by size and collect them. More information about the cough aerosol simulator is provided in the SI.

downward deflection may be counteracted by the buoyancy of the breath for smaller aerosols. In addition, if the respiratory aerosols are deflected sideways, they may be diverted away from a person directly in front of the wearer but toward someone to the side or behind the wearer.

Studies using manikins (Lai, Poon, and Cheung 2012; Patel et al. 2016) and patients with respiratory infections (Leung et al. 2020; Milton et al. 2013) have shown that wearing medical face masks can reduce the dispersion of potentially infectious aerosols from patients. Two studies in which face masks were required for visitors and healthcare workers interacting with patients in bone marrow transplant centers found a reduction in respiratory viral infections among patients (Sokol et al. 2016; Sung et al. 2016). Studies of cloth face masks have suggested that they also can be effective at reducing the release of respiratory aerosols into the environment (Asadi et al. 2020; Davies et al. 2013; Konda et al. 2020). Several computational fluid dynamics studies have examined the generation and expulsion of respiratory aerosols and have provided important insights into the ability of face coverings to reduce the dispersion of large and small aerosols from the wearer (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020).

Unfortunately, the use of face masks and other face coverings by the general public can present challenges. People often dislike wearing masks, and compliance can be low and inconsistent (Longtin et al. 2009). Mask wearers may repeatedly don, doff and adjust face masks, which can contaminate the hands and potentially lead to disease transmission, especially when the masks are reused (Brady et al. 2017; Casanova et al. 2008). For cloth masks, the filtration efficiency and air flow resistance of different textiles varies widely (Konda et al. 2020; Teesing et al. 2020; Wilson et al. 2020). Alternative face coverings such as neck gaiters (an elastic fabric tube that fits snugly around the head and neck) are commonly used, but information about their performance as source control devices is limited. Factors such as how well the mask fits the face and the coverage provided by a mask can have a substantial impact on the effectiveness of face masks (Davies et al. 2013; Lawrence et al. 2006). Comparisons of face coverings have found substantial differences in the ability of different types of these devices to reduce the release of respiratory aerosols (Asadi et al. 2020; Davies et al. 2013).

An opinion article in JAMA proposed that face shields would be more effective than face masks at reducing community disease transmission, in large part because the authors felt that face shields were more comfortable and thus that they were more likely to be widely adopted by the public (Perencevich, Diekema, and Edmond 2020). A previous study by our group of face shields used as personal protective devices showed that face shields protect the wearer from large cough aerosols directed at the face but are much less effective against smaller aerosols which were able to flow around the edges of the shield and be inhaled (Lindsley et al. 2014). However, very little work has been done examining face shields as source control devices. Two qualitative flow visualization studies of face shields and masks found that, although face shields deflected the air flow from the mouth, they did not stop aerosol particles from traveling around the face shield and entering the environment

(Verma, Dhanak, and Frankenfield 2020; Viola et al. 2020). Beyond these studies, quantitative data on the efficacy of face shields for source control are lacking.

The objective of our study was to conduct a quantitative comparison of the efficacy of an N95 respirator, a medical procedure mask, a commercial 3-ply cloth face mask, a single and double layer fabric neck gaiter, and a commercial disposable face shield as source control devices to reduce the expulsion of small cough-generated aerosol particles into the environment. Our results provide more information about the effectiveness of different types of source control devices and will help the public health community make recommendations about the best ways to use these devices to help reduce the spread of COVID-19.

Materials and methods

Experimental design

In our experiments, a cough aerosol simulator propelled a test aerosol through a headform into a collection chamber (Figure 1), and the amount of aerosol in the collection chamber was measured in each of six size fractions. The collection efficiency of each face mask, neck gaiter, or face shield was determined by comparing the amount of aerosol that was collected from the chamber with and without the device. Our test method was similar to the modified Greene and Vesley method used to test medical masks (Quesnel 1975), with the human test subject replaced by the cough aerosol simulator.

Cough aerosol simulator

The cough aerosol simulator is a modified version of the NIOSH cough aerosol simulator described previously (Lindsley et al. 2019; Lindsley et al. 2014; Lindsley et al. 2013). The experimental cough aerosol was generated by nebulizing a solution of 14% KCl and 0.4% sodium fluorescein using a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2), passing the aerosol through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), and mixing it with 10 L/min of dry filtered air. The test aerosol was loaded into an elastomeric bellows, and the cough airflow was produced by a computer-controlled linear motor that compresses the bellows. The cough aerosol was expelled through the mouth of a headform into a collection chamber. The headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each face covering or shield would fit a human face (Bergman et al. 2014).

Source control devices

The source control devices tested were an N95 medical respirator (3 M model 1860), a medical grade (ASTM Level 3) procedure mask with ear loops (Kimberly Clark model 47107), a cloth face mask with 3 layers of cotton fabric and ear loops (Hanes Defender), a fabric neck gaiter (FKGIONG Sun UV Protection Neck Gaiter, 95% polyester, 5% Spandex) and a disposable face shield (Fisher Scientific # 19-181-600 A). The neck gaiter was tested both as a single layer of fabric and doubled over to provide two layers of fabric. The masks and respirator were not equipped with exhalation valves. The face shield was 25 cm tall and extended from the forehead of the headform to 3 cm below the chin and around the side to 3 cm before the front of the ear. Photographs of the source control devices on the headform are shown in the online supplementary information (SI).

Mask fit test

For the experiments, either no device, a face mask, a neck gaiter, or a face shield were placed on the head form. Each device was used for two consecutive tests. For face masks and gaiters, a respirator fit test was performed using a PortaCount (TSI). The fit factor is a measure of the protection against airborne particles that is provided by a respiratory protective device. It is defined as the ratio of the aerosol concentration outside the respiratory protective device to the aerosol concentration inside the device (i.e., the aerosol concentration that is inhaled by the wearer). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the mask, and that the mask is therefore filtering out 90% of the ambient aerosol.

Aerosol collection and analysis

After placing the device on the headform and performing the fit test, the system was sealed. The test aerosol was then generated and propelled with a simulated cough through the headform and into the collection chamber. The Andersen impactor at the bottom of the collection chamber collected the aerosol particles that traveled through or around the device for 20 min after each cough. The Andersen impactor operates at a flow rate of 28.3 liters/minute and has six collection stages and a filter that separate the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm;

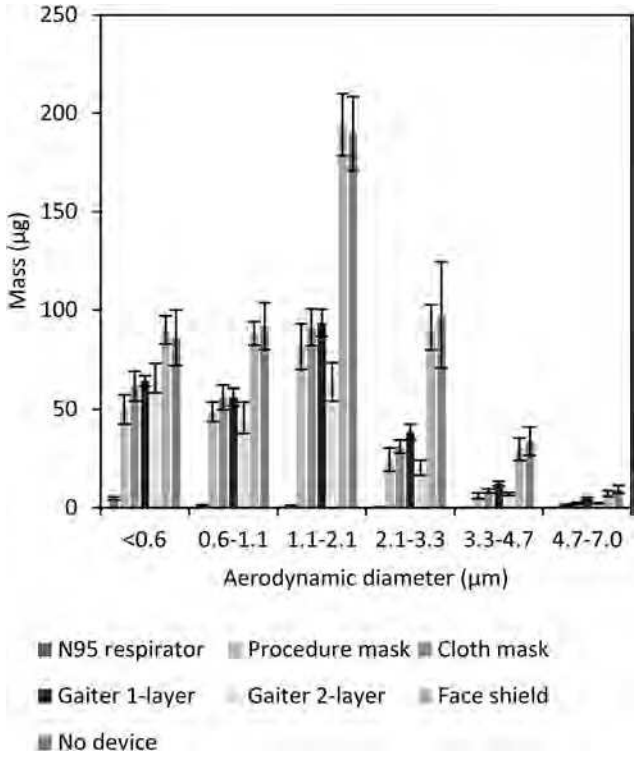

Figure 2. Mass of aerosol collected in each size fraction. The graph shows the amount of simulated respiratory aerosol that was collected from the collection chamber in each aerosol particle size fraction after a single simulated cough. The bars show the mean and standard deviation. A larger color version of this figure is shown in the SI.

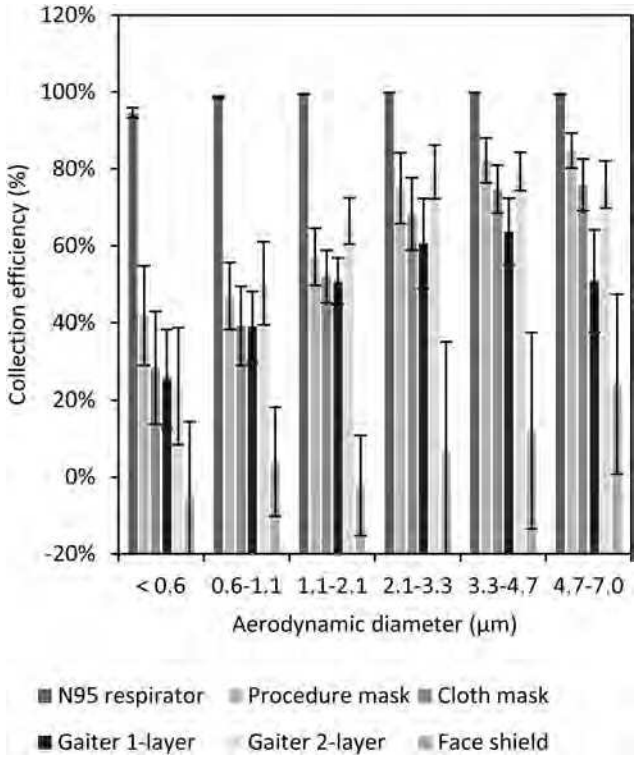

Figure 3. Collection efficiency of face masks, neck gaiter and face shield. The collection efficiency is the percentage of aerosol particles that were blocked by the face mask, neck gaiter or face shield compared with experiments without a device. The plot shows the means and standard deviations of the collection efficiency in each size fraction. A larger version of this figure is shown in color in the SI.

4.7–7.0 µm; and >7 µm. Because the amount of aerosol in the largest size fraction was small and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction was not included in the analysis. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). After aerosol collection was completed, the impactor plates were rinsed with 0.1 M Tris solution and the fluorescence of the solution was measured using a fluorometer (SpectraMax M4, Molecular Devices). The complete experimental protocol is given in the SI.

Statistical analysis

The performance of each device was evaluated by comparing the total mass of the aerosol particles from a single cough that passed through or around the device and was collected by the Andersen impactor. The results were evaluated using a one-way ANOVA and multiple comparisons among the different devices and the control experiments without a device were conducted using a Tukey-Kramer test. To control for variations in the amount of aerosol in each cough, a sample of each cough aerosol was collected from the bellows prior to coughing and used to normalize the aerosol mass collection results for each experiment.

Results

The cough aerosol simulator provides a cough with a controlled cough airflow rate containing a test aerosol with a consistent aerosol size distribution. The simulator allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough aerosol particles of different sizes into the environment. The flow rate of the simulated cough used in our experiments was based on cough flow profiles recorded from influenza patients and had a volume of 4.2 L with a peak flow rate of 11 L/s (Lindsley et al. 2013). The cough aerosol collected from the control experiments without a face covering had a mass median aerodynamic diameter of 1.3 µm, a geometric standard deviation of 2.3 and a total aerosol mass of 505 µg (standard deviation 69).

For our study, we tested the collection efficiencies (that is, the fraction of the cough aerosol that was

Table 1. Total mass of aerosol expelled into collection chamber and device collection efficiencies.

Device tested	Number of experiments	Fit factor	Aerosol mass (μg)	Collection efficiency
No device	12	n/a	512 (64)	n/a
Procedure mask	6	2.9 (0.5)	212 (23)	58.5% (6.9%)
Cloth mask	6	1.3 (0.1)	251 (23)	50.9% (7.7%)
Neck gaiter (single layer)	6	1.7 (0.5)	270 (18)	47.2% (7.5%)
Neck gaiter (double layer)	6	1.9 (0.4)	206 (26)	59.8% (7.2%)
Face shield	6	n/a	502 (46)	1.8% (15.3%)
N95 respirator	6	198 (3.5)	7.2 (1.2)	98.6% (0.3%)

Note: The fit factor, aerosol mass, and collection efficiency are given as mean (standard deviation).

blocked) of a medical grade procedure mask, a cotton cloth face mask, a polyester neck gaiter, an N95 medical respirator and a disposable face shield. These source control devices were chosen to provide representative samples of the different types of face coverings and face shields that are in common use during the pandemic. Neck gaiters are typically worn either as a single layer of fabric over the mouth and nose or doubled over to provide two layers of fabric; for our experiments, we tested both configurations. The quantity of aerosol particles in six size fractions that were able to travel through or around each source control device are shown in Figure 2. The collection efficiencies of the devices are shown as a function of aerosol size in Figure 3. All the devices showed increased collection efficiencies as the aerosol size increased.

On average, the N95 respirator blocked 99% of the total mass of test aerosol from being released into the environment, while the medical procedure mask blocked 59%, the cloth face mask blocked 51%, the single-layer gaiter blocked 47%, the double-layer gaiter blocked 60%, and the face shield blocked 2% of the total aerosol (Table 1). The N95 respirator, procedure mask, cloth mask, and the single-layer and double-layer gaiters all significantly reduced the aerosol emitted into the environment compared with no device ($P < 0.0001$ for each), but the face shield did not ($P = 0.9993$). The collection efficiencies of the procedure mask, cloth mask, and the single and double-layer gaiters did not differ significantly from each other, but all blocked cough aerosols significantly better than did the face shield ($P < 0.0001$). The N95 respirator outperformed all the other devices ($P < 0.0001$) (Table 2).

Discussion

Humans continuously emit aerosols of respiratory fluids as they breathe, talk, cough, sneeze, sing, or carry out other respiratory activities. These respiratory aerosols can have a very broad size range, from tens of nanometers in diameter to visible droplets of a millimeter or more (Bourouiba, Dehandschoewercker, and Bush 2014; Fennelly 2020; Gralton et al. 2011; Morawska et al. 2009). Airborne particles larger than 100 μm are ballistic; that is, they are affected primarily by gravity and fall quickly to the ground. Respiratory aerosol particles in this size range tend to deposit within a few meters of the source (Prather et al. 2020). As the aerosol particle diameter decreases from 100 μm, a gradual transition occurs where the settling velocity rapidly decreases and the particles remain airborne for longer times. For example, a 100 μm aerosol particle takes 4 s to fall 1 m in still air, while a 10 μm aerosol particle takes 5.4 min and a 1 μm aerosol particle takes 8 h to settle the same distance (Hinds 1999). Air currents such as plumes of warm air rising from the body can lift these particles and extend the time for which they stay in the air. Thus, small aerosol particles can remain airborne for minutes to hours and can accumulate over time in environments with poor ventilation (Bahl et al. 2020). Small aerosol particles also are easier to inhale and can travel more deeply into the lungs (Vincent 2005).

The amount and sizes of aerosol particles containing SARS-CoV-2 that are expelled by people who are infected are not yet known. Two studies of aerosol samples collected in patient rooms found infectious (replication-competent) SARS-CoV-2 in aerosol particles <4 μm in diameter (Santarpia et al. 2020a) and <10 μm in diameter (Lednicky et al. 2020). Other studies have reported SARS-CoV-2 RNA in exhaled breath from infected patients (Ma et al. 2020), aerosol samples from biocontainment and quarantine units housing SARS-CoV-2 infected persons (Santarpia et al. 2020b), and in aerosol samples at multiple locations throughout two hospitals in Wuhan, China during a COVID-19 outbreak (Liu et al. 2020). The presence of small aerosol particles containing

infectious SARS-CoV-2 detected in these studies suggests that in addition to large aerosols, these small aerosols might play a role in SARS-CoV-2 transmission (Anderson et al. 2020; Bahl et al. 2020; Ma et al. 2020; Morawska and Milton 2020).

Source control devices like face coverings and face shields collect respiratory particles larger than 0.3 μm primarily by impaction and interception of the aerosol particles against the fibers or solid surfaces of the device. As noted earlier, source control devices may also deflect aerosols, but this mechanism can be problematic as a means of source control because the infectious aerosol is not prevented from entering the surrounding environment; it is merely sent in a different direction which may or may not be protective depending upon local airflows and the locations of other people. Our experimental system measures particle collection only; any particles that are deflected but not collected by the face covering are still collected by the Andersen impactor. Thus, we are able to measure the particle collection efficiency of the face coverings without the potentially confounding variable of particle deflection. On the other hand, this does means that any potential benefits from, for example, deflecting large aerosol particles toward the ground were not measured by our system.

Small aerosols require much higher air velocities to deposit by impaction than do larger aerosols, and thus are more difficult to block with source control devices (Hinds 1999; Lindsley 2016). Consequently, small aerosols present the most challenging scenario for testing source control devices since devices that block small aerosol particles would be expected to block larger ones as well. Our results show that face masks and neck gaiters can significantly reduce the expulsion of small respiratory aerosol particles during coughing. This suggests that various types of face coverings can make an important contribution to reducing the quantity of aerosol particles containing SARS-CoV-2 released into the environment by people who are infected. N95 respirators, which are worn for personal protection by healthcare workers and others at highest risk of exposure, are also very effective source control devices. In contrast, the face shield blocked very little of the cough aerosol, indicating that face shields are not effective as source control devices for small respiratory aerosols.

The collection efficiencies of all the devices tested increased as the aerosol particle size increased, and this trend would be expected to continue for larger aerosol particles than were tested here. For example, the collection efficiency of the cloth face mask was 28% for the <0.6 μm particles and increased to 76% for the 4.7 to 7 μm particles. Similarly, the double-layer gaiter blocked 24% of the <0.6 μm particles and 76% of the 4.7 to 7 μm particles. These results suggest that cloth face coverings would be effective as source control devices against the large respiratory aerosols that are thought to play an important role in SARS-CoV-2 transmission.

Our study has several limitations. We used a single cough volume, air flow profile, and aerosol size distribution for our studies; these parameters can vary greatly from person to person. We examined the

performance of these devices during simulated coughing but not breathing or speaking, which have different air flow rates and aerosol size distributions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We only used a single representative example of each type of device. The shape and composition of face coverings vary widely, and this would be expected to affect the performance of individual devices. Some face masks have exhalation valves or vents which could reduce their efficacy as source control devices. The fit of a particular mask to an individual wearer and compliance in wearing the mask correctly (i.e., over the nose and mouth) also are important factors in how well the mask performs as a source control device. Because we used a < 0.6 to 7 µm test aerosol, our results do not indicate if face shields would be more effective as source control devices for large droplets. The face shield that we tested has a widely used design, but alternative designs are being marketed that provide greater facial coverage and, in some cases, include fabric skirts between the shield and the face. These alternative face shield designs might perform better as source control devices.

Previous studies have shown that face shields provide eye and facial protection to the wearer from droplets and splashes (Lindsley et al. 2014; Roberge 2016). When a face shield is worn in addition to a face mask, the face shield can also help reduce surface contamination of the mask by large aerosols and reduce the likelihood of hand contamination when the mask is removed or inadvertently touched (Lindsley et al. 2014). Our previous study showed that face shields provide some benefits as personal protective equipment when face masks cannot be worn (Lindsley et al. 2014), but as with all personal protection and source control devices, their limitations must be respected. Our results suggest that face masks and neck gaiters are more effective than face shields as source control devices to reduce the expulsion of respiratory aerosols into the environment as a public health measure to reduce the community transmission of SARS-CoV-2.

Acknowledgments

We would like to thank NIOSH machinist Bryan Williamson for manufacturing the parts for the cough simulator. We also would like to thank the NIOSH Morgantown maintenance, security, warehouse and housekeeping departments for their assistance and dedication during the ongoing pandemic. Subject: N95 effectiveness as source control

Dear Partners,

We have had a number of questions from you and others about N95 effectiveness as source control and wanted to share some information back with you.

National Institute for Occupational Safety and Health (NIOSH) researchers have evaluated N95s as source control in two different peer reviewed publications. In the first paper (Lindsley et al. 2021a- attached), NIOSH researchers found that a N95 respirator (3M model 1860) was 99% effective at blocking cough aerosols. In a second paper (Lindsley et al. 2021b- attached), NIOSH researchers found that one N95 respirator (3M 1860 N95) was 99% effective at blocking coughed and exhaled aerosols, and a second N95 Respirator (BYD) was 83% effective at blocking cough aerosols and 95% effective at blocking exhaled aerosols.

To: CDC IMS 2019 NCOV Response STLT Policy and Public Health Partnerships <eocevent382@cdc.gov>
Subject: PARTNER ALERT: CDC Expands Booster Shot Eligibility

Dear Partners –

Yesterday, CDC adjusted our recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months.

Earlier this week CDC made this recommendation for recipients of a Pfizer-BioNTech primary seriesand, after FDA action this morning, we're extending this recommendation to recipients of a Moderna primary series. This means that people 12 and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.

Recently CDC strengthened our COVID-19 vaccination recommendations for children, now recommending that:

- Moderately to severely immunocompromised children ages 5–11 years receive an additional primary dose of Pfizer-BioNTech to ensure optimal protection from the vaccine.
- Children and teens ages 12–17 years should receive a booster shot.

Thank you,

Vaccine Task Force
COVID-19 Response

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC Partner Alert: N95 Effectiveness as Source Control [Attachments]
    - Today, **Tuesday, January 11**, CDC issued a partner update (attached) in response to numerous questions about N95 mask effectiveness as source control. The update shared two peer reviewed publications from National Institute for Occupational Safety and Health (NIOSH) researchers (both attached) on N95 mask effectiveness, including findings that a N95 respirator was 99% effective at blocking cough aerosols.
- HHS Update: COVID-19 Allocation Projections for January [Attachments]
    - On **Friday, January 7**, the U.S. Department of Health and Human Services (HHS) issued an update with a projected calendar of allocation amounts and cadence of COVID-19 therapeutics for the remainder of January (attached). Questions may be directed to us COVID19Therapetuics@hhs.gov.
- Partner Alert: CDC Expands Booster Shot Eligibility [Attachment, Link]
    - On **Saturday, January 6**, CDC issued a partner alert (attached) adjusting its recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months. CDC has extended this recommendation to recipients of a Moderna primary series. This means that people 12 years of age and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.
- CDC COCA Call: What Clinicians Need to Know About the New Oral Antiviral Medications for COVID-19 [Links]
    - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **tomorrow, Wednesday, January 12 at 2:00 pm EST** to discuss the recent emergency use authorizations (EUAs) for new oral antiviral medications intended to decrease hospitalizations, as well as prevent severe COVID-19 and death Call information is below:
        - Weblink: https://www.zoomgov.com/j/1612974214?pwd=VitYMEorako1YWhCaXpnaWdsc2Ixdz09
          Telephone: (660) 254-5252 or (646) 828-7666 or (669) 216-1590 or (551) 285-1373
          Webinar ID: 161 297 4214
          Passcode: 180866
          Post-Event Recording:
          https://emergency.cdc.gov/coca/calls/2021/callinfo_011222.asp
- Reminder: CDC Preventive Medicine Grand Rounds: "The Public Health System of the Future – Moving Ahead in Partnership with Health Care & Other Sectors" [Link]
    - CDC will host its monthly Preventive Medicine Grand Rounds **tomorrow, Wednesday, January 12** at **1:30 pm EST**. The session will focus on the public health system of the

future and the speaker is John Auerbach, Director of Intergovernmental and Strategic Affairs for CDC. Continuing education (CE) is available at no cost. Registration information is available here.

Standing Updates

- CDC Partner Update – January 10 [Attachment]
  - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – January 10 [Link]
  - Please click here for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
  - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am ET**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC Resources

New & Updated

- CDC Recommends Moderna Booster at 5 Months: On January 4th, CDC made this recommendation for recipients of a Pfizer-BioNTech primary series. After FDA action on January 7th, we're extending this recommendation to recipients of a Moderna primary series. This means that people who initially received an mRNA vaccine series——two doses of Moderna or Pfizer-BioNTech —can now receive an mRNA booster shot 5 months after completing their initial series.
- Guidance for COVID-19 Prevention in K-12 Schools was recently updated to reflect new recommendations for isolation for people with COVID-19 and recommendations for people who have come into close contact with a person with COVID-19.
- CDC Expands Booster Shot Eligibility and Strengthens Recommendations for 12-17 Year Olds: CDC now recommends that adolescents age 12 to 17 years old should receive a booster shot 5 months after their initial Pfizer-BioNTech vaccination series.
- CDC Recommends Pfizer Booster at 5 Months, Additional Primary Dose for Certain Immunocompromised Children: On January 4th, CDC updated its recommendation for when many people can receive a booster shot, shortening the interval from 6 months to 5 months for people who received the Pfizer-BioNTech COVID-19 Vaccine.
- Stay Up to Date with Your Vaccines: To align with standard language CDC uses about other vaccinations, CDC is now using the phrase "up to date" when talking about COVID-19 vaccination. CDC recommends that individuals stay "up to date" by receiving any additional doses they are eligible for, according to CDC's recommendations, to ensure they have optimal protection against COVID-19. The technical definition of "fully vaccinated"—two doses of an mRNA vaccine or one dose of the J&J vaccine—has not changed.
- What We Know About Quarantine and Isolation provides information on why CDC shortened quarantine and isolation guidance for the general population.

School and Work

Subject: HHS Update: COVID-19 allocation projections for January

Dear State and Territorial Health Officials,

Thank you for your continued partnership in this all-of-America approach to fighting the COVID-19 pandemic. It remains our goal to facilitate a fair and equitable process in the allocation of COVID-19 therapeutics, and we certainly couldn't do this without you. We know that providing a longer look ahead for expected allocation amounts will help further support your jurisdictional planning. As such, attached is a projected calendar of allocation amounts and cadence for the remainder of January. Of course, the COVID-19 environment is very dynamic; so, these projections could change based on daily analysis of related data.

Additionally, we wanted to provide you with an update regarding Gilead's product - VEKLURY(tm) (remdesivir), which is not allocated by the federal government but is available commercially. Following the recent statement from the National Institutes of Health (NIH) COVID-19 Treatment Guidelines Panel regarding therapies for the COVID-19 Omicron variant, CMS created HCPCS code J0248 for the VEKLURY(tm) (remdesivir) antiviral medication when administered in an outpatient setting. This code is available for use by all payers and is effective for dates of service on or after December 23, 2021:

* Long descriptor: Injection, remdesivir, 1 mg
* Short descriptor: Inj, remdesivir, 1 mg

Medicare Administrative Contractors (MACs) determine Medicare coverage when there is no national coverage determination, including in cases when providers use FDA-approved drugs for indications other than what is on the approved label. The MACs consider the major drug compendia, authoritative medical literature and accepted standards of medical practice to determine medical necessity when considering coverage. Therefore, the MACs will determine Medicare coverage for HCPCS code J0248 for VEKLURY(tm) (remdesivir) administered in an outpatient setting.

ABSTRACT

Universal mask wearing is recommended to help control the spread of COVID-19. Masks reduce the expulsion of aerosols of respiratory fluids into the environment (called source control) and offer some protection to the wearer. Masks are often characterized using filtration efficiency, airflow resistance, and manikin or human fit factors, which are standard metrics used for personal protective devices. However, none of these metrics are direct measurements of how effectively a mask blocks coughed and exhaled aerosols. We studied the source control performance of 15 cloth masks (face masks, neck gaiters, and bandanas), two medical masks, and two N95 filtering facepiece respirators by measuring their ability to block aerosols $\leq$7 µm expelled during simulated coughing and exhalation (called source control collection efficiency). These measurements were compared with filtration efficiencies, airflow resistances, and fit factors measured on manikin headforms and humans. Collection efficiencies for the cloth masks ranged from 17% to 71% for coughing and 35% to 66% for exhalation. Filtration efficiencies for the cloth masks ranged from 1.4% to 98%, while the fit factors were 1.3 to 7.4 on headforms and 1.0 to 4.0 on human subjects. The Spearman's rank correlation coefficients between the source control collection efficiencies and the standard metrics ranged from 0.03 to 0.68 and were significant in all but two cases. However, none of the standard metrics were strongly correlated with source control performance. A better understanding of the relationships between source control collection efficiency, filtration efficiency, airflow resistance, and fit factor is needed.

Introduction

Humans infected with SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can produce droplets and aerosols of respiratory fluids containing the virus when they cough, breathe, talk, sing and sneeze (Anderson et al. 2020; CDC 2020b; Hamner et al. 2020; Ma et al. 2020; Morawska and Milton 2020). To reduce the transmission of SARS-CoV-2, public health agencies have recommended that the general public wear cloth masks (CDC 2020c, 2020d, 2021; Edelstein and Ramakrishnan 2020; WHO 2020). The primary purpose of masks (which in this article includes face masks, neck gaiters, bandanas and other face coverings) is to block the expulsion of infectious droplets and aerosols from the wearer into the environment (called source control) and thereby reduce the exposure of other people to the virus (CDC 2020a). Laboratory studies using manikins and human subjects have shown that cloth face masks can partially block respiratory aerosols produced during coughing, breathing and talking (Asadi et al. 2020; Davies et al. 2013; Lindsley et al. 2021; Pan et al.

This work was authored as part of the Contributor's official duties as an Employee of the United States Government and is therefore a work of the United States Government. In accordance with 17 USC. 105, no copyright protection is available for such works under US Law.
This is an Open Access article distributed under the terms of the Creative Commons Attribution-NonCommercial-NoDerivatives License (http://creativecommons.org/licenses/by-nc-nd/4.0/), which permits non-commercial re-use, distribution, and reproduction in any medium, provided the original work is properly cited, and is not altered, transformed, or built upon in any way.

2021). Wearing medical face masks (i.e., "surgical masks" as defined by the U.S. Food and Drug Administration [FDA 2004]) reduces the dispersion of potentially infectious aerosols from patients with respiratory infections (Leung et al. 2020; Milton et al. 2013). Masks may also provide some personal protection to the wearer by reducing their exposure to infectious droplets and aerosols produced by others, although they are not as effective as a respiratory protective device such as a NIOSH-approved N95 filtering facepiece respirator (N95 respirator) (CDC 2020a; Lawrence et al. 2006; Oberg and Brosseau 2008; Pan et al. 2021). Several community level studies have shown that universal masking helps reduce the spread of COVID-19 (CDC 2020a). For example, a comparison of counties in the US state of Kansas found that mask mandates were associated with lower incidence rates of COVID-19 (Van Dyke et al. 2020). A study of 10 US states found that statewide mask mandates were associated with a decline in weekly COVID-19–associated hospitalization growth compared to states without such mandates (Joo et al. 2021).

In response to the need for source control devices for the general public, manufacturers worldwide have produced a broad array of masks. Unfortunately, because of the many different designs and construction materials, it is not possible to predict how well a particular mask will perform as a source control device without testing, which is rarely done for non-medical masks not intended for occupational use. Although general guidelines have been developed (CDC 2020d), it is very difficult for public health organizations, governments, medical facilities, and the general public to know which of the available devices are most effective.

Test methods and performance standards do exist for regulated medical face masks and respiratory protective devices (Rengasamy et al. 2017). In the United States, respiratory protective devices, which are devices such as N95 filtering facepiece respirators that are intended to protect the wearer from airborne particles, must be approved by the National Institute for Occupational Safety and Health (NIOSH) under 42 Code of Federal Regulations (CFR) Part 84 (NIOSH 1995). The approval process includes testing the filtration efficiency for the most-penetrating aerosol particle size and measuring the airflow resistance of the device (NIOSH 2019). Medical face masks that are not intended to be used as respiratory protective devices are cleared by the Food and Drug Administration (FDA), which reviews manufacturer-supplied information on filtration efficiency, airflow resistance, resistance to fluid penetration and flammability (FDA 2004). The FDA recommends that manufacturers use the ASTM standards F2299 for measuring particle filtration efficiency through the mask material using latex microspheres (ASTM 2003), and the F2101 Standard test method of evaluating the bacterial filtration efficiency (BFE) of medical face mask materials, using a biological aerosol of *Staphylococcus aureus* (ASTM 2019). Bacterial filtration efficiency can also be measured with the modified Greene and Vesley method using human test subjects (Greene and Vesley 1962; Quesnel 1975).

In addition to filtration performance, how well a respiratory protective device protects the wearer depends upon how well the device fits the face and whether the seal between the face and the device has gaps or leaks (Lawrence et al. 2006). ASTM Standard F3407-20 outlines procedures for testing respirators using a bivariate panel of human test subjects with different facial dimensions (ASTM 2020). The NIOSH approval test for respirators measures the filtration properties but does not include tests of how well the device fits faces of different shapes, although this has been proposed. Consequently, in the United States, when a worker is required to wear a respirator, the Occupational Safety and Health Administration (OSHA) requires that a respirator fit test be performed annually for each worker to determine how well the respirator protects the worker (OSHA 2020). Quantitative fit tests measure the aerosol particle concentration inside and outside the respirator during a series of exercises, and this information is used to calculate the fit factor (outside concentration/inside concentration) (Janssen and McKay 2017). The minimum acceptable fit factor for a respirator depends upon the exposure level and potential health consequences of the hazards to which the worker may be exposed (OSHA 2020).

The existing test methods for respirators and medical face masks provide a possible basis for developing standards for non-medical masks used as source control devices. The American Association of Textile Chemists and Colorists (AATCC) published guidelines for cloth face coverings that include the use of ASTM F2299 and other national and international performance standards (AATCC 2020). Leith, L'Orange, and Volckens (2021) proposed an estimated mask protection factor that is calculated based on tests of filtration efficiency and fit and on estimates of the average time spent speaking, inhaling, and exhaling. ASTM International has released a standard for testing barrier face coverings that includes tests of filtration efficiency and airflow resistance, and an assessment of leakage, which are standard metrics that are commonly used to test personal protective devices (ASTM 2021). The use of these standard performance metrics has many advantages, most notably that the equipment and procedures needed to conduct the tests are widely available. However, none of these metrics are

Table 1. Performance metrics used in this study. Outward mask airflow is in the direction of exhalation. Inward airflow is in the direction of inhalation.

Performance metric	**Parameter measured**	Mask airflow direction	Measurement instrument	**Measurement method**	Particle size	**Instrument airflow rate (liters/minute)**
Cough aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Outward	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Exhaled aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Cyclical	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Filtration efficiency	Aerosol mass concentration upstream & downstream of mask	Inward	TSI 8130 A	Photometer	75 nm count median diameter (GSD 1.86)	85
Airflow resistance	Pressure required for 85 lpm flow	Inward	TSI 8130 A	Manometer	n/a	85
Manikin fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode)	0.35
Human fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode) 0.02–1.0 μm (Class 100 mode)	0.35

direct measurements of the ability of a mask to block aerosols expelled during coughing and exhalation. To assist in the further development of these types of standards and guidelines, the relationship between the efficacy of masks as source control devices and their performance using standard metrics needs to be better understood. For example, it is possible to measure the filtration efficiency of the mask material, but it is not clear how that filtration efficiency translates to source control efficacy or what minimum performance level should be required.

The purpose of this study was to compare the performance of a variety of N95 respirators, medical masks, and cloth masks as source control devices with their filtration efficiencies, airflow resistances, fit factors measured using manikin headforms, and fit factors measured on humans. The results of these experiments will assist in the development of appropriate test methods and standardized performance metrics to evaluate the efficacy of cloth masks as source control devices for respiratory aerosols.

Materials and methods

Experimental design

A source control measurement system was used to assess the efficacy of N95 respirators, medical masks, and cloth masks as source control devices. The source control performance was determined by measuring the source control collection efficiency of the mask, which is the fraction of the mass of the coughed or exhaled test aerosol particles that were blocked by the mask from reaching the collection chamber. The filtration efficiencies and airflow resistance of the construction materials were measured using a modified version of the test method used for respirator approvals. Fit tests were performed both on a manikin headform with pliable skin and with human test subjects. The source control collection efficiencies were then compared with the fit factors, filtration efficiencies and airflow resistances measured on the same devices. A summary of the performance metrics used in the study is shown in Table 1.

Respiratory aerosol source control measurement system

The efficacy of respirators, medical masks, and cloth masks as source control devices for aerosols produced during coughing and exhalation was determined using a respiratory aerosol source control measurement system described previously (Lindsley et al. 2021). The system includes a coughing and breathing aerosol simulator, a manikin headform, an 136 L aerosol collection chamber, and a cascade impactor (Figure 1). The manikin headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each source control device would fit a human face (Bergman et al. 2014).

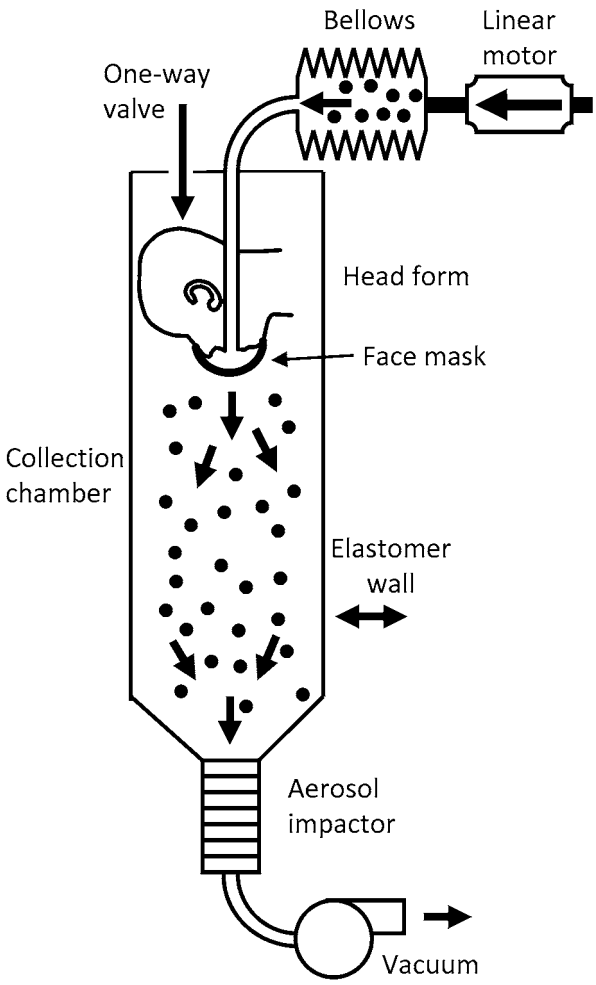

Figure 1. Source control measurement system. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated coughing and breathing, a pliable skin headform on which the source control device is placed, a 136 liter collection chamber into which the aerosol is coughed or exhaled, and a cascade impactor to separate the aerosol particles by size and collect them. The system is oriented vertically as shown to minimize the loss of aerosol particles due to settling before collection. The system is described in more detail in Lindsley et al. (2021).

The test aerosol was produced using a solution of 14% potassium chloride (KCl) and 0.4% sodium fluorescein in a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2). The aerosol passed through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), mixed with dry filtered air flowing at 10 L/min for the cough tests and 15 L/min for the breathing tests, and neutralized using a bipolar ionizer (Model HPX-1, Electrostatics). An elastomeric bellows driven by a computer-controlled linear motor produced the coughing or breathing airflow.

For cough tests, the test aerosol was loaded into the elastomeric bellows and then coughed out using a single cough with a volume of 4.2 L and a peak flow rate of 11 L/s (Lindsley et al. 2013). An Andersen cascade impactor (Model TE-10-830, Tisch Environmental) collected all aerosol particles that traveled through or around the device for 20 min after each cough. For breathing tests, the system used a ventilation rate of 15 L/min with a breathing rate of 12 breathes/min and a tidal volume of 1.25 liters, which corresponds to the ISO standard for a female performing light work (ISO 2015). The test aerosol was only generated for the first 30 s of breathing to avoid overloading the impactor. The breathing continued for 20 min total. The impactor collected the aerosol particles in the chamber during the 20-minute breathing period followed by an additional five minutes of collection after the breathing had stopped.

The impactor operated at a flow rate of 28.3 liters/minute and had six collection stages and a filter that separated the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm; 4.7–7.0 µm; and >7 µm. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). Because the amount of aerosol in the largest size fraction was small (<0.7% of total aerosol mass) and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction were not included in the analysis. After aerosol collection was completed, the aerosol particles were eluted from the impactor plates using a 0.1 M Tris solution and the fluorescence of the solution was read using a spectrofluorometer (SpectraMax M4, Molecular Devices).

To control for variations in the amount of aerosol in each experiment, a sample of each test aerosol was collected from the bellows prior to coughing or breathing using a 47 mm 5 µm PVC filter. The aerosol was eluted from the filter using 0.1 M Tris. An adjustment factor for the experiment (A) was calculated as:

$$A = \frac{Mass\ of\ aerosol\ on\ filter}{Mean\ (mass\ of\ aerosol\ on\ filter\ for\ all\ control\ experiments)} \quad (1)$$

The adjusted mass of aerosol on each impactor stage for the experiment was then calculated as:

$$M_{stage,\ adjusted} = \frac{M_{stage,\ unadjusted}}{A} \quad (2)$$

The adjusted masses were used for all subsequent calculations. The adjusted aerosol masses collected by the cascade impactor during the experiments are

Table 2. Source control devices used in experiments.

Type	Manufacturer	Product	Fastener	Material
Medical masks & respirators	3M	Model 1860 N95 respirator and surgical mask (TC-84A-0006)	Two elastic straps around head	Polypropylene and polyethylene composition

In this article, the reusable cloth face masks, neck gaiters and bandanas are referred to collectively as "cloth masks". IL is inner layer, ML is middle layer, and OL is outer layer. Photographs are shown in Figures S3–S5 (SI).

shown in Tables S1 and S2 in the supplemental information (SI).

The source control performance, or source control collection efficiency, of a face covering is defined as the fraction of the mass of the respiratory aerosol that is blocked from entering the environment around the wearer. For example, if 80% of the mass of the aerosol from a cough is blocked by a face mask and 20% of the aerosol mass is able to flow through or around the mask into the air around the wearer, then the mask is said to have a collection efficiency of 80%. The performance of each source control device was evaluated by calculating the collection efficiency as:

$$Collection\ efficiency = 1 - \frac{M_{mask}}{M_{control}} \qquad (3)$$

where:

M_{mask} = adjusted total mass of the aerosol particles that passed through or around the source control device and was collected by the impactor.

$M_{control}$ = adjusted total mass of the aerosol particles collected by the impactor while not wearing a source control device.

Note that the collection efficiency is based on the mass of the aerosol rather than a measure such as particle counts. Also, the aerosol is flowing from the inside of the mask toward the outside; that is, in our test system the aerosol flows in the same direction as it would flow during a cough or exhalation by a person wearing the mask.

Respirators, medical masks, and cloth masks

In our study, the term "cloth mask" refers to a cloth face mask, neck gaiter or bandana constructed from textiles or fabrics (both natural and synthetic) that is not a surgical mask or N95 respirator and is not intended for use as personal protective equipment. The term "medical masks" in this article refers to non-woven disposable masks that are held on the face with elastic ear loops. These masks are loose-fitting and are not expected to provide the wearer with as reliable a level of protection against airborne or aerosolized particles as N95 respirators regulated by NIOSH. Commercial manufacturers often refer to

masks held on by ear loops as procedure masks and masks that tie behind the head as surgical masks. However, the U.S. Food and Drug Administration uses the term "surgical mask" to describe commercially produced masks regulated by the under 21 CFR 878.4040 for performing medical procedures (FDA 2004). The FDA definition applies to all masks that cover the user's nose and mouth and provides a physical barrier to fluids and particulate materials, and includes masks that are labeled as surgical, laser, isolation, dental or medical procedure masks with or without a face shield.

Nineteen commercially available N95 respirators, medical masks, and cloth masks were selected to provide a broad cross-section of the different types of source control devices that are available (Table 2). For the source control tests, each device was placed on the headform as it would normally be worn by a person. Three of the neck gaiters were tested both as a single layer of fabric and folded over to provide two layers of fabric. Before the source control test, the manikin fit factor (Janssen and McKay 2017) was measured by performing a respirator fit test (Bergman et al. 2015) for each device using a PortaCount® Pro + respirator fit tester (Model 8038, TSI, Shoreview, MN) in N95 mode with the system breathing at 36 L/min but not producing an aerosol. Each device was used for two consecutive tests. Photographs of the source control devices on the headform are shown in the SI (SI; Figures S1–S3).

Filtration efficiency and airflow resistance measurements

The filtration efficiency of the face covering is the fraction of the test aerosol that is collected as the aerosol passes through the mask material. For example, if 70% of the test aerosol is collected by the mask material and 30% of the aerosol passes through it, then the filtration efficiency is 70%. Note that the filtration efficiency tests are performed by fastening the mask to a holder so that all the aerosol flows through the mask material, and none can escape through face seal leaks. Thus, the filtration efficiency is a property of the mask material.

The filtration efficiency and airflow resistance of the construction materials were measured using automated filter testers (Models 8130 and 8130 A, TSI). Material samples were secured to a test plate using beeswax as shown in Figure S4 in the SI. Measurements were made using a modified version of the NIOSH standard testing procedure (STP) (NIOSH 2019). Under the modified STP, samples were tested at ambient temperature and humidity but were not subjected to conditioning at 38°C and 85% relative humidity for 25 h, and sample testing was limited to 10 min. The device to be tested was oriented in the filter tester so that the air and aerosol flowed from the exterior of the device toward the interior (that is, as if the wearer were inhaling, which is the same direction as when testing a respirator as a personal protective device). The challenge aerosol was generated using a 2% sodium chloride (NaCl) solution in distilled water, conditioned to 25 °C and 30% relative humidity and neutralized to the Boltzmann equilibrium state. The challenge aerosol had a count median diameter of 75 nm ± 20 nm, a mass mean diameter of 260 nm and a geometric standard deviation (GSD) $\leq$ 1.86 (TSI 8130 A specifications). The automated filter tester compares particle mass concentration readings from upstream and downstream light-scattering laser photometers to calculate the material filtration efficiency. An electronic pressure transducer measures the pressure difference across the material sample to indicate airflow resistance. Tests were performed with an airflow of 85 L/minute.

Fit tests on human subjects

A convenience sample of eleven subjects (six males and five females) participated in fit testing. Subjects complied with CDC/NIOSH guidelines for facial hair styles intended for workers who wear tight-fitting respirators (CDC 2017). Fit testing was performed with a PortaCount® fit tester (model 8038, TSI) using OSHA's modified ambient aerosol condensation nuclei counter (CNC) protocol for filtering facepiece respirators (OSHA 2019). Because only fit factors were measured and no identifiable private information was collected, the West Virginia University Office of Human Research Protections determined that Institutional Review Board approval was not required. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy (see e.g., 45 C.F.R. part 46; 21 C.F.R. part 56; 42 U.S.C. §241(d), 5 U.S.C. §552a, 44 U.S.C. §3501 et seq.). All measurements were performed in a room with volume of 43.4 m^3 (1531 ft^3) at 19 °C (67 °F).

An NaCl aerosol generator (Model 8026, TI) was used to supplement the naturally occurring particles in the air. The particle generator was placed 10 feet away from all sampling apparatus and fit testing equipment. The generator was turned on ten minutes prior to testing to seed aerosols and turned off while

a triplicate series of fit tests were performed (around 7 min). As the aerosol concentration in the room had started to slightly decline at this point, the generator was turned on between tests (around 7 min) and then turned off during subsequent tests. This process was repeated until testing for the day was completed.

To verify that suitable aerosol concentrations were present during testing, particle concentrations were measured with a condensation particle counter (CPC Model 3775, TSI) for 25 min beginning at 2 min prior to the nebulizer being initially turned on. Particle size distributions were measured for 20 min with a scanning mobility particle sizer (SMPS Model 3938, TSI) and an electrical low-pressure impactor (ELPI+, Dakati). Information on the aerosol particle size distribution and concentration are shown in the SI (Figures S5 and S6).

Each source control device was tested by three subjects; for each subject three replicate measurements were made using each of the two protocols described below. One individual administered all fit tests. Subjects were instructed in the proper donning of medical masks and respirators, and they were asked to don cloth masks in the manner that they ordinarily don similar coverings for public use. If a cloth mask was too large, it was modified using materials that would be accessible to most lay individuals: tape was used to shorten mask ear loops or head straps, and a binder clip was used to decrease the circumference of neck gaiters. These adjustments were made so that the covering was held flush to the face, but the materials were not under tension.

Two particle measurement protocols were performed on all source control devices: the PortaCount® N95 Companion protocol (referred to here as N95 mode), which counts negatively charged particles 40–70 nm (mean 55 nm) in diameter; and the PortaCount® standard protocol (referred to here as Class 100 mode), which counts all particles from 0.02–1.0 µm (TSI 2010). The "Class 100 mode" is also called "N99 mode". For both modes, the fit factor (FF) was calculated by the PortaCount® software as (Janssen and McKay 2017; TSI 2015):

$$FF = \frac{C_B + C_A}{2C_R} \quad (4)$$

where:

C_B = ambient particle concentration measured before the particle concentration is measured inside the respirator.

C_A = ambient particle concentration measured after the particle concentration is measured inside the respirator.

C_R = particle concentration measured inside the respirator.

Note that the TSI PortaCount instrument used in our experiments measures the aerosol concentration based on the number of aerosol particles rather than the particle mass.

Data analysis

The source control results were compared with the filtration efficiencies, airflow resistances, and fit factor measurements by calculating the Spearman's rank correlation coefficients (ρ) between the metrics. Fit factors were transformed into fit efficiencies (= 1-1/fit factor) to allow for a direct comparison with the other parameters. For example, a fit factor of 5 corresponds to a fit efficiency of 80%, indicating that the mask blocked 80% of the ambient aerosol from being inhaled by the wearer. Because the replicate numbers were different for the different performance metrics, the correlations were calculated based on the mean results for each device. When analyzing the human fit factor results, we did not attempt to account for differences among test subjects. The p-value was calculated based on ρ and the number of types of devices that were tested (22 for all source control devices and 18 for the cloth masks alone, with the 1-layer and 2-layer gaiter tests counted separately). Correlations were considered significant if $p \leq 0.05$.

Results

Efficacy of N95 respirators, medical masks, and cloth masks as source control devices for respiratory aerosols

Twenty-six cough experiments were performed without a source control device to measure the cough aerosol output from the source control measurement system. The cough aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 525 µg (standard deviation [SD] 65; Figure 2 and SI Figure S7). Thirty-five breathing aerosol experiments were performed without a source control device to measure the exhaled aerosol output. The exhaled aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 495 µg (SD 68; Figure 2 and SI Figure S8). The experiments without source control devices were used as control experiments when evaluating performance of the devices.

The collection efficiencies of the 19 source control devices are shown in Figure 3 and Table 3. The mean

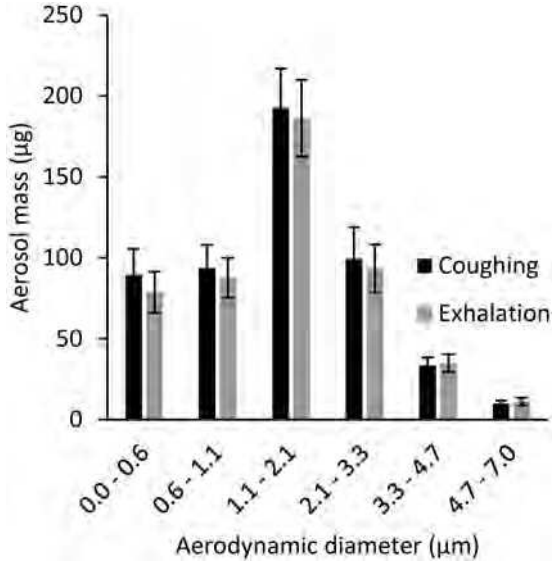

Figure 2. Mass of aerosol expelled by the source control measurement system during coughs and exhalations. The size bins correspond to the stages of the Andersen impactor. The size distribution is shown in units of µg/µm in Figures S7 and S8 in the SI.

collection efficiencies of the N95 respirators and the surgical mask ranged from 83% to 99% for aerosol particles during coughing and exhalation. For the procedure and cloth masks, the mean collection efficiencies ranged from 35% to 71% for coughing (except for the bandana at 17%) and 35% to 66% for exhalation. The collection efficiencies for the coughing and breathing source control experiments were correlated, with a Spearman's correlation coefficient (ρ) of 0.76 ($p < 0.001$; Table 4) when considering all the devices and 0.67 ($p = 0.003$; Table 4) when considering only the cloth face masks, gaiters and bandanas. The amounts of aerosol collected on each stage of the impactor are shown in Tables S1 and S2 in the SI.

Filtration efficiencies and inhalation airflow resistance

The mean material filtration efficiencies were >99% for the respirators, 80% to 93% for the medical masks, and 1.4% to 36% for the cloth face masks, neck gaiters, and bandanas, except for the Besungo sports mask at 98% (Figure 4 and Table 3). The inhalation

Manikin fit factors were measured with the fit tester in N95 mode only (as described in the Discussion). Human fit factors were measured using both the N95 mode and Class 100 mode.

Table 4. Correlations between different performance metrics for all source control devices.

		All source control devices		Cloth face masks, gaiters, and bandanas only	
Correlation parameter #1	Correlation parameter #2	ρ	*p*-value	ρ	*p*-value
Cough aerosol collection efficiency	Exhaled aerosol collection efficiency	0.76	<0.001	0.67	0.003
	Filtration efficiency of material	0.69	0.001	0.51	0.032
	Airflow resistance of material	0.55	0.009	0.54	0.020
	Human subject fit (N95 mode)	0.57	0.005	0.30	0.208
	Human subject fit (Class 100 mode)	0.68	<0.001	0.48	0.035
	Manikin fit before coughing	0.39	0.076	0.03	0.890
Exhaled aerosol collection efficiency	Filtration efficiency of material	0.60	0.004	0.54	0.023
	Airflow resistance of material	0.51	0.016	0.58	0.012
	Human subject fit (N95 mode)	0.60	0.003	0.51	0.024
	Human subject fit (Class 100 mode)	0.71	<0.001	0.63	0.003
	Manikin fit before breathing	0.72	<0.001	0.68	0.002
Manikin fit before coughing	Manikin fit before breathing	0.61	0.003	0.38	0.112
Filtration efficiency of material	Airflow resistance of material	0.78	<0.001	0.78	<0.001

Each Spearman's rank coefficient (ρ) was calculated based on data from 22 experiments for all source control devices and 18 experiments for cloth masks (cloth face masks, gaiters, and bandanas). A correlogram of the ρ values in shown in Figure S9 in the SI.

airflow resistances were from 5.2 to 154 Pa (Table 3). When comparing the data for all devices, the filtration efficiencies were correlated with cough aerosol collection efficiency ($\rho = 0.69$, $p = 0.001$) and exhaled aerosol collection efficiency ($\rho = 0.60$, $p = 0.004$; Table 4). For the group of cloth masks, the correlations were not as strong; the cough aerosol collection efficiency and filtration efficiency had an ρ of 0.51 ($p = 0.032$) while the exhaled aerosol collection efficiency and filtration efficiency had an ρ of 0.54 ($p = 0.023$; Table 4). The airflow resistance did not correlate as well as the filtration efficiency when all devices were considered ($\rho = 0.55$ and $p = 0.009$ for coughing; $\rho = 0.51$ and $p = 0.016$ for exhalation). However, when examining the cloth masks alone, the airflow resistance was slightly better correlated than filtration efficiency ($\rho = 0.54$ and $p = 0.020$ for coughing; $\rho = 0.58$ and $p = 0.012$ for exhalation).

Human fit tests

The fit factors measured on the human test subjects are shown in Table 3 and Figure 5. The mean fit factors for the two N95 respirators were 148 and 164

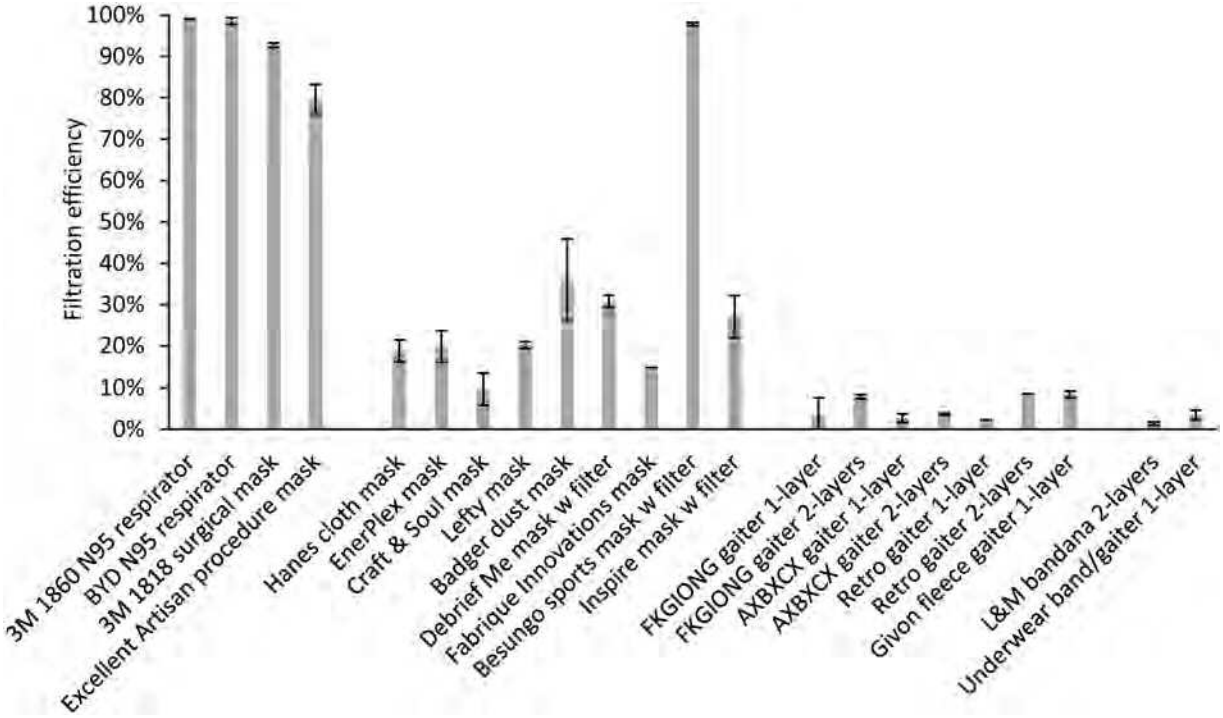

Figure 4. Filtration efficiencies for the source control devices used in the study. Three samples of each device were tested, except for the 3 M 1860 N95 respirator and Hanes cloth mask (10 samples each) and the Fabrique Innovations mask, Retro gaiter 1-layer, and Retro gaiter 2-layers (one sample each). Error bars show the standard deviation.

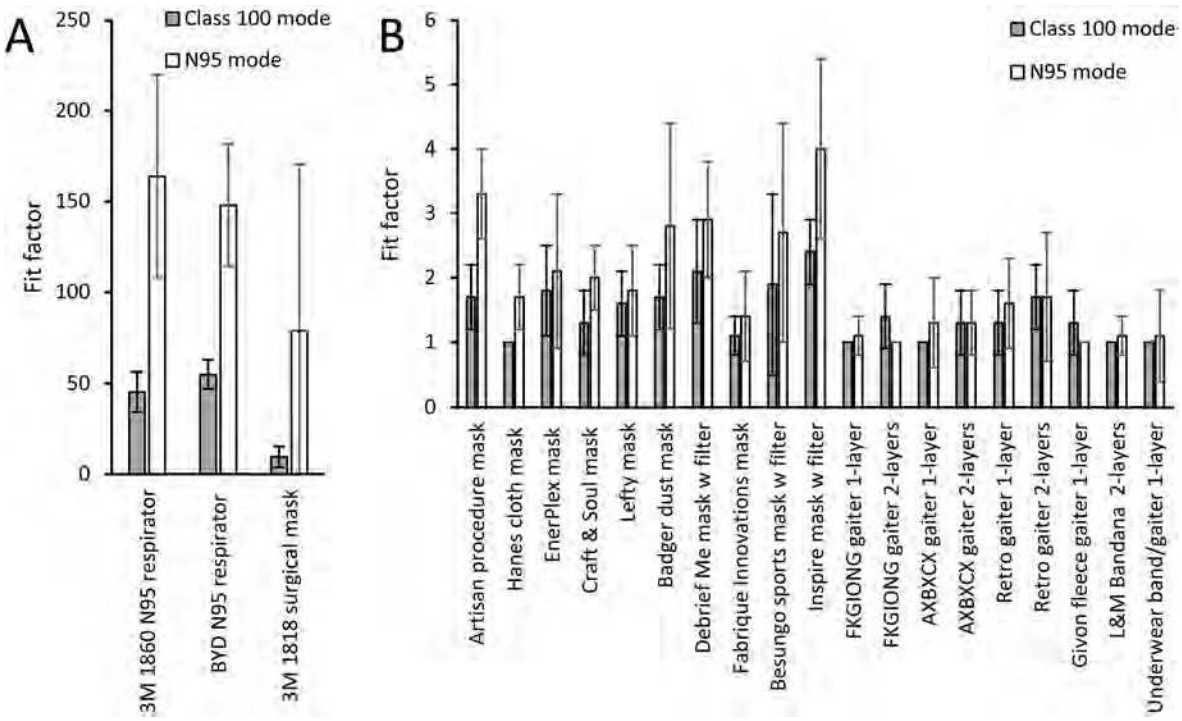

Figure 5. Fit factors measured with human subjects for (a) N95 respirators and surgical mask and (b) procedure mask, cloth face masks, gaiters and bandanas. The plot shows the means and standard deviations. Results for all human fit tests are given in Table S3 in the SI.

when using the N95 mode on the fit tester and 55 and 45 with the Class 100 mode. The surgical mask provided a mean N95 mode fit factor of 79 and a much lower mean fit factor of 9.6 in Class 100 mode. The mean N95 mode fit factor of the reusable cloth face masks ranged from 1.4 to 4.0, and the all sizes

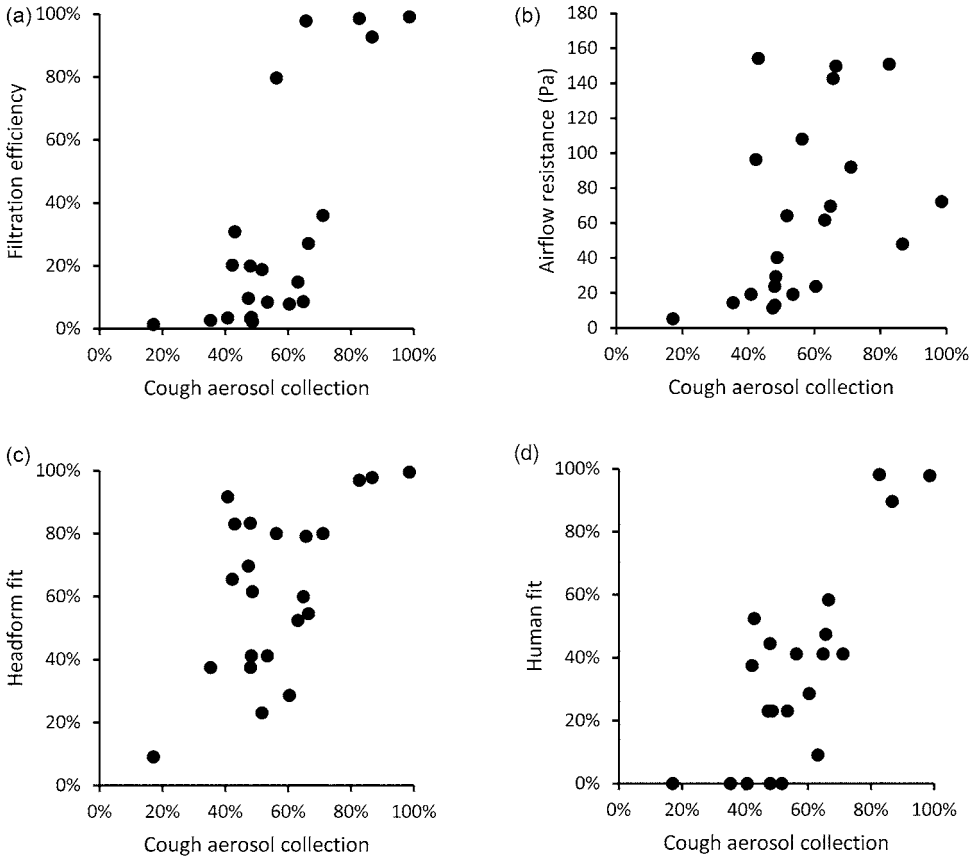

Figure 6. Comparison of collection efficiencies for aerosols from coughs to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot corresponds to the mean result for one type of source control device.

mode mean fit factors ranged from 1.0 to 2.4. Neck gaiters and bandanas demonstrated N95 mode fit factors ranging from 1.0 to 1.7 and all particle size mode mean fit factors from 1.0 to 1.7. The performance of cloth masks sometimes varied considerably when worn by different subjects. The fit test results for individual subjects are shown in Table S3 in the SI.

The cough and exhalation aerosol collection efficiencies for all devices were well correlated with the fit factors when measured using the Class 100 mode ($\rho = 0.68$ and $p < 0.001$ for coughing, $\rho = 0.71$ and $p < 0.001$ for exhalation, Table 4). When looking at the results for the cloth masks, gaiters, and bandanas in the all sizes mode, the correlations were not as strong, with $\rho = 0.48$ for coughing ($p = 0.035$), and $\rho = 0.63$ for exhalation ($p = 0.003$; Table 4). In all cases, the correlation coefficients were higher when the fit tester was in the Class 100 mode than when the tester was in N95 mode.

Manikin fit tests

The manikin fit factor measurements found using the source control measurement system before the cough tests were 25 to 198 for the N95 respirators and the surgical mask and 1.3 to 7.4 for the procedure mask and cloth masks (Table 3). Before the breathing tests, the manikin fit factors were 28 to 133 for the N95 respirators and the surgical mask and 1.4 to 6.1 for the procedure mask and cloth masks. The cough aerosol collection efficiencies and the pre-cough manikin fit factors were not significantly correlated, with a ρ of 0.39 ($p = 0.076$) for all devices (Table 4 and Figure 6) and a ρ of only 0.03 ($p = 0.890$) for the cloth masks (Table 4). The correlation was better between the exhaled aerosol collection efficiency and pre-breathing manikin fit factors, with a ρ of 0.72 ($p < 0.001$) for all devices (Table 4 and Figure 7) and 0.68 ($p = 0.002$) for the cloth masks (Table 4).

Discussion

The COVID-19 pandemic has resulted in considerable interest in the performance characteristics of masks and respirators as a means of reducing the person-to-person transmission of SARS-CoV-2. Some studies have looked at the emission of particles from human volunteers wearing different face coverings, which has

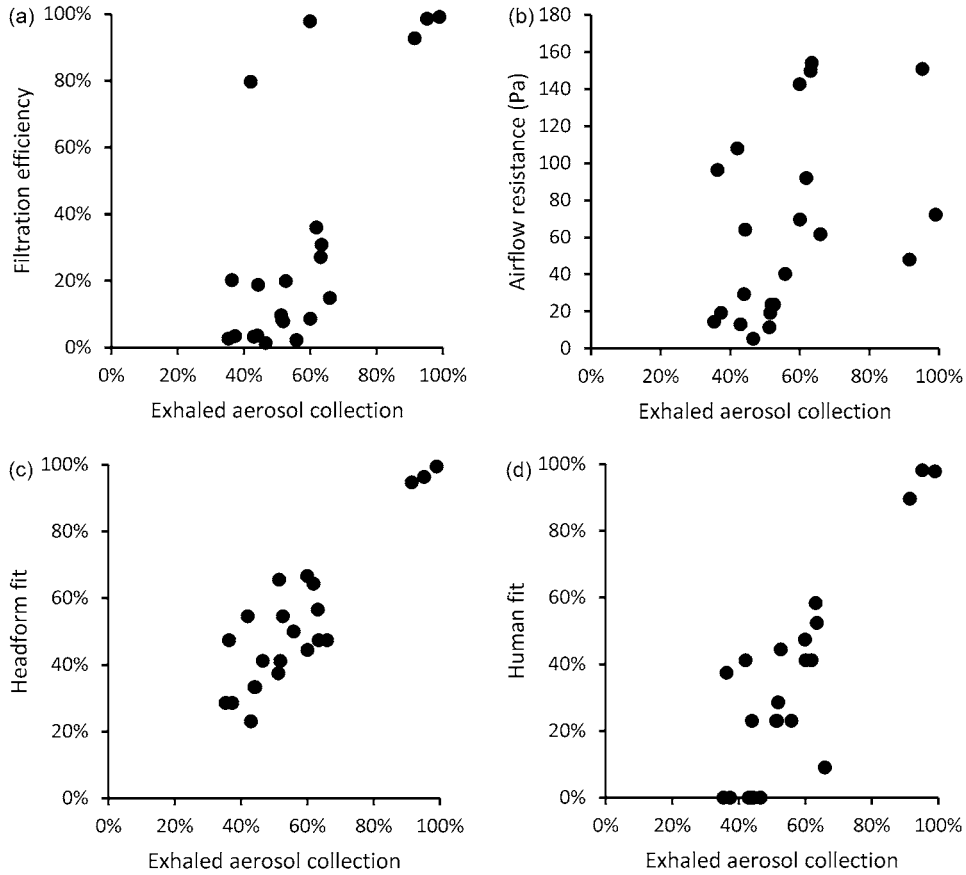

Figure 7. Comparison of collection efficiencies for exhaled aerosols from simulated breathing to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot shows the mean result for one type of source control device.

the advantage of directly examining the expulsion of aerosols into the environment by people (Asadi et al. 2020; Davies et al. 2013; Leung et al. 2020; Li, Niu, and Zhu 2021). However, the collection and measurement of human-generated respiratory aerosols is challenging and can be hazardous when the subject has a contagious respiratory infection. In addition, the amount and size distribution of aerosol particles produced by people during coughing, breathing and other respiratory activities varies tremendously from person to person and even for a particular person over time, which makes it difficult to compare results (Asadi et al. 2019; Fennelly 2020; Gralton et al. 2011; Lindsley et al. 2012). Consequently, lab-based surrogate techniques are more frequently used to study source control devices. The most commonly reported methods have been tests of filtration efficiencies and fit factors (Clapp et al. 2021; Guha et al. 2021; Konda et al. 2020; Wang et al. 2020; Zhao et al. 2020). Other studies have used manikins in a chamber or room to assess the efficacy of medical masks and cloth masks both as source control devices and as personal protective equipment (Pan et al. 2021; Patel et al. 2016; Rothamer et al. 2021). Experimental data have also been used to develop computational fluid dynamics models of medical and cloth masks performance (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020). These studies have provided valuable information about the properties of masks and respirators. However, it is unclear how the various metrics used in these studies are related to source control performance.

The source control measurement system used in this study allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough and exhaled breath aerosol particles into the environment (Lindsley et al. 2021). However, the system is complex and requires expertise to operate, and it is neither commercially sold nor easily constructed. In contrast, filtration measurement systems and respirator fit testers are widely available. If a methodology could be developed to gauge source control performance using existing commercially available equipment, it could be rapidly expanded and adopted by manufacturers and public health entities.

The filtration efficiency of a mask or respirator is a measurement of the ability of the mask material to remove aerosol particles from an airstream traveling through the fabric. Filtration efficiency tests typically use aerosol particles at or near the most-penetrating aerosol particle size, which is around 300 nm for an uncharged filter at low air velocities but shifts to smaller sizes at higher velocities and when the filter and particles are electrostatically charged (Martin and Moyer 2000; Rengasamy, BerryAnn, and Szalajda 2013; Rengasamy et al. 2017). The mechanisms by which filters collect aerosol particles are strongly dependent upon the size of the particles; for example, large particles are more likely to be collected by impaction or interception while small particles are more likely to be collected by diffusion (Lindsley 2016). Although the SARS-CoV-2 virus is about 100 nm in diameter, contagious humans do not shed bare viral particles. Instead, they expel aerosols and droplets of respiratory fluids that contain respiratory virus, and the size of these virus-laden aerosols and droplets can range from hundreds of nanometers to visible droplets of 1 mm or more (Fennelly 2020; Gralton et al. 2011). Thus, the collection efficiencies for 100-300 nm particles may not predict the performance for larger particles (Drewnick et al. 2021). In our experiments, the coughing and exhalation source control collection efficiencies increased as the particle size increased (Tables S1 and S2 in the SI) and in most cases were higher than the filtration efficiencies, likely because our coughing and exhalation test aerosols were much larger than the 75 nm aerosol used for filtration tests.

The fit factor is normally used to determine how well a respiratory protective device fits the wearer by measuring the degree to which aerosol particles can enter through gaps between the wearer's face and the respirator (face seal leaks). It is determined by placing the device on a person or on a manikin headform and measuring the ratio of the aerosol concentration outside the respirator to the aerosol concentration inside the respirator (Janssen and McKay 2017). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the respirator. Fit factor measurements are not intended to test the filtration efficiency of the device itself. In fact, the calculation of the fit factor for a respirator assumes that any ambient aerosol particles passing through respirator material are filtered out and that any particles detected inside the respirator are due to face seal leaks, not penetration of particles through the filter material (Halvorsen 1998). For example, a fit factor of 10 is interpreted as indicating that 90% of the air inside the respirator has passed through the respirator filtration media (with aerosol particles being completely removed) and that 10% of the air bypassed the media and entered through face seal leaks.

For high efficiency filters such as P100 respirator filters, which filter out 99.97% of airborne particles, a respirator fit test is performed by measuring the concentrations of aerosol particles of all sizes inside and outside the respirator (referred to here as Class 100 mode). However, N95 respirators can allow up to 5% of aerosol particles of the most penetrating size to pass through the filtration media. These particles would reduce the apparent fit factor if they were included in the calculation. Thus, when fit testing N95 respirators, the respirator fit tester used in our experiments has a size classifier to count only negatively charged aerosol particles near 55 nm in size (referred to here as N95 mode). For an N95 respirator, these charged 55 nm particles are almost entirely filtered out by the filtration media, and thus any particles detected inside the respirator can then be assumed to have entered through face seal leaks and not through the respirator (Halvorsen 1998; Han and Prell 2010).

It is important to note, however, that this assumption is not correct when using the fit tester with cloth masks. As can be seen in Table 3, the filtration efficiencies of most cloth masks are much lower than those of respirators, and ambient particles therefore can penetrate more easily through the cloth material. Thus, the fit factor for a cloth mask is not a true measurement of face seal leakage alone; instead, it represents a combination of face seal leakage and particle penetration through the mask material.

Our findings suggest that the results from filtration efficiency, airflow resistance and fit factor tests are correlated with measurements made using our source control measurement system. For the cloth masks, all but two of the standard performance metrics were significantly correlated with the cough and exhaled aerosol collection efficiencies, which suggests that these other measures could be useful as part of a method for testing the performance of cloth masks. However, none of the standard metrics were strong predictors of source control performance, and no metric was clearly superior to the others.

The limited correlations between the different test methods in our study likely have several explanations. First, filtration efficiency and airflow resistance measurements do not account for how well the devices fit the wearer or for face seal leaks around the edges of

the device. Thus, for example, the Artisan procedure mask had an 80% filtration efficiency but a 56% collection efficiency for cough aerosols and a 42% collection efficiency for exhaled aerosols. The most likely explanation is that this mask's material is an efficient filter but that aerosol particles were able to travel around the mask through face seal leaks because the Artisan mask fits loosely on the headform. On the other hand, the Hanes Defender cloth mask had only a 19% filtration efficiency but had similar aerosol collection efficiencies of 52% for coughs and 44% for exhalations. In this case, the cloth mask was not an effective filter for the 75 nm aerosol used in filtration testing, but the Hanes mask fit the manikin headform more tightly. Thus, much of the aerosol then flowed through the mask rather than around it during coughing and breathing tests and the larger aerosol particles that were used in the coughing and breathing tests were filtered out more effectively than the 75 nm particles used in filtration testing. The results presented here are consistent with a previous study by our group in which knotting the Artisan procedure mask to improve the fit increased the cough aerosol collection efficiency to 77%, while wearing a Hanes Defender cloth mask on top of an Artisan procedure mask increased the cough collection efficiency to 85% (Brooks et al. 2021). Together, these results also support the recommendation by Gandhi and Marr that members of the public wear a high-quality mask that fits tightly or wear a tight-fitting cloth mask over a surgical mask in order to reduce face seal leaks and improve the source control performance and protection offered by the masks (Gandhi and Marr 2021).

Fit tests are designed to measure the effects of face seal leaks but have their own limitations when applied to cloth masks. As noted above, fit factor measurements for cloth masks reflect some combination of particle penetration through the media and face seal leakage which will likely vary from mask to mask. Thus, it is neither clear how to interpret fit factor measurements for cloth masks nor is it clear how this relates to the effectiveness of the mask as a source control device. In addition, fit test results can vary greatly from person to person and even somewhat for the same person during repeated tests (Lawrence et al. 2006). Similarly, a comparison of fit tests between humans and a pliable skin manikin headform found significant differences (Bergman et al. 2015). Much of this discrepancy is likely due to facial variations and differences in how the mask is placed on the person or manikin headform. It is possible to shift, stretch, tighten, loosen, or adjust the masks in many ways,

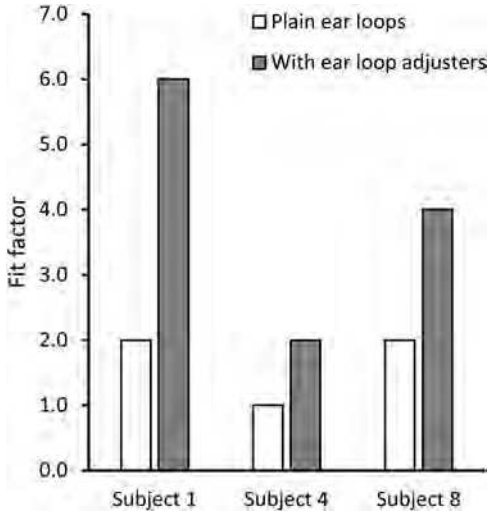

Figure 8. Effect on mask fit factor of adding ear loop adjusters to tighten the mask fit. Subjects were wearing the Excellent Artisan procedure mask. Tests were conducted with the fit tester in Class 100 mode. Each bar is the mean of three trials. All standard deviations were zero.

and small differences in how the mask is worn may have substantial effects on the fit test results. For example, in tests with three subjects using the Artisan procedure mask, we found that tightening the mask against the face by using silicone ear loop adjusters increased the mean fit factor from 1.7 to 4.0 (Figure 8). In experiments with cloth masks, the ρ value for the manikin headform fit tests done before coughing experiments compared with tests done before exhalation experiments was only 0.38, suggesting that differences were occurring even when the same model of mask was being placed on the same headform.

Finally, our study has several limitations. The source control measurement system produced a test aerosol with particles $\leq$7 µm in diameter, which is the size range of aerosol particles most likely to remain airborne and most difficult to block with source control devices. However, humans expel aerosol particles in a much broader range of sizes, particularly when coughing. We used a single cough flowrate profile and a single breathing ventilation rate for our studies; these parameters can vary greatly from person to person under different physiological conditions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We used representative examples of different types of source control devices, but many such devices are available with a wide range of shapes and compositions, which would be expected to affect their individual performance. As shown in Table 1, the instrumentation used for the

different performance metrics are based on different operating principles and thus caution should be used when comparing results; for example, the collection efficiency results from the impactors are based on aerosol mass, while the fit factor results from the PortaCount are based on particle counts. Lastly, because of the need to rapidly produce results in response to the COVID-19 pandemic, we only tested 2-3 samples of each source control device (each sample was used in two consecutive tests). By comparison, for example, the NIOSH procedure for evaluating N95 respirators calls for 20 samples to be tested (NIOSH 2019).

Current evidence indicates that masks like those tested in our experiments can substantially decrease the amount of respiratory aerosols released by the wearer, and also help reduce what the wearer breathes in (CDC 2020a). Both effects vary depending upon the material and construction of the mask, as well as how it is worn. In addition to consistent and correct mask use when in the company of others, other measures such as physical separation are important, particularly during brief exposures. In a room where someone sneezes, being six feet or further away is better than being closer. However, with prolonged exposure in the same space for more than a few minutes, the benefit of distance fades as exhaled respiratory aerosols drift, mix, and accumulate in the enclosed air space. Optimizing ventilation, air filtration, and the introduction of fresh air can help counter this effect, but at every distance, correct mask use reduces the risk for everyone.

Conclusions

The ongoing COVID-19 pandemic has created an urgent need for simple methods to evaluate cloth masks as respiratory aerosol source control devices and to produce meaningful performance metrics that can be used to determine the effectiveness of different materials and designs. Our results suggest that test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements on manikin headforms or human subjects have potential as ways to estimate the performance of masks as source control devices for respiratory aerosols. However, more research and improvements in the test methodologies are needed before such methods can be reliably implemented. Until the factors controlling the performance of source control devices are better understood and better testing methodologies are developed, results from test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements should be interpreted cautiously when used to evaluate source control devices for respiratory aerosols.

Efficacy of face masks, neck gaiters and face shields for reducing the expulsion of simulated cough-generated aerosols

William G. Lindsley, Francoise M. Blachere, Brandon F. Law, Donald H. Beezhold, and John D. Noti

Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Morgantown, West Virginia, USA

ABSTRACT

Face masks are recommended to reduce community transmission of SARS-CoV-2. One of the primary benefits of face masks and other coverings is as source control devices to reduce the expulsion of respiratory aerosols during coughing, breathing, and speaking. Face shields and neck gaiters have been proposed as an alternative to face masks, but information about face shields and neck gaiters as source control devices is limited. We used a cough aerosol simulator with a pliable skin headform to propel small aerosol particles (0 to 7 μm) into different face coverings. An N95 respirator blocked 99% (standard deviation (SD) 0.3%) of the cough aerosol, a medical grade procedure mask blocked 59% (SD 6.9%), a 3-ply cotton cloth face mask blocked 51% (SD 7.7%), and a polyester neck gaiter blocked 47% (SD 7.5%) as a single layer and 60% (SD 7.2%) when folded into a double layer. In contrast, the face shield blocked 2% (SD 15.3%) of the cough aerosol. Our results suggest that face masks and neck gaiters are preferable to face shields as source control devices for cough aerosols.

Introduction

SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can be transmitted from person-to-person by large respiratory aerosols (airborne liquid droplets and dried particles greater than about 10 μm in diameter) produced by people who are infectious while they are talking, singing, coughing, breathing or sneezing (CDC 2020a; Hamner et al. 2020). Smaller aerosols also are emitted by people during these activities, suggesting that short-range airborne transmission of SARS-CoV-2 might be possible under some circumstances (Anderson et al. 2020; CDC 2020a; Fennelly 2020; Ma et al. 2020; Morawska and Milton 2020).

To interrupt this potential transmission route, the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO), and other public health organizations recommend the wearing of face masks or other face coverings by the general public during the ongoing COVID-19 pandemic (CDC 2020b, 2020c; Edelstein and Ramakrishnan 2020; WHO 2020). One of the primary benefits of face coverings is to act as source control devices to reduce the expulsion of aerosols containing the virus from people who are infectious during coughing, breathing, and speaking. Source control devices are intended to protect other people from infectious aerosols emitted by the wearer, as compared with personal protective equipment such as N95 respirators which are primarily intended to protect the wearer. A face covering can provide source control in two ways (Diaz and Smaldone 2010). First, and most importantly, the covering may collect aerosol particles by filtration, impaction, or other mechanisms, and thus prevent infectious aerosols from entering the environment. Second, the face covering may change the direction of travel and the velocity of the aerosol stream and thus possibly divert the aerosol away from a potential recipient. However, deflection is more uncertain as a source control mechanism. For example, if large aerosols are deflected downward, they may settle to the floor or otherwise be unable to reach the breathing zones of other people. However, since exhaled breath is often warmer than the surrounding air, this

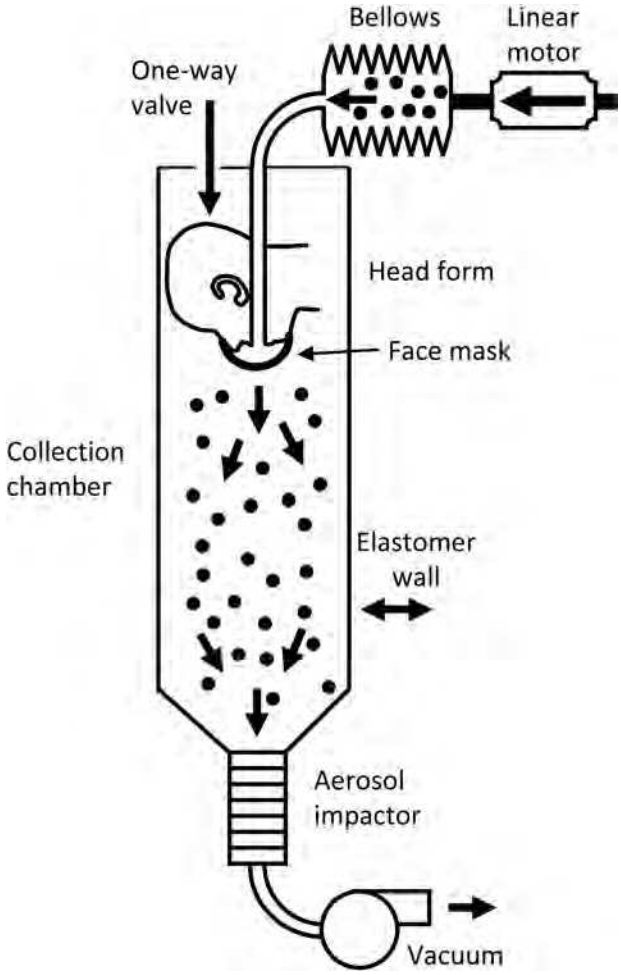

Figure 1. Cough aerosol simulator system for source control measurements. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated cough, a pliable skin head form on which the face mask, neck gaiter or face shield is placed, a 105 liter collection chamber into which the aerosol is coughed, and an Andersen impactor to separate the aerosol particles by size and collect them. More information about the cough aerosol simulator is provided in the SI.

downward deflection may be counteracted by the buoyancy of the breath for smaller aerosols. In addition, if the respiratory aerosols are deflected sideways, they may be diverted away from a person directly in front of the wearer but toward someone to the side or behind the wearer.

Studies using manikins (Lai, Poon, and Cheung 2012; Patel et al. 2016) and patients with respiratory infections (Leung et al. 2020; Milton et al. 2013) have shown that wearing medical face masks can reduce the dispersion of potentially infectious aerosols from patients. Two studies in which face masks were required for visitors and healthcare workers interacting with patients in bone marrow transplant centers found a reduction in respiratory viral infections among patients (Sokol et al. 2016; Sung et al. 2016). Studies of cloth face masks have suggested that they also can be effective at reducing the release of respiratory aerosols into the environment (Asadi et al. 2020; Davies et al. 2013; Konda et al. 2020). Several computational fluid dynamics studies have examined the generation and expulsion of respiratory aerosols and have provided important insights into the ability of face coverings to reduce the dispersion of large and small aerosols from the wearer (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020).

Unfortunately, the use of face masks and other face coverings by the general public can present challenges. People often dislike wearing masks, and compliance can be low and inconsistent (Longtin et al. 2009). Mask wearers may repeatedly don, doff and adjust face masks, which can contaminate the hands and potentially lead to disease transmission, especially when the masks are reused (Brady et al. 2017; Casanova et al. 2008). For cloth masks, the filtration efficiency and air flow resistance of different textiles varies widely (Konda et al. 2020; Teesing et al. 2020; Wilson et al. 2020). Alternative face coverings such as neck gaiters (an elastic fabric tube that fits snugly around the head and neck) are commonly used, but information about their performance as source control devices is limited. Factors such as how well the mask fits the face and the coverage provided by a mask can have a substantial impact on the effectiveness of face masks (Davies et al. 2013; Lawrence et al. 2006). Comparisons of face coverings have found substantial differences in the ability of different types of these devices to reduce the release of respiratory aerosols (Asadi et al. 2020; Davies et al. 2013).

An opinion article in JAMA proposed that face shields would be more effective than face masks at reducing community disease transmission, in large part because the authors felt that face shields were more comfortable and thus that they were more likely to be widely adopted by the public (Perencevich, Diekema, and Edmond 2020). A previous study by our group of face shields used as personal protective devices showed that face shields protect the wearer from large cough aerosols directed at the face but are much less effective against smaller aerosols which were able to flow around the edges of the shield and be inhaled (Lindsley et al. 2014). However, very little work has been done examining face shields as source control devices. Two qualitative flow visualization studies of face shields and masks found that, although face shields deflected the air flow from the mouth, they did not stop aerosol particles from traveling around the face shield and entering the environment

(Verma, Dhanak, and Frankenfield 2020; Viola et al. 2020). Beyond these studies, quantitative data on the efficacy of face shields for source control are lacking.

The objective of our study was to conduct a quantitative comparison of the efficacy of an N95 respirator, a medical procedure mask, a commercial 3-ply cloth face mask, a single and double layer fabric neck gaiter, and a commercial disposable face shield as source control devices to reduce the expulsion of small cough-generated aerosol particles into the environment. Our results provide more information about the effectiveness of different types of source control devices and will help the public health community make recommendations about the best ways to use these devices to help reduce the spread of COVID-19.

Materials and methods

Experimental design

In our experiments, a cough aerosol simulator propelled a test aerosol through a headform into a collection chamber (Figure 1), and the amount of aerosol in the collection chamber was measured in each of six size fractions. The collection efficiency of each face mask, neck gaiter, or face shield was determined by comparing the amount of aerosol that was collected from the chamber with and without the device. Our test method was similar to the modified Greene and Vesley method used to test medical masks (Quesnel 1975), with the human test subject replaced by the cough aerosol simulator.

Cough aerosol simulator

The cough aerosol simulator is a modified version of the NIOSH cough aerosol simulator described previously (Lindsley et al. 2019; Lindsley et al. 2014; Lindsley et al. 2013). The experimental cough aerosol was generated by nebulizing a solution of 14% KCl and 0.4% sodium fluorescein using a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2), passing the aerosol through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), and mixing it with 10 L/min of dry filtered air. The test aerosol was loaded into an elastomeric bellows, and the cough airflow was produced by a computer-controlled linear motor that compresses the bellows. The cough aerosol was expelled through the mouth of a headform into a collection chamber. The headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each face covering or shield would fit a human face (Bergman et al. 2014).

Source control devices

The source control devices tested were an N95 medical respirator (3 M model 1860), a medical grade (ASTM Level 3) procedure mask with ear loops (Kimberly Clark model 47107), a cloth face mask with 3 layers of cotton fabric and ear loops (Hanes Defender), a fabric neck gaiter (FKGIONG Sun UV Protection Neck Gaiter, 95% polyester, 5% Spandex) and a disposable face shield (Fisher Scientific # 19-181-600 A). The neck gaiter was tested both as a single layer of fabric and doubled over to provide two layers of fabric. The masks and respirator were not equipped with exhalation valves. The face shield was 25 cm tall and extended from the forehead of the headform to 3 cm below the chin and around the side to 3 cm before the front of the ear. Photographs of the source control devices on the headform are shown in the online supplementary information (SI).

Mask fit test

For the experiments, either no device, a face mask, a neck gaiter, or a face shield were placed on the head form. Each device was used for two consecutive tests. For face masks and gaiters, a respirator fit test was performed using a PortaCount (TSI). The fit factor is a measure of the protection against airborne particles that is provided by a respiratory protective device. It is defined as the ratio of the aerosol concentration outside the respiratory protective device to the aerosol concentration inside the device (i.e., the aerosol concentration that is inhaled by the wearer). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the mask, and that the mask is therefore filtering out 90% of the ambient aerosol.

Aerosol collection and analysis

After placing the device on the headform and performing the fit test, the system was sealed. The test aerosol was then generated and propelled with a simulated cough through the headform and into the collection chamber. The Andersen impactor at the bottom of the collection chamber collected the aerosol particles that traveled through or around the device for 20 min after each cough. The Andersen impactor operates at a flow rate of 28.3 liters/minute and has six collection stages and a filter that separate the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm;

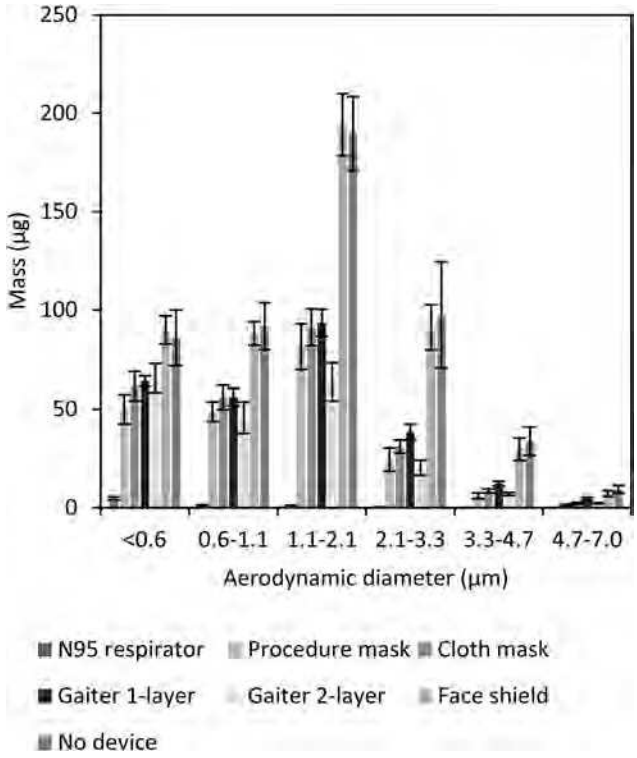

Figure 2. Mass of aerosol collected in each size fraction. The graph shows the amount of simulated respiratory aerosol that was collected from the collection chamber in each aerosol particle size fraction after a single simulated cough. The bars show the mean and standard deviation. A larger color version of this figure is shown in the SI.

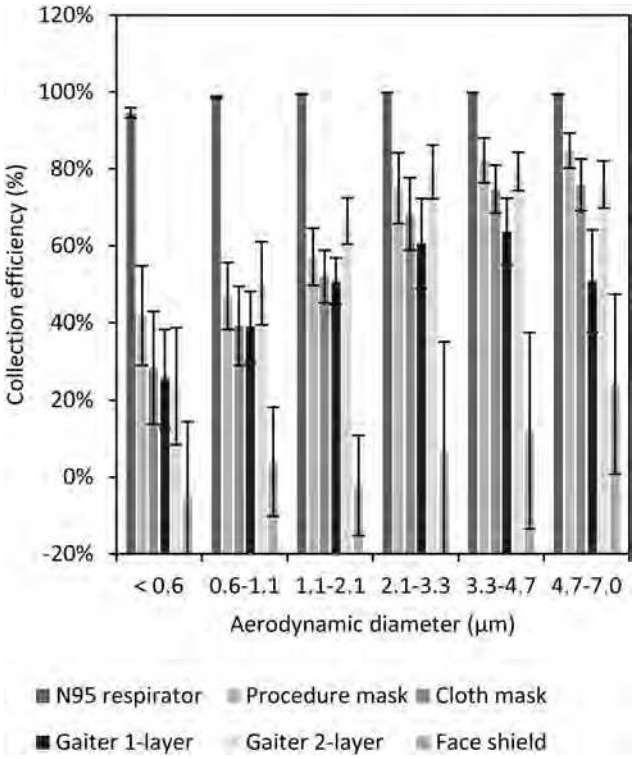

Figure 3. Collection efficiency of face masks, neck gaiter and face shield. The collection efficiency is the percentage of aerosol particles that were blocked by the face mask, neck gaiter or face shield compared with experiments without a device. The plot shows the means and standard deviations of the collection efficiency in each size fraction. A larger version of this figure is shown in color in the SI.

4.7–7.0 µm; and >7 µm. Because the amount of aerosol in the largest size fraction was small and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction was not included in the analysis. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). After aerosol collection was completed, the impactor plates were rinsed with 0.1 M Tris solution and the fluorescence of the solution was measured using a fluorometer (SpectraMax M4, Molecular Devices). The complete experimental protocol is given in the SI.

Statistical analysis

The performance of each device was evaluated by comparing the total mass of the aerosol particles from a single cough that passed through or around the device and was collected by the Andersen impactor. The results were evaluated using a one-way ANOVA and multiple comparisons among the different devices and the control experiments without a device were conducted using a Tukey-Kramer test. To control for variations in the amount of aerosol in each cough, a sample of each cough aerosol was collected from the bellows prior to coughing and used to normalize the aerosol mass collection results for each experiment.

Results

The cough aerosol simulator provides a cough with a controlled cough airflow rate containing a test aerosol with a consistent aerosol size distribution. The simulator allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough aerosol particles of different sizes into the environment. The flow rate of the simulated cough used in our experiments was based on cough flow profiles recorded from influenza patients and had a volume of 4.2 L with a peak flow rate of 11 L/s (Lindsley et al. 2013). The cough aerosol collected from the control experiments without a face covering had a mass median aerodynamic diameter of 1.3 µm, a geometric standard deviation of 2.3 and a total aerosol mass of 505 µg (standard deviation 69).

For our study, we tested the collection efficiencies (that is, the fraction of the cough aerosol that was

Table 1. Total mass of aerosol expelled into collection chamber and device collection efficiencies.

Device tested	Number of experiments	Fit factor	Aerosol mass (μg)	Collection efficiency
No device	12	n/a	512 (64)	n/a
Procedure mask	6	2.9 (0.5)	212 (23)	58.5% (6.9%)
Cloth mask	6	1.3 (0.1)	251 (23)	50.9% (7.7%)
Neck gaiter (single layer)	6	1.7 (0.5)	270 (18)	47.2% (7.5%)
Neck gaiter (double layer)	6	1.9 (0.4)	206 (26)	59.8% (7.2%)
Face shield	6	n/a	502 (46)	1.8% (15.3%)
N95 respirator	6	198 (3.5)	7.2 (1.2)	98.6% (0.3%)

Note: The fit factor, aerosol mass, and collection efficiency are given as mean (standard deviation).

blocked) of a medical grade procedure mask, a cotton cloth face mask, a polyester neck gaiter, an N95 medical respirator and a disposable face shield. These source control devices were chosen to provide representative samples of the different types of face coverings and face shields that are in common use during the pandemic. Neck gaiters are typically worn either as a single layer of fabric over the mouth and nose or doubled over to provide two layers of fabric; for our experiments, we tested both configurations. The quantity of aerosol particles in six size fractions that were able to travel through or around each source control device are shown in Figure 2. The collection efficiencies of the devices are shown as a function of aerosol size in Figure 3. All the devices showed increased collection efficiencies as the aerosol size increased.

On average, the N95 respirator blocked 99% of the total mass of test aerosol from being released into the environment, while the medical procedure mask blocked 59%, the cloth face mask blocked 51%, the single-layer gaiter blocked 47%, the double-layer gaiter blocked 60%, and the face shield blocked 2% of the total aerosol (Table 1). The N95 respirator, procedure mask, cloth mask, and the single-layer and double-layer gaiters all significantly reduced the aerosol emitted into the environment compared with no device ($P < 0.0001$ for each), but the face shield did not ($P = 0.9993$). The collection efficiencies of the procedure mask, cloth mask, and the single and double-layer gaiters did not differ significantly from each other, but all blocked cough aerosols significantly better than did the face shield ($P < 0.0001$). The N95 respirator outperformed all the other devices ($P < 0.0001$) (Table 2).

Discussion

Humans continuously emit aerosols of respiratory fluids as they breathe, talk, cough, sneeze, sing, or carry out other respiratory activities. These respiratory aerosols can have a very broad size range, from tens of nanometers in diameter to visible droplets of a millimeter or more (Bourouiba, Dehandschoewercker, and Bush 2014; Fennelly 2020; Gralton et al. 2011; Morawska et al. 2009). Airborne particles larger than 100 μm are ballistic; that is, they are affected primarily by gravity and fall quickly to the ground. Respiratory aerosol particles in this size range tend to deposit within a few meters of the source (Prather et al. 2020). As the aerosol particle diameter decreases from 100 μm, a gradual transition occurs where the settling velocity rapidly decreases and the particles remain airborne for longer times. For example, a 100 μm aerosol particle takes 4 s to fall 1 m in still air, while a 10 μm aerosol particle takes 5.4 min and a 1 μm aerosol particle takes 8 h to settle the same distance (Hinds 1999). Air currents such as plumes of warm air rising from the body can lift these particles and extend the time for which they stay in the air. Thus, small aerosol particles can remain airborne for minutes to hours and can accumulate over time in environments with poor ventilation (Bahl et al. 2020). Small aerosol particles also are easier to inhale and can travel more deeply into the lungs (Vincent 2005).

The amount and sizes of aerosol particles containing SARS-CoV-2 that are expelled by people who are infected are not yet known. Two studies of aerosol samples collected in patient rooms found infectious (replication-competent) SARS-CoV-2 in aerosol particles <4 μm in diameter (Santarpia et al. 2020a) and <10 μm in diameter (Lednicky et al. 2020). Other studies have reported SARS-CoV-2 RNA in exhaled breath from infected patients (Ma et al. 2020), aerosol samples from biocontainment and quarantine units housing SARS-CoV-2 infected persons (Santarpia et al. 2020b), and in aerosol samples at multiple locations throughout two hospitals in Wuhan, China during a COVID-19 outbreak (Liu et al. 2020). The presence of small aerosol particles containing

infectious SARS-CoV-2 detected in these studies suggests that in addition to large aerosols, these small aerosols might play a role in SARS-CoV-2 transmission (Anderson et al. 2020; Bahl et al. 2020; Ma et al. 2020; Morawska and Milton 2020).

Source control devices like face coverings and face shields collect respiratory particles larger than 0.3 μm primarily by impaction and interception of the aerosol particles against the fibers or solid surfaces of the device. As noted earlier, source control devices may also deflect aerosols, but this mechanism can be problematic as a means of source control because the infectious aerosol is not prevented from entering the surrounding environment; it is merely sent in a different direction which may or may not be protective depending upon local airflows and the locations of other people. Our experimental system measures particle collection only; any particles that are deflected but not collected by the face covering are still collected by the Andersen impactor. Thus, we are able to measure the particle collection efficiency of the face coverings without the potentially confounding variable of particle deflection. On the other hand, this does means that any potential benefits from, for example, deflecting large aerosol particles toward the ground were not measured by our system.

Small aerosols require much higher air velocities to deposit by impaction than do larger aerosols, and thus are more difficult to block with source control devices (Hinds 1999; Lindsley 2016). Consequently, small aerosols present the most challenging scenario for testing source control devices since devices that block small aerosol particles would be expected to block larger ones as well. Our results show that face masks and neck gaiters can significantly reduce the expulsion of small respiratory aerosol particles during coughing. This suggests that various types of face coverings can make an important contribution to reducing the quantity of aerosol particles containing SARS-CoV-2 released into the environment by people who are infected. N95 respirators, which are worn for personal protection by healthcare workers and others at highest risk of exposure, are also very effective source control devices. In contrast, the face shield blocked very little of the cough aerosol, indicating that face shields are not effective as source control devices for small respiratory aerosols.

The collection efficiencies of all the devices tested increased as the aerosol particle size increased, and this trend would be expected to continue for larger aerosol particles than were tested here. For example, the collection efficiency of the cloth face mask was 28% for the <0.6 μm particles and increased to 76% for the 4.7 to 7 μm particles. Similarly, the double-layer gaiter blocked 24% of the <0.6 μm particles and 76% of the 4.7 to 7 μm particles. These results suggest that cloth face coverings would be effective as source control devices against the large respiratory aerosols that are thought to play an important role in SARS-CoV-2 transmission.

Our study has several limitations. We used a single cough volume, air flow profile, and aerosol size distribution for our studies; these parameters can vary greatly from person to person. We examined the

performance of these devices during simulated coughing but not breathing or speaking, which have different air flow rates and aerosol size distributions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We only used a single representative example of each type of device. The shape and composition of face coverings vary widely, and this would be expected to affect the performance of individual devices. Some face masks have exhalation valves or vents which could reduce their efficacy as source control devices. The fit of a particular mask to an individual wearer and compliance in wearing the mask correctly (i.e., over the nose and mouth) also are important factors in how well the mask performs as a source control device. Because we used a < 0.6 to 7 µm test aerosol, our results do not indicate if face shields would be more effective as source control devices for large droplets. The face shield that we tested has a widely used design, but alternative designs are being marketed that provide greater facial coverage and, in some cases, include fabric skirts between the shield and the face. These alternative face shield designs might perform better as source control devices.

Previous studies have shown that face shields provide eye and facial protection to the wearer from droplets and splashes (Lindsley et al. 2014; Roberge 2016). When a face shield is worn in addition to a face mask, the face shield can also help reduce surface contamination of the mask by large aerosols and reduce the likelihood of hand contamination when the mask is removed or inadvertently touched (Lindsley et al. 2014). Our previous study showed that face shields provide some benefits as personal protective equipment when face masks cannot be worn (Lindsley et al. 2014), but as with all personal protection and source control devices, their limitations must be respected. Our results suggest that face masks and neck gaiters are more effective than face shields as source control devices to reduce the expulsion of respiratory aerosols into the environment as a public health measure to reduce the community transmission of SARS-CoV-2.

Acknowledgments

We would like to thank NIOSH machinist Bryan Williamson for manufacturing the parts for the cough simulator. We also would like to thank the NIOSH Morgantown maintenance, security, warehouse and housekeeping departments for their assistance and dedication during the ongoing pandemic. Subject: N95 effectiveness as source control

Dear Partners,

We have had a number of questions from you and others about N95 effectiveness as source control and wanted to share some information back with you.

National Institute for Occupational Safety and Health (NIOSH) researchers have evaluated N95s as source control in two different peer reviewed publications. In the first paper (Lindsley et al. 2021a- attached), NIOSH researchers found that a N95 respirator (3M model 1860) was 99% effective at blocking cough aerosols. In a second paper (Lindsley et al. 2021b- attached), NIOSH researchers found that one N95 respirator (3M 1860 N95) was 99% effective at blocking coughed and exhaled aerosols, and a second N95 Respirator (BYD) was 83% effective at blocking cough aerosols and 95% effective at blocking exhaled aerosols.

Subject: PARTNER ALERT: CDC Expands Booster Shot Eligibility

Dear Partners –

Yesterday, CDC adjusted our recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months.

Earlier this week CDC made this recommendation for recipients of a Pfizer-BioNTech primary seriesand, after FDA action this morning, we're extending this recommendation to recipients of a Moderna primary series. This means that people 12 and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.

Recently CDC strengthened our COVID-19 vaccination recommendations for children, now recommending that:

- Moderately to severely immunocompromised children ages 5–11 years receive an additional primary dose of Pfizer-BioNTech to ensure optimal protection from the vaccine.
- Children and teens ages 12–17 years should receive a booster shot.

Thank you,

Vaccine Task Force

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC Partner Alert: N95 Effectiveness as Source Control [Attachments]
    - Today, **Tuesday, January 11**, CDC issued a partner update (attached) in response to numerous questions about N95 mask effectiveness as source control. The update shared two peer reviewed publications from National Institute for Occupational Safety and Health (NIOSH) researchers (both attached) on N95 mask effectiveness, including findings that a N95 respirator was 99% effective at blocking cough aerosols.

HHS Update: COVID-19 Allocation Projections for January [Attachments]

- On **Friday, January 7**, the U.S. Department of Health and Human Services (HHS) issued an update with a projected calendar of allocation amounts and cadence of COVID-19 therapeutics for the remainder of January (attached). Questions may be directed to us COVID19Therapetuics@hhs.gov.

- Partner Alert: CDC Expands Booster Shot Eligibility [Attachment, Link]
  - On **Saturday, January 6**, CDC issued a partner alert (attached) adjusting its recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months. CDC has extended this recommendation to recipients of a Moderna primary series. This means that people 12 years of age and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.
- CDC COCA Call: What Clinicians Need to Know About the New Oral Antiviral Medications for COVID-19 [Links]
  - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **tomorrow, Wednesday, January 12 at 2:00 pm EST** to discuss the recent emergency use authorizations (EUAs) for new oral antiviral medications intended to decrease hospitalizations, as well as prevent severe COVID-19 and death Call information is below:
    - Weblink: https://www.zoomgov.com/j/1612974214?pwd=VitYMEorako1YWhCaXpnaWdsc2Ixdz09
      Telephone: (660) 254-5252 or (646) 828-7666 or (669) 216-1590 or (551) 285-1373
      Webinar ID: 161 297 4214
      Passcode: 180866
      Post-Event Recording:
      https://emergency.cdc.gov/coca/calls/2021/callinfo_011222.asp
- Reminder: CDC Preventive Medicine Grand Rounds: "The Public Health System of the Future – Moving Ahead in Partnership with Health Care & Other Sectors" [Link]
  - CDC will host its monthly Preventive Medicine Grand Rounds **tomorrow, Wednesday, January 12** at **1:30 pm EST**. The session will focus on the public health system of the future and the speaker is John Auerbach, Director of Intergovernmental and Strategic Affairs for CDC. Continuing education (CE) is available at no cost. Registration information is available here.

Standing Updates

- CDC Partner Update – January 10 [Attachment]
  - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – January 10 [Link]
  - Please click here for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.

- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am ET**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
    - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC Resources

New & Updated

- CDC Recommends Moderna Booster at 5 Months: On January 4th, CDC made this recommendation for recipients of a Pfizer-BioNTech primary series. After FDA action on January 7th, we're extending this recommendation to recipients of a Moderna primary series. This means that people who initially received an mRNA vaccine series——two doses of Moderna or Pfizer-BioNTech —can now receive an mRNA booster shot 5 months after completing their initial series.
- Guidance for COVID-19 Prevention in K-12 Schools was recently updated to reflect new recommendations for isolation for people with COVID-19 and recommendations for people who have come into close contact with a person with COVID-19.
- CDC Expands Booster Shot Eligibility and Strengthens Recommendations for 12-17 Year Olds: CDC now recommends that adolescents age 12 to 17 years old should receive a booster shot 5 months after their initial Pfizer-BioNTech vaccination series.
- CDC Recommends Pfizer Booster at 5 Months, Additional Primary Dose for Certain Immunocompromised Children: On January 4th, CDC updated its recommendation for when many people can receive a booster shot, shortening the interval from 6 months to 5 months for people who received the Pfizer-BioNTech COVID-19 Vaccine.
- Stay Up to Date with Your Vaccines: To align with standard language CDC uses about other vaccinations, CDC is now using the phrase "up to date" when talking about COVID-19 vaccination. CDC recommends that individuals stay "up to date" by receiving any additional doses they are eligible for, according to CDC's recommendations, to ensure they have optimal protection against COVID-19. The technical definition of "fully vaccinated"—two doses of an mRNA vaccine or one dose of the J&J vaccine—has not changed.
- What We Know About Quarantine and Isolation provides information on why CDC shortened quarantine and isolation guidance for the general population.

Dear State and Territorial Health Officials,

Thank you for your continued partnership in this all-of-America approach to fighting the COVID-19 pandemic. It remains our goal to facilitate a fair and equitable process in the allocation of COVID-19 therapeutics, and we certainly couldn't do this without you. We know that providing a longer look ahead for expected allocation amounts will help further support your jurisdictional planning. As such, attached is a projected calendar of allocation amounts and cadence for the remainder of January. Of course, the COVID-19 environment is very dynamic; so, these projections could change based on daily analysis of related data.

Additionally, we wanted to provide you with an update regarding Gilead's product - VEKLURY(tm) (remdesivir), which is not allocated by the federal government but is available commercially. Following the recent statement from the National Institutes of Health (NIH) COVID-19 Treatment Guidelines Panel regarding therapies for the COVID-19 Omicron variant, CMS created HCPCS code J0248 for the VEKLURY(tm) (remdesivir) antiviral medication when administered in an outpatient setting. This code is available for use by all payers and is effective for dates of service on or after December 23, 2021:

* Long descriptor: Injection, remdesivir, 1 mg
* Short descriptor: Inj, remdesivir, 1 mg

Medicare Administrative Contractors (MACs) determine Medicare coverage when there is no national coverage determination, including in cases when providers use FDA-approved drugs for indications other than what is on the approved label. The MACs consider the major drug compendia, authoritative medical literature and accepted standards of medical practice to determine medical necessity when considering coverage. Therefore, the MACs will determine Medicare coverage for HCPCS code J0248 for VEKLURY(tm) (remdesivir) administered in an outpatient setting.

Thank you, again, and please contact us at COVID19Therapetuics@hhs.gov with any questions.

Regards,
HHS - Coordination Operations and Response Element (H-CORE)

ABSTRACT

Universal mask wearing is recommended to help control the spread of COVID-19. Masks reduce the expulsion of aerosols of respiratory fluids into the environment (called source control) and offer some protection to the wearer. Masks are often characterized using filtration efficiency, airflow resistance, and manikin or human fit factors, which are standard metrics used for personal protective devices. However, none of these metrics are direct measurements of how effectively a mask blocks coughed and exhaled aerosols. We studied the source control performance of 15 cloth masks (face masks, neck gaiters, and bandanas), two medical masks, and two N95 filtering facepiece respirators by measuring their ability to block aerosols $\leq$7 µm expelled during simulated coughing and exhalation (called source control collection efficiency). These measurements were compared with filtration efficiencies, airflow resistances, and fit factors measured on manikin headforms and humans. Collection efficiencies for the cloth masks ranged from 17% to 71% for coughing and 35% to 66% for exhalation. Filtration efficiencies for the cloth masks ranged from 1.4% to 98%, while the fit factors were 1.3 to 7.4 on headforms and 1.0 to 4.0 on human subjects. The Spearman's rank correlation coefficients between the source control collection efficiencies and the standard metrics ranged from 0.03 to 0.68 and were significant in all but two cases. However, none of the standard metrics were strongly correlated with source control performance. A better understanding of the relationships between source control collection efficiency, filtration efficiency, airflow resistance, and fit factor is needed.

Introduction

Humans infected with SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can produce droplets and aerosols of respiratory fluids containing the virus when they cough, breathe, talk, sing and sneeze (Anderson et al. 2020; CDC 2020b; Hamner et al. 2020; Ma et al. 2020; Morawska and Milton 2020). To reduce the transmission of SARS-CoV-2, public health agencies have recommended that the general public wear cloth masks (CDC 2020c, 2020d, 2021; Edelstein and Ramakrishnan 2020; WHO 2020). The primary purpose of masks (which in this article includes face masks, neck gaiters, bandanas and other face coverings) is to block the expulsion of infectious droplets and aerosols from the wearer into the environment (called source control) and thereby reduce the exposure of other people to the virus (CDC 2020a). Laboratory studies using manikins and human subjects have shown that cloth face masks can partially block respiratory aerosols produced during coughing, breathing and talking (Asadi et al. 2020; Davies et al. 2013; Lindsley et al. 2021; Pan et al.

2021). Wearing medical face masks (i.e., "surgical masks" as defined by the U.S. Food and Drug Administration [FDA 2004]) reduces the dispersion of potentially infectious aerosols from patients with respiratory infections (Leung et al. 2020; Milton et al. 2013). Masks may also provide some personal protection to the wearer by reducing their exposure to infectious droplets and aerosols produced by others, although they are not as effective as a respiratory protective device such as a NIOSH-approved N95 filtering facepiece respirator (N95 respirator) (CDC 2020a; Lawrence et al. 2006; Oberg and Brosseau 2008; Pan et al. 2021). Several community level studies have shown that universal masking helps reduce the spread of COVID-19 (CDC 2020a). For example, a comparison of counties in the US state of Kansas found that mask mandates were associated with lower incidence rates of COVID-19 (Van Dyke et al. 2020). A study of 10 US states found that statewide mask mandates were associated with a decline in weekly COVID-19–associated hospitalization growth compared to states without such mandates (Joo et al. 2021).

In response to the need for source control devices for the general public, manufacturers worldwide have produced a broad array of masks. Unfortunately, because of the many different designs and construction materials, it is not possible to predict how well a particular mask will perform as a source control device without testing, which is rarely done for non-medical masks not intended for occupational use. Although general guidelines have been developed (CDC 2020d), it is very difficult for public health organizations, governments, medical facilities, and the general public to know which of the available devices are most effective.

Test methods and performance standards do exist for regulated medical face masks and respiratory protective devices (Rengasamy et al. 2017). In the United States, respiratory protective devices, which are devices such as N95 filtering facepiece respirators that are intended to protect the wearer from airborne particles, must be approved by the National Institute for Occupational Safety and Health (NIOSH) under 42 Code of Federal Regulations (CFR) Part 84 (NIOSH 1995). The approval process includes testing the filtration efficiency for the most-penetrating aerosol particle size and measuring the airflow resistance of the device (NIOSH 2019). Medical face masks that are not intended to be used as respiratory protective devices are cleared by the Food and Drug Administration (FDA), which reviews manufacturer-supplied information on filtration efficiency, airflow resistance, resistance to fluid penetration and flammability (FDA 2004). The FDA recommends that manufacturers use the ASTM standards F2299 for measuring particle filtration efficiency through the mask material using latex microspheres (ASTM 2003), and the F2101 Standard test method of evaluating the bacterial filtration efficiency (BFE) of medical face mask materials, using a biological aerosol of *Staphylococcus aureus* (ASTM 2019). Bacterial filtration efficiency can also be measured with the modified Greene and Vesley method using human test subjects (Greene and Vesley 1962; Quesnel 1975).

In addition to filtration performance, how well a respiratory protective device protects the wearer depends upon how well the device fits the face and whether the seal between the face and the device has gaps or leaks (Lawrence et al. 2006). ASTM Standard F3407-20 outlines procedures for testing respirators using a bivariate panel of human test subjects with different facial dimensions (ASTM 2020). The NIOSH approval test for respirators measures the filtration properties but does not include tests of how well the device fits faces of different shapes, although this has been proposed. Consequently, in the United States, when a worker is required to wear a respirator, the Occupational Safety and Health Administration (OSHA) requires that a respirator fit test be performed annually for each worker to determine how well the respirator protects the worker (OSHA 2020). Quantitative fit tests measure the aerosol particle concentration inside and outside the respirator during a series of exercises, and this information is used to calculate the fit factor (outside concentration/inside concentration) (Janssen and McKay 2017). The minimum acceptable fit factor for a respirator depends upon the exposure level and potential health consequences of the hazards to which the worker may be exposed (OSHA 2020).

The existing test methods for respirators and medical face masks provide a possible basis for developing standards for non-medical masks used as source control devices. The American Association of Textile Chemists and Colorists (AATCC) published guidelines for cloth face coverings that include the use of ASTM F2299 and other national and international performance standards (AATCC 2020). Leith, L'Orange, and Volckens (2021) proposed an estimated mask protection factor that is calculated based on tests of filtration efficiency and fit and on estimates of the average time spent speaking, inhaling, and exhaling. ASTM International has released a standard for testing barrier face coverings that includes tests of filtration efficiency and airflow resistance, and an assessment of leakage, which are standard metrics that are commonly used to test personal protective devices (ASTM 2021). The use of these standard performance metrics has many advantages, most notably that the equipment and procedures needed to conduct the tests are widely available. However, none of these metrics are

Table 1. Performance metrics used in this study. Outward mask airflow is in the direction of exhalation. Inward airflow is in the direction of inhalation.

Performance metric	**Parameter measured**	Mask airflow direction	Measurement instrument	**Measurement method**	Particle size	**Instrument airflow rate (liters/minute)**
Cough aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Outward	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Exhaled aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Cyclical	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Filtration efficiency	Aerosol mass concentration upstream & downstream of mask	Inward	TSI 8130 A	Photometer	75 nm count median diameter (GSD 1.86)	85
Airflow resistance	Pressure required for 85 lpm flow	Inward	TSI 8130 A	Manometer	n/a	85
Manikin fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode)	0.35
Human fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode) 0.02–1.0 μm (Class 100 mode)	0.35

direct measurements of the ability of a mask to block aerosols expelled during coughing and exhalation. To assist in the further development of these types of standards and guidelines, the relationship between the efficacy of masks as source control devices and their performance using standard metrics needs to be better understood. For example, it is possible to measure the filtration efficiency of the mask material, but it is not clear how that filtration efficiency translates to source control efficacy or what minimum performance level should be required.

The purpose of this study was to compare the performance of a variety of N95 respirators, medical masks, and cloth masks as source control devices with their filtration efficiencies, airflow resistances, fit factors measured using manikin headforms, and fit factors measured on humans. The results of these experiments will assist in the development of appropriate test methods and standardized performance metrics to evaluate the efficacy of cloth masks as source control devices for respiratory aerosols.

Materials and methods

Experimental design

A source control measurement system was used to assess the efficacy of N95 respirators, medical masks, and cloth masks as source control devices. The source control performance was determined by measuring the source control collection efficiency of the mask, which is the fraction of the mass of the coughed or exhaled test aerosol particles that were blocked by the mask from reaching the collection chamber. The filtration efficiencies and airflow resistance of the construction materials were measured using a modified version of the test method used for respirator approvals. Fit tests were performed both on a manikin headform with pliable skin and with human test subjects. The source control collection efficiencies were then compared with the fit factors, filtration efficiencies and airflow resistances measured on the same devices. A summary of the performance metrics used in the study is shown in Table 1.

Respiratory aerosol source control measurement system

The efficacy of respirators, medical masks, and cloth masks as source control devices for aerosols produced during coughing and exhalation was determined using a respiratory aerosol source control measurement system described previously (Lindsley et al. 2021). The system includes a coughing and breathing aerosol simulator, a manikin headform, an 136 L aerosol collection chamber, and a cascade impactor (Figure 1). The manikin headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each source control device would fit a human face (Bergman et al. 2014).

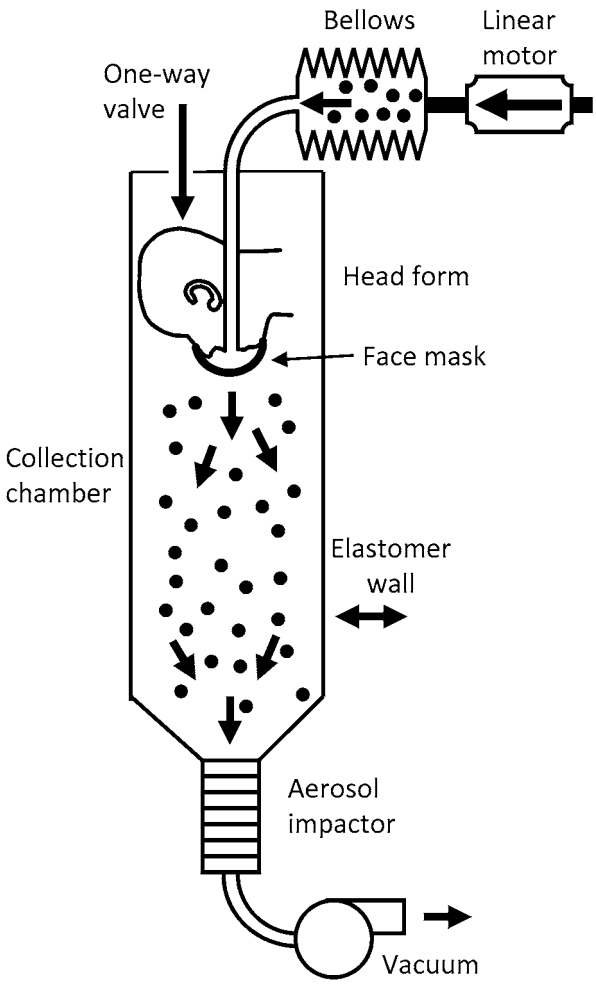

Figure 1. Source control measurement system. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated coughing and breathing, a pliable skin headform on which the source control device is placed, a 136 liter collection chamber into which the aerosol is coughed or exhaled, and a cascade impactor to separate the aerosol particles by size and collect them. The system is oriented vertically as shown to minimize the loss of aerosol particles due to settling before collection. The system is described in more detail in Lindsley et al. (2021).

The test aerosol was produced using a solution of 14% potassium chloride (KCl) and 0.4% sodium fluorescein in a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2). The aerosol passed through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), mixed with dry filtered air flowing at 10 L/min for the cough tests and 15 L/min for the breathing tests, and neutralized using a bipolar ionizer (Model HPX-1, Electrostatics). An elastomeric bellows driven by a computer-controlled linear motor produced the coughing or breathing airflow.

For cough tests, the test aerosol was loaded into the elastomeric bellows and then coughed out using a single cough with a volume of 4.2 L and a peak flow rate of 11 L/s (Lindsley et al. 2013). An Andersen cascade impactor (Model TE-10-830, Tisch Environmental) collected all aerosol particles that traveled through or around the device for 20 min after each cough. For breathing tests, the system used a ventilation rate of 15 L/min with a breathing rate of 12 breathes/min and a tidal volume of 1.25 liters, which corresponds to the ISO standard for a female performing light work (ISO 2015). The test aerosol was only generated for the first 30 s of breathing to avoid overloading the impactor. The breathing continued for 20 min total. The impactor collected the aerosol particles in the chamber during the 20-minute breathing period followed by an additional five minutes of collection after the breathing had stopped.

The impactor operated at a flow rate of 28.3 liters/minute and had six collection stages and a filter that separated the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm; 4.7–7.0 µm; and >7 µm. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). Because the amount of aerosol in the largest size fraction was small (<0.7% of total aerosol mass) and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction were not included in the analysis. After aerosol collection was completed, the aerosol particles were eluted from the impactor plates using a 0.1 M Tris solution and the fluorescence of the solution was read using a spectrofluorometer (SpectraMax M4, Molecular Devices).

To control for variations in the amount of aerosol in each experiment, a sample of each test aerosol was collected from the bellows prior to coughing or breathing using a 47 mm 5 µm PVC filter. The aerosol was eluted from the filter using 0.1 M Tris. An adjustment factor for the experiment (A) was calculated as:

$$A = \frac{Mass\ of\ aerosol\ on\ filter}{Mean\ (mass\ of\ aerosol\ on\ filter\ for\ all\ control\ experiments)} \quad (1)$$

The adjusted mass of aerosol on each impactor stage for the experiment was then calculated as:

$$M_{stage,\ adjusted} = \frac{M_{stage,\ unadjusted}}{A} \quad (2)$$

The adjusted masses were used for all subsequent calculations. The adjusted aerosol masses collected by the cascade impactor during the experiments are

Table 2. Source control devices used in experiments.

Type	Manufacturer	Product	Fastener	Material
Medical masks & respirators	3M	Model 1860 N95 respirator and surgical mask (TC-84A-0006)	Two elastic straps around head	Polypropylene and polyethylene composition
	BYD	N95 filtering facepiece respirator (TC-84A-9221)	Two elastic straps around head	IL and OL: Polypropylene spun-bound nonwoven fabric. ML: Polypropylene melt-blown nonwoven + hot air cotton

In this article, the reusable cloth face masks, neck gaiters and bandanas are referred to collectively as "cloth masks". IL is inner layer, ML is middle layer, and OL is outer layer. Photographs are shown in Figures S3–S5 (SI).

shown in Tables S1 and S2 in the supplemental information (SI).

The source control performance, or source control collection efficiency, of a face covering is defined as the fraction of the mass of the respiratory aerosol that is blocked from entering the environment around the wearer. For example, if 80% of the mass of the aerosol from a cough is blocked by a face mask and 20% of the aerosol mass is able to flow through or around the mask into the air around the wearer, then the mask is said to have a collection efficiency of 80%. The performance of each source control device was evaluated by calculating the collection efficiency as:

$$Collection\ efficiency = 1 - \frac{M_{mask}}{M_{control}} \qquad (3)$$

where:

M_{mask} = adjusted total mass of the aerosol particles that passed through or around the source control device and was collected by the impactor.

$M_{control}$ = adjusted total mass of the aerosol particles collected by the impactor while not wearing a source control device.

Note that the collection efficiency is based on the mass of the aerosol rather than a measure such as particle counts. Also, the aerosol is flowing from the inside of the mask toward the outside; that is, in our test system the aerosol flows in the same direction as it would flow during a cough or exhalation by a person wearing the mask.

Respirators, medical masks, and cloth masks

In our study, the term "cloth mask" refers to a cloth face mask, neck gaiter or bandana constructed from textiles or fabrics (both natural and synthetic) that is not a surgical mask or N95 respirator and is not intended for use as personal protective equipment. The term "medical masks" in this article refers to non-woven disposable masks that are held on the face with elastic ear loops. These masks are loose-fitting and are not expected to provide the wearer with as reliable a level of protection against airborne or aerosolized particles as N95 respirators regulated by NIOSH. Commercial manufacturers often refer to

masks held on by ear loops as procedure masks and masks that tie behind the head as surgical masks. However, the U.S. Food and Drug Administration uses the term "surgical mask" to describe commercially produced masks regulated by the under 21 CFR 878.4040 for performing medical procedures (FDA 2004). The FDA definition applies to all masks that cover the user's nose and mouth and provides a physical barrier to fluids and particulate materials, and includes masks that are labeled as surgical, laser, isolation, dental or medical procedure masks with or without a face shield.

Nineteen commercially available N95 respirators, medical masks, and cloth masks were selected to provide a broad cross-section of the different types of source control devices that are available (Table 2). For the source control tests, each device was placed on the headform as it would normally be worn by a person. Three of the neck gaiters were tested both as a single layer of fabric and folded over to provide two layers of fabric. Before the source control test, the manikin fit factor (Janssen and McKay 2017) was measured by performing a respirator fit test (Bergman et al. 2015) for each device using a PortaCount® Pro + respirator fit tester (Model 8038, TSI, Shoreview, MN) in N95 mode with the system breathing at 36 L/min but not producing an aerosol. Each device was used for two consecutive tests. Photographs of the source control devices on the headform are shown in the SI (SI; Figures S1–S3).

Filtration efficiency and airflow resistance measurements

The filtration efficiency of the face covering is the fraction of the test aerosol that is collected as the aerosol passes through the mask material. For example, if 70% of the test aerosol is collected by the mask material and 30% of the aerosol passes through it, then the filtration efficiency is 70%. Note that the filtration efficiency tests are performed by fastening the mask to a holder so that all the aerosol flows through the mask material, and none can escape through face seal leaks. Thus, the filtration efficiency is a property of the mask material.

The filtration efficiency and airflow resistance of the construction materials were measured using automated filter testers (Models 8130 and 8130 A, TSI). Material samples were secured to a test plate using beeswax as shown in Figure S4 in the SI. Measurements were made using a modified version of the NIOSH standard testing procedure (STP) (NIOSH 2019). Under the modified STP, samples were tested at ambient temperature and humidity but were not subjected to conditioning at 38°C and 85% relative humidity for 25 h, and sample testing was limited to 10 min. The device to be tested was oriented in the filter tester so that the air and aerosol flowed from the exterior of the device toward the interior (that is, as if the wearer were inhaling, which is the same direction as when testing a respirator as a personal protective device). The challenge aerosol was generated using a 2% sodium chloride (NaCl) solution in distilled water, conditioned to 25 °C and 30% relative humidity and neutralized to the Boltzmann equilibrium state. The challenge aerosol had a count median diameter of 75 nm ± 20 nm, a mass mean diameter of 260 nm and a geometric standard deviation (GSD) $\leq$ 1.86 (TSI 8130 A specifications). The automated filter tester compares particle mass concentration readings from upstream and downstream light-scattering laser photometers to calculate the material filtration efficiency. An electronic pressure transducer measures the pressure difference across the material sample to indicate airflow resistance. Tests were performed with an airflow of 85 L/minute.

Fit tests on human subjects

A convenience sample of eleven subjects (six males and five females) participated in fit testing. Subjects complied with CDC/NIOSH guidelines for facial hair styles intended for workers who wear tight-fitting respirators (CDC 2017). Fit testing was performed with a PortaCount® fit tester (model 8038, TSI) using OSHA's modified ambient aerosol condensation nuclei counter (CNC) protocol for filtering facepiece respirators (OSHA 2019). Because only fit factors were measured and no identifiable private information was collected, the West Virginia University Office of Human Research Protections determined that Institutional Review Board approval was not required. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy (see e.g., 45 C.F.R. part 46; 21 C.F.R. part 56; 42 U.S.C. §241(d), 5 U.S.C. §552a, 44 U.S.C. §3501 et seq.). All measurements were performed in a room with volume of 43.4 m^3 (1531 ft^3) at 19 °C (67 °F).

An NaCl aerosol generator (Model 8026, TI) was used to supplement the naturally occurring particles in the air. The particle generator was placed 10 feet away from all sampling apparatus and fit testing equipment. The generator was turned on ten minutes prior to testing to seed aerosols and turned off while

a triplicate series of fit tests were performed (around 7 min). As the aerosol concentration in the room had started to slightly decline at this point, the generator was turned on between tests (around 7 min) and then turned off during subsequent tests. This process was repeated until testing for the day was completed.

To verify that suitable aerosol concentrations were present during testing, particle concentrations were measured with a condensation particle counter (CPC Model 3775, TSI) for 25 min beginning at 2 min prior to the nebulizer being initially turned on. Particle size distributions were measured for 20 min with a scanning mobility particle sizer (SMPS Model 3938, TSI) and an electrical low-pressure impactor (ELPI+, Dakati). Information on the aerosol particle size distribution and concentration are shown in the SI (Figures S5 and S6).

Each source control device was tested by three subjects; for each subject three replicate measurements were made using each of the two protocols described below. One individual administered all fit tests. Subjects were instructed in the proper donning of medical masks and respirators, and they were asked to don cloth masks in the manner that they ordinarily don similar coverings for public use. If a cloth mask was too large, it was modified using materials that would be accessible to most lay individuals: tape was used to shorten mask ear loops or head straps, and a binder clip was used to decrease the circumference of neck gaiters. These adjustments were made so that the covering was held flush to the face, but the materials were not under tension.

Two particle measurement protocols were performed on all source control devices: the PortaCount® N95 Companion protocol (referred to here as N95 mode), which counts negatively charged particles 40–70 nm (mean 55 nm) in diameter; and the PortaCount® standard protocol (referred to here as Class 100 mode), which counts all particles from 0.02–1.0 µm (TSI 2010). The "Class 100 mode" is also called "N99 mode". For both modes, the fit factor (FF) was calculated by the PortaCount® software as (Janssen and McKay 2017; TSI 2015):

$$FF = \frac{C_B + C_A}{2C_R} \quad (4)$$

where:

C_B = ambient particle concentration measured before the particle concentration is measured inside the respirator.

C_A = ambient particle concentration measured after the particle concentration is measured inside the respirator.

C_R = particle concentration measured inside the respirator.

Note that the TSI PortaCount instrument used in our experiments measures the aerosol concentration based on the number of aerosol particles rather than the particle mass.

Data analysis

The source control results were compared with the filtration efficiencies, airflow resistances, and fit factor measurements by calculating the Spearman's rank correlation coefficients (ρ) between the metrics. Fit factors were transformed into fit efficiencies (= 1-1/fit factor) to allow for a direct comparison with the other parameters. For example, a fit factor of 5 corresponds to a fit efficiency of 80%, indicating that the mask blocked 80% of the ambient aerosol from being inhaled by the wearer. Because the replicate numbers were different for the different performance metrics, the correlations were calculated based on the mean results for each device. When analyzing the human fit factor results, we did not attempt to account for differences among test subjects. The p-value was calculated based on ρ and the number of types of devices that were tested (22 for all source control devices and 18 for the cloth masks alone, with the 1-layer and 2-layer gaiter tests counted separately). Correlations were considered significant if $p \leq 0.05$.

Results

Efficacy of N95 respirators, medical masks, and cloth masks as source control devices for respiratory aerosols

Twenty-six cough experiments were performed without a source control device to measure the cough aerosol output from the source control measurement system. The cough aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 525 µg (standard deviation [SD] 65; Figure 2 and SI Figure S7). Thirty-five breathing aerosol experiments were performed without a source control device to measure the exhaled aerosol output. The exhaled aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 495 µg (SD 68; Figure 2 and SI Figure S8). The experiments without source control devices were used as control experiments when evaluating performance of the devices.

The collection efficiencies of the 19 source control devices are shown in Figure 3 and Table 3. The mean

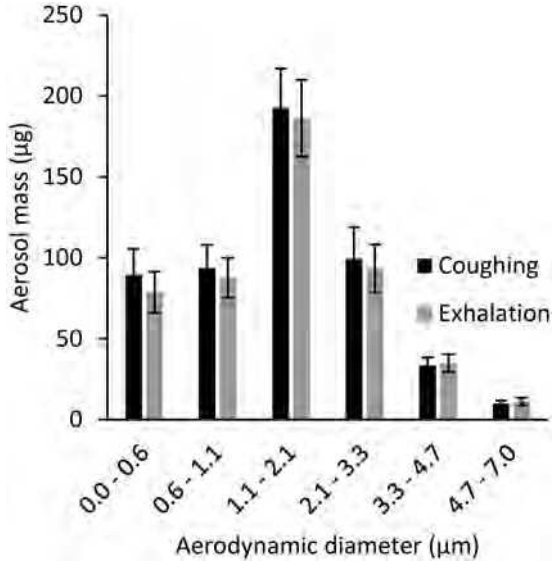

Figure 2. Mass of aerosol expelled by the source control measurement system during coughs and exhalations. The size bins correspond to the stages of the Andersen impactor. The size distribution is shown in units of µg/µm in Figures S7 and S8 in the SI.

collection efficiencies of the N95 respirators and the surgical mask ranged from 83% to 99% for aerosol particles during coughing and exhalation. For the procedure and cloth masks, the mean collection efficiencies ranged from 35% to 71% for coughing (except for the bandana at 17%) and 35% to 66% for exhalation. The collection efficiencies for the coughing and breathing source control experiments were correlated, with a Spearman's correlation coefficient (ρ) of 0.76 ($p < 0.001$; Table 4) when considering all the devices and 0.67 ($p = 0.003$; Table 4) when considering only the cloth face masks, gaiters and bandanas. The amounts of aerosol collected on each stage of the impactor are shown in Tables S1 and S2 in the SI.

Filtration efficiencies and inhalation airflow resistance

The mean material filtration efficiencies were >99% for the respirators, 80% to 93% for the medical masks, and 1.4% to 36% for the cloth face masks, neck gaiters, and bandanas, except for the Besungo sports mask at 98% (Figure 4 and Table 3). The inhalation

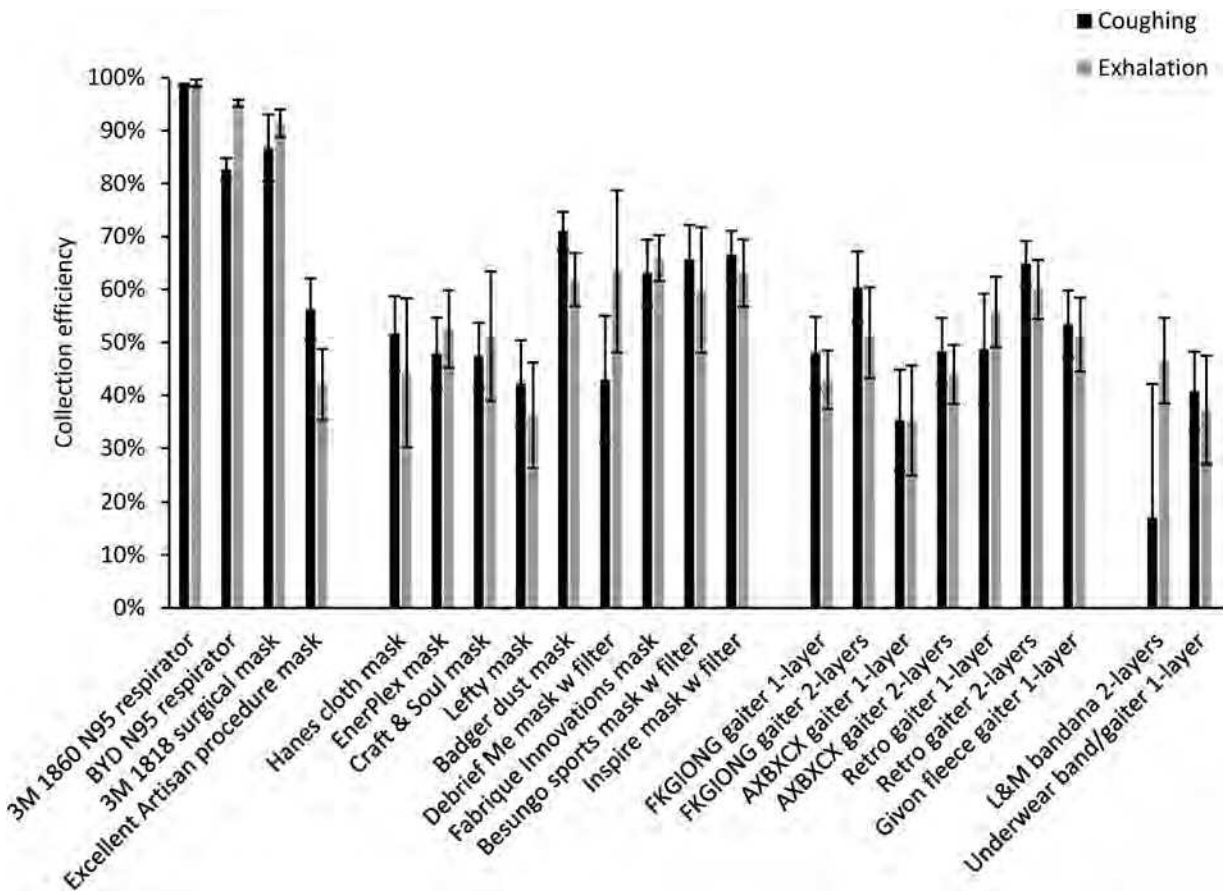

Figure 3. Source control collection efficiencies of N95 respirators, medical masks, cloth face masks, neck gaiters and bandanas during coughing and exhalation aerosol tests with the respiratory aerosol source control measurement system. Each bar is the mean of 4 or 6 experiments. Error bars show the standard deviation.

Manikin fit factors were measured with the fit tester in N95 mode only (as described in the Discussion). Human fit factors were measured using both the N95 mode and Class 100 mode.

Table 4. Correlations between different performance metrics for all source control devices.

		All source control devices		Cloth face masks, gaiters, and bandanas only	
Correlation parameter #1	Correlation parameter #2	ρ	*p*-value	ρ	*p*-value
Cough aerosol collection efficiency	Exhaled aerosol collection efficiency	0.76	<0.001	0.67	0.003
	Filtration efficiency of material	0.69	0.001	0.51	0.032
	Airflow resistance of material	0.55	0.009	0.54	0.020
	Human subject fit (N95 mode)	0.57	0.005	0.30	0.208
	Human subject fit (Class 100 mode)	0.68	<0.001	0.48	0.035
	Manikin fit before coughing	0.39	0.076	0.03	0.890
Exhaled aerosol collection efficiency	Filtration efficiency of material	0.60	0.004	0.54	0.023
	Airflow resistance of material	0.51	0.016	0.58	0.012
	Human subject fit (N95 mode)	0.60	0.003	0.51	0.024
	Human subject fit (Class 100 mode)	0.71	<0.001	0.63	0.003
	Manikin fit before breathing	0.72	<0.001	0.68	0.002
Manikin fit before coughing	Manikin fit before breathing	0.61	0.003	0.38	0.112
Filtration efficiency of material	Airflow resistance of material	0.78	<0.001	0.78	<0.001

Each Spearman's rank coefficient (ρ) was calculated based on data from 22 experiments for all source control devices and 18 experiments for cloth masks (cloth face masks, gaiters, and bandanas). A correlogram of the ρ values in shown in Figure S9 in the SI.

airflow resistances were from 5.2 to 154 Pa (Table 3). When comparing the data for all devices, the filtration efficiencies were correlated with cough aerosol collection efficiency ($\rho = 0.69$, $p = 0.001$) and exhaled aerosol collection efficiency ($\rho = 0.60$, $p = 0.004$; Table 4). For the group of cloth masks, the correlations were not as strong; the cough aerosol collection efficiency and filtration efficiency had an ρ of 0.51 ($p = 0.032$) while the exhaled aerosol collection efficiency and filtration efficiency had an ρ of 0.54 ($p = 0.023$; Table 4). The airflow resistance did not correlate as well as the filtration efficiency when all devices were considered ($\rho = 0.55$ and $p = 0.009$ for coughing; $\rho = 0.51$ and $p = 0.016$ for exhalation). However, when examining the cloth masks alone, the airflow resistance was slightly better correlated than filtration efficiency ($\rho = 0.54$ and $p = 0.020$ for coughing; $\rho = 0.58$ and $p = 0.012$ for exhalation).

Human fit tests

The fit factors measured on the human test subjects are shown in Table 3 and Figure 5. The mean fit factors for the two N95 respirators were 148 and 164

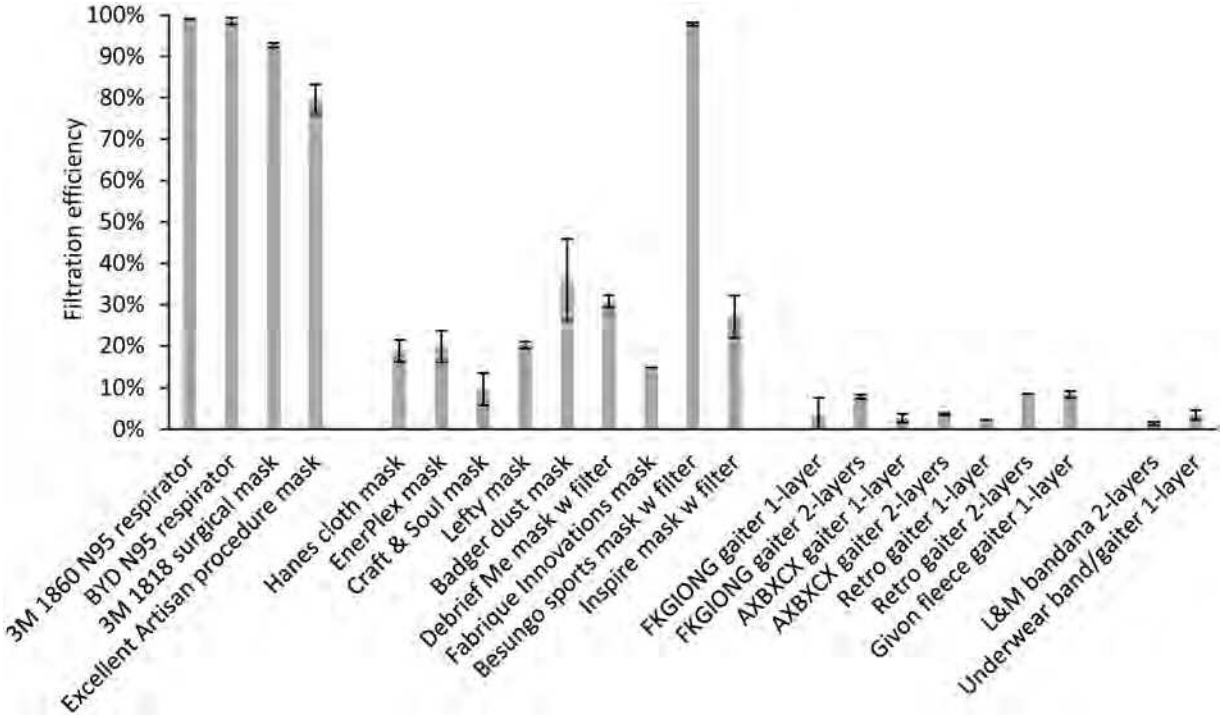

Figure 4. Filtration efficiencies for the source control devices used in the study. Three samples of each device were tested, except for the 3 M 1860 N95 respirator and Hanes cloth mask (10 samples each) and the Fabrique Innovations mask, Retro gaiter 1-layer, and Retro gaiter 2-layers (one sample each). Error bars show the standard deviation.

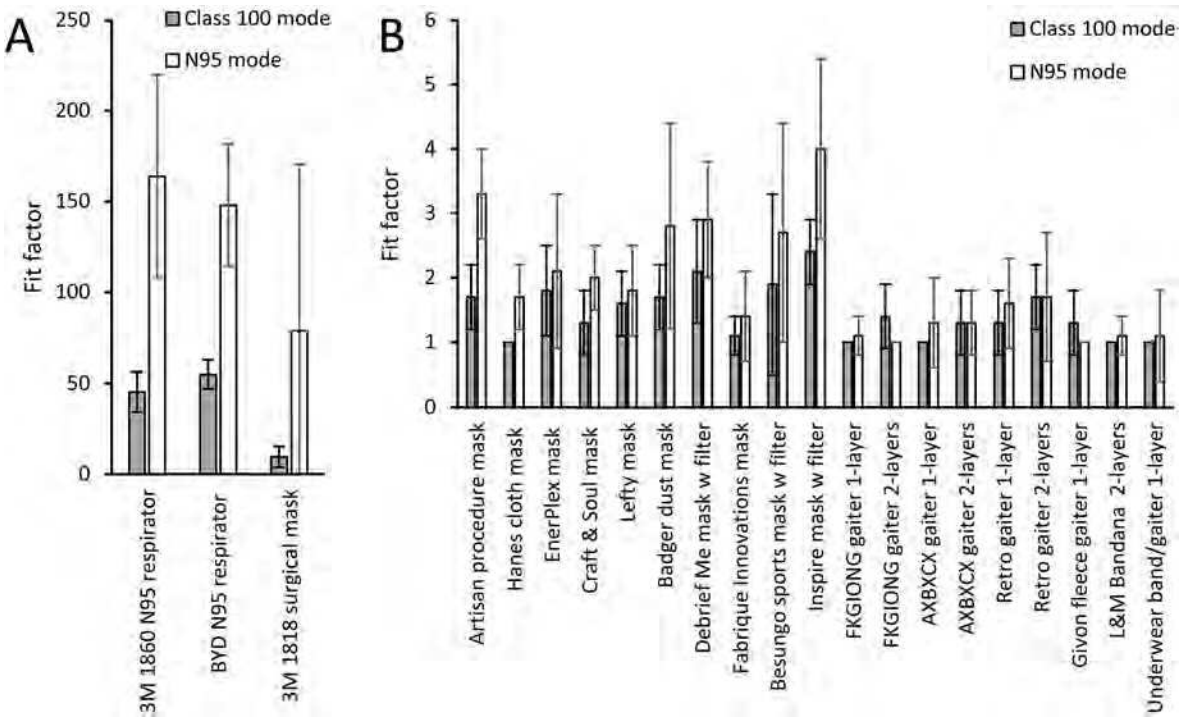

Figure 5. Fit factors measured with human subjects for (a) N95 respirators and surgical mask and (b) procedure mask, cloth face masks, gaiters and bandanas. The plot shows the means and standard deviations. Results for all human fit tests are given in Table S3 in the SI.

when using the N95 mode on the fit tester and 55 and 45 with the Class 100 mode. The surgical mask provided a mean N95 mode fit factor of 79 and a much lower mean fit factor of 9.6 in Class 100 mode. The mean N95 mode fit factor of the reusable cloth face masks ranged from 1.4 to 4.0, and the all sizes

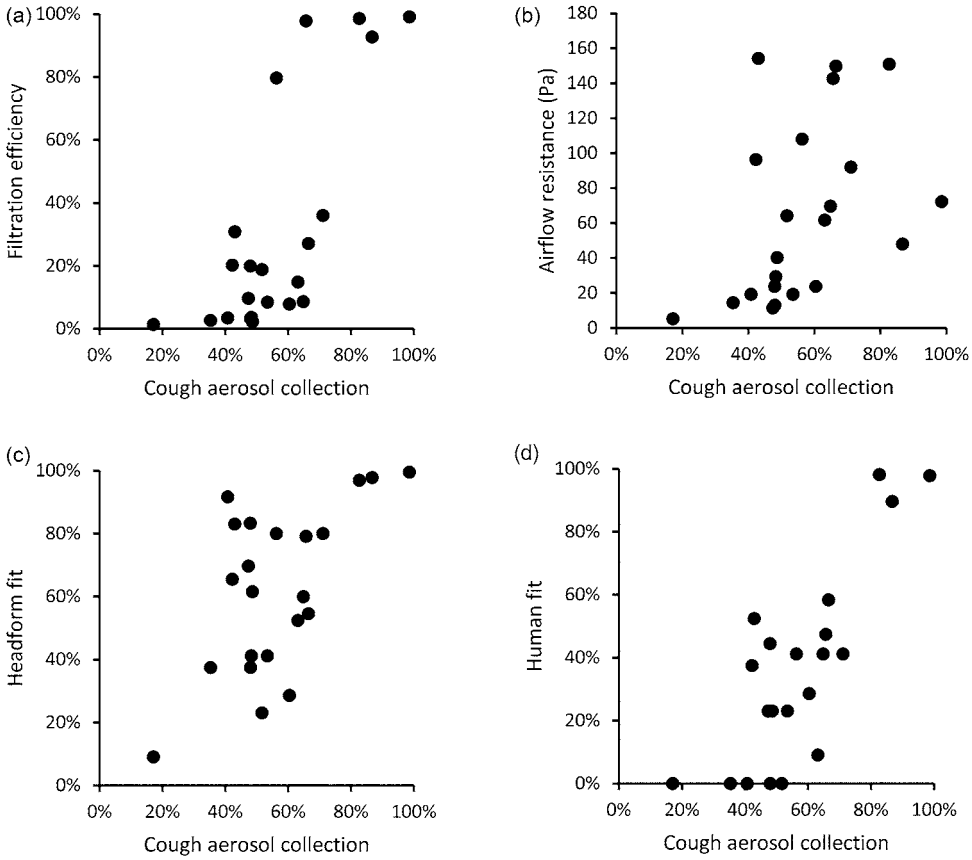

Figure 6. Comparison of collection efficiencies for aerosols from coughs to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot corresponds to the mean result for one type of source control device.

mode mean fit factors ranged from 1.0 to 2.4. Neck gaiters and bandanas demonstrated N95 mode fit factors ranging from 1.0 to 1.7 and all particle size mode mean fit factors from 1.0 to 1.7. The performance of cloth masks sometimes varied considerably when worn by different subjects. The fit test results for individual subjects are shown in Table S3 in the SI.

The cough and exhalation aerosol collection efficiencies for all devices were well correlated with the fit factors when measured using the Class 100 mode ($\rho = 0.68$ and $p < 0.001$ for coughing, $\rho = 0.71$ and $p < 0.001$ for exhalation, Table 4). When looking at the results for the cloth masks, gaiters, and bandanas in the all sizes mode, the correlations were not as strong, with $\rho = 0.48$ for coughing ($p = 0.035$), and $\rho = 0.63$ for exhalation ($p = 0.003$; Table 4). In all cases, the correlation coefficients were higher when the fit tester was in the Class 100 mode than when the tester was in N95 mode.

Manikin fit tests

The manikin fit factor measurements found using the source control measurement system before the cough tests were 25 to 198 for the N95 respirators and the surgical mask and 1.3 to 7.4 for the procedure mask and cloth masks (Table 3). Before the breathing tests, the manikin fit factors were 28 to 133 for the N95 respirators and the surgical mask and 1.4 to 6.1 for the procedure mask and cloth masks. The cough aerosol collection efficiencies and the pre-cough manikin fit factors were not significantly correlated, with a ρ of 0.39 ($p = 0.076$) for all devices (Table 4 and Figure 6) and a ρ of only 0.03 ($p = 0.890$) for the cloth masks (Table 4). The correlation was better between the exhaled aerosol collection efficiency and pre-breathing manikin fit factors, with a ρ of 0.72 ($p < 0.001$) for all devices (Table 4 and Figure 7) and 0.68 ($p = 0.002$) for the cloth masks (Table 4).

Discussion

The COVID-19 pandemic has resulted in considerable interest in the performance characteristics of masks and respirators as a means of reducing the person-to-person transmission of SARS-CoV-2. Some studies have looked at the emission of particles from human volunteers wearing different face coverings, which has

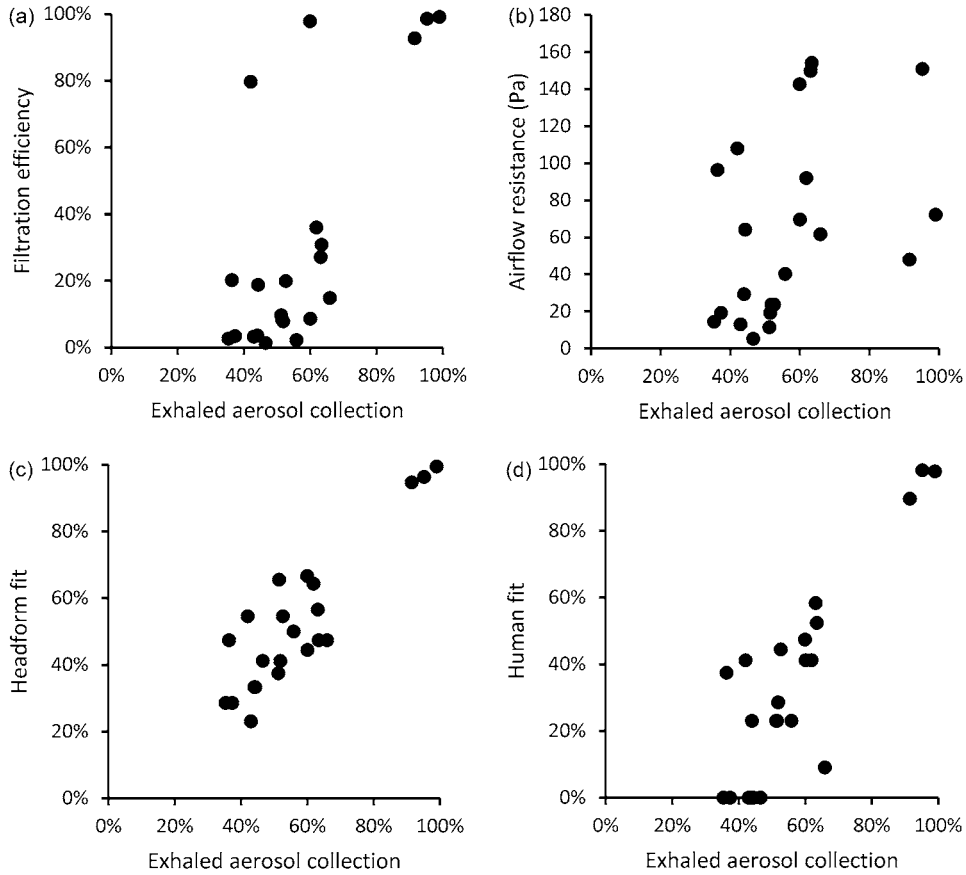

Figure 7. Comparison of collection efficiencies for exhaled aerosols from simulated breathing to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot shows the mean result for one type of source control device.

the advantage of directly examining the expulsion of aerosols into the environment by people (Asadi et al. 2020; Davies et al. 2013; Leung et al. 2020; Li, Niu, and Zhu 2021). However, the collection and measurement of human-generated respiratory aerosols is challenging and can be hazardous when the subject has a contagious respiratory infection. In addition, the amount and size distribution of aerosol particles produced by people during coughing, breathing and other respiratory activities varies tremendously from person to person and even for a particular person over time, which makes it difficult to compare results (Asadi et al. 2019; Fennelly 2020; Gralton et al. 2011; Lindsley et al. 2012). Consequently, lab-based surrogate techniques are more frequently used to study source control devices. The most commonly reported methods have been tests of filtration efficiencies and fit factors (Clapp et al. 2021; Guha et al. 2021; Konda et al. 2020; Wang et al. 2020; Zhao et al. 2020). Other studies have used manikins in a chamber or room to assess the efficacy of medical masks and cloth masks both as source control devices and as personal protective equipment (Pan et al. 2021; Patel et al. 2016; Rothamer et al. 2021). Experimental data have also been used to develop computational fluid dynamics models of medical and cloth masks performance (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020). These studies have provided valuable information about the properties of masks and respirators. However, it is unclear how the various metrics used in these studies are related to source control performance.

The source control measurement system used in this study allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough and exhaled breath aerosol particles into the environment (Lindsley et al. 2021). However, the system is complex and requires expertise to operate, and it is neither commercially sold nor easily constructed. In contrast, filtration measurement systems and respirator fit testers are widely available. If a methodology could be developed to gauge source control performance using existing commercially available equipment, it could be rapidly expanded and adopted by manufacturers and public health entities.

The filtration efficiency of a mask or respirator is a measurement of the ability of the mask material to remove aerosol particles from an airstream traveling through the fabric. Filtration efficiency tests typically use aerosol particles at or near the most-penetrating aerosol particle size, which is around 300 nm for an uncharged filter at low air velocities but shifts to smaller sizes at higher velocities and when the filter and particles are electrostatically charged (Martin and Moyer 2000; Rengasamy, BerryAnn, and Szalajda 2013; Rengasamy et al. 2017). The mechanisms by which filters collect aerosol particles are strongly dependent upon the size of the particles; for example, large particles are more likely to be collected by impaction or interception while small particles are more likely to be collected by diffusion (Lindsley 2016). Although the SARS-CoV-2 virus is about 100 nm in diameter, contagious humans do not shed bare viral particles. Instead, they expel aerosols and droplets of respiratory fluids that contain respiratory virus, and the size of these virus-laden aerosols and droplets can range from hundreds of nanometers to visible droplets of 1 mm or more (Fennelly 2020; Gralton et al. 2011). Thus, the collection efficiencies for 100-300 nm particles may not predict the performance for larger particles (Drewnick et al. 2021). In our experiments, the coughing and exhalation source control collection efficiencies increased as the particle size increased (Tables S1 and S2 in the SI) and in most cases were higher than the filtration efficiencies, likely because our coughing and exhalation test aerosols were much larger than the 75 nm aerosol used for filtration tests.

The fit factor is normally used to determine how well a respiratory protective device fits the wearer by measuring the degree to which aerosol particles can enter through gaps between the wearer's face and the respirator (face seal leaks). It is determined by placing the device on a person or on a manikin headform and measuring the ratio of the aerosol concentration outside the respirator to the aerosol concentration inside the respirator (Janssen and McKay 2017). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the respirator. Fit factor measurements are not intended to test the filtration efficiency of the device itself. In fact, the calculation of the fit factor for a respirator assumes that any ambient aerosol particles passing through respirator material are filtered out and that any particles detected inside the respirator are due to face seal leaks, not penetration of particles through the filter material (Halvorsen 1998). For example, a fit factor of 10 is interpreted as indicating that 90% of the air inside the respirator has passed through the respirator filtration media (with aerosol particles being completely removed) and that 10% of the air bypassed the media and entered through face seal leaks.

For high efficiency filters such as P100 respirator filters, which filter out 99.97% of airborne particles, a respirator fit test is performed by measuring the concentrations of aerosol particles of all sizes inside and outside the respirator (referred to here as Class 100 mode). However, N95 respirators can allow up to 5% of aerosol particles of the most penetrating size to pass through the filtration media. These particles would reduce the apparent fit factor if they were included in the calculation. Thus, when fit testing N95 respirators, the respirator fit tester used in our experiments has a size classifier to count only negatively charged aerosol particles near 55 nm in size (referred to here as N95 mode). For an N95 respirator, these charged 55 nm particles are almost entirely filtered out by the filtration media, and thus any particles detected inside the respirator can then be assumed to have entered through face seal leaks and not through the respirator (Halvorsen 1998; Han and Prell 2010).

It is important to note, however, that this assumption is not correct when using the fit tester with cloth masks. As can be seen in Table 3, the filtration efficiencies of most cloth masks are much lower than those of respirators, and ambient particles therefore can penetrate more easily through the cloth material. Thus, the fit factor for a cloth mask is not a true measurement of face seal leakage alone; instead, it represents a combination of face seal leakage and particle penetration through the mask material.

Our findings suggest that the results from filtration efficiency, airflow resistance and fit factor tests are correlated with measurements made using our source control measurement system. For the cloth masks, all but two of the standard performance metrics were significantly correlated with the cough and exhaled aerosol collection efficiencies, which suggests that these other measures could be useful as part of a method for testing the performance of cloth masks. However, none of the standard metrics were strong predictors of source control performance, and no metric was clearly superior to the others.

The limited correlations between the different test methods in our study likely have several explanations. First, filtration efficiency and airflow resistance measurements do not account for how well the devices fit the wearer or for face seal leaks around the edges of

the device. Thus, for example, the Artisan procedure mask had an 80% filtration efficiency but a 56% collection efficiency for cough aerosols and a 42% collection efficiency for exhaled aerosols. The most likely explanation is that this mask's material is an efficient filter but that aerosol particles were able to travel around the mask through face seal leaks because the Artisan mask fits loosely on the headform. On the other hand, the Hanes Defender cloth mask had only a 19% filtration efficiency but had similar aerosol collection efficiencies of 52% for coughs and 44% for exhalations. In this case, the cloth mask was not an effective filter for the 75 nm aerosol used in filtration testing, but the Hanes mask fit the manikin headform more tightly. Thus, much of the aerosol then flowed through the mask rather than around it during coughing and breathing tests and the larger aerosol particles that were used in the coughing and breathing tests were filtered out more effectively than the 75 nm particles used in filtration testing. The results presented here are consistent with a previous study by our group in which knotting the Artisan procedure mask to improve the fit increased the cough aerosol collection efficiency to 77%, while wearing a Hanes Defender cloth mask on top of an Artisan procedure mask increased the cough collection efficiency to 85% (Brooks et al. 2021). Together, these results also support the recommendation by Gandhi and Marr that members of the public wear a high-quality mask that fits tightly or wear a tight-fitting cloth mask over a surgical mask in order to reduce face seal leaks and improve the source control performance and protection offered by the masks (Gandhi and Marr 2021).

Fit tests are designed to measure the effects of face seal leaks but have their own limitations when applied to cloth masks. As noted above, fit factor measurements for cloth masks reflect some combination of particle penetration through the media and face seal leakage which will likely vary from mask to mask. Thus, it is neither clear how to interpret fit factor measurements for cloth masks nor is it clear how this relates to the effectiveness of the mask as a source control device. In addition, fit test results can vary greatly from person to person and even somewhat for the same person during repeated tests (Lawrence et al. 2006). Similarly, a comparison of fit tests between humans and a pliable skin manikin headform found significant differences (Bergman et al. 2015). Much of this discrepancy is likely due to facial variations and differences in how the mask is placed on the person or manikin headform. It is possible to shift, stretch, tighten, loosen, or adjust the masks in many ways,

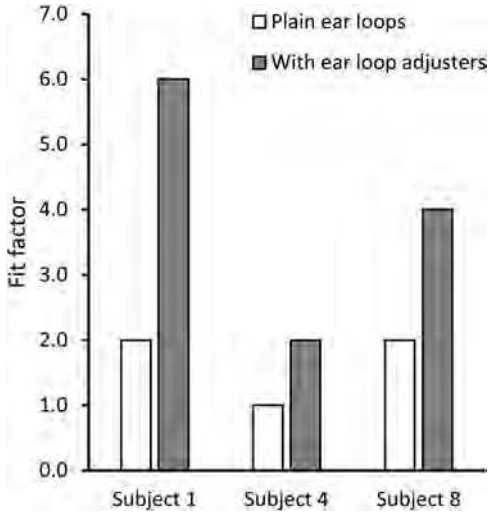

Figure 8. Effect on mask fit factor of adding ear loop adjusters to tighten the mask fit. Subjects were wearing the Excellent Artisan procedure mask. Tests were conducted with the fit tester in Class 100 mode. Each bar is the mean of three trials. All standard deviations were zero.

and small differences in how the mask is worn may have substantial effects on the fit test results. For example, in tests with three subjects using the Artisan procedure mask, we found that tightening the mask against the face by using silicone ear loop adjusters increased the mean fit factor from 1.7 to 4.0 (Figure 8). In experiments with cloth masks, the ρ value for the manikin headform fit tests done before coughing experiments compared with tests done before exhalation experiments was only 0.38, suggesting that differences were occurring even when the same model of mask was being placed on the same headform.

Finally, our study has several limitations. The source control measurement system produced a test aerosol with particles $\leq$7 µm in diameter, which is the size range of aerosol particles most likely to remain airborne and most difficult to block with source control devices. However, humans expel aerosol particles in a much broader range of sizes, particularly when coughing. We used a single cough flowrate profile and a single breathing ventilation rate for our studies; these parameters can vary greatly from person to person under different physiological conditions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We used representative examples of different types of source control devices, but many such devices are available with a wide range of shapes and compositions, which would be expected to affect their individual performance. As shown in Table 1, the instrumentation used for the

different performance metrics are based on different operating principles and thus caution should be used when comparing results; for example, the collection efficiency results from the impactors are based on aerosol mass, while the fit factor results from the PortaCount are based on particle counts. Lastly, because of the need to rapidly produce results in response to the COVID-19 pandemic, we only tested 2-3 samples of each source control device (each sample was used in two consecutive tests). By comparison, for example, the NIOSH procedure for evaluating N95 respirators calls for 20 samples to be tested (NIOSH 2019).

Current evidence indicates that masks like those tested in our experiments can substantially decrease the amount of respiratory aerosols released by the wearer, and also help reduce what the wearer breathes in (CDC 2020a). Both effects vary depending upon the material and construction of the mask, as well as how it is worn. In addition to consistent and correct mask use when in the company of others, other measures such as physical separation are important, particularly during brief exposures. In a room where someone sneezes, being six feet or further away is better than being closer. However, with prolonged exposure in the same space for more than a few minutes, the benefit of distance fades as exhaled respiratory aerosols drift, mix, and accumulate in the enclosed air space. Optimizing ventilation, air filtration, and the introduction of fresh air can help counter this effect, but at every distance, correct mask use reduces the risk for everyone.

Conclusions

The ongoing COVID-19 pandemic has created an urgent need for simple methods to evaluate cloth masks as respiratory aerosol source control devices and to produce meaningful performance metrics that can be used to determine the effectiveness of different materials and designs. Our results suggest that test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements on manikin headforms or human subjects have potential as ways to estimate the performance of masks as source control devices for respiratory aerosols. However, more research and improvements in the test methodologies are needed before such methods can be reliably implemented. Until the factors controlling the performance of source control devices are better understood and better testing methodologies are developed, results from test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements should be interpreted cautiously when used to evaluate source control devices for respiratory aerosols.

Efficacy of face masks, neck gaiters and face shields for reducing the expulsion of simulated cough-generated aerosols

William G. Lindsley, Francoise M. Blachere, Brandon F. Law, Donald H. Beezhold, and John D. Noti

Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Morgantown, West Virginia, USA

ABSTRACT

Face masks are recommended to reduce community transmission of SARS-CoV-2. One of the primary benefits of face masks and other coverings is as source control devices to reduce the expulsion of respiratory aerosols during coughing, breathing, and speaking. Face shields and neck gaiters have been proposed as an alternative to face masks, but information about face shields and neck gaiters as source control devices is limited. We used a cough aerosol simulator with a pliable skin headform to propel small aerosol particles (0 to 7 μm) into different face coverings. An N95 respirator blocked 99% (standard deviation (SD) 0.3%) of the cough aerosol, a medical grade procedure mask blocked 59% (SD 6.9%), a 3-ply cotton cloth face mask blocked 51% (SD 7.7%), and a polyester neck gaiter blocked 47% (SD 7.5%) as a single layer and 60% (SD 7.2%) when folded into a double layer. In contrast, the face shield blocked 2% (SD 15.3%) of the cough aerosol. Our results suggest that face masks and neck gaiters are preferable to face shields as source control devices for cough aerosols.

Introduction

SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can be transmitted from person-to-person by large respiratory aerosols (airborne liquid droplets and dried particles greater than about 10 μm in diameter) produced by people who are infectious while they are talking, singing, coughing, breathing or sneezing (CDC 2020a; Hamner et al. 2020). Smaller aerosols also are emitted by people during these activities, suggesting that short-range airborne transmission of SARS-CoV-2 might be possible under some circumstances (Anderson et al. 2020; CDC 2020a; Fennelly 2020; Ma et al. 2020; Morawska and Milton 2020).

To interrupt this potential transmission route, the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO), and other public health organizations recommend the wearing of face masks or other face coverings by the general public during the ongoing COVID-19 pandemic (CDC 2020b, 2020c; Edelstein and Ramakrishnan 2020; WHO 2020). One of the primary benefits of face coverings is to act as source control devices to reduce the expulsion of aerosols containing the virus from people who are infectious during coughing, breathing, and speaking. Source control devices are intended to protect other people from infectious aerosols emitted by the wearer, as compared with personal protective equipment such as N95 respirators which are primarily intended to protect the wearer. A face covering can provide source control in two ways (Diaz and Smaldone 2010). First, and most importantly, the covering may collect aerosol particles by filtration, impaction, or other mechanisms, and thus prevent infectious aerosols from entering the environment. Second, the face covering may change the direction of travel and the velocity of the aerosol stream and thus possibly divert the aerosol away from a potential recipient. However, deflection is more uncertain as a source control mechanism. For example, if large aerosols are deflected downward, they may settle to the floor or otherwise be unable to reach the breathing zones of other people. However, since exhaled breath is often warmer than the surrounding air, this

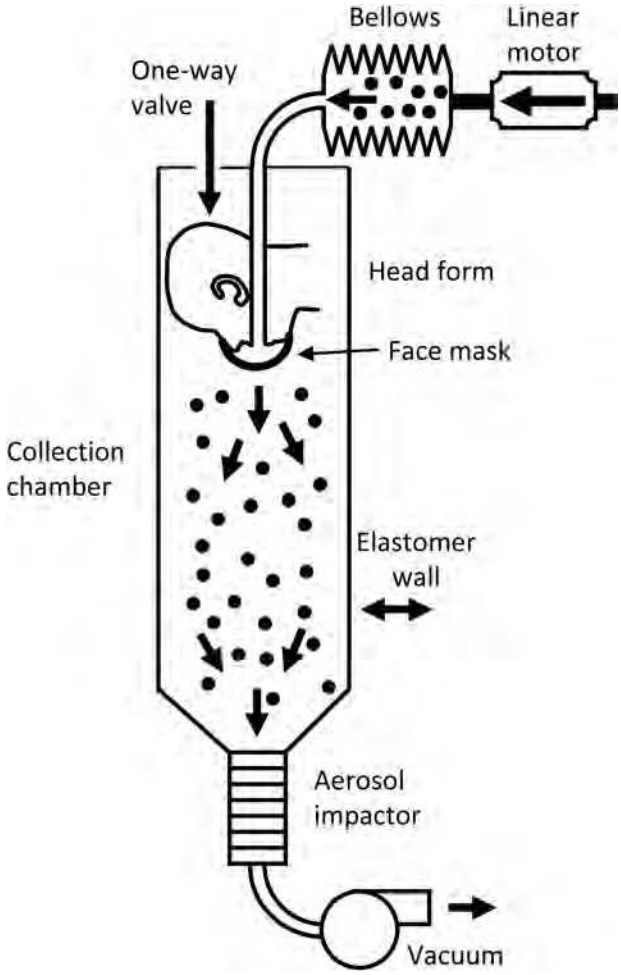

Figure 1. Cough aerosol simulator system for source control measurements. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated cough, a pliable skin head form on which the face mask, neck gaiter or face shield is placed, a 105 liter collection chamber into which the aerosol is coughed, and an Andersen impactor to separate the aerosol particles by size and collect them. More information about the cough aerosol simulator is provided in the SI.

downward deflection may be counteracted by the buoyancy of the breath for smaller aerosols. In addition, if the respiratory aerosols are deflected sideways, they may be diverted away from a person directly in front of the wearer but toward someone to the side or behind the wearer.

Studies using manikins (Lai, Poon, and Cheung 2012; Patel et al. 2016) and patients with respiratory infections (Leung et al. 2020; Milton et al. 2013) have shown that wearing medical face masks can reduce the dispersion of potentially infectious aerosols from patients. Two studies in which face masks were required for visitors and healthcare workers interacting with patients in bone marrow transplant centers found a reduction in respiratory viral infections among patients (Sokol et al. 2016; Sung et al. 2016). Studies of cloth face masks have suggested that they also can be effective at reducing the release of respiratory aerosols into the environment (Asadi et al. 2020; Davies et al. 2013; Konda et al. 2020). Several computational fluid dynamics studies have examined the generation and expulsion of respiratory aerosols and have provided important insights into the ability of face coverings to reduce the dispersion of large and small aerosols from the wearer (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020).

Unfortunately, the use of face masks and other face coverings by the general public can present challenges. People often dislike wearing masks, and compliance can be low and inconsistent (Longtin et al. 2009). Mask wearers may repeatedly don, doff and adjust face masks, which can contaminate the hands and potentially lead to disease transmission, especially when the masks are reused (Brady et al. 2017; Casanova et al. 2008). For cloth masks, the filtration efficiency and air flow resistance of different textiles varies widely (Konda et al. 2020; Teesing et al. 2020; Wilson et al. 2020). Alternative face coverings such as neck gaiters (an elastic fabric tube that fits snugly around the head and neck) are commonly used, but information about their performance as source control devices is limited. Factors such as how well the mask fits the face and the coverage provided by a mask can have a substantial impact on the effectiveness of face masks (Davies et al. 2013; Lawrence et al. 2006). Comparisons of face coverings have found substantial differences in the ability of different types of these devices to reduce the release of respiratory aerosols (Asadi et al. 2020; Davies et al. 2013).

An opinion article in JAMA proposed that face shields would be more effective than face masks at reducing community disease transmission, in large part because the authors felt that face shields were more comfortable and thus that they were more likely to be widely adopted by the public (Perencevich, Diekema, and Edmond 2020). A previous study by our group of face shields used as personal protective devices showed that face shields protect the wearer from large cough aerosols directed at the face but are much less effective against smaller aerosols which were able to flow around the edges of the shield and be inhaled (Lindsley et al. 2014). However, very little work has been done examining face shields as source control devices. Two qualitative flow visualization studies of face shields and masks found that, although face shields deflected the air flow from the mouth, they did not stop aerosol particles from traveling around the face shield and entering the environment

(Verma, Dhanak, and Frankenfield 2020; Viola et al. 2020). Beyond these studies, quantitative data on the efficacy of face shields for source control are lacking.

The objective of our study was to conduct a quantitative comparison of the efficacy of an N95 respirator, a medical procedure mask, a commercial 3-ply cloth face mask, a single and double layer fabric neck gaiter, and a commercial disposable face shield as source control devices to reduce the expulsion of small cough-generated aerosol particles into the environment. Our results provide more information about the effectiveness of different types of source control devices and will help the public health community make recommendations about the best ways to use these devices to help reduce the spread of COVID-19.

Materials and methods

Experimental design

In our experiments, a cough aerosol simulator propelled a test aerosol through a headform into a collection chamber (Figure 1), and the amount of aerosol in the collection chamber was measured in each of six size fractions. The collection efficiency of each face mask, neck gaiter, or face shield was determined by comparing the amount of aerosol that was collected from the chamber with and without the device. Our test method was similar to the modified Greene and Vesley method used to test medical masks (Quesnel 1975), with the human test subject replaced by the cough aerosol simulator.

Cough aerosol simulator

The cough aerosol simulator is a modified version of the NIOSH cough aerosol simulator described previously (Lindsley et al. 2019; Lindsley et al. 2014; Lindsley et al. 2013). The experimental cough aerosol was generated by nebulizing a solution of 14% KCl and 0.4% sodium fluorescein using a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2), passing the aerosol through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), and mixing it with 10 L/min of dry filtered air. The test aerosol was loaded into an elastomeric bellows, and the cough airflow was produced by a computer-controlled linear motor that compresses the bellows. The cough aerosol was expelled through the mouth of a headform into a collection chamber. The headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each face covering or shield would fit a human face (Bergman et al. 2014).

Source control devices

The source control devices tested were an N95 medical respirator (3 M model 1860), a medical grade (ASTM Level 3) procedure mask with ear loops (Kimberly Clark model 47107), a cloth face mask with 3 layers of cotton fabric and ear loops (Hanes Defender), a fabric neck gaiter (FKGIONG Sun UV Protection Neck Gaiter, 95% polyester, 5% Spandex) and a disposable face shield (Fisher Scientific # 19-181-600 A). The neck gaiter was tested both as a single layer of fabric and doubled over to provide two layers of fabric. The masks and respirator were not equipped with exhalation valves. The face shield was 25 cm tall and extended from the forehead of the headform to 3 cm below the chin and around the side to 3 cm before the front of the ear. Photographs of the source control devices on the headform are shown in the online supplementary information (SI).

Mask fit test

For the experiments, either no device, a face mask, a neck gaiter, or a face shield were placed on the head form. Each device was used for two consecutive tests. For face masks and gaiters, a respirator fit test was performed using a PortaCount (TSI). The fit factor is a measure of the protection against airborne particles that is provided by a respiratory protective device. It is defined as the ratio of the aerosol concentration outside the respiratory protective device to the aerosol concentration inside the device (i.e., the aerosol concentration that is inhaled by the wearer). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the mask, and that the mask is therefore filtering out 90% of the ambient aerosol.

Aerosol collection and analysis

After placing the device on the headform and performing the fit test, the system was sealed. The test aerosol was then generated and propelled with a simulated cough through the headform and into the collection chamber. The Andersen impactor at the bottom of the collection chamber collected the aerosol particles that traveled through or around the device for 20 min after each cough. The Andersen impactor operates at a flow rate of 28.3 liters/minute and has six collection stages and a filter that separate the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm;

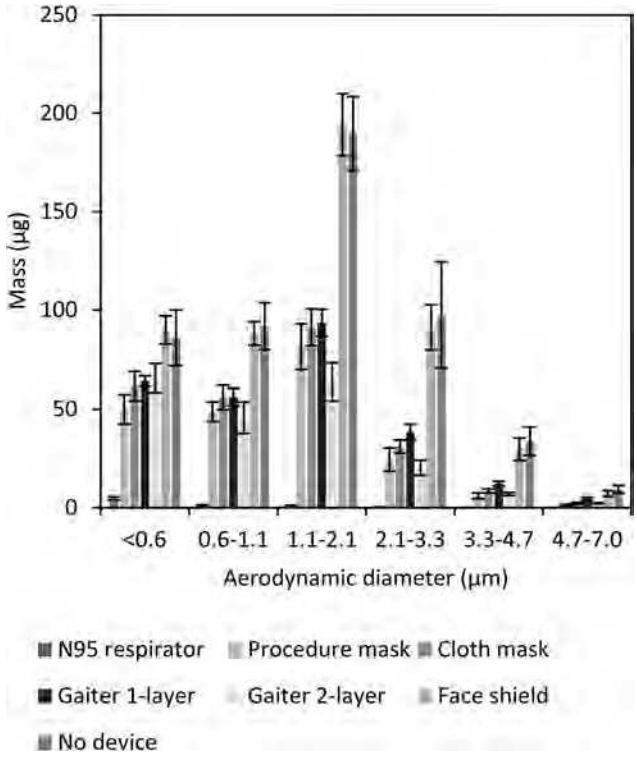

Figure 2. Mass of aerosol collected in each size fraction. The graph shows the amount of simulated respiratory aerosol that was collected from the collection chamber in each aerosol particle size fraction after a single simulated cough. The bars show the mean and standard deviation. A larger color version of this figure is shown in the SI.

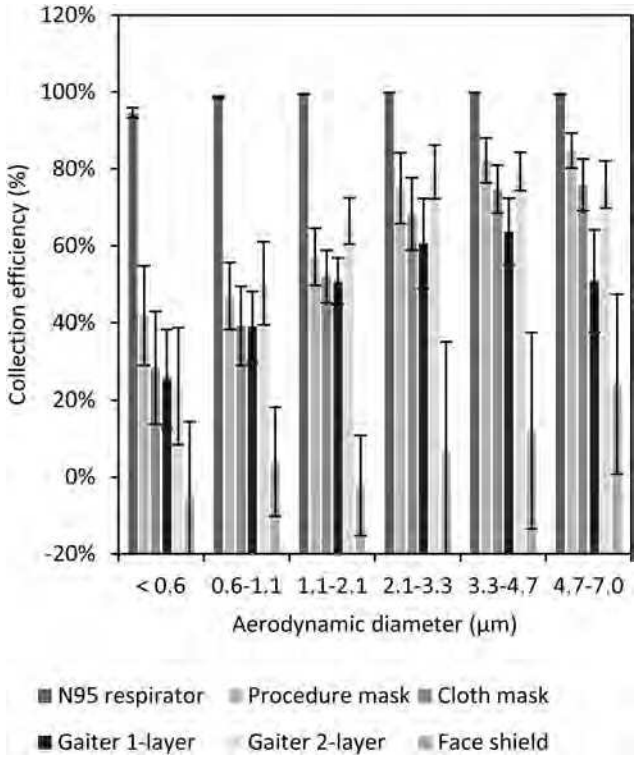

Figure 3. Collection efficiency of face masks, neck gaiter and face shield. The collection efficiency is the percentage of aerosol particles that were blocked by the face mask, neck gaiter or face shield compared with experiments without a device. The plot shows the means and standard deviations of the collection efficiency in each size fraction. A larger version of this figure is shown in color in the SI.

4.7–7.0 µm; and >7 µm. Because the amount of aerosol in the largest size fraction was small and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction was not included in the analysis. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). After aerosol collection was completed, the impactor plates were rinsed with 0.1 M Tris solution and the fluorescence of the solution was measured using a fluorometer (SpectraMax M4, Molecular Devices). The complete experimental protocol is given in the SI.

Statistical analysis

The performance of each device was evaluated by comparing the total mass of the aerosol particles from a single cough that passed through or around the device and was collected by the Andersen impactor. The results were evaluated using a one-way ANOVA and multiple comparisons among the different devices and the control experiments without a device were conducted using a Tukey-Kramer test. To control for variations in the amount of aerosol in each cough, a sample of each cough aerosol was collected from the bellows prior to coughing and used to normalize the aerosol mass collection results for each experiment.

Results

The cough aerosol simulator provides a cough with a controlled cough airflow rate containing a test aerosol with a consistent aerosol size distribution. The simulator allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough aerosol particles of different sizes into the environment. The flow rate of the simulated cough used in our experiments was based on cough flow profiles recorded from influenza patients and had a volume of 4.2 L with a peak flow rate of 11 L/s (Lindsley et al. 2013). The cough aerosol collected from the control experiments without a face covering had a mass median aerodynamic diameter of 1.3 µm, a geometric standard deviation of 2.3 and a total aerosol mass of 505 µg (standard deviation 69).

For our study, we tested the collection efficiencies (that is, the fraction of the cough aerosol that was

Table 1. Total mass of aerosol expelled into collection chamber and device collection efficiencies.

Device tested	Number of experiments	Fit factor	Aerosol mass (μg)	Collection efficiency
No device	12	n/a	512 (64)	n/a
Procedure mask	6	2.9 (0.5)	212 (23)	58.5% (6.9%)
Cloth mask	6	1.3 (0.1)	251 (23)	50.9% (7.7%)
Neck gaiter (single layer)	6	1.7 (0.5)	270 (18)	47.2% (7.5%)
Neck gaiter (double layer)	6	1.9 (0.4)	206 (26)	59.8% (7.2%)
Face shield	6	n/a	502 (46)	1.8% (15.3%)
N95 respirator	6	198 (3.5)	7.2 (1.2)	98.6% (0.3%)

Note: The fit factor, aerosol mass, and collection efficiency are given as mean (standard deviation).

blocked) of a medical grade procedure mask, a cotton cloth face mask, a polyester neck gaiter, an N95 medical respirator and a disposable face shield. These source control devices were chosen to provide representative samples of the different types of face coverings and face shields that are in common use during the pandemic. Neck gaiters are typically worn either as a single layer of fabric over the mouth and nose or doubled over to provide two layers of fabric; for our experiments, we tested both configurations. The quantity of aerosol particles in six size fractions that were able to travel through or around each source control device are shown in Figure 2. The collection efficiencies of the devices are shown as a function of aerosol size in Figure 3. All the devices showed increased collection efficiencies as the aerosol size increased.

On average, the N95 respirator blocked 99% of the total mass of test aerosol from being released into the environment, while the medical procedure mask blocked 59%, the cloth face mask blocked 51%, the single-layer gaiter blocked 47%, the double-layer gaiter blocked 60%, and the face shield blocked 2% of the total aerosol (Table 1). The N95 respirator, procedure mask, cloth mask, and the single-layer and double-layer gaiters all significantly reduced the aerosol emitted into the environment compared with no device ($P < 0.0001$ for each), but the face shield did not ($P = 0.9993$). The collection efficiencies of the procedure mask, cloth mask, and the single and double-layer gaiters did not differ significantly from each other, but all blocked cough aerosols significantly better than did the face shield ($P < 0.0001$). The N95 respirator outperformed all the other devices ($P < 0.0001$) (Table 2).

Discussion

Humans continuously emit aerosols of respiratory fluids as they breathe, talk, cough, sneeze, sing, or carry out other respiratory activities. These respiratory aerosols can have a very broad size range, from tens of nanometers in diameter to visible droplets of a millimeter or more (Bourouiba, Dehandschoewercker, and Bush 2014; Fennelly 2020; Gralton et al. 2011; Morawska et al. 2009). Airborne particles larger than 100 μm are ballistic; that is, they are affected primarily by gravity and fall quickly to the ground. Respiratory aerosol particles in this size range tend to deposit within a few meters of the source (Prather et al. 2020). As the aerosol particle diameter decreases from 100 μm, a gradual transition occurs where the settling velocity rapidly decreases and the particles remain airborne for longer times. For example, a 100 μm aerosol particle takes 4 s to fall 1 m in still air, while a 10 μm aerosol particle takes 5.4 min and a 1 μm aerosol particle takes 8 h to settle the same distance (Hinds 1999). Air currents such as plumes of warm air rising from the body can lift these particles and extend the time for which they stay in the air. Thus, small aerosol particles can remain airborne for minutes to hours and can accumulate over time in environments with poor ventilation (Bahl et al. 2020). Small aerosol particles also are easier to inhale and can travel more deeply into the lungs (Vincent 2005).

The amount and sizes of aerosol particles containing SARS-CoV-2 that are expelled by people who are infected are not yet known. Two studies of aerosol samples collected in patient rooms found infectious (replication-competent) SARS-CoV-2 in aerosol particles <4 μm in diameter (Santarpia et al. 2020a) and <10 μm in diameter (Lednicky et al. 2020). Other studies have reported SARS-CoV-2 RNA in exhaled breath from infected patients (Ma et al. 2020), aerosol samples from biocontainment and quarantine units housing SARS-CoV-2 infected persons (Santarpia et al. 2020b), and in aerosol samples at multiple locations throughout two hospitals in Wuhan, China during a COVID-19 outbreak (Liu et al. 2020). The presence of small aerosol particles containing

infectious SARS-CoV-2 detected in these studies suggests that in addition to large aerosols, these small aerosols might play a role in SARS-CoV-2 transmission (Anderson et al. 2020; Bahl et al. 2020; Ma et al. 2020; Morawska and Milton 2020).

Source control devices like face coverings and face shields collect respiratory particles larger than 0.3 μm primarily by impaction and interception of the aerosol particles against the fibers or solid surfaces of the device. As noted earlier, source control devices may also deflect aerosols, but this mechanism can be problematic as a means of source control because the infectious aerosol is not prevented from entering the surrounding environment; it is merely sent in a different direction which may or may not be protective depending upon local airflows and the locations of other people. Our experimental system measures particle collection only; any particles that are deflected but not collected by the face covering are still collected by the Andersen impactor. Thus, we are able to measure the particle collection efficiency of the face coverings without the potentially confounding variable of particle deflection. On the other hand, this does means that any potential benefits from, for example, deflecting large aerosol particles toward the ground were not measured by our system.

Small aerosols require much higher air velocities to deposit by impaction than do larger aerosols, and thus are more difficult to block with source control devices (Hinds 1999; Lindsley 2016). Consequently, small aerosols present the most challenging scenario for testing source control devices since devices that block small aerosol particles would be expected to block larger ones as well. Our results show that face masks and neck gaiters can significantly reduce the expulsion of small respiratory aerosol particles during coughing. This suggests that various types of face coverings can make an important contribution to reducing the quantity of aerosol particles containing SARS-CoV-2 released into the environment by people who are infected. N95 respirators, which are worn for personal protection by healthcare workers and others at highest risk of exposure, are also very effective source control devices. In contrast, the face shield blocked very little of the cough aerosol, indicating that face shields are not effective as source control devices for small respiratory aerosols.

The collection efficiencies of all the devices tested increased as the aerosol particle size increased, and this trend would be expected to continue for larger aerosol particles than were tested here. For example, the collection efficiency of the cloth face mask was 28% for the <0.6 μm particles and increased to 76% for the 4.7 to 7 μm particles. Similarly, the double-layer gaiter blocked 24% of the <0.6 μm particles and 76% of the 4.7 to 7 μm particles. These results suggest that cloth face coverings would be effective as source control devices against the large respiratory aerosols that are thought to play an important role in SARS-CoV-2 transmission.

Our study has several limitations. We used a single cough volume, air flow profile, and aerosol size distribution for our studies; these parameters can vary greatly from person to person. We examined the

performance of these devices during simulated coughing but not breathing or speaking, which have different air flow rates and aerosol size distributions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We only used a single representative example of each type of device. The shape and composition of face coverings vary widely, and this would be expected to affect the performance of individual devices. Some face masks have exhalation valves or vents which could reduce their efficacy as source control devices. The fit of a particular mask to an individual wearer and compliance in wearing the mask correctly (i.e., over the nose and mouth) also are important factors in how well the mask performs as a source control device. Because we used a < 0.6 to 7 µm test aerosol, our results do not indicate if face shields would be more effective as source control devices for large droplets. The face shield that we tested has a widely used design, but alternative designs are being marketed that provide greater facial coverage and, in some cases, include fabric skirts between the shield and the face. These alternative face shield designs might perform better as source control devices.

Previous studies have shown that face shields provide eye and facial protection to the wearer from droplets and splashes (Lindsley et al. 2014; Roberge 2016). When a face shield is worn in addition to a face mask, the face shield can also help reduce surface contamination of the mask by large aerosols and reduce the likelihood of hand contamination when the mask is removed or inadvertently touched (Lindsley et al. 2014). Our previous study showed that face shields provide some benefits as personal protective equipment when face masks cannot be worn (Lindsley et al. 2014), but as with all personal protection and source control devices, their limitations must be respected. Our results suggest that face masks and neck gaiters are more effective than face shields as source control devices to reduce the expulsion of respiratory aerosols into the environment as a public health measure to reduce the community transmission of SARS-CoV-2.

Acknowledgments

We would like to thank NIOSH machinist Bryan Williamson for manufacturing the parts for the cough simulator. We also would like to thank the NIOSH Morgantown maintenance, security, warehouse and housekeeping departments for their assistance and dedication during the ongoing pandemic. Subject: N95 effectiveness as source control

Dear Partners,

We have had a number of questions from you and others about N95 effectiveness as source control and wanted to share some information back with you.

National Institute for Occupational Safety and Health (NIOSH) researchers have evaluated N95s as source control in two different peer reviewed publications. In the first paper (Lindsley et al. 2021a- attached), NIOSH researchers found that a N95 respirator (3M model 1860) was 99% effective at blocking cough aerosols. In a second paper (Lindsley et al. 2021b- attached), NIOSH researchers found that one N95 respirator (3M 1860 N95) was 99% effective at blocking coughed and exhaled aerosols, and a second N95 Respirator (BYD) was 83% effective at blocking cough aerosols and 95% effective at blocking exhaled aerosols.

Subject: PARTNER ALERT: CDC Expands Booster Shot Eligibility

Dear Partners –

Yesterday, CDC adjusted our recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months.

Earlier this week CDC made this recommendation for recipients of a Pfizer-BioNTech primary seriesand, after FDA action this morning, we're extending this recommendation to recipients of a Moderna primary series. This means that people 12 and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.

Recently CDC strengthened our COVID-19 vaccination recommendations for children, now recommending that:

- Moderately to severely immunocompromised children ages 5–11 years receive an additional primary dose of Pfizer-BioNTech to ensure optimal protection from the vaccine.
- Children and teens ages 12–17 years should receive a booster shot.

Thank you,

Vaccine Task Force
COVID-19 Response

Subject: Follow up from 11/16 ASTHO IDPC call

Good afternoon,

Thank you for participation in last week's IDPC call. Attached please see notes from the call and an updated draft of the *Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease* policy statement.

- Since we met last week, we have been fortunate to gain a new IDPC member! **Dr. Manisha Juthani (SHO-CT)** has agreed to serve on the IDPC and plans to join us on our next call. Please join me in welcoming her to our group.
- *Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease* policy statement: Andy incorporated edits from our call in the attached draft. **If you are interested in meeting with Andy as a small group to wordsmith the draft, please let me know and I'll work to propose a few dates and times for that conversation.**
- As I mentioned during the call, Alyssa Boyea from our staff will be also be sending a request for your feedback to the questionnaire to assess public opinion on rebuilding trust and confidence in public health after the Thanksgiving holiday.
- Additionally, CDC's National Center for HIV, Viral Hepatitis, STD, and TB Prevention (NCHHSTP) will soon be updating its Data Security and Confidentiality Guidelines. The purpose of the document is to recommend standards for all NCHHSTP programs that, when adopted, will facilitate the secure collection, storage, and use of data while maintaining confidentiality. NCHHSTP has requested that ASTHO provide concrete examples and feedback on what needs to be updated in these guidelines. Please share anything you think should be added, removed, or reframed within these guidelines with me by **December 15.**

Lastly, the next IDPC call is scheduled for **February 15, 2022 at 12PM ET**. An agenda and call-in information will be sent closer to the call. Please send any suggested agenda topics to me.

Thank you all for your continued support of the IDPC and have a wonderful Thanksgiving.

PUBLIC HEALTH AUTHORITY TO PREVENT AND CONTROL THE SPREAD OF COMMUNICABLE AND INFECTIOUS DISEASE

POSITION

The Association of State and Territorial Health Officials (ASTHO) supports the establishment of robust public health legal authorities to facilitate the timely and adequate response to communicable and infectious disease outbreaks. These legal authorities are often exercised without the need of an emergency declaration and may allow, among other things, the abatement of nuisances, investigation of the causes of disease, institution of quarantine measures, ordering individuals or groups to isolate, conducting contact tracing and case investigations, collecting data, temporarily limiting or canceling public events, temporarily restricting or closing venues, and requiring vaccination verification for certain conduct and activities (e.g., school attendance). Beyond their use in the response to the historic pandemic caused by the novel coronavirus, in the past, these powers have been routinely exercised for more commonly experienced disease outbreaks, such as mumps and measles. Additionally, other societal sectors, such as business, education, cultural, and religion often depend on public health to stop the spread of infectious disease, prevent widespread disruptions, and quell public anxiety and fear. Maintaining these state and territorial legal authorities are key to being prepared for communicable and infectious disease outbreaks both now and in the future.

Summary of Recommendations:

- Ensure public health authority that can respond to future disease outbreaks without undue delay.
- Support public health authority that is guided by data and science.
- Ensure public health authority that protects the public's interest and well-being.

BACKGROUND

Establishing and using legal authority to control the spread of infectious disease dates to before the founding of the country. For example, colonial governments implemented isolation and quarantine precautions for incoming ships to prevent the introduction and spread of smallpox and other contagions.[1] These powers and activities were seen not only as a way of protecting the health of the local communities but also protective of trade and commerce.[2] As the scientific understanding of communicable and infectious disease grew, new tools such as contact tracing, disease investigation, data collection, and vaccines were added to public health's legal authority and practice. During the current pandemic public health authority has been used, with evidenced benefit, to slow the spread of the coronavirus by limiting the size of gatherings, encouraging social distancing, temporarily closing high-risk venues, and requiring the use of face coverings in certain places.[3,4,5,6,7,8,9]

Despite the successes in exercising public health authority, grave questions and negative perceptions about the role and use of public health powers in response to the pandemic and, by implication, future infectious disease outbreaks have arisen. Over the last year, the critical attitude toward the pandemic response has led to the rolling back of public health authority in several jurisdictions.[10] The reductions in public health legal authority will conceivably make it more difficult to respond to future disease outbreaks. As state and territorial policy makers continue to address the many issues related to the current pandemic, they are encouraged to consider these potential impacts and costs.

RECOMMENDATIONS

With regards to state and territorial public health authority to prevent and control the spread of communicable and infectious disease, ASTHO recommends:

- Ensuring public health legal authority that is appropriate and necessary for the prevention and control of future communicable and infectious disease outbreaks. Highly contagious illnesses, like measles, can be effectively contained through the public health measures and activities that are being questioned and criticized during the COVID-19 pandemic. We are unsure how the next major disease outbreak will spread and public health authority must be ready and able to respond to future diseases. Public health authority to implement non-medical and medical interventions swiftly and adeptly must be maintained and the creation of administrative burdens that delay public health action, endangers the public well-being, and leaves communities vulnerable to infectious disease outbreaks, should be avoided.
- Supporting evidence-based laws and policies for the identification, prevention, and control of communicable and infectious diseases. Public health authority should align with present and future diseases that public health agencies are obligated and required to confront and the authority should also be exercised in a manner that addresses the identifiable, known characteristics of the disease outbreak.
- Ensuring that public health legal authority properly and adequately balances a public health agency's obligations and requirements to protect the public's health and well-being with the rights of individuals. Laws and policies that undermine and encumber a public health agency's obligations or arbitrarily limit the agency's authority, impede disease prevention and control. Public health authority that is reasonable and aligned with the preventing and controlling the spread of infectious disease should be established and maintained.

APPROVAL DATES

Prevention Policy Committee Approval:
Board of Directors Approval:
Policy Expires:

ASTHO membership supported the development of this policy, which was subsequently approved by the ASTHO Board of Directors. Be advised that the statements are approved as a general framework on the issue at a point in time. Any given state or territorial health official must interpret the issue within the current context of his/her jurisdiction and therefore may not adhere to all aspects of this Policy Statement.

- Kris Ehresmann
- Jeff Stover
- Carolyn McCoy
- Kate Heyer
- Grace Lee
- Andy Baker-White
- Meredith Allen
- Ericka McGown
- Marcus Plescia

Meeting Notes

- Carolyn McCoy (ASTHO) provided an update on her discussion between staff in Rep. Rosa De Lauro's office from the Appropriations Committee with Dr. Dobbs on flexible funding.
    - ASTHO has been tracking three key issues:
        - Bipartisan Infrastructure Bill was signed into law.
        - Build Back Better Act, which is awaiting a score from the Congressional Budget Office (CBO) before being sent to members of Congress who will move on a vote.
            - The House may take it to the floor this week, despite parts of the CBO scoring estimates not coming out until the end of this week.
            - ASTHO is keeping track of this proposal because 7.5 billion is allocated for PH preparedness in the proposal.
        - The Fiscal Year 2022 Fiscal Appropriations process is underway.
            - Dr. Dobbs spoke to Senate Appropriations y staff. There is $1 billion proposed in the House, $600 million proposed in the Senate for flexible funding for PH infrastructure.
    - Federal funding runs out on Dec 3rd, and it is largely acknowledged that there is a need for a short-term continuing resolution. There is a question on how long this funding will last and if it will go into the 2022 election year. Likely fiscal fallout from not raising the debt ceiling would be catastrophic.

Andy Baker-White (ASTHO) shared the draft of the ***Public Health Authority to Prevent and Control the Spread of Communicable and Infectious Disease*** policy statement

- IDPC members discussed some edits that could be made on the list of recommendations.
    - State health officials shared that they have gotten far less resistance on isolation/quarantine mandates directed towards individuals compared to broader

PH-based population-based interventions (mask and vaccine mandates, school closures, etc.)

- Members emphasized the need to make sure that the recommendations section needs to be concise as some may not read the rest of the statement.
- Members expressed appreciation for the statement striking a balance between protecting individual rights and ensuring the public wellbeing. Many people do not recognize their obligation to protecting community health, so making this statement stronger would be a suggestion.
    - Joe McLaughlin said that CSTE has a public health law subcommittee, and it be helpful to reach out to them for some collaboration.
        - ASTHO has a steering committee of attorneys to who can also provide feedback.
    - Dr. Dobbs said many people don't respect the individual liberties of people who want to be safe during the pandemic. The pandemic has allowed those who are reckless to rob freedoms from people who want to live safely.

- The ***Preparing for the Next Pandemic/Public Health Crisis*** white paper was presented to the IDPC to gather feedback and edits.
    - The pandemic has highlighted how the PH sector has received a lot of funding, but that it is not always at the right time or for the right activities. Action-based flexible funding is necessary.
    - Members expressed a need for an all-hazards preparedness and response plan that is more nimble, more useful, less cumbersome, and easy for all those in the workforce to access and execute a pandemic response plan.
        - The white paper should acknowledge the role of misinformation during a pandemic response. Communications have been a challenge, especially for those whose first language was English. It's important to think about non-English speaking populations when planning for and throughout a response.
        - Ensuring judicious use of FEMA funds, proposing requiring a 100% federal match, and increasing surveillance capacity were all discussed as additional recommendations to the white paper.
    - Depoliticization of public health is vital in future pandemic responses. State leaders should be trained to be prepared to navigate political environments early and frequently in their work at a health agency. Legislators must support state health departments and the science.
    - There is a critical need to instill and boost trust in public health.
        - Mandates are challenging to explain when you're trying to increase trust in public health because they further emphasize and exacerbate public health fears of government overreach.
        - Emphasizing that PH is prevalent in everyday life, not just during a pandemic, is crucial for boosting the public's education on the role of PH.
            - State health agencies should emphasize that we train for PH responses through everyday PH initiatives.

- Another white paper is currently being drafted by MIT. It may be useful to reference this document, specifically on using technology for surveillance. Having an IT infrastructure is part of the PH infrastructure.
- Members emphasized that now, during the COVID-19 pandemic, is the most important time to get ahead of PH fear and mistrust.
- Members discussed ways to build back trust in public health. Members discussed whether the IDPC believes that a year from now there is going to be this level of mistrust. He wanted more perspective on trust as an issue going into the future, or if mistrust is just an issue now.
    - Dr. Dobbs said that they are using their roles as leaders to promote other important PH topics, because PH is broader than a pandemic.
    - Jeff Stover said VA is doing some marketing on a "PH Reality Campaign". Using the environment of the COVID-19 pandemic right now serves as platform to educate people on what PH really is.

- Next topics for future IDPC calls:
    - Trust in public health institutions.
    - Negative test reporting, contact tracing (for conditions outside of COVID such as STDs and TB), frequency of case reporting, and what the markers are for COVID becoming endemic.

Action Items

- Andy Baker-White will incorporate the IDPC's suggested edits in the draft of the policy statement. Any members who wish to send proposed edits via e-mail can e-mail kheyer@astho.org or reach out to set up a time for a call with Andy
- ASTHO will incorporate the IDPC's suggestions into the white paper and consider whether to engage public health attorneys to review. The ASTHO team will also solicit feedback from the ASTHO Preparedness Policy Committee and provide a draft back for IDPC review.

Subject: HHS COVID-19 Update - 3/31

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for March 31, 2021:

Highlights from the White House COVID-19 Response Team briefing:

Andy Slavitt:

- **Increasing Vaccination Sites:** The President committed to opening at least 12 more federally run mass vaccination sites, adding to the existing total of 25 sites. Three new sites will open next week in Memphis, Tennessee, Milwaukee, Wisconsin, and Greenbelt, Maryland, in addition to the two we announced on Monday in St. Louis, Missouri, and Gary, Indiana. Each of these sites is the first federally run mass vaccination site in its respective state, and each can administer 3,000 vaccinations a day.
- **Mask Mandates:** We need every governor, mayor, and local leader to maintain or reinstate mask mandates. And we need every American to do their part so that we can win this race and save lives.

Dr. Walensky:

- **Case Update:** CDC's most recent data show that the seven-day average of new cases is slightly less than 62,000 cases per day. We continue to see an increase, and this is almost a 12 percent increase from the seven-day period prior. Hospitalizations also continue to increase. The most recent seven-day average — about 4,900 admissions per day — is up from 4,600 admissions per day in the prior seven-day period. The seven-day average of deaths remains slightly above 900 deaths per day.
- **Inequities in COVID-19 Deaths:** COVID-19 deaths were highest for older adults and males, and were higher, as we previously saw, among American Indian and Alaska Natives, Hispanics, non-Hispanic Blacks, and non-Hispanic Native Hawaiian and Pacific Islander persons compared

to non-Hispanic whites. In fact, among nearly all these ethnic and racial minority groups, the COVID-19-related deaths were more than double the death rate of non-Hispanic white persons. Based on the current state of the pandemic, these impacts have remained in 2021, where we continue to see that communities of color account for an outsize portion of these deaths.

- **Number of People Vaccinated:** This week, we will reach 100 million people who have received at least one dose of the COVID-19 vaccine in the United States — a remarkable feat in such a short period of time. Further, over 70 percent of people over age 65, our most vulnerable group, have received at least one vaccine dose. In addition to increasing the number of mass vaccination sites across the country with FEMA, expanding the Federal Retail Pharmacy Program, and ensuring that all Americans have a vaccine site within five miles of their home, we are also activating mobile vaccination units and clinics. CDC is also excited to partner with the Administration for Community Living to support their efforts to get older, at-risk adults and those with disabilities vaccinated.
- **Guidance for Adult Day Service Centers:** CDC updated COVID-19 guidance for adult day service centers. These populations are at high risk for severe COVID-19 disease, and this guidance will help center administrators and staff protect themselves and adults receiving their services by promoting and engaging in preventive behaviors that reduce COVID-19 spread and help maintain healthy operations and environments of these facilities.
- **B.1.1.7 Variant:** We now have B.1.1.7 (U.K. variant) as 26 percent of the circulating variant across the United states, and it is the predominant strain in at least five regions of the United States. The variant is more transmissible – somewhere between 50 and 70 percent more transmissible than the wild-type strain. Therefore, to the extent that people are not practicing those standard mitigation strategies, we do think that more infections will result because of B.1.1.7. We believe that the current mitigation strategies of masking and distancing would work just as well against the current, the wild-type strain, as they do the B.1.1.7 strain.

Dr. Fauci:

- **Importance of Getting Vaccinated:** We are seeing now immune protection against COVID-19 variants when individuals are vaccinated against the wild-type strain, namely the common virus in society, on two mechanisms: the antibody response that has a spillover effect and the cross-reactivity. Vaccination is not only going to protect us against the common COVID-19 virus in society, but it has the potential, to a greater or lesser degree, to also protect against a range of variants. So, when vaccination becomes available, get vaccinated.

Vaccine Updates

Federal Retail Pharmacy Program: CDC updated their general information on the Federal Retail Pharmacy Program for COVID-19 Vaccination. As the program expands and supply becomes more readily available, the allocation may be adjusted to reflect partner size (number of store locations nationwide), reach (percent of the total US population living within 5 miles of a store location), and ability to vaccinate (throughput). The program, which will scale up to eventually include COVID-19 vaccination at all 40,000+ retail locations, will make it easier for individuals to access free COVID-19 vaccine at a pharmacy in their community, and improve vaccine uptake while decreasing the

logistical and operations burden on state, local, and territorial health departments.

Johnson & Johnson Janssen Vaccine: CDC updated their general information on the Johnson & Johnson Vaccine. The J&J/Janssen vaccine is recommended for people aged 18 years and older. Learn more about how CDC is making COVID-19 vaccine recommendations and CDC's vaccine rollout recommendations.

FEMA Vaccination Sites: FEMA announced that it will open a COVID-19 vaccination site in Greenbelt, Maryland on April 7th. The center's capacity is expected to be up to 3,000 shots per day. President Biden also committed to opening sites in Memphis, TN and Milwaukee, WI. These sites join many new FEMA vaccination sites recently announced, including in Boston, Massachusetts; Essex, New Jersey; Norfolk, Virginia; and Yakima, Washington, all of which open today. In the next week, federal communication vaccination center pilot sites in Gary, Indiana and St. Louis, Missouri are scheduled to open, as well. The agency has provided more than $4.47 billion for expenses related to COVID-19 vaccination at 100% federal cost share.

Peace Corps Assistance in COVID-19 Response: FEMA and the Peace Corps announced a historic partnership to combat the COVID-19 pandemic, marking only the second time in the Peace Corp's history where volunteers will serve a domestic deployment. The Peace Corps will soon begin recruiting for the special domestic deployment through Peace Corps Response, a program that sends in individuals with specialized experienced to short-term service assignment of up to 12 months. Assignments will focus on urgent needs as identified by FEMA and on communities that have been traditionally under-served.

Evaluating Moderna COVID-19 Variant Vaccine: An investigational vaccine designed to protect against the B.1.351 SARS-CoV-2 variant has been administered as part of a new Phase 1 clinical trial evaluating the vaccine candidate's safety and immunogenicity in adult volunteers. The vaccine, known as mRNA-1273.351, was developed by the biotechnology company ModernaTX, Inc., based in Cambridge, Massachusetts. The trial is led and funded by the National Institute of Allergy and Infectious Diseases (NIAID), part of the National Institutes of Health. The trial will enroll approximately 210 healthy adult volunteers at four clinical research sites in the United States that are part of the NIAID-funded Infectious Diseases Clinical Research Consortium (IDCRC).

HHS Podcast: HHS's new podcast, *COVID-19 Immunity in Our Community*, features top medical experts to answer questions on COVID-19 vaccines. Today's episode, "Building Vaccine Trust Within the Black Community," discusses how we can start to rebuild the Black community's trust in the vaccines, in order to achieve herd immunity and, hopefully, regain some sense of normalcy in our everyday lives.

Testing and Treatment

Covid-19 Precautions: CDC updated their COVID-19 page, reiterating that it is critical to keep taking precautions to prevent COVID-19. Learn more about how to protect yourself and others from CDC's recommendations.

COVID-19 Self Testing: CDC and NIH launched an innovative community health initiative called "Say Yes! COVID Test" starting in two locales, Pitt County, North Carolina, and coming soon to Chattanooga/Hamilton County, Tennessee. As many as 160,000 residents across the two communities will have access to free, rapid antigen tests that they can administer themselves to use three times a week for one month. NIH will provide the tests (also called a home-test or at-home test) and evaluate the effectiveness of the initiative, which aims to determine if frequent self-administered COVID-19 testing helps residents reduce community transmission of SARS-CoV-2, the virus that causes COVID-19 disease.

$147 Million to Expand Production of Swabs: DOD and HHS awarded $146.7 million to Puritan Medical Products on March 26 for renovations in the company's Orlinda, Tenn. facility to increase production capacity of foam tip swabs used in COVID-19 diagnostic tests. Funded through HCEA, the award will help the company boost total production capacity of the swabs to 250 million per month by February 2022.

Monoclonal Antibody Treatments: 3 EUAs for monoclonal antibody (mAb) treatments for mild-to-moderate COVID-19 in at-risk patients: bamlanivimab, casirivimab/imdevimab, and bamlanivimab/etesevimab. Learn more about FDA-authorized monoclonal treatments that can help at-risk patients fight the disease.

HHS Innovative Challenge for Masks: The U.S. Department of Health and Human Services launches $500,000 innovation challenge competition today encouraging American inventors to aid the nation's COVID-19 response by designing effective, comfortable face masks for personal use that resolve the common complaints people have about wearing masks. The contest taps into the nation's creativity and entrepreneurial spirit to help curb the spread of SARS-CoV-2, the virus that causes COVID-19.

Information for Specific Populations

Healthcare Workers: CDC updated their guidance for managing patients with COVID-19, including clinical guidance, home and hospital care, care for special populations, disease severity, and more.

Guidance for Adult Day Services Centers: CDC released guidance for administrators and staff to prevent the spread of COVID-19. Adult Day Services Centers (ADSCs) provide social or health services to community-dwelling adults aged 65 and over and adults of any age living with disability. Older adults and persons with disabilities are at highest risk for severe illness from COVID-19 including hospitalization, intensive care, and death. ADSC administrators and staff can help protect themselves and program participants (that is, adults attending ADSCs) from COVID-19 by promoting and engaging in preventive behaviors that reduce spread and maintain healthy operations and environments at ADSC facilities. This guidance is meant to supplement — not replace — any Federal, state, tribal, local, or territorial public health and safety laws, rules, and regulations with which adult day services center programs must comply. CDC has also developed recommendations for participants at ADSCs and their caregivers.

Suggestions for Youth and Summer Camps: CDC offers suggestions for ways in which camp administrators can help protect campers, staff, and communication, and prevent the spread of COVID-19. Camp administrators can determine, in collaboration with state and local health officials, whether and how to implement these considerations, making adjustments to meet the unique needs and circumstances of the local community. Implementation should be guided by what is feasible, practical, acceptable, and tailored to the needs of each community. These suggestions are meant to supplement— not replace —any state, local, territorial, or tribal health and safety laws, rules, and regulations with which camps must comply.

Essential Services for Malaria: CDC updated their key considerations for continuing essential

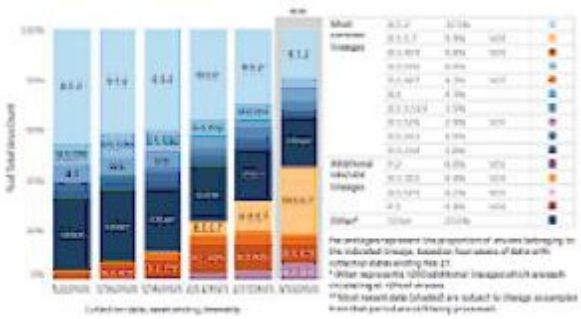
malaria prevention and control activities safely and effectively. These considerations should supplement country Ministry of Health guidance.

CMS Updates

Medicare Fee-for-Service Billing: CMS updated their COVID-19 Frequently Asked Questions on Medicare Fee-for-Service (FFS) Billing. The policies set out in this FAQ are effective for the duration of the public health emergency unless superseded by future legislation. The FAQs in this document supplement the previously released FAQs, 1135 Waiver FAQs.

Research

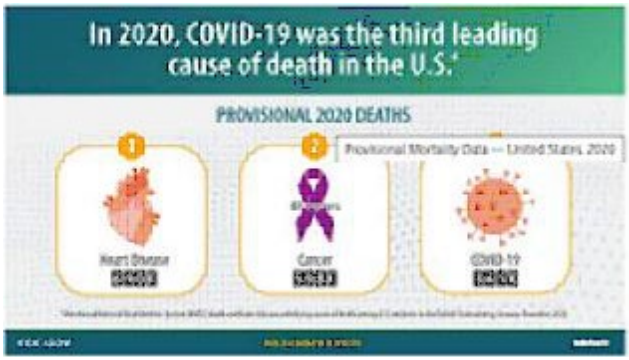
Variant Proportions in the U.S: CDC's national genomic surveillance program identifies new and emerging SARS-CoV-2 variants to determine implications for COVID-19 diagnostics, treatments, or vaccines authorized for use in the United States. Monitoring the spread of emerging variants in the United States relies on widespread, rapid sequencing. To accelerate sequencing in the United States, CDC has contracted with commercial diagnostic laboratories, and, in partnership with the Association of Public Health Laboratories (APHL), has implemented the National SARS-CoV-2 Strain Surveillance (NS3) program to provide a comprehensive and population-based US surveillance system. This data, along with data from many other sources, are used to inform national and state public health actions related to variants.



COVID-19 2020 Mortality Surveillance: The Morbidity and Mortality Weekly Report (*MMWR*) on death certificate-based ICD-10 diagnosis codes for COVID-19 mortality surveillance addresses that among the 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record.

Provisional 2020 Mortality Data: The Morbidity and Mortality Weekly Report (*MMWR*) on provisional mortality data in the United States in 2020 addresses that the age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics. Provisional death estimates

provide an early indication of shifts in mortality trends. Timely and actionable data can guide public health policies and interventions for populations experiencing higher numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic.



Case Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 cases will remain stable or have an uncertain trend over the next 4 weeks, with 223,000 to 723,000 new cases likely reported in the week ending April 24, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of new reported cases per week will likely decrease in 4 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported cases are uncertain or predicted to remain stable in the other states and territories. View previous case forecasts.

Hospitalization Forecasts: This week's national ensemble predicts that the number of new daily confirmed COVID-19 hospital admissions will remain stable or have an uncertain trend over the next 4 weeks, with 2,300 to 8,700 new confirmed COVID-19 hospital admissions likely reported on April 26, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of daily confirmed COVID-19 hospital admissions will likely increase in 6 jurisdictions and decrease in 12 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported hospital admissions are uncertain or predicted to remain stable in the other states and territories. View previous hospitalization forecasts.

Death Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 deaths will remain stable or have an uncertain trend over the next 4 weeks, with 3,100 to 10,200 new deaths likely reported in the week ending April 24, 2021. The national ensemble predicts that a total of 565,000 to 585,000 COVID-19 deaths will be reported by this date. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of newly reported deaths per week will likely decrease in 8 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported deaths are uncertain or predicted to remain stable in the other states and territories. View previous death forecasts.

Dear State Health Official,

TFAH will release its annual report *Ready or Not: Protecting the Public's Health from Diseases, Disasters, and Bioterrorism* measuring states' health emergencies preparedness on Wednesday, March 10. Not surprisingly, this year the report has a special focus on the impact of COVID-19, highlighting the need to increase resources for emergency preparedness. We clarify that our report measures all-hazards preparedness and is not a measure of any state's COVID-19 response.

As we have done in past years, we measure 10 health security indicators in each state and discuss the relationship of each to all-hazard preparedness. We placed states into one of three performance tiers (high, middle and low) based on these indicators. Twenty states and the District of Columbia placed in the high-performance tier, 15 states placed in the middle performance tier and 15 states placed in the low performance tier.

Particularly significant in this year's report is our emphasis on how the pandemic demonstrated the importance of the federal government's role in a health emergency on the scale of a pandemic, the impact of structural racism on a community's resilience during a health emergency, and, the critical need for core public health funding including workforce and infrastructure support.

The report is being shared with news media ahead of the Wednesday morning lift of the embargo. It is likely to be covered in news markets across the country. I recommend you share these materials with your communications staff today so they can prepare for any media requests.

I'd be happy to answer any questions.

Thank you,
Rhea

Rhea K. Farberman, Director

New Report Finds Gaps in States' Preparedness for Public Health Emergencies

COVID-19 Illuminated critical harm of underinvestment in public health infrastructure

(Washington, DC) --- March 10, 2021 – The COVID-19 pandemic has starkly demonstrated that underinvestment in preparedness to respond to public health emergencies can cost hundreds of thousands of lives and wreak havoc on the economy. A new report released today by Trust for America's Health (TFAH) measured states' performance on 10 key emergency preparedness indicators and found room for improvement in every jurisdiction.

The report, *Ready or Not 2021: Protecting the Public's Health from Diseases, Disasters and Bioterrorism* measured states' readiness for health emergencies of any kind (not just the COVID-19 crisis). It placed 20 states and the District of Columbia in a high level of preparedness category, 15 states in a middle preparation tier and 15 states in a low degree of preparation tier.

State performance, by scoring tier, 2020

Performance Tier	States	Number of States
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

For nearly two decades, TFAH has examined the nation's public health emergency preparedness in this annual report. During that time, all states have made improvements in their emergency preparedness, but all continue to have room for additional strengthening of their public health preparedness and response.

"The importance of this report is that it gives states actionable data to adopt policies that save lives. The COVID-19 crisis shows that we have much more work to do to protect Americans from health threats, particularly in the ways in which structural racism create and exacerbate health risks within communities of color," said John Auerbach, President and CEO of Trust for America's Health. "States need to take aggressive steps to shore up their preparedness for all types of public health emergencies."

While the report's findings are not a measure of any state's COVID-19 response, they demonstrate that while states' readiness is important, national health emergencies on the scale of a pandemic require strong federal leadership and coordination, and long-term investment in public health infrastructure and workforce. States alone, even those that rank high in this report, are not sufficiently equipped to respond to a pandemic without federal help, say the report's authors.

The report found:

A majority of states have made preparations to expand healthcare and public health capabilities in an emergency, often through collaboration. Thirty-four states participated in the Nurse Licensure Compact, up from 26 in 2017. The compact allows registered nurses and licensed practical or vocational nurses to practice in multiple jurisdictions with a single license. In an emergency, this enables health officials to quickly increase their staffing levels. In addition, **hospitals in most states have a high degree of participation in healthcare coalitions**. On average, 89 percent of hospitals were in a coalition and 17 states and the District of Columbia had universal participation, meaning every hospital in the jurisdiction was part of a coalition. Such coalitions bring hospitals and other healthcare facilities together with emergency management and public health officials to plan for and respond to incidents. **Every state and the District of Columbia had public health laboratories that had plans for a large influx of testing needs.** This ability to surge laboratory testing capacity during the COVID-19 crisis was extremely critical.

Most states are accredited in the areas of public health, emergency management, or both. As of December 2020, the Public Health Accreditation Board (PHAB) or the Emergency Management Accreditation Program (EMAP) accredited 42 states and the District of Columbia; 29 states and the District of Columbia were accredited by both groups, a net increase of one since November 2019. Both programs help ensure that necessary emergency preparation and response systems are in place and staffed by qualified personnel.

Seasonal flu vaccination rates, while still too low, have risen significantly. The seasonal flu vaccination rate among Americans ages 6 months or older rose from 42 percent during the 2017–2018 season to 52 percent during the 2019–2020 season but is still below the 70 percent target vaccination rate set by *Healthy People 2030.*

In 2019, only 55 percent of employed state residents, on average, used paid time off, the same percentage as in 2018. Those without paid leave are more likely to work when they are sick and risk spreading infection. This became particularly relevant during the COVID-19 pandemic, as isolation and quarantine are important tools for controlling the outbreak.

Most residents who got their household water through a community water system had access to safe water. On average, just 5 percent of state residents used a community water system in 2019 that did not meet all applicable health-based standards.

The report includes recommendations for actions by federal and state policymakers to improve the nation's public health emergency preparedness in seven priority areas:

- Provide stable, sufficient funding for domestic and global public health security.
- Strengthen policies and systems to prevent and respond to outbreaks and pandemics.
- Build resilient communities and promote health equity generally and in preparedness.
- Ensure effective public health leadership, coordination, and workforce.
- Accelerate development and distribution, including last mile distribution, of medical countermeasures.
- Strengthen the healthcare system's ability to respond and recover during and from health emergencies.
- Prepare for environmental threats and extreme weather.

The *Ready or Not* report series is funded by the Robert Wood Johnson Foundation with additional support from The California Endowment, W.K. Kellogg Foundation and The Kresge Foundation.

EXECUTIVE SUMMARY

Ready or Not 2021

MARCH 2021

Executive Summary

The past year, 2020, will long be remembered as the year more than 2 million people lost their lives due to a global pandemic. Not since the 1918 influenza pandemic has a single event so urgently demonstrated the criticality of a strong public health system. This *Ready or Not* report has tracked the country's level of public health emergency preparedness since 2003. For nearly two decades, it has asked the fundamental question: "are we ready?" Unfortunately, the COVID-19 crisis has provided a clear answer: an emphatic "no."

The COVID-19 crisis has illuminated the urgent need for federal, state, local, tribal, and territorial leaders to take aggressive steps to shore up the nation's preparedness for all types of emergency events. The pandemic put a spotlight on a public health system hollowed-out by years of insufficient funding. Health departments were overstretched, responding to the pandemic with archaic technologies[1] and with overworked staff who faced threats and retribution.[2] These gaps were all the more critical in 2020 because the federal government failed to take an evidence based, leadership role in the pandemic response, with many decisions being left to states that would ordinarily be federally coordinated. It also demonstrated the harm that can be done when science and public health expertise are stifled by political interference and misinformation.

In addition, the pandemic has once again demonstrated and exacerbated the impact of structural racism, both historic and current, on the health and well-being of communities of color and Tribal Nations. Acknowledging the lingering health impacts of slavery and the treatment of native peoples and addressing current day racist policies, systems, and attitudes must be part of building the nation's resilience. In short, equity is not separate from preparedness. Ensuring an equitable opportunity for the health and well-being of all residents before a disaster creates more resilient communities during an emergency. Equity must be an explicit and foundational principle in all emergency planning. Achieving equity in all facets of emergency response requires including equity accountability metrics in emergency preparation and management.

MS-DOH-21-1816-A-000655

Foundational capabilities are necessary throughout the public health system, from the Centers for Disease Control and Prevention (CDC) to state, local, tribal, and territorial health departments, including:[3]

- Health monitoring and assessment, comprising surveillance, epidemiology, and laboratory capacity;
- All-hazards preparedness and response;
- Policy development and support;
- Public communications;
- Community outreach and partnership development;
- Organizational and administrative competencies (i.e., leadership, governance, and health equity); and
- Accountability and performance management.[4]

Today, only half of Americans are protected by a comprehensive local public health system.[5] The Public Health Leadership Forum estimates a $4.5 billion annual shortfall in the spending necessary to meet the infrastructure needs of public health agencies nationwide.[6] This shortfall was on display throughout the COVID-19 pandemic, as decades of chronic underfunding hindered communications, disease surveillance, contact tracing, vaccine delivery, and other key health department activities.

"A powerful aspect of this report is its long history objectively measuring states' preparedness. This year's recommendations are almost identical to past years. Had the nation paid more attention to pandemic threats and TFAH's commonsense and consistent recommendations, this country would be in a very different place today."

Shelley A. Hearne, DrPH
Johns Hopkins University Bloomberg School of Public Health

It is also important to note that the infusion of COVID-19 emergency funding was onetime funding—critical to the pandemic response but not a solution to the system's longtime underinvestment.

This report is designed to give policymakers at all levels of government actionable data and recommendations with which they can target policies and spending to strengthen their jurisdiction's emergency preparedness. The report's 10 key public health preparedness indicators give state officials benchmarks for progress, point out gaps within their states all-hazards preparedness, and provide data to compare states' performance against like jurisdictions. These data points, or ones similar to them, have been the focus of this report for over a decade and are meant to measure readiness for a broad set of health security threats. They are not tailored to an assessment of a given state's response to the COVID-19 pandemic, as widescale political, funding, economic, and social factors all influenced the virus impact and local responses. A state may do well in terms of its ranking in this report but poorly in its response to the COVID-19 pandemic—and vice versa. While no state has been spared, what seems to have mattered most in the pandemic response is a state's socioeconomic and racial profile, as well as the adherence of elected leaders and residents to evidence-based public health guidelines. The pandemic has illustrated that robust and sustained funding, elected officials' leadership, and federal-state coordination and planning are key to protecting Americans' health security. Moreover, there is no substitute at the state or local level for a strong federal response.

MS-DOH-21-1816-A-000656

COVID-19 AND EMERGENCY PREPAREDNESS: TRAGIC LESSONS

TFAH's *Ready or Not: Protecting the Public's Health from Diseases, Disasters and Bioterrorism* report has tracked the nation's readiness to respond to a public health emergency for nearly two decades. During that time, no event highlighted the critical importance of this report's purpose—measuring and promoting readiness to safeguard Americans' health during an emergency—to the degree the COVID-19 crisis has.

The COVID-19 pandemic is an on-the-ground, real-time measure of the nation's public health emergency response system—a test the federal government failed according to most public health experts. An October 2020 report by Columbia University Earth Institute's National Center for Disaster Preparedness estimated that the federal government's inadequate pandemic response led to between 130,000 and 210,00 avoidable deaths. The report submits that if the United States had implemented sufficient testing, earlier lockdowns, a national mask-wearing mandate, and provided federal guidance on social distancing, over 200,000 lives could have been saved.[7]

With a possible single exception (water system safety), all of the readiness indicators measured annually by this *Ready or Not* report played a role in jurisdictions' COVID-19 response. Seven were relevant to the effort to control the pandemic and save lives: (1) nurse licensure compact (allowing jurisdictions to borrow medical personnel when they need to surge capacity), (2) hospital participation in healthcare coalitions, (3) public health and emergency management accreditation, (4) public health funding, (5) access to paid time off, (6) flu vaccination rates (as a proxy for a community's vaccination infrastructure and receptivity), and (7) laboratory surge capacity. TFAH will continue to measure states on these indicators, as they play a central role in the standing-ready, public health protection capacity that every state needs.

The pandemic has also spotlighted a number of issues not currently measured by the report but critical and dramatically apparent if absent during a health emergency: federal and state political leadership, interagency coordination, consistent and well-executed public communications, and health equity.

Importance of Federal Leadership

Government at multiple levels shares responsibility for emergency planning and response. Under this tiered structure, when an event requires a larger response than a local entity can provide, government from the tier above it—typically a tribal, territorial or state agency—provides assistance. When a state's response resources are not enough to meet demands during an emergency, the federal government provides support. For a public health emergency as significant and contagious as COVID-19, clear communication and strong leadership and coordination by the federal government are essential, elements

MS-DOH-21-1816-A-000657

that were lacking during the initial months of the pandemic response. Instead, inconsistent messages between federal agencies and the White House; lack of centralized coordination, such as for procurement of personal protective equipment (PPE); and political interference with guidance from scientific agencies—all led to confusion and contradictory policies among states and weakened the emergency response.

TFAH has made a number of policy recommendations designed to ensure robust and nonpartisan federal leadership during future public health emergencies, including:

- Create a White House Health Security Directorate, including senior advisors to the president with public health expertise on health security issues. This directorate would oversee the national biodefense strategy and all interagency emergency responses.
- Ensure full transparency and consistency in federal messaging from the White House, CDC, ASPR, FDA, and National Institutes of Health (NIH) concerning public health issues to ensure message clarity, avoid confusion, and build trust.
- Ensure that federal public health officials are fully empowered to make decisions based on science and without undue political influence. Efforts to infuse politics into public health decision-making puts the public's health at risk.
- HHS should strengthen leadership by working with states and suppliers to ensure adequate stockpiling and distribution of medical countermeasures and ancillary emergency response products, such as personnel protective equipment.

Overcoming the Legacy of Racism

The legacy of slavery, genocide, and centuries of racism, combined with current day interpersonal and structural racism, is at the root of the disproportionate impact COVID-19 has had on communities of color and Tribal Nations. These systemic inequities, in access to healthcare, housing, education, transportation, and employment, existed before the pandemic and have been exacerbated by it. Health inequities due to disadvantages experienced by racial, ethnic, or other population groups are preventable differences in the burden of disease, injury, and health emergencies and to opportunities to achieve good health.[8] Addressing issues at the root of health inequity is imperative to ensuring all people, regardless of their race or ethnicity or where they live, have the opportunity for good health and are protected during a health emergency.

TFAH has called on the administration and Congress to make advancing health equity and eliminating health disparities a national priority by:

- Ensuring that all COVID-19 response actions prioritize advancing health equity, including access to COVID-19 testing and vaccinations.
- Creating a Truth, Racial Healing, and Transformation Commission, and provide funding to communities to begin the process of acknowledging a history of racism and working to dismantle the myth of hierarchy based on race.
- Expanding funding for initiatives serving communities that have been marginalized by disinvestment, and ensure that federal funding supports processes that meaningfully engage the most affected communities in the planning and implementation of such initiatives.
- Developing a White House led strategy focused on addressing the root causes of disease and on promoting health equity.
- Creating a *social determinants of health* line item at the Centers for Disease Control and Prevention (CDC), authorized and fully funded by Congress, with sufficient funding to guarantee grant-funded efforts throughout the nation.
- Requiring all agencies to collect, disaggregate, and report health data in such a way that the impact of health conditions, policies, or interventions on specific population groups are known, including health status data by race, ethnicity, sexual orientation, gender identity, primary language, and disability status.

The tragedy of the COVID-19 pandemic, including over 500,000 deaths in the United States (as this publication was being prepared) and unprecedented harm to the economic security of millions of American families, will forever be a painful reminder of the critical importance of pre-event public health emergency preparations, investments in public health infrastructure, and evidence-based policy and communications. The pandemic has undeniably demonstrated that historical discrimination coupled with current-day racism impacts a community's health status and ability to weather a disaster. The COVID-19 crisis has also painfully reinforced that national leadership must be grounded in science and committed to addressing structural racism, both of which are imperative to saving lives during an emergency.

MS-DOH-21-1816-A-000658

This edition of the *Ready or Not series* finds that states have made progress in most of the report's measured areas, especially rates of seasonal flu vaccination. However, improvement in other areas—such as paid time off for workers and hospital patient safety—has stalled. In this 2021 report, Trust for America's Health (TFAH) found that three states improved their standing compared with last year, while eight fell behind. Three states improved by one tier, six states dropped one tier, and two dropped two tiers.

TABLE 1: Top-Priority Indicators of State Public Health Preparedness

INDICATORS			
1	**Incident Management:** Adoption of the Nurse Licensure Compact.	6	**Water Security:** Percentage of the population that used a community water system that failed to meet all applicable health-based standards.
2	**Cross-Sector Community Collaboration:** Percentage of hospitals participating in healthcare coalitions.	7	**Workforce Resiliency and Infection Control:** Percentage of employed population that used paid time off.
3	**Institutional Quality:** Accreditation by the Public Health Accreditation Board.	8	**Countermeasure Utilization:** Percentage of people ages 6 months or older who received a seasonal flu vaccination.
4	**Institutional Quality:** Accreditation by the Emergency Management Accreditation Program.	9	**Patient Safety:** Percentage of hospitals with a top-quality ranking ("A" grade) on the Leapfrog Hospital Safety Grade.
5	**Institutional Quality:** Size of the state public health budget compared with the past year.	10	**Health Security Surveillance:** The public health laboratory has a plan for a six- to eight-week surge in testing capacity.

Notes: The National Council of State Boards of Nursing organizes the Nurse Licensure Compact. The federal Hospital Preparedness Program of the U.S. Office of the Assistant Secretary for Preparedness and Response supports healthcare coalitions. The U.S. Environmental Protection Agency assesses community water systems. Paid time off includes sick leave, vacation time, or holidays, among other types of leave. The Leapfrog Group is an independent nonprofit organization. TFAH drew every indicator, and some categorical descriptions, from the National Health Security Preparedness Index, with one exception: public health funding. See "Appendix A: Methodology" for a description of TFAH's funding data-collection process, including its definition.

Source: National Health Security Preparedness Index [9]

The *Ready or Not* report groups states and the District of Columbia into one of three tiers (high, middle, low) based on their performances across the 10 indicators. This year, 20 states and the District of Columbia scored in the high-performance tier, 15 placed in the middle-performance tier, and 15 were in the low-performance tier (see Table 2). (See "Appendix A: Methodology" for more information on the scoring process.)

Three states showed notable improvement, moving up a tier: Georgia, Montana, and Rhode Island. Georgia, which rose from the middle tier to the high tier, improved its standing by achieving accreditation by the Emergency Management Accreditation Program and by having a greater share of its hospitals receive high marks on patient safety. Montana, which elevated from the low tier to the middle tier, increased its public health funding level in fiscal year 2020. And Rhode Island, which rose from the middle tier to the high tier, did so by dramatically increasing its community drinking-water security.

Two states fell from the high tier to the low tier: Missouri and Pennsylvania. Missouri cut its public health funding in FY 2020 and saw an increase in the share of its residents that used a community water system with one or more health-based violations. Its flu vaccination rate ticked up marginally, but by less than the nation as a whole. Likewise, Pennsylvania also cut its public health funding level, and its share of hospitals that received an "A" rating—one of the highest in the nation—rose by slightly less than the national average. Other steps it could take to improve its standing include joining the Nurse Licensure Compact or increasing its below-average share of residents who take paid time off from work.

Five states fell from the high tier to the middle tier: Alabama, Illinois, Iowa, New Jersey, and Tennessee. These states did not experience significant backsliding overall, but they lost ground, as a number of other states took greater steps that increased their standing.

One state fell from the middle tier to the low tier: Arizona. Arizona's below-average flu vaccination rate rose, but by less than the nation overall, so its overall standing fell back.

MS-DOH-21-1816-A-000659

TABLE 2: State Public Health Emergency Preparedness State performance, by scoring tier, 2020		
Performance Tier	**States**	**Number of States**
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

Note: See "Appendix A: Methodology" for scoring details. Complete data were not available for U.S. territories.

TFAH's Analysis Found:

A majority of states have made preparations to expand healthcare and public health capabilities in an emergency, often through collaboration. Thirty-four states participated in the Nurse Licensure Compact, up from 26 in 2017,[10] with Indiana and New Jersey being the most recent adopters.[11] The compact allows registered nurses and licensed practical or vocational nurses to practice in multiple jurisdictions with a single license. In an emergency, this enables health officials to quickly increase their staffing levels. For example, nurses may cross state lines to work at evacuation sites or other healthcare facilities. In addition, **hospitals in most states have a high degree of participation in healthcare coalitions.** On average, 89 percent of hospitals were in a coalition, and 17 states and the District of Columbia had universal participation, meaning every hospital in the jurisdiction was part of a coalition. Such coalitions bring hospitals and other healthcare facilities together with emergency management and public health officials to plan for and respond to incidents or events requiring extraordinary action. This increases the likelihood that providers serve patients in a coordinated and efficient manner during an emergency. What's more, **every state had public health laboratories that had plans for how to manage a large influx of testing needs.** States had a plan to surge public health laboratory capacity for six to eight weeks as necessary during overlapping emergencies or large outbreaks, an increase of six states since 2017.

Most states are accredited in the areas of public health, emergency management, or both. As of December 2020, the Public Health Accreditation Board (PHAB) or the Emergency Management Accreditation Program (EMAP) accredited 42 states and the District of Columbia; 29 states and the District of Columbia were accredited by both groups, a net increase of one since November 2019. (EMAP has now accredited Delaware and Georgia; Maryland transitioned from being accredited by both bodies to the PHAB only, with the EMAP providing conditional accreditation.) Eight states (Alaska, Hawaii, Indiana, New Hampshire, South Dakota, Texas, West Virginia, and Wyoming) were not accredited by either group. Both programs help ensure that necessary emergency prevention and response systems are in place and staffed by qualified personnel.

MS-DOH-21-1816-A-000660

Seasonal flu vaccination rates, while still too low, have risen significantly. The seasonal flu vaccination rate among Americans ages 6 months or older rose from 42 percent during the 2017–2018 season to 52 percent during the 2019–2020 season.[12] However, *Healthy People 2030*, a set of federal 10-year objectives and benchmarks for improving the health of all Americans by 2030, set a seasonal influenza vaccination-rate target of 70 percent annually.[13]

In 2019, only 55 percent of employed state residents, on average, used paid time off, the same percentage as in 2018. Those without paid leave are more likely to work when they are sick and risk spreading infection. In the past, the absence of dedicated paid sick leave has been linked to or has exacerbated some infectious disease outbreaks.[14] This became particularly relevant during the COVID-19 pandemic, as isolation and quarantine were important tools for controlling the outbreak. The Families First Coronavirus Response Act helped address this issue during the early stages of the pandemic for employers with fewer than 500 employees and certain public employers, temporarily requiring employees to be paid up to 80 hours of sick leave benefits under certain conditions.[15] In January 2021, the Biden administration economic stimulus package proposal included extending paid sick leave to over 100 million U.S. workers.

Only 31 percent of hospitals, on average, earned a top-quality patient safety grade, up slightly from 30 percent in 2019. Hospital safety scores measure performance on such issues as healthcare-associated infection rates, intensive-care capacity, and an overall culture of error prevention. In January 2021, the Biden administration's economic aid package included extending paid sick leave to over 100 million U.S. workers.

Most residents who received their household water through a community water system had access to safe water. On average, just 5 percent of state residents used a community water system in 2019 (latest available data) that did not meet all applicable health-based standards, down slightly from 7 percent in 2018. Water systems with such violations increase the chances of water-based emergencies in which contaminated water supplies place the public at risk.

Based on its policy research and analysis, consultation with experts, and review of progress and gaps in federal and state preparedness—with a particular focus on the preparation gaps and shortfalls identified by the COVID-19 pandemic—**TFAH is recommending policy action in seven priority areas:**

1. **Provide stable, sufficient funding for domestic and global public health security.**
2. **Strengthen policies and systems to prevent and respond to outbreaks and pandemics.**
3. **Build resilient communities and promote health equity generally and in preparedness.**
4. **Ensure effective public health leadership, coordination, and workforce.**
5. **Accelerate development and distribution, including last-mile distribution, of medical countermeasures.**
6. **Strengthen the healthcare system's ability to respond to and recovery from health emergencies.**
7. **Prepare for environmental threats and extreme weather.**

MS-DOH-21-1816-A-000661

Report Purpose and Methodology

TFAH's annual *Ready or Not* report series tracks states' readiness for public health emergencies based on 10 key indicators that collectively provide a checklist of top-priority issues and action items for states and localities to continuously address. By gathering together timely data on all 50 states and the District of Columbia, the report assists states in benchmarking their performance against comparable jurisdictions. TFAH completed this research after consultation with a diverse group of subject-matter experts and practitioners.

Ready or Not and the National Health Security Preparedness Index

The indicators included in this report were drawn from, and identified in partnership with, the National Health Security Preparedness Index (NHSPI),[16] with one exception: a measure of state public health funding-level trends, which reflects how well-resourced key agencies are to prepare and respond to emergencies. The NHSPI is a joint initiative of the Robert Wood Johnson Foundation, the University of Kentucky, and the University of Colorado. (See "Appendix A: Methodology" for a detailed description of how TFAH selected and scored the indicators.)

While state placements in *Ready or Not* and the NHSPI largely align, there are some important differences. The two projects have somewhat different purposes and are meant to be complementary, rather than duplicative. With more than 100 indicators, the Index paints a broad picture of national health security, allowing users to zoom out and holistically understand the extent of both individual states' and the entire nation's preparedness for large-scale public health threats. In slight contrast, *Ready or Not,* with its focus on 10 select indicators, focuses attention on state performances on a subset of the Index and spotlights important areas for stakeholders to prioritize. TFAH and the NHSPI work together to help federal, state, and local officials use data and findings from each project to make Americans safer and healthier.

MS-DOH-21-1816-A-000662

Earning Vaccine Confidence in Communities of Color

Interview with Claude A. Jacob, Dr.PH(c), MPH, the chief public health officer at the Cambridge, Massachusetts, Public Health Department, and **Maria Lemus,** the executive director of Visión y Compromiso, about barriers—both historic and contemporary—to COVID-19 vaccinations within communities of color. This interview was conducted in December 2020.

TFAH: As this report is being finalized, the United States is nearing a time when many Americans, particularly those at the highest risk of infection or the most serious impact if infected, can be vaccinated. What are the barriers to high rates of vaccination in communities of color and among Tribal nations?

Dr. Jacob: We are fortunate in Cambridge. Flu vaccine participation is strong and childhood vaccine compliance is also very high, which we view as rough proxies for COVID-19 vaccine acceptance. That being said, there is a long and sordid history of abuse and mistreatment of these communities by the U.S. government and healthcare system. That many Black and Brown people continue to feel deep mistrust of the healthcare system is understandable. All of us in healthcare and public health must understand that this mistrust goes back to slavery for Black Americans and the genocide perpetuated against indigenous people that lasted for centuries.

We have strong relationships with community organizations, leaders in the faith community, and others who are well known and trusted among communities of color, and we will partner with them to overcome these barriers to vaccine uptake. Recent national and state surveys have told us that Americans view their personal physician as the most trusted voice on COVID-19. Given this finding, we plan to work closely with our hospitals, ambulatory sites, and healthcare providers to help spread the message.

Ms. Lemus: There are many barriers. The ones I'm most concerned about are myths and misinformation, including crazy social media propaganda, fear of adverse reactions, and problems with vaccine accessibility. High rates of the uninsured among some populations groups and misconceptions about who is at risk are additional concerns.

TFAH: The pace of COVID-19 vaccines development has been quicker than many people expected. In some communities this may mean that the vaccine will be available before communications programs about the vaccine's safety and availability have fully taken root. What do those responsible for vaccine distribution need to do when distributing the vaccine under these circumstances?

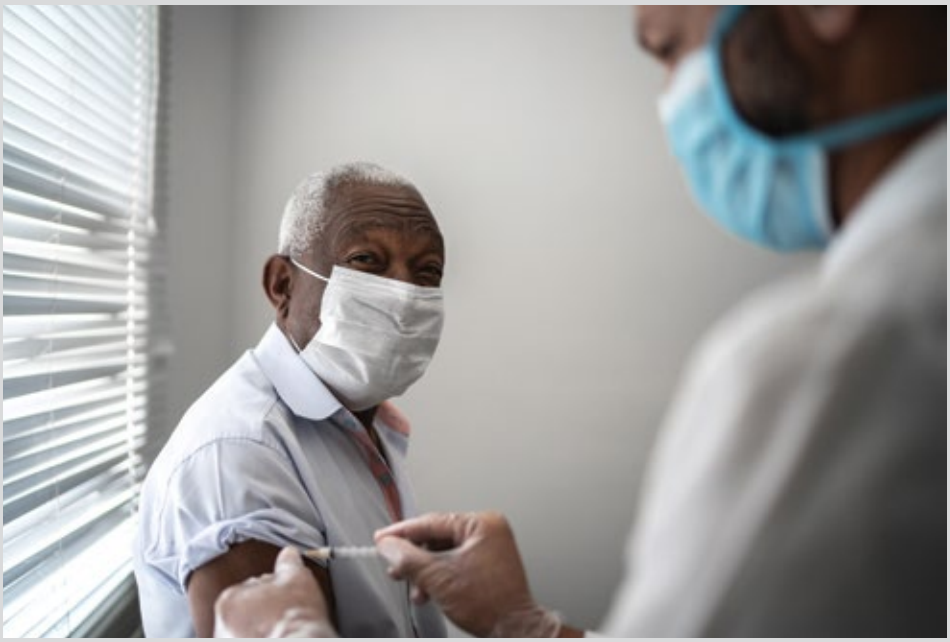
Dr. Jacob: First of all, we need to celebrate the news that, so far, two vaccines have received FDA emergency use authorization. That two vaccines were developed, tested, and manufactured in less than 12 months is a breathtaking achievement. While we can't let down our guard on physical distancing, wearing masks,

MS-DOH-21-1816-A-000663

and continuing to practice good hand hygiene, the COVID-19 vaccine marks a watershed moment in the pandemic. We now see the light at the end of the tunnel. At the same time, it's understandable that people have many questions and deep concerns given how quickly the vaccine was developed and approved. For communities of color, the concern over safety comes with a long-standing, entrenched, and well-placed mistrust of the healthcare system.

Communication will be pivotal in educating everyone, especially communities of color, about the safety and importance of this vaccine. To start, we need to have communities of color and physicians of color at the decision-making table to inform and ensure a vaccine rollout that is equitable for all members of our community. Messaging around the vaccine also needs to be informed by, and tested with, communities of color to make sure that these communication efforts resonate. We have a superb opportunity to work with those on the front line of this pandemic, especially doctors, nurses, and physicians' assistants, to help amplify the message in core communities. By all accounts, frontline medical workers are the most trusted source of health information and they are the first to be vaccinated, starting this past December. We should use their voices of trust and reason to speak to communities of color about the safety and critical importance of getting this vaccine.

Ms. Lemus: It will be imperative to share data about the vaccine without jargon and to have trusted messengers deliver the information. I heard a quote recently in response to the question, "Do you know what's in Tylenol?": "No, but I trust it will help me."



TFAH: A woeful history of mistreatment of people of color by government and the healthcare system is at the root of much of the lack of trust in the COVID-19 vaccine within those communities but there are other barriers to vaccine access. What are they and how can they be overcome?

Ms. Lemus: The understandable distrust of government is going to be a huge barrier to the vaccine. A specific example for my community is the Bracero Program, which between 1942 and 1964, based on a series of bilateral agreements between the U.S. and Mexican governments, brought nearly 4.6 million Mexican citizens to work on U.S. farms, railroads, and factories. Those workers experienced racial and wage discrimination and were forced to live and work in substandard conditions. More recently, there have been allegations of unnecessary hysterectomies being performed in ICE detention centers.

The only way to overcome these histories will be to first acknowledge them. Leaders must acknowledge and speak to these injustices; they must denounce them and support remedies. They need to give real-time examples of the efforts being made to engage with and empower communities and to correct past wrongs. Only then will government be able to be heard and only by using trusted messengers and community navigators.

It's also important to remember that the reasons for distrust of government within underrepresented communities is not only about historical legacies; it is based on current-day events and climates. However, it can be corrected. My organization, Visión y Compromiso, has as its mission providing leadership-development and capacity-building opportunities for *promotores* and community health workers in over 4,000 communities. These community-based *promotores* will have a critical role to play in reducing vaccine hesitancy in communities of color. Messaging to convince people to be vaccinated has to feature their heroes, their community leaders, their voices.

MS-DOH-21-1816-A-00664

Dr. Jacob: Communities of color have historically had difficulty accessing healthcare. Lack of transportation, work schedules, childcare needs, and competing financial interests—such as paying rent and bills—pose significant barriers to healthcare, as do other social determinants of health, such as poverty and lack of education. Even with the Affordable Care Act—which greatly expanded access to health insurance for everyone—Hispanic, Black, and some Asian communities have lower insurance coverage rates than any other population. Many of them remain uninsured altogether.

The cost of the vaccine is being covered by the federal government through tax dollars, but providers can charge to administer the vaccine, if they choose. We need to do everything we can and work with providers to eliminate fees they may charge in the interest of overcoming this public health emergency. When it is available, we need to bring the vaccine to the public rather than making people come to the vaccine. In Cambridge, the public health department, through its partnership with the city's first-responders and others, have made free COVID-19 testing available to all residents (regardless of symptoms) since July 2020. Starting in November 2020, this "no-barrier," city-funded testing program expanded to seven days a week (from two days/week) and from two neighborhood sites to four. These testing sites are geographically dispersed, and all but one are located in neighborhoods with disproportionately high rates of new COVID-19 infections.

TFAH: What is the importance of where the COVID-19 vaccine is available in your community?

Ms. Lemus: Where the vaccine will be available is another critical issue. The credibility, location, hours, accessibility, relationship to community, their staff, and emissaries are important to individual and families' decision to be vaccinated. *Promotores* are important also in gathering information to contribute to the vaccine distribution and administration, planning implementation, and communications. Community-based organizations must be included in all planning and execution; they are a big part of the solution. Partnering with community-based organizations allows local officials to scale means and resources.

Dr. Jacob: As I have already mentioned, the Cambridge Public Health Department has had enormous success with COVID-19 testing and flu vaccinations by bringing these services to people in the communities where they live and work. We have taken a traditional grassroots approach—going door to door in harder-hit neighborhoods and providing information in eight languages—to build trust and understanding. We need to use this same approach with the COVID-19 vaccine and build on these robust community linkages, which are anchored to the long-standing relationships that we have with partners on the ground.

TFAH: As the chief public health officer for the city of Cambridge, Massachusetts, what is your department's role in increasing vaccine uptake in your community? What resources do you need to be successful?

Dr. Jacob: Local public health has an important role and responsibility in educating communities about the safety and importance of the COVID-19 vaccine, as it does with all vaccinations. Once the vaccine is made available to the general public, the Cambridge Public Health Department, through its partnership with city agencies and the private sector, will be ready to provide vaccines to residents. Throughout the pandemic, our department has worked hand in hand with city partners, especially first-responders, to provide testing and flu shots, and we will rely on this strong, successful relationship to provide the COVID vaccine. It is critically important to note that we could not do our work without strong financial support. Our city manager, Louis A. DePasquale, and the Cambridge City Council have provided financial resources to fight this pandemic and keep our residents and those who work in Cambridge safe. They have long been committed to the important work of the public health department, which is enhanced by the Cambridge Health Alliance led by Dr. Assaad Sayah, who is the commissioner of public health for the city of Cambridge.

Dr. Claude A. Jacob is the chief public health officer for the City of Cambridge, Massachusetts. He served as the president of the National Association of City and County Health Officials in 2016–2017.

Maria Lemus is the executive director of Visión y Compromiso, headquartered in San Francisco, California. Visión y Compromiso provides leadership, advocacy, and capacity-development training to community health workers.

MS-DOH-21-1816-A-000665

Assessing State Preparedness

Every state needs to be prepared to respond to a variety of potential public health emergencies; such readiness requires understanding an individual state's preparedness strengths, risks, and vulnerabilities. To help states assess their readiness, and to highlight a checklist of top-priority concerns and action areas, this report examines a set of 10 select indicators. The indicators, used consistently year to year, draw heavily from the National Health Security Preparedness Index (NHSPI), a joint initiative of the Robert Wood Johnson Foundation, the University of Kentucky, and the University of Colorado. They capture core elements of emergency preparedness.

Based on states' standing across the 10 indicators (see "Appendix A: Methodology" for scoring details), TFAH placed states into three performance tiers: high, middle, and low. (See Table 3.)

TABLE 3: State Public Health Emergency Preparedness
State performance, by scoring tier, 2020

Performance Tier	States	Number of States
High Tier	CO, CT, DC, DE, GA, ID, KS, MA, MD, ME, MS, NC, NE, NM, OK, RI, UT, VA, VT, WA, WI	20 states and DC
Middle Tier	AL, CA, FL, IA, IL, KY, LA, MI, MN, MT, ND, NJ, OR, TN, TX	15 states
Low Tier	AK, AR, AZ, HI, IN, MO, NH, NV, NY, OH, PA, SC, SD, WV, WY	15 states

Note: See "Appendix A: Methodology" for scoring details. Complete data were not available for U.S. territories.

Importantly, the implications of this assessment, and responsibility for continuously improving, extend beyond any one state or local agency. Such improvement typically requires sustained engagement and coordination by a broad range of policymakers and administrators. Moreover, some indicators are under the direct control of federal and state lawmakers, whereas improvement in other indicators requires multisector, statewide efforts, including by residents.

MARCH 2021

MS-DOH-21-1816-A-000666

INDICATOR 1: ADOPTION OF NURSE LICENSURE COMPACT

KEY FINDING: 34 states participate in the Nurse Licensure Compact.

Workforce shortages can impair a state's ability to effectively manage disasters or disease outbreaks, potentially resulting in poorer health outcomes for those affected. This reality was starkly illuminated by the COVID-19 pandemic as healthcare capacity in some parts of the country was overwhelmed by the number of people needing care. In an event like a pandemic, the ability to quickly surge qualified medical personnel by bringing healthcare workers from out of state is a key component of healthcare readiness.

This indicator examines whether states have adopted legislation to participate in the Nurse Licensure Compact (NLC). Launched in 2000 by the National Council of State Boards of Nursing, the NLC permits registered nurses and licensed practical nurses to practice with a single multistate license—physically or remotely—in any state that has joined the compact. The NLC provides standing reciprocity, with no requirement that an emergency be formally declared.

Throughout much of 2020, the COVID-19 pandemic placed extraordinary pressure on hospitals across the country as surging infections sent admissions soaring. States that were members of the NLC were well positioned to bring in nurses from other member states, without harmful delays, or to send nurses to other member states that were experiencing acute shortages. For example, New Jersey, which experienced one of the most severe outbreaks in spring 2020, began implementing the NLC, immediately qualifying out-of-state nurses with a multistate license to practice.[17] "I think the COVID-19 outbreak is going to cause the states that are not in the compact now to really take a second look at it," says NLC Director Jim Puente. "If the NLC was expanded to all 50 states, none of the guesswork with emergency orders would be necessary because nurses could travel to other states where they are needed. No applications, fees, or background checks would be necessary."

As of December 2020, 34 states had adopted the NLC, with Indiana and New Jersey being the most recent adopters.[18] This was a net increase of two since 2019 and eight since 2017. Toni Herron, the education compliance officer of the Indiana State Board of Nursing, which joined the compact on July 1, 2020, said that the NLC "presents innovative ways for our Indiana nurses to improve both access to care for patients, while simultaneously reducing the regulatory burden on licensees." [19]

MS-DOH-21-1816-A-000667

MS-DOH-21-1816-A-000668

INDICATOR 2: HOSPITAL PARTICIPATION IN HEALTHCARE COALITIONS

KEY FINDING: Widespread hospital participation in healthcare coalitions was common in 2017*; only four states (California, New Hampshire, Ohio, and South Carolina) reported 70 percent or less of their hospitals participated in coalitions supported by the HHS Hospital Preparedness Program.

The federal Hospital Preparedness Program (HPP), which is managed by the HHS Office of the Assistant Secretary for Preparedness and Response, provides cooperative agreements to states, localities, and territories to develop regional coalitions of healthcare organizations that collaborate to prepare for, and in many cases respond to, medical surge events.[21] Coalitions prepare members with critical tools, including medical equipment and supplies, real-time information, enhanced communication systems, and exercises and training for healthcare personnel.[22] A healthcare coalition must contain a minimum of two acute-care hospitals, emergency medical services, emergency management, and public health agencies.[23] Healthcare coalitions invest in local capacity to prepare for and respond to events, reducing jurisdictions' reliance on federal medical assets during disasters.

Broad and meaningful participation by hospitals in healthcare coalitions means that when disaster strikes, systems are in place to coordinate the response, freeing hospitals to focus on clinical care. In the past, healthcare coalitions have assisted in patient transfer, evacuations, and information sharing in events such as Hurricane Harvey in 2017.[24] More recently, the COVID-19 pandemic presented the most intense, widespread, and prolonged test of U.S. hospital systems in a century, threatening at several points to overwhelm facilities' capacities. Healthcare coalitions performed roles such as facilitating the transport of equipment and supplies, sharing information about available beds and ICU capacity, and training healthcare workers on PPE use, treatments, and testing guidelines.[25] During a pandemic, coordination across a region is essential to alleviate pressure on any single facility, to promote cooperation and information sharing for supplies and bed availability, and to facilitate training of healthcare personnel.[26] The extent to which healthcare systems leveraged the resources of their coalitions during the pandemic is a subject that requires further research.

On average, 89 percent of hospitals in states belonged to a healthcare coalition in 2017, with universal participation, meaning every hospital in the state was part of a coalition, in 17 states (Alaska, Colorado, Connecticut, Delaware, Hawaii, Louisiana, Minnesota, Mississippi, Nevada, North Dakota, Oregon, Rhode Island, South Dakota, Utah, Vermont, Virginia, and Washington) and the District of Columbia. (See Table 5.) However, some states, such as Ohio (25 percent) and New Hampshire (47 percent) lagged behind.

The pandemic exposed major gaps in healthcare preparedness, mentioned in TFAH's 2020 report, including coordinating surge capacity across the healthcare system;[27] building and maintaining preparedness for high-consequence infectious diseases;[28] preparedness of facilities that serve people at higher risk, such as long-term care facilities; and lack of training and preparedness for events in healthcare.[29] Experts have also identified additional gaps, such as pediatric surge capacity,[30] burn capacity and other specialty

MS-DOH-21-1816-A-000669

care needed for emerging threats, and ongoing stress on the healthcare system's ability to provide emergency care. While healthcare coalitions can help address some of these vulnerabilities, systemwide approaches to preparedness are needed.

**This summary reflects the latest available data (2017). Because these data are no longer being updated, TFAH will consider replacing this measure in future assessments.*

TABLE 5: Widespread Participation of Hospitals in Healthcare Coalitions

Percent of hospitals participating in healthcare coalitions, 2017

States	Percent of Participating Hospitals
AK, CO, CT, DC, DE, HI, LA, MN, MS, NV, ND, OR, RI, SD, UT, VT, VA, WA	100%
ID, WI	98%
GA, WV	97%

MS-DOH-21-1816-A-000670

INDICATORS 3 AND 4: ACCREDITATION

KEY FINDING: Most states are accredited by one or both of two well-regarded bodies—the Public Health Accreditation Board and the Emergency Management Accreditation Program—but eight are not accredited by either.

The Public Health Accreditation Board (PHAB), a nonprofit organization that administers the national public health accreditation program, advances quality within public health departments by providing a framework and a set of evidence-based standards against which they can measure their performance. Among standards with direct relevance to emergency preparedness are assurances of laboratory, epidemiologic, and environmental expertise to investigate and contain serious public health problems, policies, and procedures for urgent communications and maintenance of an all-hazards emergency operations plan.[32] Through the process of accreditation, health departments identify their strengths and weaknesses, increase their accountability and transparency, and improve their management processes, which all promote continuous quality improvement.[33]

Emergency management, as defined by the Emergency Management Accreditation Program (EMAP), encompasses all organizations in a given jurisdiction with emergency or disaster functions, which may include prevention, mitigation, preparedness, response, and recovery. The EMAP helps applicants ensure—through self-assessment, documentation, and peer review—that they meet national standards for emergency response capabilities.[34]

The PHAB and the EMAP each provide important mechanisms for improving evaluation and accountability. Accreditation by these entities demonstrates that a state's public health and emergency management systems are capable of effectively responding to a range of health threats. The priority capabilities that the PHAB and the EMAP test include identification, investigation, and mitigation of health hazards; a robust and competent workforce; incident, resource, and logistics management; and communications and community-engagement plans.[35,36] States sometimes aim to meet applicable standards but do not pursue accreditation.

As of December 2020, 29 states and the District of Columbia were accredited by both the PHAB and the EMAP—a net increase of one (Delaware and Georgia are now accredited by the EMAP; Maryland transitioned from being accredited by both bodies to the PHAB only, with the EMAP providing conditional accreditation) since November 2019. Nevada is once again accredited by the EMAP, alongside an additional 12 states that have received accreditation from one or the other. (See Table 6.) "Over the last eighteen months we have worked diligently to review our processes, plans, and relationships," said the director of Delaware's Emergency Management Agency, A.J. Schall. "Over that time, we learned a tremendous amount and modernized procedures."[37]

Just eight states (Alaska, Hawaii, Indiana, New Hampshire, South Dakota, Texas, West Virginia, and Wyoming) received no accreditation from either body. A state without an accreditation has not necessarily been denied accreditation; the state may not have pursued accreditation. This analysis includes state-level accreditations only, it does not include accredited local or tribal health departments. In some instances, local public health departments have an accreditation in states that do not.

MS-DOH-21-1816-A-000671

TABLE 6: 42 States and the District of Columbia Accredited by the PHAB and/or EMAP

Accreditation status by state, December 2020

PHAB and EMAP			PHAB only	EMAP only	No Accreditation
Alabama	Idaho	New Mexico	Maine	Kentucky	Alaska
Arizona	Illinois	New York	Maryland	Michigan	Hawaii
Arkansas	Iowa	North Dakota	Minnesota	Nevada	Indiana
California	Kansas	Ohio	Montana	North Carolina	New Hampshire
Colorado	Louisiana	Oklahoma	Oregon	South Carolina	South Dakota
Connecticut	Massachusetts	Pennsylvania	Washington	Tennessee	Texas
Delaware	Mississippi	Rhode Island		Virginia	West Virginia
District of Columbia	Missouri	Utah			Wyoming
Florida	Nebraska	Vermont			
Georgia	New Jersey	Wisconsin			
29 states + DC			**6 states**	**7 states**	**8 states**

Note: These indicators track accreditation by the PHAB and the EMAP. TFAH classified states with conditional or pending accreditation at the time of data collection as having no accreditation. States sometimes aim to meet applicable standards but do not pursue accreditation.

MS-DOH-21-1816-A-000672

INDICATOR 5: STATE PUBLIC HEALTH FUNDING TRENDS

Key Finding: Most states held their public health funding steady or increased it in FY 2020, but seven reduced funding.

The COVID-19 pandemic showed how sufficient and sustained funding for a comprehensive public health system is integral to preparedness and response, including the ability to detect, prevent, and control disease outbreaks and mitigate the health consequences of disasters. General public health capabilities—such as those pertaining to epidemiology, environmental hazard detection and control, infectious disease prevention and control, and risk communications—and targeted emergency response resources are necessary to ensure that officials maintain routine capabilities and that surge capacity is readily available for emergencies. A trained and standing public health workforce, and one that knows its community, is critical to the surge capacity that is so often necessary during an emergency.

According to the Public Health Activities and Services Tracking project at the University of Washington, state public health programming and services span six core areas:[39]

1. **Communicable disease control.** Public health services related to communicable disease epidemiology, hepatitis, HIV/AIDS, immunization, sexually transmitted diseases, tuberculosis, etc.
2. **Chronic disease prevention.** Public health services related to asthma, cancer, cardiovascular disease, diabetes, obesity, tobacco, etc.
3. **Injury prevention.** Public health services related to firearms, motor vehicles, occupational injuries, senior fall prevention, substance-use disorder, other intentional and unintentional injuries, etc.
4. **Environmental public health.** Public health services related to air and water quality, fish and shellfish, food safety, hazardous substances and sites, lead, onsite wastewater, solid and hazardous waste, zoonotic diseases, etc.
5. **Maternal, child, and family health.** Public health services related to the coordination of services; direct service; family planning; newborn screening; population-based maternal, child, and family health; supplemental nutrition; etc.
6. **Access to and linkage with clinical care.** Public health services related to beneficiary eligibility determination, provider or facility licensing, etc.

The overall infrastructure of public health supports states' ability to promote health equity, build resilience in the population, and carry out emergency response activities. But public health funding is typically discretionary, making it vulnerable to neglect or retrenchment, especially when times are tight. This can undermine emergency preparedness activities and weaken response and recovery efforts. State investment in public health is important for the operations of health agencies: about 28 percent of state and territorial health department revenues are from state sources,[40] while 21 percent of local health department revenue is from state sources, on average.[41]

Fortunately, 43 states and the District of Columbia maintained or increased public health funding in FY 2020. (See Table 7.) But seven states reduced the money they directed to these vital activities, increasing the likelihood that they will be less prepared and less responsive in the moments that matter most. (This indicator does not assess the adequacy of states' public health funding. It should also be noted that due to inflation and population growth, stable funding is in some cases a funding reduction.) The COVID-19 economic recession has already had a severe impact on state revenue,[42] which could constrain state public health funding levels over the coming years.

MS-DOH-21-1816-A-000673

TABLE 7: State Public Health Funding Held Stable or Increased in 43 states and DC

Public Health Funding, by state FY 2019 – 2020

State	Percentage Change
Alabama	-4%
Alaska	118%
Arizona	52%
Arkansas	-2%
California	40%
Colorado	9%

floridastock

Note: While states received federal one-time COVID response funding, those funds are not included in these tallies, as all federal funds are excluded from this measure. However, in some cases, state funding for pandemic response may have been included in the data reported to TFAH. For some states, COVID response funding may have resulted in an increase in the state's overall public health expenditure for the year. Other states may have reallocated money from one line to another with little impact on the overall funding level.

Owing to differences in organizational responsibilities and budgeting, funding data are not necessarily comparable across states. See "Appendix A: Methodology" for a description of TFAH's data-collection process, including its definition of public health funding.

Source: TFAH analysis of states' publicly available funding data.

MS-DOH-21-1816-A-000674

INDICATOR 6: COMMUNITY WATER SYSTEM SAFETY

KEY FINDING: Few Americans drink from community water systems that are in violation of applicable health-based standards required by the Safe Drinking Water Act. But room for improvement remains.

Access to safe water is essential for consumption, sanitation, and the efficient operation of the healthcare system. In the United States, the vast majority of the population gets water from a public water system,[43] and the U.S. Environmental Protection Agency (EPA) sets legal limits on contaminants in drinking water, including microorganisms, disinfectants, and their byproducts, chemicals, and radionuclides;[44] the EPA also requires states to periodically report drinking-water quality information.[45] Water systems must report any violations, such as failing to follow established monitoring and reporting schedules, failing to comply with mandated treatment techniques, violating any maximum contaminant levels, and failing to meet customer-notification requirements.[46]

The United States has one of the safest public drinking-water supplies in the world, but some communities, particularly low-income communities, struggle to maintain constant access to safe water. When water safety issues occur, it can require a multisector emergency response, as well as a long-term public health response. The most prominent water-contamination crisis in recent years occurred in Flint, Michigan, where a 2014 change in water supply caused distribution pipes to corrode and to leach lead and other contaminants into the drinking water. Tens of thousands of residents, including young children, were exposed to high levels of lead and other toxins.[47] In 2019, residents of Newark, New Jersey, had to rely on bottled water due to high levels of lead in their tap water.[48] In children, even low levels of lead exposure can damage the nervous system and contribute to developmental delays, learning disabilities, weight and hearing loss.[49] These incidents could have long-term consequences on the health and brain development of children, as well as the mental health and trust of the community.

As climate change contributes to more frequent wildfires, a residual danger is the release of toxic chemicals into community water systems. For example, months after the deadly Camp Fire in Paradise, California, in 2018, experts still advised residents not to drink or cook with the water due to concerns about benzene contamination.[50,51] Among the health effects of long-term exposure to unsafe levels of benzene is a decrease in red blood cells, which can lead to anemia. It can also cause excessive bleeding and can affect the immune system, increasing the chance for infection.[52]

Other water-related emergencies and concerns in the United States include harmful algal blooms,[53] which can impact human and animal health, the safety of seafood, damage the economies of affected communities, increase the presence of toxic chemicals like per- and polyfluoroalkyl substances (PFAS), and reduce the availability of clean water during power outages,[54] a particular concern in rural areas where smaller utilities may not have enough backup power to meet the demands of the water and sewage services. Water shortages can have a particularly dire impact on healthcare systems, which rely on clean water for many procedures and hygiene practices.

MS-DOH-21-1816-A-000675

New CDC data indicate waterborne pathogens cause nearly 7,000 deaths, seven million illnesses and more than $3 billion in healthcare costs each year. The risks around drinking water disproportionately threaten communities of color, highlighting the impact historical structural racism and continued institutional bias can have on a critical resource most Americans take for granted. In some areas, redlining has kept peri-urban communities of color, tribal lands and rural agricultural areas out of municipal water systems, thereby increasing their potential exposure to waterborne illness. In addition, older buildings are more vulnerable to waterborne pathogens in their pipes.[55]

According to the EPA, across the nation, 5 percent of state residents on average used a community water system in 2019 that failed to meet all applicable health-based standards, down from 7 percent in 2018. That share was 0 to 1 percent in Hawaii, Maryland, Minnesota, Nevada, North Dakota, Vermont, and Washington. (See Table 8.) But in four states (New Jersey, New York, Oregon, and West Virginia), more than 15 percent of residents used a community water system with health-based violations.

TABLE 8: Few Americans Used Contaminated Community Water Systems
Percent of state populations who used a community water system in violation of health-based standards, 2019

States	Percent of Population
HI, MD, MN, ND, NV, VT, WA	0%
CA, ID, IL, IN, ME, OH	1%
AL, CO, DE, MI, NC, NE, NH, WY	2%
CT, FL, SC, VA	3%
AK, IA, KY, RI, SD, TN, TX,	4%
AZ, DC, KS, UT, WI	5%
NM	6%
GA, MA	7%
AR, MS, MT	8%
MO, PA	9%
LA	13%
OK	15%
NJ, OR, WV	16%
NY	45%

Note: The EPA estimates that more than 13 million American households get their drinking water from private wells.[56] The data reported by this indicator do not reflect the water quality of those households. Only regulated contaminants are measured. These data do not include water safety on Indian reservations.

According to health officials in New York, a drinking water system in New York City is in violation because of an uncovered reservoir, but it has no current violations with respect to contaminants.

Source: NHSPI analysis of data from the EPA.[57]

INDICATOR 7: USE OF PAID TIME OFF

KEY FINDING: Just over half of workers in states, on average, used some type of paid time off—sick leave, vacation, holidays—in 2019. Most states were closely clustered to that midpoint, with few outliers.

Note: The specification of this indicator has been adjusted slightly from a measure of those who received paid time off to a measure of those who used it.

The need for paid time off was obvious during the pandemic, when frontline and essential workers—people who could not work from home during the outbreak—were often compelled to work when sick themselves or caring for a sick family member. Black and Hispanic workers typically have less access to paid sick leave and are overrepresented in groups of frontline workers.[58]

When workers without paid leave get sick, they face the choice of going to work and potentially infecting others or staying home and losing pay—or even their jobs. They encounter similarly impossible decisions when a child or another dependent family member gets sick. Therefore, access and the ability to use job-protected paid time off, especially dedicated paid sick leave, can strengthen infection control and resilience in communities by reducing the spread of contagious diseases and bolstering workers' financial security. This is particularly important for industries and occupations that require frequent contact with the public. For example, people working in food service, older adults and nursing care facilities and childcare commonly have no paid sick leave.[59] Low-wage workers[60] and workers of color are also less likely to have access to paid leave compared with white and higher-earning workers.[61] This often leads employees to work throughout an illness or return to work before their symptoms have fully subsided, when time off could have dramatically reduced the potential of workplace infections.[62,63]

The public health benefit is clear: at a societal level, flu rates have been shown to be lower in cities and states that mandate paid sick leave.[64,65] When employees who previously did not have access are granted paid or unpaid sick leave, rates of flu infections decrease.[66]

During the COVID-19 pandemic, studies consistently showed that access to paid sick leave helped slow the spread of the virus.[67] The Families First Coronavirus Response Act helped temporarily address this issue for employers with fewer than 500 employees and certain public employers, temporarily requiring employees to be paid sick leave benefits under certain conditions. This helped reduce the spread of the virus in workplaces and communities by removing a barrier to employees staying home when necessary. However, these protections expired on December 31, 2020, despite the ongoing need for the use of paid leave to control the pandemic; instead, Congress provided a tax credit for employers to offer paid sick leave.[68]

But many workers, particularly low-wage workers, did not have access to paid sick leave during the pandemic and were therefore left to make impossible choices between protecting their health and that of their family or protecting their financial security. State paid leave laws helped in a few jurisdictions. Beginning in March 2020, two states with existing state paid sick leave policies, California and Rhode Island, experienced large increases in temporary disability and family caregiving leave claims. California claims rose by 43 percent between February and March 2020.[69] Rhode Island claims nearly tripled between February and March 2020.[70] A January Biden administration proposal, if adopted by Congress, would provide paid leave to people who are: sick with

MS-DOH-21-1816-A-000677

Covid-19 symptoms; quarantining because of Covid-19 exposure; needing time off to get the vaccine; caring for family members who are sick with Covid-19 symptoms; caring for children whose school or day care center is closed because of the pandemic; caring for older relatives or adult dependents whose long-term care facility is closed because of the pandemic.[71]

Paid time off also increases access to preventive care among workers and their families, including routine checkups, screenings, and immunizations. Delaying or skipping such care can result in poor health outcomes and can ultimately lead to costlier treatments. Workers without paid sick days are less likely to get a flu shot, and their children are less likely to receive routine checkups, dental care, and flu shots.[72]

In 2019, 55 percent of workers in states, on average, took some type of paid time off—the same percentage as in 2018—according to the Current Population Survey, which is sponsored jointly by the U.S. Census Bureau and the U.S. Bureau of Labor Statistics.[73] Connecticut (64 percent), the District of Columbia (65 percent), Mississippi and Oregon (63 percent), and Texas (68 percent) stood out as states where relatively high percentages of workers used such benefits, whereas fewer workers used them in Arkansas (45 percent), South Carolina (45 percent), South Dakota (44 percent), Utah (45 percent), and Wyoming (47 percent).[74] (See Table 9.)

TABLE 9: 55 Percent of Workers, On Average, Used Paid Time Off
Percent of employed population that took paid time off, 2019

SD	44%

Note: Paid time off includes sick leave, vacations, and holidays. The data are measured based on a survey of a sample of the general population. The specification of this indicator has been adjusted slightly from a measure of those who received paid time off to a measure of those who used it.

Source: NHSPI analysis of data from the Annual Social and Economic Supplement of the Current Population Survey.[75]

MS-DOH-21-1816-A-000678

INDICATOR 8: FLU VACCINATION RATE

KEY FINDING: Flu vaccination coverage rose for the second consecutive year during the 2019–2020 season, with a greater share of every age group analyzed receiving a vaccine. Overall, 52 percent of U.S. residents ages 6 months or older received vaccinations—still well below the overall target level of 70 percent of the population vaccinated annually.

The CDC recommends that, with few exceptions, everyone ages 6 months or older get vaccinated for seasonal influenza annually; yet, year after year, even with a steady increase among adults over the past three decades, coverage estimates indicate that just over half of Americans do.[76] *Healthy People 2030* set federal 10-year benchmarks for improving the health of all Americans, including an overall seasonal influenza vaccination-rate target of 70 percent annually.[77]

Vaccination is the long-standing best prevention against the seasonal flu, particularly for people at high risk of severe flu-related outcomes, including people with certain chronic health conditions and older adults, groups that are also at higher risk from COVID-19. In addition to protecting Americans from the seasonal flu, establishing a cultural norm of vaccination, building vaccination infrastructure, and establishing policies that support vaccinations can help prepare the country to vaccinate all Americans quickly during the pandemic. A major concern as the 2020–2021 flu season opened was that a high incidence of seasonal flu coupled with the amount of illness caused by the pandemic would overwhelm health systems. During 2021, as the country works to deliver the COVID-19 vaccine, seasonal flu vaccination programs provide important process lessons, networks, communications strategies, and goals for the COVID-19 vaccination effort.

Under the Affordable Care Act, all routine vaccines recommended by the Advisory Committee on Immunization Practices, including flu vaccines, are fully covered when provided by in-network providers, except in states that have not expanded their Medicaid programs in accordance with the act. Some barriers to flu vaccination may

MS-DOH-21-1816-A-000679

include a belief that the vaccine does not work very well; misconceptions about the safety of the vaccine;[78] or a belief that the flu does not carry serious risks.[79] State laws may also make it more difficult for parents to get their children vaccinated by a pharmacist, as some states do not allow children to get flu vaccines at a pharmacy and even more have age restrictions and/or require a physician's prescription.

During the 2019–2020 flu season, 52 percent of residents ages 6 months or older were vaccinated, according to the CDC, the highest rate in at least a decade. This was a notable uptick from 42 percent during the 2017–2018 flu season. One possible explanation is the increased awareness of the public, clinicians, and public health officials about the importance of vaccination, owing to the high number of illnesses and deaths two years prior. The major role that vaccination will play in the country's—and the world's—recovery from the extraordinarily deadly COVID-19 pandemic will, hopefully, make an indelible impression on all Americans about the value of vaccination.

Across the country, states have taken noteworthy actions to vaccinate residents against seasonal flu. For example, during the 2018–2019 flu season, the Tennessee Department of Health organized statewide Fight Flu TN events with vaccination clinics, and last year, it launched a statewide media campaign.[80] The state's flu vaccine rate (ages 6 months or older) increased from 36 percent during the 2017–2018 flu season to 49 percent during the 2019–2020 season. Indiana's Department of Health has also engaged in focused efforts to increase vaccination rates, particularly among people who are uninsured or underinsured. One way it has done this is by partnering with local health departments and pharmacies to provide vaccinations, and by working with the Indiana Immunization Coalition to create education and outreach materials and social media messaging.[81] Indiana's flu vaccination rate (ages 6 months or older) improved from 37 percent for the 2017–2018 flu season to 51 percent for the 2019–2020 season.

Rhode Island (61 percent), Connecticut (61 percent), and Massachusetts (61 percent) had the highest coverage, while vaccination rates were lowest in Nevada (44 percent), Florida (45 percent), and Idaho (45 percent). (See Table 10.)

Children, particularly young children, were more likely to receive vaccinations than were adults. Nearly 64 percent of those ages 6 months to 17 years received vaccinations in 2019–2020, compared with 48 percent of adults.[82]

TABLE 10: Just Over Half of Americans Received a Seasonal Flu Vaccination
States' seasonal flu vaccination rates for people ages 6 months or older, 2019–2020

State	Vaccination Rate, Ages 6 Months or Older
Rhode Island	60.9
Connecticut	60.7
Massachusetts	60.6
Virginia	58.8
South Dakota	58.7
Nebraska	58.3
Wisconsin	58.3
Maryland	57.8
District of Columbia	57.6
New Hampshire	57.6
Vermont	57
Iowa	56.6
North Dakota	56.5
Minnesota	56.3
Washington	56.3
Pennsylvania	56.1
North Carolina	55.8
Colorado	55.6
Maine	55.6
Delaware	55
Arkansas	54.9
Kansas	54.5
New Jersey	54

MS-DOH-21-1816-A-000680

INDICATOR 9: PATIENT SAFETY IN HOSPITALS

KEY FINDING: On average, 31 percent of hospitals received an "A" grade in the fall 2020 hospital safety assessment administered by the Leapfrog Group, a nonprofit advocate for safety, quality, and transparency in hospitals.

Every year, hundreds of thousands of people die from hospital errors, injuries, accidents, and infections, collectively making such incidents a leading cause of death in the United States.[85,86] Keeping hospital patients safe from preventable harm is an important element of preparedness; those hospitals that excel in safety are less likely to cause or contribute to a public health emergency and are better positioned to handle any emergencies that put routine quality standards to the test.

During the COVID-19 pandemic, hospitals were an active setting for viral transmission, threatening the safety of patients, staff and visitors, and also discouraging people in need of urgent or emergency care from going to the ER, likely contributing to overall excess mortality.[87] But universal masking and availability and proper use of PPE, in addition to other steps, such as adequate ventilation, limiting the sharing of patient rooms, and universal hand hygiene, proved to be critical in preventing outbreaks in hospitals.

The Leapfrog Group calculates its hospital safety score by using 28 evidence-based metrics that measure the success of healthcare processes and outcomes. The measures track such issues as healthcare-associated infection rates, the number of available beds and qualified staff in intensive-care units, patients' assessments of staff communications and responsiveness, and a hospital's overall culture of error prevention.[88] These measures are especially critical for health systems' readiness for emergencies and outbreak prevention and control, which include workforce training and availability, surge capacity, and infection-control practices.

In the Leapfrog Group's fall 2020 assessment, 31 percent of general acute-care hospitals across the United States, on average, met the requirements for an "A" grade—a slight increase from fall 2018, when the share was 28 percent. But results varied widely state to state, from no hospitals in Alaska, North Dakota, or South Dakota receiving the top score, to a majority of hospitals doing so in Maine (63 percent), Idaho (58 percent), Delaware (57 percent), Massachusetts (57 percent), Oregon (55 percent), Virginia (53 percent), and North Carolina (52 percent). (See Table 11.)

MS-DOH-21-1816-A-000682

INDICATOR 10: STATE SURGE CAPACITY

KEY FINDING: Every state reported having a plan in 2020 for a six- to eight-week surge in laboratory-testing capacity to respond to an outbreak or other public health event.

Public health laboratories have been essential to emergency response and effective disease surveillance systems throughout the pandemic. They help detect and diagnose health threats as they emerge, and they track and monitor the spread of those threats, which can help public health officials learn how to control them. Public health labs exist in every state and territory and are the backbone of the Laboratory Response Network (LRN), a national network of laboratories that provide the infrastructure and capacity to respond to public health emergencies.[90]

When a disaster or disease outbreak strikes, public health laboratories must be able to surge to meet increased demand, just like hospitals and other responders. The Association of Public Health Laboratories defines internal surge capacity as a "sudden and sustained increase in the volume of testing that a LRN reference laboratory can perform in an emergency situation, implementing substantial operational changes as defined in laboratory emergency response plans and using all resources available within the laboratory."[91] Surging capacity can require staff movement or reassignment, extra shifts, and hiring. Labs also have to plan for infrastructure factors, such as sufficient biological safety cabinets and chemical fume hoods; amount and type of supplies; space for intake, processing, and storage of samples; versatility and capacity of analytical equipment and instruments; availability of PPE; and power supply.[92] It should also be noted that while the existence of surge plans are important, these plans have to be funded, tested, and regularly updated.

State public health laboratories have been critical assets throughout the COVID-19 pandemic, especially in early 2020, when they were the only laboratories outside the CDC authorized to conduct testing.[93] Despite early challenges in the tests rolled out to states, at least one public health laboratory in every state, DC, Puerto Rico, and Guam was able to test for COVID-19 as of June 2020.[94] Testing capacity increased over time, as private labs received authorization and ramped up capacity, and as a variety of rapid molecular tests were manufactured and approved for use at home; but the processing of the CDC's 2019-nCoV Real-Time RT-PCR Diagnostic Panel assisted officials throughout with monitoring the course of the pandemic. Still, the country's testing capacity never reached what most experts argued was necessary to allow for comprehensive, timely surveillance of the virus's spread during the height of the pandemic. This problem was most acute in spring 2020, when an estimated one in 10 infections were confirmed, improving somewhat to roughly one in three in late 2020.[95,96]

In addition, public health laboratories are studying the genetic sequencing of the COVID-19 virus to identify variants. Such genomic surveillance is critical to understanding and preventing the spread of the virus but more federal funding is needed to support the work.[97]

Going forward, some challenges to the effectiveness of public health laboratory preparedness include funding gaps to invest in infrastructure and modernization, workforce shortages, a lack of standardized platforms to exchange data electronically, and a limited ability to detect radiological, nuclear, and chemical threats.[98]

In 2020, the District of Columbia and all states reported to the Association of Public Health Laboratories that they had a plan for a six- to eight-week surge in testing capacity, a net increase of six since 2017 and 2018. (See Table 12.)

MS-DOH-21-1816-A-000683

TABLE 12: Every State Planned for a Laboratory Surge.

State public health laboratories with a plan for a six- to eight-week surge in testing capacity, 2020

Had a Plan

MS-DOH-21-1816-A-000686

Recommendations for Policy Actions

As 2020 has shown, saving lives and protecting the country's economic stability during a pandemic requires pre-event investment and planning, a strong public health system, federal leadership, and a coordinated response. The same is true for all types of public health emergencies. Effective preparedness and response require sufficient funding, a trained workforce, and multisector teamwork. Authentic engagement with community-based leaders and organizations are also necessary.

TFAH based the following policy recommendations on research and analysis, consultation with experts, and a review of gaps in federal and state preparedness. TFAH offers the following recommendations for federal, state, local, tribal, and territorial policymakers and other stakeholders to improve public health emergency readiness.

Priority Area 1: Provide Stable, Sufficient Funding for Domestic and Global Public Health Security

The COVID-19 pandemic has uncovered the tragic consequences of the nation's long-term neglect of public health capacity at the global, federal, state, local, tribal, and territorial levels. Understaffed health departments are in some cases using 20th-century tools, such as telephones and fax machines,[100,101] to respond to a 21st-century pandemic.[102] At the same time, funding for the Public Health Emergency Preparedness cooperative agreement, a critical source of funding for health departments to build capabilities to effectively respond to a range of public health threats, has been cut by just over one-quarter since FY 2003, or about half, after adjusting for inflation.[103] The HPP, the only federal source of funding to help the healthcare delivery system prepare for and respond to disasters, has been cut by nearly half over the same time period, or by nearly two-thirds, after adjusting for inflation.[104] Therefore, health departments were already working from a deficit when the pandemic emerged. Federal policymakers need to rapidly improve the COVID-19 response and build back a system currently unprepared to address future emergencies. Short-term investments made through COVID response funding legislation cannot fill the gap left by ongoing public health funding shortfalls, nor can they address underlying health inequities that are making the nation less resilient.

MS-DOH-21-1816-A-000687

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Rebuild and modernize the public health system, including by creating a mandatory $4.5 billion per year Public Health Infrastructure Fund to support foundational public health capabilities at the state, local, territorial, and tribal levels (STLT).** Strong foundational capabilities would improve the protection of all communities across a range of threats. However, a nationwide funding shortage, exacerbated by the pandemic, has prevented health departments across the country from developing and maintaining these capabilities. An additional funding limitation is that health departments receive very little funding that is not tied to specific diseases or categories. Congress should invest in cross-cutting public health capabilities, such as proposed in the Public Health Infrastructure Saves Lives Act.[105] Congress must also increase funding for specific programs that support health security, including the Public Health Emergency Preparedness and the HPP cooperative agreements. These state and local preparedness programs have demonstrated their value by saving lives, improving the speed and quality of response during emergencies, and ensuring that local authorities can adequately respond to most local health emergencies and outbreaks without federal assistance. Congress should provide additional funding to modernize public health and response functions at the CDC and ensure the agency has the capacity to respond to any event.

- **Invest in sustained public health data modernization.** Sustained investment in health data systems at the federal, state, and local levels is imperative. The CDC is the world's premier public health agency, yet years of inadequate funding has meant that the agency and its partners are reliant on archaic data systems. Americans felt the pain of delayed and disjointed disease surveillance throughout the pandemic, as the public health surveillance infrastructure relied on antiquated, disconnected systems and methods for tracking and responding to diseases. Congress wisely invested $500 million in the Coronavirus Aid, Relief, and Economic Security Act (P.L.116-136) and $50 million in the FY 2020 and FY 2021 appropriations bills as a down-payment on the CDC's data modernization initiative. These investments will help build the foundations for data sharing across public health, modernize the CDC's services and systems, leverage new data sources, and ensure public health can act on innovative data analytics. However, these advancements must be augmented and sustained, making up for decades of neglect. Congress should build on these initial investments with at least $450 million in immediate funding and at least $100 million per year to the CDC's data modernization initiative to modernize and sustain these systems. New data systems should be interoperable and cloud-based.

- **Ensure complete, disaggregated demographic data collection and reporting during public health emergencies.** The gaps in COVID-19 data reporting by race, ethnicity, sexual identity, gender identity, primary language, disability status, the intersections of these demographics, and other factors hindered the response and masked the true breadth of inequities during the pandemic. These gaps exposed long-standing shortcomings in demographic data collection and reporting in public health. Congress should invest in data modernization for STLT public health to enable accurate and comprehensive data collection. In addition, HHS should stand up a task force—including the Office of the Assistant Secretary for Planning and Evaluation, CDC, Office of the National Coordinator on Health Information Technology, Office of Minority Health,

MS-DOH-21-1816-A-000688

and CMS, in consultation with state, local, territorial and tribal agencies and private-sector stakeholders—to identify and address barriers to the collection and regular reporting of disaggregated, detailed demographic data during the pandemic and beyond. If needed, Congress should provide HHS agencies the authority to require jurisdictions to report race and ethnicity during public health emergencies.[106]

- **Accelerate crisis responses through a standing public health emergency response fund and faster supplemental funding.** In addition to stable core funding, the federal government needs readily available funds on hand to enable a rapid response while Congress assesses the necessity for supplemental funding. Congress should continue a no-year infusion of funds into the Public Health Emergency Rapid Response Fund and/or the Infectious Disease Rapid Response Fund to serve as available funding that would provide a temporary bridge between preparedness and supplemental emergency funds. Congress should replenish such funding on an annual basis, and funding should not come from existing preparedness resources, as response capacity cannot substitute for adequate readiness. The HHS secretary should only use such funding for acute emergencies that require a rapid response to save lives and protect the public.

- **Demonstrate a long-term commitment to global health security.** The United States should recommit to partnerships with international bodies such as the WHO, and Congress should solidify America's role as a global health leader, commit to implementing the Global Health Security Strategy,[107] and provide sustained annual funding for global health security programs at the CDC and the U.S. Agency for International Development. Congress should fund and the CDC should implement the modernization of the U.S. quarantine system, including IT systems, quarantine stations, regulatory framework, and traveler engagement and information.

Editor's note: on January 21, 2021, the Biden administration restored U.S. membership in the WHO.

RECOMMENDATION FOR FEDERAL AND STATE GOVERNMENT:

- **Enable efficient use of emergency funding.** During an emergency, responding agencies at all levels of government must be able to adapt spending policies. States should review their administrative preparedness to ensure they can efficiently use emergency monies, including speeding up contracting and hiring procedures. In addition, Congress may allocate emergency funding to multiple federal agencies. However, differing agency policies and practices can impede speed and coordination of funding across agencies. This can lead to disconnected and less effective emergency responses on the ground. The Office of Management and Budget, HHS, and FEMA should allow waivers of regulatory or administrative requirements to awardees of emergency response funding to allow funding braiding, to encourage coordination between programs and funding streams with similar goals, to provide flexibility to best meet the needs of the affected populations, and to increase efficiencies and reduce administrative duplication, such as in grant reporting.

MS-DOH-21-1816-A-000689

Priority Area 2: Prevent Outbreaks and Pandemics

Infectious diseases represent a threat to the health, safety, and economic and social stability of the country. The COVID-19 pandemic has cost the nation hundreds of thousands of lives and at least $16 trillion in losses to the U.S. gross domestic product as of October 2020.[108] The toll in lost educational achievement and long-term mental health impacts have yet to be fully understood. As TFAH, scientists, and public health experts have warned for many years, the nation was not prepared for a severe pandemic. At the same time as the nation battles the worst pandemic in a century, public health and medical providers continue to respond to "everyday" outbreaks: seasonal influenza, vaccine-preventable diseases, healthcare-associated infections, and antibiotic resistance continue to pose threats to health and safety. The United States must be able to prevent and respond to both major pandemics and localized outbreaks.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT, HEALTHCARE, AND AGRICULTURE:

- **Support the vaccine infrastructure.** The CDC's immunization program, sometimes called the "317 program," supports state and local immunization systems to increase vaccination rates among uninsured and underinsured adults and children, to respond to outbreaks, to educate the public, to target hard-to-reach populations, to improve vaccine confidence, to establish partnerships, and to improve information systems. Yet, funding has not kept up with needs, as states have to spend immunization dollars to respond to outbreaks,[109] deal with increases in the numbers of residents who lack health insurance,[110] and attempt to manage the impact of vaccine underutilization. State, local, and tribal health departments are depending on this underfunded infrastructure to distribute and dispense the COVID-19 vaccine, yet COVID funding was not distributed until January 2021. Congress should monitor the COVID-19 vaccination progress and provide additional funding, if needed. Congress should also increase annual funding for the CDC's immunization program as well as the seasonal influenza program and post-licensure vaccine safety monitoring. Congress should also provide needed resources to HHS to study the causes of vaccine resistance and to educate clinical providers on methods for improving vaccine acceptance, such as those proposed in the VACCINES Act.[111]

- **Ensure first-dollar coverage for recommended vaccines under Medicaid, Medicare, and commercial insurance.** Public and private payers should ensure that all vaccines recommended by the Advisory Committee on Immunization Practices (ACIP) are fully covered, as cost sharing, such as co-pays, can be a significant barrier to vaccination.[112] Congress should require zero cost sharing in Medicare Part D and B plans, and CMS should incentivize Part D plans to eliminate cost sharing and increase receipt of vaccines.[113] An example of legislation that takes steps to improve senior vaccination rates is the Protecting Seniors Through Immunization Act. CMS should encourage state Medicaid plans in states that have not expanded Medicaid to cover all ACIP-recommended vaccines without cost sharing.[114]

- **Significantly increase investments in public health initiatives to combat antibiotic resistance.** Congress should increase funding for innovative prevention methods of detecting and containing outbreaks supported by the Antibiotic Resistance Solutions Initiative at the CDC. The CDC is investing in prevention measures in every state to strengthen lab capacity, track infections across healthcare systems, detect new threats, disrupt pathogens, coordinate prevention strategies, educate healthcare providers on appropriate antibiotic use, and advocate for other innovations. To fully address the scope of AR spread, particularly in healthcare settings, Congress should increase funding for healthcare associated infection/antibiotic resistance programs and activities at state and local health departments. In addition, increases in funding are necessary to build global capacity to prevent and detect resistant infections and to combat the threat to national security.

- **Create incentives for new-product discovery to fight resistant infections.** It is extremely challenging for companies to earn a return on their investments for the development of new antibiotics: (1) antibiotics are typically given for a short duration; (2) the most highly resistant infections are still relatively rare; and (3) new antibiotics must be used judiciously to preserve their effectiveness. These

MS-DOH-21-1816-A-000690

factors have resulted in nearly all major pharmaceutical companies exiting the antibiotics market, leaving the critical innovation domain of discovering and developing new antibiotics to small biotech companies with limited budgets and limited research and development capacity. Legislation, such as the DISARM Act, would strengthen the market for antibiotic developers, improving patient access for those who need it most.

- **Eliminate overuse of antibiotics in agriculture.** The FDA should enforce rules regarding veterinary oversight and the judicious use of antibiotics in food animals, ensure data collection and publication, promote antibiotic stewardship programs, and track the impact of these policies on resistance patterns. Farmers and the food industry should stop using medically important antibiotics to promote growth and prevent disease in healthy animals, as recommended by the WHO,[115] and they should invest in research to develop and adopt husbandry practices that reduce the need for routine antibiotics.
- **Decrease over-prescription of antibiotics through implementation of antibiotic stewardship and antibiotic-use reporting.** The CDC estimates that improving prescribing practices and preventing infections could save 37,000 lives over five years.[116] CMS should finalize, implement, and enforce requirements for all CMS-enrolled facilities to have effective antibiotic stewardship programs that align with the CDC's Core Elements guidance and to work with public health stakeholders to track progress in prescribing rates and resistance patterns.[117] All relevant facilities must drastically improve their reporting of antibiotic use and resistance through the National Healthcare Safety Network and should adopt stewardship programs that meet the CDC's Core Elements.[118]
- **Fund the CDC to support state and local public health laboratories.** The CDC should be sufficiently funded to strengthen the Laboratory Response Network and to support state and local public health laboratories; currently, the Epidemiology and Laboratory Capacity grant is only funding approximately half of what laboratories and health department epidemiologists nationwide have requested.

RECOMMENDATIONS FOR FEDERAL AND STATE GOVERNMENT:

- **Provide job-protected paid leave.** The pandemic has called attention to the fact that paid family and medical leave are important infection-control measures, protecting both workers and customers, in addition to creating economic security. Workers are unable to adhere to public health guidance to isolate if they risk losing their jobs or paychecks. While Congress temporarily expanded access to paid leave during the pandemic, a permanent fix is needed. Congress should enact a permanent federal paid family and medical leave policy and dedicated paid sick days protections, and states should ensure effective implementation by passing paid leave laws and/or removing preemption exemptions.
- **Minimize state vaccine exemptions for schoolchildren and increase vaccination of healthcare workers.** States should enact policies that enable universal childhood vaccinations to ensure children, their classmates, educators, and the general public are protected from vaccine-preventable diseases. This includes eliminating nonmedical exemptions and opposing legislation to expand exemptions.[119] States should ensure medical vaccine exemptions are only given when appropriate and are not used as a de facto personal-belief exemption in states where those exemptions have been eliminated. States should require healthcare personnel to receive all ACIP-recommended vaccinations to protect staff and patients, assure continuity of operations in the event of an outbreak, and achieve necessary healthcare infection control. As this report was being prepared for publication, the COVID-19 vaccine was not an ACIP-required vaccine. Healthcare facilities should ensure access to vaccines for all staff and contractors, and they should remove any barriers to staff receiving vaccines. Healthcare facilities should also report healthcare worker vaccination status, such as for seasonal flu and COVID-19, to the CDC's National Healthcare Safety Network.

MS-DOH-21-1816-A-000691

Priority Area 3: Build Resilient Communities and Promote Health Equity in Preparedness

Social, economic, and health disparities impact how people within specific communities' experience disasters and how quickly they can recover. Unfortunately, the disproportionate impact of COVID-19 on communities of color and Tribal Nations was foreseeable: underlying health conditions driven by years of structural racism; uneven access to prevention and care during the pandemic; increased risk of exposure due to being frontline workers, such as in food processing, food service, or healthcare;[120] increased risk of exposure due to living in crowded or inadequate housing;[121] and more severe economic impacts for lower-income workers has meant that people of color and Tribal Nations are bearing a disproportionate burden from the pandemic. When intersectional issues, such as homelessness, incarceration, disability, age, lack of access to paid leave, LGBTQ+ status, and immigration status are also at play, the inequities are more pronounced. Addressing underlying inequities and intentionally and meaningfully engaging with the people and communities most likely to be impacted throughout the emergency planning and response process are critical to reducing vulnerability and ensuring that all receive appropriate services, regardless of circumstance. Equity must be an explicit and foundational principle in all emergency planning. Some communities have taken steps to integrate principles of equity throughout public health emergency activities,[122] but more needs to be done.

RECOMMENDATIONS FOR FEDERAL, STATE, AND LOCAL GOVERNMENT:

- **Examine and address gaps in equity in response capabilities.** An external body (such as the GAO or the National Academy of Sciences, Engineering and Medicine) should conduct an assessment of the pandemic specifically focused on gaps in equitable response, including inequities in allocation of scarce resources, healthcare capacity, data collection and reporting, and planning for communities at higher risk, underserved communities, and communities of color.
- **Invest in policies and capacity to address the social determinants of health (SDOH):** People at highest risk during disasters and those who have the hardest time recovering are often those with unstable or unhealthy housing, those with limited access to transportation, and those who live in low-socioeconomic-status communities,[123] all of which bore out during the COVID-19 pandemic. Addressing SDOH can improve resilience, but it must be a cross-sector effort to increase healthy, affordable housing; improve transportation access; fight poverty; and implement other policies proven to advance health. Congress should fund a public health approach to address SDOH, such as the approach proposed in the Improving Social Determinants of Health Act. The legislation would strengthen SDOH capacity at the CDC and enable grants to public health agencies to build cross-sector partnerships and develop community solutions to SDOH. For further discussion on policy options to address SDOH, see TFAH's Blueprint and PHACCS reports.[124,125]
- **Provide resources and technical assistance to communities to enhance equity and resilience before, during, and after an event.** Rather than a top-down approach to promote equity and resilience, policymakers should support an asset-based approach that relies on communities identifying and leveraging their assets. Congress should direct targeted resources to community-based organizations and existing community health networks that focus on the health of communities of color and other groups that bear a disproportionate burden during disasters. Evacuation plans should be inclusive of the community as a whole by meeting and enforcing the requirements of the Americans with Disabilities Act. Grants should support culturally and linguistically appropriate public health campaigns that address prevention and treatment, providing community leaders the opportunity to fully participate in planning activities, allowing organizations to hire and engage community members so emergency plans better reflect the community, and improving data collection and sharing. Federal and other grant makers and states should ensure that existing grants and sub-awards reach the grassroots level and communities most in need.
- **Public health agencies should strengthen their health equity leadership and adopt strategies and accountability metrics to incorporate equity into preparedness.** Equity must not be considered separate from preparedness activities but must serve as the foundation for a more resilient

MS-DOH-21-1816-A-000692

community. Ensuring equity is central to all preparedness activities and requires integrating equity accountability measures into all elements of emergency response. Congress should provide the CDC funding to extend its COVID-19 Health Equity Strategy[126] to ongoing preparedness and response work at the agency and with partners. All state and local governments, including health departments, should build up internal infrastructure to drive equity, including by identifying a chief health equity officer who has a leadership role in the emergency operations center and/or incident command structure for all-hazards events and is engaged in every emergency operation center activation. Health equity and emergency preparedness officials should work across programs to incorporate equity issues and goals into preparedness policies and plans;[127] to improve staff capacity to understand how the legacies of discrimination, current-day racial trauma, and other structural inequities affect disaster resilience and recovery; develop and disseminate communications materials that are culturally and linguistically tailored; and to collect and leverage data to identify unique community assets and advance equity before and during events.

RECOMMENDATIONS FOR STATE AND LOCAL GOVERNMENT AND COMMUNITY LEADERS:

- **Plan *with* communities, not for them, and empower their involvement with resources.** Emergency planners must conduct meaningful engagement, partnerships, and listening efforts as well as ongoing inclusion and local hiring (especially from communities typically at higher risk in disasters) in emergency planning and response. Officials should establish relationships with services and organizations that serve these populations before emergencies take place, and government should fund community leaders and community-based organizations to participate in preparedness efforts. Health departments and emergency management agencies should rely on the expertise, community trust, and networks of those who may bear a disproportionate risk, such as older adults, people with disabilities, and individuals with chronic health conditions to ensure emergency plans, procedures, and evacuation shelters meet the needs of all in the community.
- **Address mental health and substance use gaps, bolster crisis resources, and incorporate mental health first-aid and long-term treatment into disaster response and recovery strategies.** Emergencies can exacerbate existing mental health and substance use concerns and disrupt access to care. During the COVID-19 pandemic, there have been reports of increases in a number of mental health concerns,[128] including suicide ideation[129] and drug overdoses.[130] Short-term regulatory relief, like take-home medication for opioid use disorder[131] and waivers for telehealth,[132] have helped, but coordination among state, local, and federal agencies remains vital to delivering resources to affected communities. Policymakers should also incorporate behavioral health needs into disaster planning, as required by the Pandemic and All-Hazards Preparedness and Advancing Innovation Act.

MS-DOH-21-1816-A-000693

Priority Area 4: Ensure Effective Leadership, Coordination, and Workforce

The political polarization and contradictory messaging exhibited throughout the pandemic contributed to a wide variation in how individuals and communities responded. Issues such as face coverings, business- and school-closure decisions, and even the mortality numbers became matters for debate by a vocal minority of Americans.[133] Clear national leadership and communication, following the advice of public health and scientific experts, is needed to ensure consistent policies and messaging during a situation as complicated and dangerous as a public health emergency. Perhaps more important than any technology or invention is the presence of trained, experienced people, from the frontline responder to the top of government. The nation's local public health departments responded to the pandemic with an estimated 26,000 fewer public health workers compared with before the 2008 recession.[134] The state budget cuts likely to continue in the years following the pandemic threaten to intensify this workforce shortage. Effective crisis response requires coordination, cooperation, and leadership—elements that governments must build and sustain over time.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Strengthen federal leadership, guidance and regulatory authorities for public health emergencies.** During the COVID-19 pandemic, authority and decision-making over the response was ceded to states to an unprecedented degree. This diffusion of responsibility meant wide variation in policy and response decisions regarding business closures, mask mandates, testing strategies, and other tactics. The CDC must be empowered to lead the public health response during a pandemic and issue clear, feasible guidance and regulations for state, local, tribal, and territorial officials and to the public to minimize variation across jurisdictions. The optimal approach is a federal-state partnership rooted in shared decision-making and a clear division of labor.
- **Rebuild trust in federal public health agencies.** The COVID-19 pandemic has damaged faith in federal agencies, including public health agencies such as the CDC and the FDA. Policy decisions from the federal to the local level should be based on the best available science, led by public health experts, and free from any perception of political interference. The president, the HHS secretary, and the leadership of federal public health and emergency response agencies, including the CDC, ASPR, DHS, FEMA and the FDA, must conduct a thorough review on the independence and performance of these agencies. Leaders should establish procedures and policies to ensure the scientific integrity and independence of the agencies, without political interference, and they must correct any errors made during the COVID-19 response. At the same time, elected leaders must publicly support public health to rebuild confidence in those agencies and officials. All federal messages and messengers about public health issues must be consistent and based in science.

MS-DOH-21-1816-A-000694

Sundry Photography

- **Invest in public health communications.** Congress must make a significant investment in effective public health communications, including research into best practices for different audiences. The CDC and other federal, state, and local public health agencies should engage with a diverse group of stakeholders to research and test effective public health messaging. From vaccines to mask-wearing, there are subgroups of Americans who are skeptical, hesitant, or confused about COVID-19 public health guidance for various reasons. While some will be recalcitrant, many Americans are simply hesitant or have not been properly engaged. While the substance of communications should be consistent, messages must acknowledge the historical context of distrust and be linguistically and culturally tailored for different populations, and trusted, nongovernmental messengers should receive funding to help deliver messages.

- **The White House should reestablish a health security directorate with public health expertise.** The White House should ensure senior advisors to the president have a strong background in public health and/or biodefense, and the White House should ensure that senior-level interagency cooperation is progressing before, during, and after public health emergencies.

Editor's note: on January 20, 2021, the Biden administration reestablished a National Security Council Directorate for Global Health Security and Biodefense.

- **Clarify and restore roles and responsibilities for government's emergency support functions.** The White House, HHS, CDC, ASPR, U.S. Department of Homeland Security, FEMA, and FDA should work together to clarify roles and responsibilities to improve the nation's emergency preparedness and response capacity.

- **Fund the recruitment and training of public health personnel.** The health security enterprise requires trained, experienced personnel. Federal, state, and local governments must prioritize stable, long-term funding for recruitment and retention of a diverse workforce, including one with experience in public health informatics, laboratory science, health equity, and epidemiology. Congress should also invest in public health workforce development and retention programs, such as student loan repayment and other incentives, especially in underserved areas. Public health schools should incorporate health equity and cultural competency into their preparedness curricula.

MS-DOH-21-1816-A-000695

Priority Area 5: Accelerate Development and Distribution of Medical Countermeasures

A robust Public Health Emergency Medical Countermeasures Enterprise (PHEMCE)[135] could negate a range of health threats, but a drug or vaccine is only effective if it reaches the right person at the right time. Medical countermeasures (MCM) are FDA-regulated products that could be used in the event of a public health emergency; they include biologics, drugs, and devices.[136] The challenges faced in distributing scarce medical resources during the pandemic as well as the deployment of COVID-19 vaccine demonstrate the urgency of the right-product/right-time equation. During the first ten months of the pandemic, there was a notable gap in federal coordination, with many federal responsibilities being left to states or to the private sector. The federal government circumnavigated or significantly modified established MCM and medical supply-chain coordination and distribution channels at various points in the pandemic, contributing to confusion and chaos. For example, the lack of federal coordination and transparency left individual hospitals and states to compete with each other for scarce resources,[137] and FEMA and the U.S. Department of Defense were brought in to manage some supply-chain operations despite long-standing systems in place at HHS. Clear federal coordination is necessary during the pandemic, with an eye toward preventing future shortages and shortfalls.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT:

- **Provide significant, long-term funding for the entire MCM enterprise.** The MCM enterprise involves research, manufacturing, surveillance, delivery, training, and monitoring. Long-term coordinated and transparent funding to the Biomedical Advance Research and Development Authority, Strategic National Stockpile, CDC, FDA, NIH, and other components of the PHEMCE would offer more certainty to the biotechnology industry and researchers, would strengthen public-private partnerships, and would enable the purchase of ancillary medical supplies, such as PPE. The United States should grow its investment in innovative, flexible technologies and platforms that will enable faster production of products for a range of biothreats, rather than focusing on products for a single pathogen.[138]

- **Prioritize the distribution and dispensing of MCMs.** It is important that MCMs reach the right person at the right time during emergencies; the challenges in mass vaccination were predicted by the CDC's MCM Operational Readiness Review.[139,140] HHS along with state, local, tribal, and territorial health departments should be properly resourced and require integration of private-sector healthcare supply distributors and supply-chain partners into planning, exercises, and emergency responses to better leverage existing systems and resources. Once

the COVID-19 vaccination campaign is complete, HHS should access and address gaps in vaccine development, procurement, maintenance, deployment and administration; and improve the training of state and local personnel to ensure vaccine administration is well-coordinated.

- **Clarify and strengthen MCM and supply-chain management for emergencies.** HHS must maintain primary authority over public health emergency response, including deployment of the Strategic National Stockpile and emergency medical supply-chain management, in coordination with other federal agencies and in consultation with private-sector and public health partners. Federal agencies should also explore all available authorities, such as through the Defense Production Act, and communicate strategies with stakeholders to bolster the supply chain during emergencies. The HHS secretary should clarify roles and responsibilities for supply-chain management throughout the pandemic and, moving forward, should develop and disseminate best practices for supply management.[141] HHS should strengthen the PHEMCE's work, including regular interagency meetings; engagement with private-sector, supply-chain partners; and improved transparency and communication with state, local, tribal, and territorial partners.

RECOMMENDATIONS FOR FEDERAL, STATE, AND LOCAL GOVERNMENTS AND PARTNERS:

- **Improve MCM guidance and communications for groups at higher risk during an event.** HHS, including the CDC, should consult with experts and work with healthcare professionals and state, local, and tribal partners to develop standardized guidance for dispensing MCMs to groups such as children, older adults, people with disabilities, and people who are homebound. And HHS and state, local, and tribal agencies should work with organizations that reach the public, especially communities at disproportionate risk—such as groups representing older Americans, people with disabilities, and limited English-proficient communities—to improve communications around MCM issues before an event. Communities need to be engaged before an outbreak or event to ensure their understanding of the risks, benefits, and distribution challenges of introducing a medical product to a large portion of the population and ultimately improving acceptance and access to MCMs. It is important to provide clear and accurate guidance to the public in multiple formats and languages, via trusted sources and multiple communications channels, including formats that are accessible to people with hearing or vision loss.

MS-DOH-21-1816-A-000697

Priority Area 6: Ready the Healthcare System to Respond and Recover

In the 2019 and 2020 *Ready or Not* reports, TFAH warned that medical surge capacity for a pandemic remained a major gap in the nation's preparedness. The COVID-19 pandemic has placed tremendous strain on the healthcare system, from acute-care facilities[142] to long-term care facilities[143] to small outpatient clinics.[144] Overcrowded facilities, exhausted workforces, disruptions in the supply chain, shortages of PPE and other supplies, interruptions in primary and preventive care, lack of situational awareness, and loss of revenue have been among the significant challenges to the nation's healthcare system. The toll in lives lost due to these compounding issues has yet to be calculated. The NHSPI has consistently found that healthcare delivery readiness scores are in the lowest levels among preparedness domains, with little progress in the past five years.[145] Policymakers need to strengthen existing systems and consider long-term mechanisms to create sustainable healthcare readiness across systems and across geographic borders.

RECOMMENDATIONS FOR FEDERAL GOVERNMENT AND HEALTHCARE:

- **Strengthen the Hospital Preparedness Program and fund regional coordination.** HPP can help build strong healthcare coalitions capable of engaging and supporting members during disaster responses, but the program has been severely underfunded. Congress must provide more robust annual funding—which it has cut in half over the past decade. HHS and the awardees should ensure healthcare leaders takes the lead on HPP planning and implementation to the extent possible, with support and coordination from public health, emergency management, and others, and awardees should ensure as much funding as possible is reaching healthcare coalitions. Healthcare administrators should ensure their facilities have tools and support for meaningful participation in healthcare coalitions, including the ability to share information and resources across the coalition and with public health agencies. Congress should provide additional funding for a tiered regional disaster system to coordinate across coalitions and states,[146] to map specialized disaster care (such as burn or pediatric care) across the country, and to leverage those assets in a coordinated way.[147] Congress should also provide increased funding for healthcare surveillance through CDC's National Healthcare Safety Network—which is the nation's domestic tracking and response system to identify emerging and enduring threat across 37,000 healthcare facilities, including COVID-19, healthcare-associated infections (HAIs), and antibiotic-resistant (AR) infections. These data drive improvements in patient safety and monitor the surge capacity of healthcare facilities to confront new threats.
- **Create incentives and ramifications to build sustainable preparedness and surge capacity across healthcare systems.** The shortages of beds, healthcare personnel, and equipment during the pandemic underscores the need for cooperation among healthcare entities, across systems, and across geographic borders. Although there has been progress in developing healthcare coalitions in many regions and progress in meeting CMS and other accreditation preparedness standards by individual healthcare facilities, these existing mechanisms have not provided enough incentive for many healthcare facilities to create meaningful surge capacity and cooperation across competing entities. Similarly, the Joint Commission's preparedness standards apply to individual facilities and not to the readiness of the healthcare system as a whole.[148] In addition to strengthening existing systems, Congress and HHS should consider long-term sustainability for building healthcare readiness across the system, including meaningful incentives and disincentives, including:
  - An external self-regulatory body, in alignment with federal policy goals, could set, validate, and enforce standards for healthcare facility readiness, stratified by facility type, with authority for financial ramifications.[149]
  - Payment incentives could sustain preparedness, surge capacity, regional disaster partnerships, and reward facilities that maintain specialized disaster care.

MS-DOH-21-1816-A-000698

- **Expand access to healthcare.** Access to healthcare is always important and particularly so during a pandemic or disaster. Federal and state governments must ensure every person has access to healthcare, including robust insurance coverage. Millions of Americans still lack insurance coverage, and disparities by race, ethnicity, sexual or gender identity, and other factors have been exacerbated by the pandemic-induced recession.[150] Congress and the administration should strengthen incentives for states to expand Medicaid, make marketplace coverage more affordable, and improve outreach and marketing for enrollment.[151]

- **Assess impact of CMS Preparedness Standards and improve transparency.** An external review by the GAO or a similar entity should assess how CMS preparedness standards have affected overall healthcare readiness, and HHS should begin tracking progress on preparedness measures over time. CMS should also strengthen preparedness standards by adding medical surge capacity and other capabilities, including infection prevention and control, stratified by facility type, as a necessary requirement within the next iteration of the rule.[152]

RECOMMENDATIONS FOR STATE GOVERNMENT AND HEALTHCARE:

- **Integrate healthcare delivery into emergency preparedness and response.** Jurisdictions should engage and integrate the healthcare sector into emergency planning and responses, including plugging healthcare coalitions and other entities representing private healthcare and the healthcare supply chain into emergency planning and response and incident command. Health systems, healthcare coalitions, and public health should develop memoranda of understanding ahead of disasters to improve situational awareness across healthcare and to enable movement of patients, personnel, and supplies. Private-sector healthcare leadership should prioritize preparedness moving forward, including training and workforce protections, surveillance for emerging threats, stockpiling of supplies ahead of disasters, and full engagement in regional collaborations and coalitions.

- **Strengthen state policies regarding disaster healthcare delivery.** States should review credentialing standards to ensure healthcare facilities can call on providers from outside their states, and health systems should ensure they can receive outside providers quickly during a surge response. States should also adopt policies that promote healthcare readiness and ease the ability to surge care and services, such as the NLC, the Interstate Medical License Compact, the Recognition of EMS Personnel Licensure Interstate CompAct,[153] the Uniform Emergency Volunteer Health Practitioners Act,[154] emergency prescription refill laws and protocols, and implementation and education of providers regarding crisis standards of care guidelines.[155,156]

MS-DOH-21-1816-A-000699

Priority Area 7: Prepare for Environmental Threats and Extreme Weather

Climate change, environmental hazards, and extreme weather pose serious threats to human health. According to a December 2020 report by TFAH and the Johns Hopkins Bloomberg School of Public Health, many of the states most at risk from climate change are also the least ready to deal with it (see sidebar on page 60). Environmental health involves detecting and protecting communities from hazardous conditions in air, water, food, and other settings, and it is therefore a critical component of the nation's health security. Environmental hazards impact communities differently and exacerbate disparities among people living in poverty, people of color, people with underlying health conditions, and children and older people—all of whom are at particular risk.[157]

RECOMMENDATIONS FOR FEDERAL AND STATE GOVERNMENT:

- **Enact legislation requiring a national strategic plan.** The United States urgently needs a strategic action plan to address the health impacts of climate change. Policymakers should enact legislation requiring HHS to develop such a plan and to fund development and ongoing maintenance of health system capacity specifically for this purpose.
- **Support public health climate-adaptation efforts.** Funding for the CDC's Climate and Health program stands at $10 million per year, while the annual health costs of climate change events were estimated to be more than $14 billion in 2008.[158] Climate-informed health interventions include identifying likely climate impacts, potential health effects associated with these impacts, and the most at-risk populations and locations.[159] Congress should increase funding for environmental health programs, including the CDC's Climate and Health program and environmental health tracking to conduct surveillance and target interventions.
- **Develop sustainable state and local vector-control programs.** As the threat and geographic distribution of mosquitos, ticks, and other vectors changes, Congress should expand funding for the vector-borne disease program at the CDC to support state and local capacity to prevent and detect vector-borne diseases, such as Zika, West Nile Virus, and Lyme disease.
- **Guarantee clean water for all U.S. residents, including after disasters.** The administration and Congress should restore the Clean Water Rule, which includes measures to protect a safe water supply, such as addressing the ongoing problem of lead, per- and polyfluoroalkyl substances, and other toxins in drinking water; taking steps to reduce the potential for waterborne illnesses; and increasing protection against potential acts of terrorism on America's drinking and agricultural water. All states should include water security and sewage removal in their preparedness plans, and they should build relationships among health departments and local environmental and water agencies. The CDC should include national guidance and metrics for planning for a range of water-related crises.

RECOMMENDATIONS FOR STATE GOVERNMENT:

- **Every state should have a comprehensive climate vulnerability assessment and adaptation plan that incorporates public health.** Public health and environmental agencies should work together to track concerns, coordinate risk-management and communications, and prioritize necessary capabilities to reduce and address threats. States and localities should investigate what additional capacities are necessary and identify vulnerable populations and communities. State and local public health officials should incorporate environmental health into emergency operations planning and incident command.
- **Complete all steps of the CDC's Building Resilience Against Climate Effects, or "BRACE," framework, and continuously work to enhance and refine preparations for climate change.** State agencies must conduct and facilitate rigorous vulnerability assessments at the state and local levels. The assessments should focus especially on populations at highest risk and the health threats most pertinent to them. States must also push ahead to complete all steps of the framework, including identifying and implementing evidence-based interventions to protect residents. Finally, as agencies implement interventions, they should continually evaluate effectiveness and strive for quality improvement.

MS-DOH-21-1816-A-007700

Year in Review – 2020 Health Threats Incidents and Actions

This section reviews 2020's major events, research, and policy actions related to global and domestic health security.

Disease Outbreaks

Notable Incidents

- **COVID-19**
  - The novel coronavirus SARS-CoV-2, the virus that causes COVID-19, emerged internationally in late 2019. As of late February 2021, as this report was being prepared for publication, over 28 million cases; and over 500,000 deaths have been reported in the U.S. alone.[160] Globally, there have been over 109 million confirmed cases of COVID-19, and over two million deaths, reported to the World Health Organization (WHO).[161] The number of cases and the number of deaths from COVID-19 is higher in the United States than in any other country.[162] In the United States, slightly more women than men have been infected, but deaths in men are disproportionate (54 percent to 46 percent).[163] Black people account for nearly 16 percent of COVID-19 deaths, where race is known, despite representing 13 percent of the U.S. population.[164] Hispanic or Latino people account for 18 percent of reported COVID-19 cases in the U.S. as of late January 2021, a proportion approximately equal to their percentage of the U.S. population.[165] In addition, research indicates a significant level of asymptomatic cases, so true infection counts are likely higher than confirmed cases.[166] Deaths may also be underreported due to inadequate testing and given that the pandemic response itself may have indirectly caused mortality due to limited access to healthcare during pandemic surges and due to those who avoided seeking care in hospitals.[167,168] The Centers for Disease Control and Prevention (CDC) found that in the 10 weeks following declaration of the COVID-19 national emergency, emergency department visits declined 23 percent for heart attack, 20 percent for stroke, and 10 percent for hyperglycemic crisis.[169]
  - Those at highest risk for severe disease and death are the elderly and people with underlying medical conditions, but COVID-19 has severely sickened and killed many young and otherwise healthy individuals, as well. Researchers are trying to determine if certain genetic characteristics are responsible for severe versus mild disease.[170] The disease in young children is usually mild, but in rare cases it is associated with multisystem inflammatory syndrome in children, in which different body parts can become inflamed, including the heart, lungs, kidneys, brain, skin, eyes, or gastrointestinal organs.[171] National data reported between March and July 2020 showed that MIS-C disproportionately impacted Black and Latino children.[172] The long-term effects of COVID-19 infection aren't fully known, but findings show heart

and lung damage in some patients, and many patients report lingering fatigue, shortness of breath, and confusion.[173]

- In June 2020, the U.S. Department of Health and Human Services (HHS) Office of Minority Health announced Morehouse School of Medicine as the awardee for a new $40 million initiative to fight COVID-19 in racial- and ethnic-minority, rural, and socially vulnerable communities. The initiative—the National Infrastructure for Mitigating the Impact of COVID-19 within Racial and Ethnic Minority Communities (NIMIC)—is a three-year project designed to work with community-based organizations nationwide to deliver education and information on resources to help fight the pandemic. Its aim is to strengthen efforts to link communities to COVID-19 testing, healthcare, and social services and to share and implement effective response, recovery, and resilience strategies.[174]
- The United States has undertaken unprecedented efforts to accelerate the development, manufacturing, and distribution of COVID-19 vaccines and therapeutics through significant federal investments and scientific cooperation, while maintaining standards for safety and efficacy.[175] Usually, vaccines take years of research and testing before they are available to the public. As of December 2020, two vaccines, one developed and manufactured by Pfizer-BioNTech, the other by Moderna, received emergency-use authorization (EUA) from the U.S. Food and Drug Administration (FDA).[176] Initial administration of the vaccine to priority groups, including healthcare workers and residents of nursing homes, also began in December 2020.

nycshooter

- The Trump Administration created a centralized system to order, distribute, and track COVID-19 vaccines.[177] States can order vaccine quantities (as supply allows) from the CDC. Airlines worldwide are providing transportation for billions of doses of vaccine that must be stored in frigid temperatures. FedEx and UPS are installing ultracold freezers near their air-cargo hubs, and dry-ice producers are increasing production to support vaccine distribution.[178] The U.S. Department of Defense and HHS coordinated the shipment of the initial doses to states.[179] The CDC released a playbook for state, tribal, territorial, and local jurisdictions on how to plan and operationalize a vaccination response to COVID-19 within their jurisdictions.[180] The Advisory Committee on Immunization Practices recommended priority groups to receive the initial doses of the vaccines,[181] but the final decisions on population prioritization and logistics

are up to the states to determine, with most states prioritizing healthcare providers and long-term care facility residents in the initial phase.[182]

- While shipping of the vaccine began shortly after the FDA issued emergency-use authorizations, the initial administration of the newly approved vaccines fell far short of projected goals. As of December 30, 2020, 12.4 million vaccine doses had been distributed to states, but only 2.6 million had been administered. Experts called on the federal government to provide more coordination and resources to the states to increase their capacity to quickly administer the vaccine to more people.[183] The challenges in initial administration of the vaccine likely occurred for many reasons, including: funding for states to administer the vaccine was not signed into law until December 27, 2020, which hindered planning, communications, hiring, and training; the lack of a centralized planning effort; the lack of federal leadership; the lack of communication between federal, state, and local planners on the number of initial doses available and when; slow engagement with local partners; and the sheer immensity and complexity of the project.[184,185] HHS is partnering with pharmacies, including CVS and Walgreens, to deliver vaccines on-site at nursing homes and assisted-living facilities. Following distribution to the initial critical populations, states are planning for COVID-19 vaccines to be available in a phased approach to the priority groups in the broader population at locations such as retail pharmacies, healthcare facilities, and vaccination sites, but as this report was being finalized, a specific time frame for availability of the vaccine to the general population was unclear and may be different from state to state.[186]

Editor's note: In January 2021, the Biden administration set a goal and put in place a plan to administer 100 million vaccine doses during its first 100 days in office.[187] That goal was later increased to 150 million doses. FEMA and National Guard troops went to work in many states to assist in the vaccination effort. As of March 1, 2021, 96,402,490 vaccine doses had been distributed nationwide and 76,899,987 had been administered.[188] However, based on preliminary data from 17 states, during the first two months of vaccine distribution, Blacks and Hispanics were being vaccinated at a much lower rate than were whites.[189]

- **Seasonal flu.** As TFAH was preparing this report, flu rates for the 2020–2021 flu season were lower than usual for major regions of the country.[190] The 2019–2020 flu season was of "moderate severity"; however, the severity of the season in some age groups was higher: hospitalization rates among children ages 0 to 4 years old and adults ages 18 to 49 years old were higher than observed during the 2009 H1N1 pandemic.[191] The CDC estimates found that the 2019–2020 flu accounted for approximately 38 million illnesses, 405,000 hospitalizations, and 22,000 flu deaths.[192] Seasonal flu vaccine coverage rates increased modestly across all age groups in 2019–2020, with vaccine rates among adults increasing 3.1 percentage points over the previous season and up 1.2 percentage points among children—but that was still far below Healthy People 2020 and 2030 goals.[193] The CDC estimates that influenza vaccination prevented 7.5 million illnesses, 3.7 million medical visits, 105,000 hospitalizations, and 6,300

MS-DOH-21-1816-A-000703

deaths due to influenza during the 2019–2020 season.[194] The low 2020–2021 seasonal flu activity was likely a result of the mitigation measures to reduce the spread of COVID-19.[195]

- **Hepatitis A.** In 2020, 27 states experienced outbreaks of the Hepatitis A virus, driven in part by increases among those who reported drug use and homelessness.[196] Hepatitis A is a highly transmissible infection.[197] The Hepatitis A vaccine is recommended for certain populations; in 2019, the Advisory Committee on Immunization Practice updated its recommendations to include people experiencing homelessness in the populations who should receive the vaccine.[198] Hepatitis A infections had been going down between 2000 and 2012 but increased in 2013, 2016, and 2018.[199] As of December 4, 2020, there have been 36,848 reported cases that lead to 22,546 hospitalizations and 348 deaths since the ongoing outbreak began in 2016.[200]

- **Measles outbreaks, United States.** In 2020, U.S. measles cases were low—only 13 confirmed cases in eight jurisdictions, as of November 30, 2020.[201] Conversely, 31 states confirmed 1,282 individual cases of measles in 2019.[202] Measles is a highly contagious disease that predominantly affects young children and can cause hospitalization, and death and serious complications, such as pneumonia, encephalitis.[203] It can cause up to a 90 percent chance of disease contraction in unimmunized individuals.[204] Outbreaks have been linked to the sustained spread of measles among unvaccinated communities.[205]

- **Measles outbreaks, global.** The WHO reported that during 2019, there were more measles cases reported worldwide than in any year since 1996—869,770 confirmed cases and an estimated 207,500 deaths.[206] Fortunately, as of September 2020, the number of confirmed cases worldwide was much lower, though the Democratic Republic of the Congo, Brazil, and Nigeria reported high numbers and there were ongoing outbreaks in other nations.[207] However, COVID-19 is increasing the risk of measles outbreaks, following the suspension of measles vaccination campaigns in 26 countries. On the current trajectory, experts predict more child deaths from measles than from COVID-19 in Africa.[208]

- **The Democratic Republic of Congo Ebola outbreak.** On June 1, 2020, the Democratic Republic of the Congo declared its 11th outbreak of Ebola virus disease.[209] In November 2020, it was declared over, following a total of 130 cases and 55 deaths.[210]

- **Candida auris.** C. auris is an emerging drug-resistant fungus that has led to severe illnesses in hospitalized patients. A majority of reported cases in 2020 were in New Jersey, New York, and Illinois. Infection by this multi-drug-resistant fungus has a mortality rate close to 60 percent and presents a serious global health threat.[211] As of November 30, 2020, in the United States, there were 1,595 reported clinical cases of C. auris and an additional 3,056 patients identified with C. auris. There is transmission in multiple countries, as well.[212] With the increase of patient transfers from long term care facilities to ICUs due to COVID-19, the CDC said that it expects C. auris and other fungal infections to remain an infection control challenge for healthcare facilities in the U.S. and around the world.[213]

- **Cholera.** Cholera, an acute intestinal infection, is rare in the United States, but cases have increased steadily since 2005 globally,[214] and it is a major cause of epidemic diarrhea in the developing world. Regions with humanitarian crises, high rates of poverty, and a lack of water and sanitation infrastructure are at higher risk. In 2020, Yemen and Somalia faced serious outbreaks.[215] Researchers estimate that every year, there are 1.3 to 4.0 million cases and 21,000 to 143,000 deaths worldwide due to cholera.[216]

- **Polio.** In August 2020, the African Continent was certified wild poliovirus free by the World Health Organization, making the world poliovirus free except for Pakistan and Afghanistan.[217] After months of severe disruptions from the COVID-19 pandemic, polio vaccination campaigns have resumed in both countries as of August 2020. UNICEF estimates up to 50 million children missed their vaccinations when efforts were halted in March 2020 to minimize transmission of COVID-19.[218]

- **Foodborne illnesses.** In 2020, multistate foodborne illness outbreaks resulted from mushrooms, peaches, onions, clover sprouts, deli meats, and bagged salads. The pathogens involved include several strains of Salmonella and E. coli, as well as Listeria and Cyclospora.[219] The CDC estimates that 48 million people get sick, 128,000 are hospitalized, and 3,000 die from foodborne illness each year in the United States.[220] The five most common pathogens that cause foodborne illness are: (1) Norovirus, (2) Salmonella, (3) Clostridium perfringens, (4) Campylobacter, and (5) Staphylococcus aureus.[221]

Notable Events and Policy Actions:

COVID RESPONSE

- **Public Health Emergency Declaration and early COVID-19 response.** On January 31, 2020, U.S. Health and Human Services Secretary Alex Azar declared a public health emergency for the United States for the 2019 novel coronavirus.[222] Since then, HHS has renewed the declaration several times. The declaration allowed some flexibilities for states, such as temporary reassignment of personnel to the response. Before the declaration and before the Trump administration requested emergency funding, Secretary Azar tapped $105 million from the Infectious Disease Rapid Response Reserve Fund for the initial response.[223] The WHO issued a public health emergency declaration of international concern in January and labeled the outbreak as a pandemic in March, 2020.[224 225]

- **COVID Response Legislation.** Congress has enacted several public laws providing funding and authorities to assist in the response to the pandemic:[226,227]

  - **Coronavirus Preparedness and Response Supplemental Appropriations Act (P.L. 116-123).** The President signed the act into law on March 6, 2020, providing $8.3 billion in emergency funding for public health measures, including the development of medical countermeasures and grants for public health agencies.

  - **The Families First Coronavirus Response Act (P.L. 116-127).** The President signed the act into law on March 18, 2020; it included the Second Coronavirus Preparedness and Response Supplemental Appropriations Act. The legislation expanded food and nutrition programs, unemployment benefits, and emergency family and medical leave; it also required certain employers to provide paid sick leave for workers unable to work due to COVID-19, and it provided access to COVID-19 testing with no cost to the individual.

  - **The Coronavirus Aid, Relief, and Economic Security (CARES) Act (P.L. 116-136).** The President signed the act into law on March 27, 2020, providing over $2.2 trillion in relief to individuals; businesses; state, local, and federal agencies; and industry sectors affected by the COVID-19 pandemic and the government-led effort to limit its public health impact. It also included a variety of oversight provisions designed to increase the information available to Congress regarding the federal government's implementation of the CARES Act and response to the COVID-19 pandemic.[228]

  - **The Paycheck Protection Program and Health Care Enhancement Act (P.L. 116-139).** The President signed the act into law on April 24, 2020; it included Additional Emergency Appropriations for Coronavirus Response. The bill extended the Paycheck Protection Program and small-business loans and allocated funding for healthcare providers and COVID-19 testing.

  - **The Coronavirus Response and Relief Supplemental Appropriations Act, 2021 (P.L. 116-26).** Congress passed and the President signed the act with the fiscal year (FY) 2021 appropriations bills and signed it into law on December 27, 2021. The bill provided $900 billion in emergency appropriations, including $73 billion for HHS, of which $8.75 billion will support the vaccination campaign.

- **Payments to healthcare providers.** The CARES Act, Paycheck Protection Program and Health Care Enhancement Act, and the Coronavirus Response and Relief Supplemental Appropriations Act allocated $178 billion for a provider relief fund for hospitals, clinics, and other healthcare providers to recover some revenue lost due to the pandemic.[229] In addition, changes in HHS telehealth policies were put in place to expand access to telehealth services during the pandemic.[230]

COVID-19 Vaccine

- **COVID-19 Vaccine.** As of December 2020, two vaccines—one developed and manufactured by Pfizer-BioNTech, the other by Moderna—received emergency-use authorization from the FDA (see COVID sidebar, on page 55).

MS-DOH-21-1816-A-000705

COVID RESPONSE

Additional COVID-19 Response Actions:

- **Medical supply shortages.** The quantities of medical supplies in the Strategic National Stockpile and through the private-sector supply chain were not sufficient for a pandemic as widespread as COVID-19. Shortages of PPE,[231] ventilators,[232] testing supplies,[233] and other medical supplies and products reached critical levels at different phases of the pandemic. President Trump invoked the Defense Production Act in April 2020 to try to spur private-sector production of these supplies.[234]
- **National Special Pathogen System.** In March 2020, ASPR expanded the Regional Ebola Treatment Network to become the National Special Pathogen System (NSPS) through COVID-19 emergency supplemental funding. The NSPS builds on the Regional Ebola Treatment Network and was originally created to support the urgent preparedness and response needs of hospitals, health systems, and healthcare providers on the front lines of the COVID-19 outbreak. The system is designed to to help prepare hospitals and health systems to identify, isolate, assess, transport, and treat patients with COVID-19 or other special pathogens or persons under investigation for such illnesses. The long-term vision of the NSPS is to create a nationwide systems-based network approach, similar to other national systems (e.g., the national trauma system) for all special pathogens.
- **Crisis standards of care.** Major surges in COVID-19 patients caused hospitals and intensive-care units to exceed capacity. Hospitals canceled admissions and nonemergency procedures and established alternate care sites. In December 2020, 10 national organizations issued a statement outlining urgent action for states, healthcare systems, and health departments to implement crisis standards of care, including legal protections for healthcare workers, statewide information sharing, distribution of patients and resources, and care coordination across jurisdictions.[235]

Vaccines: Earning Trust and Access in Communities of Color and Tribal Nations

The reported hesitance among some populations of color and Tribal Nations toward COVID-19 vaccines[236] has a basis in historic mistreatment and the effect of current-day structural racism. These experiences could have long-term impacts on vaccine confidence and vaccination rates in these groups. In October 2020, TFAH, the National Medical Association, and UnidosUS partnered to host an expert convening on how to earn vaccine trust and increase vaccine access within communities of color and Tribal Nations. The experts concluded that earning such trust will require working with leaders in those communities to use their agency as trusted messengers. Leaders from these communities must have a place at the planning table and be provided the resources needed to engage with and share information with their stakeholders. All vaccine education messaging must be culturally and linguistically appropriate. Messaging campaigns must feature trusted messengers, and education programs should take advantage of existing health communications networks. Read the full policy brief, *Building Trust in and Access to a COVID-19 Vaccine Within Communities of Color and Tribal Nations*, or find it on the TFAH website.[237]

- **Ending the HIV epidemic.** In FY 2020, the Trump administration awarded funding to its *Ending the HIV Epidemic: A Plan for America Initiative,* which aims to reduce the number of new HIV infections in the United States by 90 percent by 2030. In December 2019, Congress approved the largest increase to domestic HIV/AIDS-prevention programs from multiple federal sources, including the CDC, in decades, bringing federal funding in FY 2020 for HIV/AIDS (across multiple programs) to just over $28 billion.[238,239] In addition, HHS, through the Health Resources and Services Administration (HRSA), awarded more than $2 billion in Ryan White HIV/AIDS Program grants to cities, counties, states, and local community-based organizations. This funding supports a comprehensive program of HIV primary medical care, medication, and essential support services with the goal of improving the health quality of more than half a million people with HIV in the United States.[240]

- **Emerging infectious diseases.** The National Institute of Allergy and Infectious Diseases (NIAID), within NIH, awarded 11 grants totaling approximately $17 million to establish the Centers for Research in Emerging Infectious Diseases. The new global network will involve multidisciplinary investigations into how and where viruses and other pathogens emerge from wildlife and spillover to cause disease in people. NIAID intends to provide approximately $82 million over five years to support the network.[241]

- **Viral hepatitis strategic plan.** HHS released the Viral Hepatitis National Strategic Plan for the United States: A Roadmap to Elimination 2021–2025, which serves as a roadmap to hepatitis elimination. HHS sought input from a broad mix of stakeholders on whether the plan's goals, objectives, and strategies appropriately address the viral hepatitis epidemic and whether there are any critical gaps.[242]

- **National Action Plan for Combating Antibiotic-Resistant Bacteria (CARB).** Antimicrobial resistance, the rise of superbugs that are resistant to existing medicines, is a major threat to health. Originally released in 2015, the 2020–2025 CARB builds on the original by expanding evidence-based activities that have been shown to stop the spread of antibiotic resistance, such as increasing infection prevention and control and improving the way antibiotics are used. Developed by the HHS Office of the Assistant Secretary for Planning and Evaluation and authored by agencies within the CARB Task Force, which is co-chaired by HHS, the U.S. Department of Agriculture, and the U.S. Department of Defense, the plan's purpose is to guide U.S. government activities, as well as action by public health, healthcare, and veterinary partners to address urgent and serious antibiotic-resistant threats that affect people in the United States and globally.[243]

- **United States officially withdraws from the World Health Organization.** In July 2020, President Trump formally announced his intention to withdraw the United States from the WHO, effective July 6, 2021.[244]

Editor's note: on January 21, 2021, the Biden administration restored U.S. membership in the WHO.

MS-DOH-21-1816-A-000707

- **Food safety.** In July 2020, the FDA released its *New Era of Smarter Food Safety Blueprint*, which reflects input from a variety of stakeholders and outlines a path forward building on the implementation of the FDA Food Safety Modernization Act.[245] Its four core elements are: (1) tech-enabled traceability and foodborne outbreak response—using technologies, data streams, and approaches that will greatly reduce the time it takes to trace the origin of a contaminated food; (2) smarter tools and approaches for prevention—identifying new tools, processes, and communications to inform prevention efforts; (3) new business models and retail modernization—advancing the safety of both new business models, such as e-commerce and home delivery of food, and traditional business models, such as retail food establishments; and (4) food safety culture—supporting and strengthening cultures that embrace food safety within the FDA, on farms, and in facilities.[246]

Notable Research Findings, Meetings, and Federal Hearings:

- **Malaria treatment and prevention.** In May 2020, the FDA approved artesunate for injection to treat severe malaria in adult and pediatric patients.[247] Treatment of severe malaria with intravenous artesunate should always be followed by a complete treatment course of an appropriate oral antimalarial regimen. According to the CDC, approximately 2,000 cases of malaria are diagnosed in the United States each year, with 300 of those infected having severe disease.[248] In addition, the first phase 1 clinical trial, testing the safety and effectiveness of a monoclonal antibody against malaria, began. If effective, it would prevent malaria infections for several months with a single dose—a benefit to tourists, medical workers, and military personnel.[249]
- **Eastern Equine Encephalitis vaccine.** In June 2020, Bavarian Nordic announced topline results from the first-in-human trial of a prophylactic vaccine candidate against three equine encephalitis viruses (EEEV): western, eastern, and Venezuelan. The study, although small, showed that the vaccine was well tolerated and immunogenic across all dose groups, with injection-site pain as the most common vaccine-related adverse event.[250]
- **Ebola treatment.** In October 2020, the FDA approved Inmazeb, a mixture of three monoclonal antibodies made by Regeneron. This is the first FDA-approved treatment for Ebola virus infection in adult and pediatric patients, following a U.S. government-supported trial and expanded-access protocol in the Democratic Republic of the Congo.[251]
- **Universal flu vaccine study.** A universal influenza vaccine, FLU-v, which could confer long-lasting immunity from multiple influenza subtypes among all age groups, demonstrated immunogenicity and safety in its phase 2b study and will enter a larger phase 3 trial.[252] The FLU-v vaccine is designed to stimulate the production of flu-specific cytotoxic T lymphocytes, which kill and remove influenza-infected cells, by targeting internal viral proteins that are not as variable as the constantly mutating surface proteins currently targeted in seasonal flu vaccines.[253]

Severe Weather and Natural Disasters

Notable Incidents:

- **Tornados.** In early March 2020 in the Nashville area, 24 people were killed by two tornadoes, one of which was an EF-4 traveling at 60 miles per hour (mph)—significantly harder to outrun (or take cover from) than a typical tornado's 10 to 20 mph speed.[254] Also during a two-day period in mid-March, over 100 tornadoes ravaged the South and Southeast,[255] causing over $450 million in damage and 32 fatalities.[256]

- **Extreme heat.** In the United States, extreme heat kills more people than any other weather-related threat.[257] July 2020 nearly tied July 2019's record of the hottest month ever recorded on Earth—coming in just 0.02 degrees shy.[258,259] In August 2020, Death Valley reached 130 degrees Fahrenheit, and on September 6, 2020, Los Angeles County recorded its highest temperature ever, at 121 degrees Fahrenheit.[260] September 2020 was also the hottest September on record.[261]

- **Hurricanes.** The 2020 Atlantic hurricane season was the most active—breaking the record for the most named storms in a season, including six major hurricanes.[262] In the United States, Hurricane Isaias made landfall in North Carolina as a Category 1 and killed nine people as it moved up the coast,[263] causing more than $4 billion in damage.[264] Laura formed in the Caribbean, leaving nine dead, before developing into a Category 4 storm and making landfall in Louisiana, where it killed 27 people[265] and caused an estimated $10 to $12 billion in damage.[266] In September 2020, Hurricane Sally hit Alabama as a Category 2 and caused major flooding but no deaths,[267] though damage is estimated at $8 to $10 billion.[268] Hurricane Delta hit Louisiana in October 2020, killing at least four.[269] Central America was hit hard in 2020 with two back-to-back Category 4 storms: just weeks after Hurricane Eta made landfall and killed over 130 people, Hurricane Iota (a massive Category 5 storm while in the Atlantic) hit the same area. Together, the storms killed over 200 people.[270] In addition, the pandemic made hurricane preparations, evacuations, and sheltering more difficult.

- **Iowa derecho.** A powerful derecho—a fast wind storm associated with strong thunderstorms—tore through central Iowa in August 2020. Winds topped 100 mph and destroyed miles of crops, homes, businesses, and vehicles, and killed four people. The derecho was officially the costliest thunderstorm event in recorded U.S. history—estimated at $7.5 billion in damages.[271]

- **Wildfires in California and other states.** Several states experienced wildfires in 2020, including California, Oregon, and Colorado.[272,273] California experienced another historic fire season in 2020—five of the six largest wildfires since 1932 in California happened in 2020.[274] As of November 29, 2020, over 4 million acres had burned, compared with just under 260,000 acres burned during the same period in 2019.[275] Thirty-three people, including four firefighters, died in California in 2020 due to wildfires.[276] California's average temperature has increased by about 3 degrees Fahrenheit over the past century, which is three times the global temperature increase of 1 degree Fahrenheit.[277] Heavy spring rains promoted extensive vegetation growth, which withered in the heat and became fuel for wildfires to spread quickly through dry land.[278] In addition, the 2020 season was a La Niña cycle—colder than average surface-water temperatures in the Pacific—which often trigger hotter and drier weather in the Southwest.[279] Oregon also experienced an especially destructive wildfire season: 4,009 homes burned down in 2020, compared with 93 homes total from 2015 to 2019.[280] In Colorado, wildfires have consumed 9 percent of Rocky Mountain National Park and destroyed several historic buildings.[281] Exacerbating these fires is an ongoing pine-beetle outbreak, which has increased the number of dead trees for fuel.[282] Across the United States, 9.5 million acres have burned as of December 4, 2020, compared with 4.6 million acres for the same period in 2019.[283]

- **California power outages.** In an attempt to reduce the risk of overloading the power grid during an extreme heatwave, California's Independent System Operator, which manages the state's power supply, ordered utilities to impose temporary blackouts for the first time in 19 years.[284] While these outages only lasted an hour or two,[285] there is potential for unplanned and planned outrages to create health emergencies for some residents, including by presenting significant risks to patients in healthcare and long-term care facilities; people with electrically dependent medical equipment or medicines, such as oxygen, wheelchairs, and insulin; and the safety of food and water.[286]

MS-DOH-21-1816-A-000709

Notable Events and Policy Actions:

- **Public health emergency declarations.** In January 2020, HHS Secretary Azar declared a public health emergency for Puerto Rico following the late-December 2019 earthquakes and continuing aftershocks.[287] Azar declared emergencies in Louisiana and Texas due to Hurricane Laura and in Oregon and California due to wildfires. The declarations and related waivers give HHS's Centers for Medicare & Medicaid Services (CMS) beneficiaries and their healthcare providers and suppliers greater flexibility in meeting emergency health needs.[288,289]

- **Health center support.** In September 2020, HHS, through HRSA, awarded more than $79 million in construction and other capital support for 165 HRSA-funded health centers impacted by Hurricanes Florence and Michael, Typhoon Mangkut, and Super Typhoon Yutu, as well as for wildfires and earthquakes that occurred in 2018 and tornadoes and floods that occurred in 2019.[290]

Notable Research Findings, Meetings, and Federal Hearings:

- **Extreme rain.** Research from the National Oceanic and Atmospheric Administration on all Atlantic hurricanes affecting the southeastern and eastern United States during the 20th century found that extreme rain risk is highest after hurricanes weaken into tropical storms. The heaviest rainfall over the largest areas occurs after major hurricanes become tropical storms, not during the hurricanes—even major hurricanes—themselves.[291]

- **National Risk Index.** In November 2020, the Federal Emergency Management Agency (FEMA) released the National Risk Index, an online tool to help illustrate the nation's communities most at risk of natural hazards. It provides a holistic view of community-level risk nationwide by combining 18 hazards with socioeconomic and built-environment factors. The tool determines risk by reviewing a community's expected annual loss, by measuring hazard frequency, exposure, and historic loss rate; social vulnerability, by measuring the susceptibility of impacted social groups; and community resilience, by measuring the ability of a community to recover from the impacts of natural hazards. These data can help in developing a FEMA-approved hazard-mitigation plan to help increase community resilience, which is a prerequisite for applying for FEMA's mitigation grants.[292]

- **Climate reports.** The United Nations' World Meteorological Organization released two reports on climate in 2020. The State of Climate Services (2020) found that between 1970 and 2019, 79 percent of disasters worldwide involved weather-, water-, and climate-related hazards, which accounted for 56 percent of deaths and 75 percent of economic losses from disasters. The report highlights progress made in early warning systems' capacity, and it identifies where and how governments can invest in effective early warning systems to strengthen countries' resilience to multiple weather-, water-, and climate-related hazards. United in Science 2020, a new multi-agency report from leading science organizations, highlights the increasing and irreversible impacts of climate change and documents how COVID-19 has impeded the ability to monitor these changes through the global observing system.[293]

MS-DOH-21-1816-A-00710

CLIMATE CHANGE & HEALTH: MEASURING STATES' VULNERABILITY AND PREPAREDNESS

TFAH and JHU Bloomberg School of Public Health study reports on states' vulnerability to and readiness for the health impacts of climate change.

Climate change poses serious, immediate threats to human health. Catastrophic impacts are well-understood, such as death and injury from more frequent and more intense hurricanes and wildfires. Many dangers, however, lack a singular, spectacular event and are therefore more insidious: longer-lasting heatwaves; poorer air quality; chronic flooding; increases in vector-, water-, and food-related infections; and the toll all of this takes on people's mental health and well-being.

The release of greenhouse gases through human activities over the past two centuries has made some level of global warming inevitable. Humans must learn to live with the effects of this change (adaptation), even as they pursue the essential objective of minimizing future warming by reducing greenhouse gas emissions (mitigation).

Climate change, however, does not affect all people and places equally. A person's experience depends, in large part, on where she lives. Many health outcomes are linked to environmental factors and, therefore, sensitive to changes in climate. Social and demographic factors also drive vulnerability, meaning that the health of some communities or people could be more affected than others. In many cases, vulnerability reflects existing health risk factors and disparities, which are in turn tied to structural and systemic racism.

Fortunately, important opportunities to protect people's health from the impacts of climate change exist at the state and local level. Adaptation, which seeks to reduce injuries, illness, death, and suffering, is an extension of public health approaches that emphasize prevention and preparedness. Many of these actions are driven by state-level plans, policies, and programs, which provide a critical foundation and supply of resources to support additional efforts at the community level.

Given the size and diversity of the country, each state and its communities will experience climate change differently. State leaders must understand their particular risks and vulnerabilities in order to plan effectively. In areas of a state where vulnerability is higher, state leaders should invest more in adaptation and preparedness. Likewise, states that are more vulnerable overall should go to greater lengths to adapt to climate-related hazards.

A December 2020 report, *Climate Change & Health: Assessing State Preparedness*, by TFAH and the Johns Hopkins Bloomberg School of Public Health, examined states' readiness to protect residents from the health impacts of climate change in light of the nature and level of risks they face.[294] While every state had engaged in at least some level of planning and preparation, there was significant variation, and, in many places, a great deal of room for improvement. Of greatest concern, states with the highest

MS-DOH-21-1816-A-000711

levels of vulnerability—predominantly located in the Southeast—tended to be among the least prepared. (See Table 14.)

Leaders at all levels of government must act with urgency and persistent focus to ensure that their people, particularly those who are most vulnerable, are safe and secure. The report offers federal and state policy and program recommendations, including enacting legislation requiring a national strategic plan, fully funding the CDC's Climate and Health program, bolstering states' core public health preparedness capabilities, and establishing ongoing, dedicated state funding and staff for climate-related preparations.

Table 14. States Grouped by Level of Vulnerability and Preparedness

Vulnerability Group	State	Vulnerability Score Least Vulnerable: 3.4-4.7 More Vulnerable: 4.8-5.3 Most Vulnerable: 5.4-6.3	Preparedness Score Least Prepared: 4.0-5.0 More Prepared: 5.1-5.8 Most Prepared: 5.9-6.6
Least Vulnerable	Utah	3.8	6.6
	Maryland	4.4	6.3
	Vermont	4.3	6.3
	Colorado	4.0	6.2
	Wisconsin	4.4	6.1
	New Hampshire	4.1	6.0
	District of Columbia	4.5	5.9
	Maine	4.5	5.9
	Minnesota	4.4	5.8
	Washington	4.5	5.8
	Michigan	4.7	5.8
	Alaska	3.4	5.4
	North Dakota	4.1	5.2
	Nebraska	4.6	5.1
	Idaho	4.2	5.0
	Montana	4.3	4.8
	Wyoming	4.2	4.5
More Vulnerable	Virginia	4.8	6.3
	Massachusetts	4.9	6.2
	Rhode Island	4.9	6.0
	Illinois	4.9	6.0
	New York	5.3	5.9
	Pennsylvania	5.3	5.9
	Connecticut	4.9	5.9
	Oregon	4.8	5.8
	Delaware	4.9	5.7
	Kansas	5.1	5.3
	Iowa	4.9	5.3
	Indiana	5.0	5.0
	Ohio	5.1	5.0
	New Jersey	5.2	4.9
	Hawaii	5.3	4.8
	Nevada	4.9	4.6
	South Dakota	4.8	4.5
Most Vulnerable	North Carolina	5.5	6.0
	Arizona	5.4	5.9
	Alabama	5.8	5.8
	California	5.5	5.8
	Louisiana	5.9	5.7
	New Mexico	5.8	5.7
	Arkansas	6.1	5.5
	Missouri	5.4	5.5
	Florida	6.3	5.1
	Tennessee	5.5	4.9
	Georgia	5.6	4.9
	Kentucky	5.9	4.8
	South Carolina	5.9	4.8
	Texas	5.5	4.6
	Mississippi	5.9	4.5
	Oklahoma	5.5	4.5
	West Virginia	5.8	4.0

"Most prepared," among states that were "least vulnerable."

"Least prepared," among states that were "least vulnerable."

MS-DOH-21-1816-A-000712

All Hazards Events and Policy Actions

Notable Incidents:

- **E-cigarette and vaping injuries and deaths.** According to the CDC, as of February 18, 2020, a total of 2,807 hospitalized e-cigarette or vaping-associated lung injuries (EVALI) or deaths were reported to the CDC from all 50 states, DC, Puerto Rico, and the U.S. Virgin Islands. Sixty-eight deaths have been confirmed in 29 states and DC. Due to continued declines in new EVALI cases since September 2019, and the identification of vitamin E acetate as a likely primary cause of EVALI, the CDC is no longer collecting case reports.[295]

- **Mass shootings.** During 2020, in the United States, there were 611 mass shootings—defined as an incident in which at least four people are shot, excluding the shooter—in 2020.[296] This is a significant increase since 2019, when there were 417 total mass shootings.[297] These events have long-term health effects on communities and survivors, including post-traumatic-stress disorder, substance abuse, anxiety, and depression.[298]

- **Terror attacks.** On Christmas day, a bomb detonated in downtown Nashville, damaging over 40 businesses in the area and injuring three people. Quick evacuations by first-responders likely saved lives in the area.[299] While the motivation for the Christmas Day bombing is not known, the Center for Strategic and International Studies reported that white supremacists and other like-minded extremists conducted two-thirds of terrorist plots and attacks in the United States as of October 2020.[300]

Notable Events and Policy Actions:

- **Animal disease research.** The U.S. Department of Homeland Security is transferring a new facility—the National Bio and Agro-Defense Facility, which will research foreign animal diseases—to the U.S. Department of Agriculture. Foreign animal diseases pose a risk to livestock (and in rare cases, people) and the facility will develop countermeasures for these diseases. A report by the Government Accountability Office (GAO) found that it may not be ready to open in December 2022 as planned, despite both departments following practices for a successful transfer.[301]

- **Radiological detection.** The Defense Advanced Research Projects Agency (DARPA) greenlit an automated, networked radiation detection system known as SIGMA for use by the Port Authority of New York and New Jersey, which is theoretically capable of providing counterterrorism support through constant monitoring for radiological and nuclear threats. DARPA has further developed and tested sensors for SIGMA to add chemical, biological, and explosive threat detection to its list of capabilities. SIGMA is based in worn, portable sensors, vehicular-mounted sensors, and stationary sensors at key transportation nodes, and it can be constantly improved through regular software updates. Officials and first-responders can use SIGMA to track alerts and threats in real time, allowing for enhanced coordination.[302]

- **Next Generation 911.** The U.S. Department of Homeland Security Science and Technology Directorate and the U.S. Department of Transportation have begun systems interoperability and compatibility testing for the Next Generation 911 (NG911) through a contract with the Critical Infrastructure Resilience Institute of the University of Illinois at Urbana-Champaign. NG911 will update the current nationwide emergency response system to an Internet Protocol (IP) platform, which will enable voice, video, photographs, text, and future communications technologies to be transmitted to and by the public and first-responders for assistance.[303] No system launch date has been announced.

- **HHS/ASPR Strategic Plan.** In April 2020, the U.S. Office of the Assistant Secretary for Preparedness and Response (ASPR) released the ASPR Strategic Plan for FY 2020-23, which organizes and identifies how ASPR will fulfill its mission of saving lives and protecting Americans from 21st-century health security threats and achieve its strategic vision: "the nation's health care and response systems and the communities they serve are prepared, responsive, and resilient, thereby limiting the adverse health impacts of emergencies and disasters." The plan builds on the successful foundation established by the ASPR strategic plans issued in 2011 and 2014, and aligns with the HHS Strategic Plan FY 2018-2022 and other relevant national strategies and legislation. It is also informed by experience and lessons from real-world incidents, exercises, and training activities occurring over more than a decade. The plan organizes ASPR's efforts under four priority goals: (1) foster strong leadership; (2) sustain robust and reliable public health security capabilities; (3) advance an innovative medical countermeasures enterprise; and (4) build a regional disaster health response system.[304]

MS-DOH-21-1816-A-000713

Notable Research Findings, Meetings, and Federal Hearings:

- **Retention of the public health workforce.** As of November 2020, at least 70 top public health officials had been fired, resigned, or planned to leave their posts since the beginning of the pandemic.[305] The alarming trend often resulted from threats, both in-person and via social media, scapegoating, or political retribution. Even before the pandemic and related recession, state health agencies had lost nearly 10 percent of their full-time equivalent (FTE) workforce from 2012 to 2019,[306] while local health departments lost about 16 percent of their FTE staff from 2008 to 2019.[307]

- **Recruitment and retention of scientists.** A May 2020 GAO report found that HHS has had trouble recruiting and retaining medical, engineering, and other science and technology professionals to support activities like biomedical and clinical research. The 21st Century Cures Act provides additional hiring and retention authority—allowing HHS to hire up to 2,000 scientists with certain specialized graduate degrees and to increase the top pay to hire and retain an expert staff.[308]

- **Rebuilding the Public Health Workforce.** State and local revenue losses due to the COVID-19 economic crisis is likely to lead to budget cuts at the state and local level and is expected to worsen the public health workforce staffing shortfall. COVID response funding did allow for short-term staffing increases but not for the hiring of the permanent public health professionals necessary to meet 21st-century challenges.[309]

- **Antibiotic resistance.** Two novel investigative drugs that target antibiotic-resistant infections began advanced development through the Biomedical Advanced Research and Development Authority to begin phase 2 and 3 clinical trials. One drug tackles Clostridioides difficile (C. difficile) infections, which causes an estimated12,800 deaths per year.[310] The second uses CRISPR technology to kill Escherichia coli (E. coli) bacteria that cause recurring or drug-resistant urinary tract infections. If successful, it would be the first CRISPR-engineered bacteriophage therapy to be FDA-approved.[311] Bacteriophages are viruses that infect and replicate only in bacterial cells. They cannot infect human cells, and because each type of bacteriophage only kills a specific set of bacteria, it's less likely to disturb the beneficial bacteria in the human body.[312] In addition, the FDA approved cefiderocol for hospital-acquired, ventilator-associated bacterial pneumonia due to multidrug-resistant gram-negative bacteria.[313]

- **Legislative pandemic preparation blueprint.** In July 2020, then–Senate Health, Education, Labor and Pensions (HELP) Committee Chairman Lamar Alexander released "Preparing for the Next Pandemic," a legislative blueprint with five recommendations for legislators to address future pandemics based on lessons learned from COVID-19 and the past 20 years of pandemic planning. The five recommendations involve: (1) accelerated research and development for tests, treatments, and vaccines; (2) expanded disease surveillance; (3) improved stockpile capacity and distribution process; (4) improved state and local response capacity; and (5) improved federal coordination.[314] Leading public health experts sent the committee over 350 recommendations of short-term and long-term proposals to address future pandemics on a range of topics, including sustaining onshore manufacturing, creating and sustaining state stockpiles, and improving the federal stockpile.[315]

- **Preparedness Summit.** In August 2020, more than 1,300 attendees—who work in all levels of government, emergency management, volunteer organizations, healthcare coalitions, and academia—participated in the first ever virtual Preparedness Summit, "Fixing Our Fault Lines: Addressing Systemic Vulnerabilities." Attendees participated in more than 115 demonstrations, workshops, and educational sessions, and heard from expert-led panels, which provided an opportunity to prepare for, respond to, and recover from the waves of the COVID-19 pandemic and the many other threats to public health and health security.[316]

- **COVID-19 and Achieving Health Equity Report.** In September 2020, then–Senate HELP Committee Ranking Member Patty Murray also released a report, "COVID-19 & Achieving Health Equity: Congressional Action is Necessary to Address Racism and Inequality in the U.S. Health Care System." The report included 30 recommendations to Congress, including dedicated funding for COVID-19 relief for communities of color, requiring an equitable vaccine distribution plan, and a federal right to paid sick days and family and medical leave.[317]

MS-DOH-21-1816-A-000714

Appendix B: Methodology

Trust for America's Health (TFAH) made major refinements to its methodology for Ready or Not in 2018. For more information, see the 2019 edition of the series, Appendix A: Methodology.[318]

To meet TFAH's criteria, each indicator must be:

- **Significant.** The indicator needed to be a meaningful measure of states' public health emergency preparedness. The NHSPI first measured significance by using a multistage Delphi process with a panel of experts and then again by TFAH through interviews with additional experts.
- **Broadly relevant and accessible.** The indicator needed to be relevant—and timely data needed to be accessible—for every state and the District of Columbia.
- **Timely.** Data for the indicator needed to be updated regularly.
- **Scientifically valid.** Data supporting the indicator needed to be credible and rigorously constructed.
- **Nonpartisan.** The indicator, and data supporting the indicator, could not be rooted in or seen as rooted in any political goals.

Using these criteria, TFAH aims to select a broad set of actionable indicators with which it—and other stakeholders, including states themselves—can continue to track states' progress. (Complete data were not available for U.S. territories.) TFAH will strive to retain all or most of these indicators for multiple years to assist states in tracking their progress against each measure.

TFAH seeks measures that are incorporated in the NHSPI and that most closely meet TFAH's criteria. There is one exception: a measure of state public health funding-level trends that the NHSPI does not track.

Indicator Data Collection

The NHSPI provided TFAH with data for every indicator except five (those data tied to the NLC, public health funding, flu vaccination, hospital patient safety, and laboratory surge capacity). In cases where newer data were available than those modeled in the 2020 edition of the NHSPI, TFAH collected and verified figures from their original sources.

Public Health Funding Data Collection and Verification

To collect public health funding data for this report, TFAH examined states' publicly available funding documents and surveyed state officials. Informed by the Public Health Activities and Services Tracking project at the University of Washington, TFAH defines public health programming and services as inclusive of communicable disease control; chronic disease prevention; injury prevention; environmental public health; maternal, child, and family health; and access to and linkage with clinical care. Specifically, this definition includes:

MS-DOH-21-1816-A-000715

- **Communicable disease control.** Public health services related to communicable disease epidemiology, hepatitis, HIV/AIDS, immunization, sexually transmitted diseases, tuberculosis, etc.
- **Chronic disease prevention.** Public health services related to asthma, cancer, cardiovascular disease, diabetes, obesity, tobacco, etc.
- **Injury prevention.** Public health services related to firearms, motor vehicles, occupational injuries, senior falls prevention, substance-use disorder, other intentional and unintentional injuries, etc.
- **Environmental public health.** Public health services related to air and water quality, fish and shellfish, food safety, hazardous substances and sites, lead, onsite wastewater, solid and hazardous waste, zoonotic diseases, etc.
- **Maternal, child, and family health.** Public health services related to the coordination of services; direct service; family planning; newborn screening; population-based maternal, child, and family health; supplemental nutrition; etc.
- **Access to and linkage with clinical care.** Public health services related to beneficiary eligibility determination, provider or facility licensing, etc.

TFAH excludes from its definition insurance coverage programs, such as Medicaid or the Children's Health Insurance Program, as well as inpatient clinical facilities.

TFAH, under the guidance of state respondents, revised data for the base year. (In this report, that was FY 2019.) For some states, this was necessary to improve comparability between the two years when a reorganization of departmental responsibilities had occurred over the period.

All states and the District of Columbia verified their funding data.

Scoring and Tier Placements

TFAH grouped states based on their performances across the 10 indicators, and TFAH gave partial credit for some indicators to draw finer distinctions among states and within states over time. TFAH placed states into three tiers—high tier, middle tier, and low tier—based on their relative performance across the indicators.

Specifically, TFAH scored each indicator as follows:

- Adoption of the NLC: 0.5 point. No adoption: 0 points.
- Percent of hospitals participating in healthcare coalitions: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - Within one standard deviation above the mean (and states with universal participation): 1 point.
  - Within one standard deviation below the mean: 0.75 point.
  - Between one and two standard deviations below the mean: 0.5 point.
  - Between two and three standard deviations below the mean: 0.25 point.
  - More than three standard deviations below the mean: 0 points.
- Accreditation by the PHAB: 0.5 point. Not accredited: 0 points.
- Accreditation by the EMAP: 0.5 point. Not accredited: 0 points.
- Size of state public health budget compared with the past year (nominally, not inflation-adjusted).
  - No change or funding increase: 0.5 point.
  - Funding decrease: 0 points.
- Percent of population who used a community water system that failed to meet all applicable health-based standards: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - Within one standard deviation above the mean (and states with 0 percent of residents who used a noncompliant community system): 1 point.
  - Within one standard deviation below the mean: 0.75 point.
  - Between one and two standard deviations below the mean: 0.5 point.
  - Between two and three standard deviations below the mean: 0.25 point.
  - More than three standard deviations below the mean: 0 points.
- Percent of employed population with paid time off: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Between one and two standard deviations below the mean: 0.25 point.
  - More than two standard deviations below the mean: 0 points.

MS-DOH-21-1816-A-007716

- Percent of people ages 6 months or older who received a seasonal flu vaccination: TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Between one and two standard deviations below the mean: 0.25 point.
  - More than two standard deviations below the mean: 0 points.
- Percent of hospitals with a top-quality ranking ("A" grade) on the Leapfrog Hospital Safety Grade. TFAH scored states according to the number of standard deviations above or below the mean of state results.
  - More than one standard deviation above the mean: 1 point.
  - Within one standard deviation above the mean: 0.75 point.
  - Within one standard deviation below the mean: 0.5 point.
  - Positive number, more than one standard deviation below the mean: 0.25 point.
  - No hospitals with a top-quality ranking ("A" grade): 0 points.
- Public health laboratory has a plan for a six- to eight-week surge in testing capacity: 0.5 point. Did not report having a plan: 0 points.

The highest possible score a state could receive was 7.5 points.

TFAH placed states whose scores ranked among the top 17 in the high-performance tier. TFAH placed states whose scores ranked between the 18th-highest and 34th-highest in the middle tier. TFAH placed states with scores ranked between the 35th-highest and 51st-highest in the low-performance tier. (Ties in states' scores can prevent an even distribution across the tiers.)

This year, states in the high tier had scores ranging from 6 to 7; states in the middle tier had scores ranging from 5.25 to 5.75; and states in the low tier had scores ranking from 4 to 5.

Assuring data quality

TFAH conducted several rigorous phases of quality assurance to strengthen the integrity of the data and to improve and deepen TFAH's understanding of states' performance, especially that of outliers on specific indicators. During collection of state public health funding data, researchers systematically inspected every verified data file to identify incomplete responses, inconsistencies, and apparent data entry errors. Following this inspection, TFAH contacted respondents and gave them the opportunity to complete or correct their funding data.

Subject: TIME SENSITIVE and EMBARGOED: TFAH's Ready or Not 2022 report on public health emergency preparedness

Dear Directors of Public Health Preparedness,

Attached is the embargoed copy, with supporting information, of the Trust for America's 2022 Health Ready or Not Preparedness Report which is **EMBARGOED UNTIL 12:01 AM, MARCH 10, 2022**.

We anticipate that this release will generate some level of national, regional, and local media coverage as well as possibly inquiries from state legislatures and/or your governors' offices, especially given ongoing response to the COVID-19 pandemic. As such, we recommend that states be prepared to share specific examples of progress, accomplishments and, yes, unmet needs, associated with all-hazards readiness, including specific recent high profile incident responses.

ASTHO has also shared this embargoed report with State and Territorial Health Officials and Senior Deputies.

Thank you,
Meredith

Meredith Allen, DrPH, MS

Ready or Not 2022

Executive Summary

As this report was being prepared, over 900,000 people in the United States and nearly 6 million worldwide had died due to COVID-19,[1] and the world had experienced two years of economic and social disruption. In addition, 2021 saw record heat in many states, extensive flooding, a highly active Atlantic hurricane season, and unusual and deadly December tornados. These events led to nearly unprecedented levels of illness, social upheaval, and economic hardship, including overwhelmed hospitals, job loss, property loss, children's learning loss, and mental health concerns.

During 2021, the nation made progress in many areas in its response to the pandemic. As this report was being produced, 62 percent of the nation's population was fully vaccinated,[2] averting an estimated 1.1 million COVID-19 deaths and over 10 million COVID-19-related hospitalizations.[3] The Biden Administration restored the White House Directorate on Global Health Security and Biodefense and created the Presidential COVID-19 Health Equity Task Force (see sidebar on pg. 15). And the approval of new treatments for COVID-19 has increased the likelihood of survival for many patients.[4]

At the same time, major challenges remained. Hospital systems in many states were overwhelmed during pandemic waves. Testing was difficult to access during surges—at-home tests were particularly difficult to find—and in some cases testing was expensive, misinformation was abundant, and public patience with and trust in public health guidance wore thin. Of great concern, lawmakers in many states introduced or enacted laws to restrict the authority of public health officials.[6] In addition, according to *The New York Times,* approximately 500 public health officials nationwide had left the field since the start of the pandemic. Some

Editor's note: as of January 16, 2022, the Centers for Disease Control and Prevention (CDC) defined "fully vaccinated" as a person who has received their primary series of COVID-19 vaccines. CDC is also using "Up to Date" to denote that a person has received all recommended COVID-19 vaccines including any booster dose(s) when eligible.[5]

MS-DOH-21-1816-A-000737

retired, some left due to threats and harassment, some due to firings when public health guidance clashed with what elected officials wanted to do.[7]

In addition, the pandemic has illuminated two stark realities: the nation and the world's public health systems are inadequate and in immediate need of significant and sustained funding. And, once again, the nation's health inequities led to some population groups, particularly communities of color and low-income communities, experiencing a disproportionate burden during the pandemic, with less access to resources like vaccines during the response, and having more barriers to recovery.[8,9]

To better meet the challenges of future public health emergencies, including climate change, the nation must address underlying drivers of economic and health inequities, including ongoing discrimination, structural racism, and social determinants of health. Investments in public health infrastructure alone, while critical, will not make the United States more resilient. Equity must be an explicit and foundational principle in all public health preparedness, response, and recovery.[8,9]

The COVID-19 pandemic's impact—including its high death tolls and extreme economic disruption—was, at least to some degree, an avoidable tragedy. But with this tragedy comes opportunity. The pandemic has shined a bright light on what's needed: robust, flexible, and sustained investment in public health infrastructure, modernization of data systems and surveillance capacity, increased public health laboratory capacity, sustained growth and increased diversity in the public health workforce, and addressing the social determinants of health. Today, only half of all U.S. residents are protected by a comprehensive local public health system,[10] and it is estimated that state and local health departments need to hire a minimum of 80,000 additional full-time workers to be able to meet their communities' basic public health needs.[11]

It is estimated that state and local health departments need to hire a minimum of 80,000 additional full-time workers to be able to meet their communities' basic public health needs.

This annual report, *Ready or Not: Protecting the Public's Health from Disease, Disasters, and Bioterrorism,* has tracked the nation's public health emergency preparedness since 2003. The report is designed to give policymakers at all levels of government actionable data and recommendations with which they can target policies and spending to strengthen their jurisdiction's emergency preparedness. The report's 10 key public health preparedness indicators give state officials benchmarks for progress, point out gaps within their states' all-hazards preparedness, and provide data to compare states' performances against similar jurisdictions.

These data points are meant to measure states' readiness on a broad set of health security measures and have been the focus of this report for over a decade. However, for this 2022 edition of the report (and going forward), there is one change to the indicators set: the hospital participation in healthcare coalitions indicator, which was based on 2017 data that has not been recently updated by the National Health Security Preparedness Index (NHSPI), has been replaced with a new indicator, also tracked by NHSPI, that measures the percentage of state populations served by a comprehensive public health system.

Readers should note that this report is not designed to be an assessment of a given state's response to the COVID-19 pandemic, as widescale political, funding, economic, and social factors all influenced the virus's impact and local responses. Controlling the pandemic has been extremely challenging in every state. Moreover, the pandemic has illustrated that being prepared to adequately respond to a public health emergency the scale of a pandemic—and execute that response—is enormously complex and beyond the sole control of state and local officials. However, this report measures critical capacities that are foundational to protecting the public's health every day and during emergencies, including robust and sustained public health funding, disease surveillance capacity, healthcare, public health laboratory and hospital surge capacity, access to safe water, and access to paid time-off. In addition, the pandemic has shown that there is no substitute at the state or local level for a strong federal response during an emergency.

MS-DOH-21-1816-A-000738

This Year's Findings

In this 2022 report, Trust for America's Health (TFAH) found that 12 states improved their relative standing—for each indicator and overall, states were scored relative to one another—compared with last year, while 16 fell behind. Nine states improved by one tier, three states improved by two tiers, and 16 states dropped one tier. *(Note:* There was greater year-over-year state movement between tiers this year than in past years—in both directions—in part because of the introduction of a new indicator.)

TABLE 1: Top-Priority Indicators of State Public Health Preparedness

INDICATORS			
1	**Incident Management:** Adoption of the Nurse Licensure Compact.	6	**Water Security:** Percentage of the population that used a community water system that failed to meet all applicable health-based standards.
2	**Public Health System Comprehensiveness:** Percentage of state population served by a comprehensive public health system **(new)**.	7	**Workforce Resiliency and Infection Control:** Percentage of employed population that used paid time off in a given month.
3	**Institutional Quality:** Accreditation by the Public Health Accreditation Board.	8	**Countermeasure Utilization:** Percentage of people ages 6 months or older who received a seasonal flu vaccination.
4	**Institutional Quality:** Accreditation by the Emergency Management Accreditation Program.	9	**Patient Safety:** Percentage of hospitals with a top-quality ranking ("A" grade) on the Leapfrog Hospital Safety Grade.
5	**Institutional Quantity:** Size of the state public health budget compared with the past year.	10	**Health Security Surveillance:** The public health laboratory has a plan for a six- to eight-week surge in testing capacity.

Notes: The 2022 edition of the report introduces a new indicator, measuring the percentage of state populations served by a comprehensive public health system. This new indicator replaces a previous indicator tracking the percentage of hospitals participating in healthcare coalitions. The National Council of State Boards of Nursing organizes the Nurse Licensure Compact. Systems for Action uses the National Longitudinal Survey of Public Health Systems to measure public health system comprehensiveness. The U.S. Environmental Protection Agency assesses community water systems. Paid time off includes sick leave, vacation time, or holidays, among other types of leave. The Leapfrog Group is an independent nonprofit organization. TFAH drew every indicator, and some categorical descriptions, from the National Health Security Preparedness Index, with one exception: public health funding. See "Appendix B: Methodology" for a description of TFAH's funding data-collection process, including its definition.

Source: National Health Security Preparedness Index[12]

The *Ready or Not* report groups states and the District of Columbia into one of three tiers (high, middle, and low) based on their relative performances across the 10 indicators. This year, 17 states and the District of Columbia scored in the high-performance tier, 20 placed in the middle-performance tier, and 13 were in the low-performance tier (see Table 2). (See "Appendix B: Methodology" for more information on the scoring process.)

Nine states showed notable improvement, moving up a tier: Alabama, Florida, Illinois, Iowa, New Jersey moved from the middle tier to the high tier, and Arizona, Missouri, New Hampshire, and New York moved from the low tier to the middle tier. As an example of the factors behind such movement, New Hampshire's rise from the low tier to the middle tier had three primary drivers. First, while still below average, the state performed better in the new indicator (Public Health System Comprehensiveness) than it had in the now-replaced measure of hospital participation in healthcare coalitions. Second, its share of employed residents who used paid time off based on a one-month sample increased, while the national average stayed flat. Third, the state's hospitals made marked improvement in the area of patient safety.

Three states—Ohio, Pennsylvania, and South Carolina—demonstrated exceptional progress, elevating from the low tier to the high tier. Ohio adopted the Nurse Licensure Compact in 2021, and its score also benefited from the introduction of the new Public Health System Comprehensiveness indicator. Pennsylvania also adopted the Nurse Licensure Compact, benefited from the new indicator, increased its public health funding, and experienced only a small reduction in the share of its hospitals who received an "A" rating for patient safety at a time when the national average fell by a greater extent. Collectively, these improvements were sufficient to offset some decline in the share of its employed residents who used paid time off. Finally, South Carolina's score benefited from the new indicator, in addition to the state achieving accreditation by the Public Health Accreditation Board and greater usage of paid time off.

MS-DOH-21-1816-A-000739

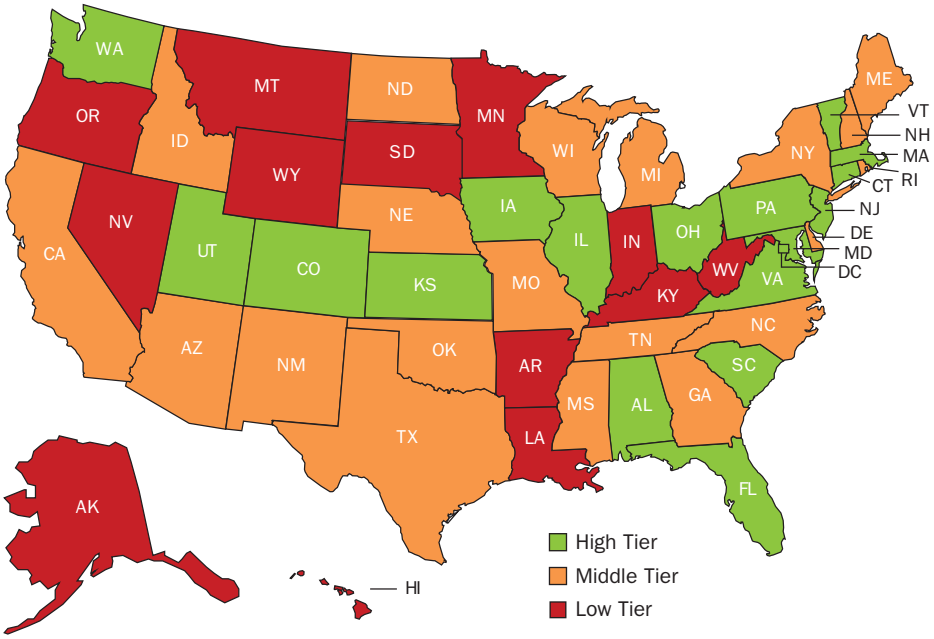
Sixteen states fell one tier: Delaware, Georgia, Idaho, Maine, Mississippi, Nebraska, New Mexico, North Carolina, Oklahoma, Rhode Island, and Wisconsin moved from the high tier to the middle tier, and Kentucky, Louisiana, Minnesota, Montana, and Oregon moved from the middle tier to the low tier). New Mexico, for instance, saw its score fall because it lost its accreditation from the Emergency Management Accreditation Program, vaccinated a smaller percentage of its residents against seasonal flu, and had a slightly smaller share of its hospitals receive an "A" rating for patient safety.

TABLE 2: State Public Health Emergency Preparedness
State performance, by scoring tier, 2021

Performance Tier	States	Number of States
High Tier	AL, CO, CT, DC, FL, IA, IL, KS, MA, MD, NJ, OH, PA, SC, UT, VA, VT, WA	17 states and DC
Middle Tier	AZ, CA, DE, GA, ID, ME, MI, MO, MS, NC, ND, NE, NH, NM, NY, OK, RI, TN, TX, WI	20 states
Low Tier	AK, AR, HI, IN, KY, LA, MN, MT, NV, OR, SD, WV, WY	13 states

Note: See "Appendix B: Methodology" for scoring details. Complete data were not available for U.S. territories.

Indicators of State Public Health Emergency Preparedness
State performance, by scoring tier, 2021



TFAH's Analysis Found:

A majority of states have made preparations to expand healthcare and public health capabilities in an emergency. Thirty-seven states participated in the Nurse Licensure Compact, up from 26 in 2017,[13] with Ohio, Pennsylvania, and Vermont being the most recent adopters.[14] The compact allows registered nurses and licensed practical or vocational nurses to practice in multiple jurisdictions with a single license. In an emergency, this enables health officials to quickly increase their staffing levels. For example, nurses may cross state lines to work at evacuation sites or other healthcare facilities. In addition, only the District of Columbia reported not having a plan to ensure public health laboratories are prepared for a large influx of testing needs. (The District of Columbia reported that it was in the process of updating its Continuity of Operations Plan and developing a discrete plan for laboratory surges.) All other states had a plan to surge public health laboratory capacity for six to eight weeks as necessary during overlapping emergencies or large outbreaks.

Most residents who received their household water through a community water system had access to safe water. On average, just 5 percent of state residents used a community water system in 2019 (latest available data) that did not meet all applicable health-based standards, down slightly from 7 percent in 2018. Water systems with such violations increase the chances of water-based emergencies in which contaminated water supplies place the public at risk.

Most states are accredited in the areas of public health, emergency management, or both. As of November 2021, the Public Health Accreditation Board or the Emergency Management Accreditation Program accredited 42 states and the District of Columbia; 32 states and the District of Columbia were accredited by both groups, a net increase of three since December 2020. Eight states (Alaska, Hawaii, Kentucky, New Hampshire, South Dakota, Texas, West Virginia, and Wyoming) were not accredited by either group. Both programs help ensure that necessary emergency prevention and response systems are in place and staffed by qualified personnel.

Seasonal flu vaccination rates, while still too low, have risen significantly in recent years. The seasonal flu vaccination rate among Americans ages 6 months and older rose from 42 percent during the 2018–2019 season to 52 percent during the 2019–2020 and 2020–2021 seasons.[15,16] However, *Healthy People 2030,* a set of federal 10-year objectives and benchmarks for improving the health of all Americans by 2030, set a seasonal influenza vaccination-rate target of 70 percent annually.[17]

Still, despite these positive steps, just half of the U.S. population is served by a comprehensive public health system—an indicator newly tracked in the 2022 edition of this series. Such systems tend to engage in a wide array of recommended activities to assess their communities' health and needs, develop evidenced-based public policy that promotes health and safety, ensure that necessary services are accessible to all residents, and cultivate a broad coalition of stakeholder partners. Comprehensive systems have been shown to contribute to positive health outcomes in a cost-effective manner. In just eight states and the District of Columbia were a majority of residents served by a comprehensive public health care system.

MS-DOH-21-1816-A-000741

In March 2020, 55 percent of employed state residents, on average, used paid time off, the same percentage as in 2018 and 2019. Those without paid leave are more likely to work when they are sick and risk spreading infection. In the past, the absence of dedicated paid sick leave has been linked to or has exacerbated some infectious disease outbreaks.[18] This has become particularly relevant during the COVID-19 pandemic, as isolation and quarantine are important tools for controlling the outbreak. The Families First Coronavirus Response Act helped address this issue during the early stages of the pandemic for employers with fewer than 500 employees and certain public employers, temporarily requiring employees to be paid up to 80 hours of sick leave benefits under certain conditions, but these protections expired on December 31, 2020.[19] Importantly, the United States could join numerous countries across the world in establishing a national minimum standard of paid family or medical leave, if proposed provisions of the Build Back Better Act become law.

Only 28 percent of hospitals, on average, earned a top-quality patient safety grade, down slightly from 31 percent in 2020. Hospital safety scores measure performance on such issues as healthcare-associated infection rates, intensive-care capacity, and an overall culture of error prevention. In the absence of diligent actions to protect patient safety, deadly infectious diseases can take hold or strengthen.

POLICY RECOMMENDATIONS

Based on the data collection and analysis summarized in this report, and consultation with public health and emergency preparedness experts, the report includes recommendations for policy action in seven priority areas:

1. **Providing stable and sufficient funding for public health security.** Congress and state and local governments must invest in the foundations of public health, including public health infrastructure, workforce, and data systems.
2. **Preventing disease outbreaks and pandemics.** Policymakers should support the vaccination infrastructure, fight antibiotic resistance, and support paid leave for all workers.
3. **Building resilient communities and promoting health equity in preparedness.** Congress and leaders at all levels of government should prioritize investments in health equity, incorporate equity leadership into preparedness and response, and invest in social determinants of health.
4. **Ensuring effective leadership and coordination.** Policymakers should strengthen public health leadership and communications and reject attempts to weaken public health authorities. Congress should create a COVID-19 Commission to review and address gaps in pandemic response.
5. **Accelerating development and distribution of medical countermeasures (MCMs).** Congress should invest in the entire MCM enterprise to enable rapid development and effective deployment of life-saving products during emergencies.
6. **Readying the healthcare system to respond during and recover from public health emergencies.** Federal and state policymakers and the healthcare system must prioritize effective coordination and planning for a surge of patients.
7. **Preparing for environmental threats and extreme weather.** Congress and the White House should develop a strategic plan, along with funding, to minimize the health impacts of climate change and promote health equity.

For a full description of the report's recommendations, see the recommendations section beginning on page 40.

MS-DOH-21-1816-A-000742

Report Purpose and Methodology

TFAH's annual *Ready or Not* report series tracks states' readiness for public health emergencies based on 10 key indicators that collectively provide a checklist of top-priority issues and action items for states and localities to continuously address. By gathering timely data on all 50 states and the District of Columbia, the report assists states in benchmarking their performance against comparable jurisdictions. TFAH completed this analysis after consultation with a diverse group of subject-matter experts and practitioners.

See Appendix B for more detail on the report's methodology.

READY OR NOT AND THE NATIONAL HEALTH SECURITY PREPAREDNESS INDEX

The indicators included in this report were drawn from, and identified in partnership with, the National Health Security Preparedness Index (NHSPI),[20] with one exception: a measure of state public health funding-level trends, which reflects how well-resourced key agencies are to prepare for and respond to emergencies. The NHSPI is a joint initiative of the Robert Wood Johnson Foundation, the University of Kentucky, and the University of Colorado. (See "Appendix B: Methodology" for a detailed description of how TFAH selected and scored the indicators.)

While state rankings in *Ready or Not* and the NHSPI largely align, there are some important differences. The two projects have somewhat different purposes and are meant to be complementary, rather than duplicative. With more than 100 indicators, the NHSPI paints a broad picture of national health security, allowing users to zoom out and holistically understand the extent of both individual states and the entire nation's preparedness for large-scale public health threats. In slight contrast, *Ready or Not,* with its focus on 10 select indicators, focuses attention on state performances on a subset of the Index and spotlights important areas for stakeholders to prioritize a smaller, more focused set of improvement goals. TFAH and the NHSPI work together to help federal, state, and local officials use data and findings from each project to make Americans safer and healthier.

MS-DOH-21-1816-A-000743

SPECIAL SECTION:

Lessons of the Pandemic's Tragic Death Toll: What Needs to be Done Now to Save Lives During the Next Public Health Emergency?

The over 900,000 U.S. lives lost due to the COVID-19 pandemic[21] is made even more tragic by the fact that many of these deaths were preventable. If the public health community's warnings of over a decade that the country's public health infrastructure was dangerously inadequate had been heeded lives would have been saved and economic upheaval lessened. In addition, misinformation, mistrust in government, and political division have driven anti-public health and anti-vaccine policies and actions. Furthermore, underinvestment in health equity and social determinants of health contributed to high rates of chronic disease, leaving some populations vulnerable to severe outcomes during the pandemic. Confusing and disjointed leadership and messaging led to disparate responses in every state. And the healthcare system, which operates near capacity on many days, was unprepared for multiple surges throughout the pandemic.

But within this tragedy is opportunity. The pandemic has shined a light on what is needed: Congress and states must work to create robust and sustained investment in public health infrastructure, modernization of data systems and surveillance capacity, increased public health laboratory capacity, sustained growth in a diverse and highly skilled public health workforce, and improved public health messaging and communications. However, these investments in public health infrastructure alone will not make America more resilient in the face of the next public health emergency. Protecting health in every community will also require addressing the systemic inequities that led to COVID-19's disproportionate health and economic impacts, particularly in communities of color and low-income communities.

What went wrong?

Policymakers did not heed the decades-long call by public health experts to fund public health on a sustained basis and not just in response to an emergency. Underfunding contributed to understaffed and overworked health departments using out-of-date technologies. In addition, lack of support and outright threats against public health officials contributed to hundreds of senior-level state and local public health officials leaving the profession.[22]

The nation's public health data systems are woefully dated and not up to the task of tracking an infectious disease outbreak on the scale of a pandemic. While data collection has improved as Congress has invested in data modernization, early in the outbreak basic questions such as how many people were infected by the virus, which population groups were at the highest risk, and where infections were surging were largely unanswerable in a timely manner due to insufficient testing and reporting processes. Where data were collected, they were spread across multiple data sets with no way to quickly roll up into one national picture.[23]

Communities of color were disproportionately affected in large part due to the ways in which structural racism and classism impacts where people are born, grow, live, work, and age; the resources available in their community; their access to healthcare; and the prevalence of chronic disease in their communities. According to the Centers for Disease Control and Prevention (CDC), as of November 2021, nationwide American Indians and Alaska Natives died due to COVID-19 at a rate that was 2.2 times higher than whites. Hispanic/Latino Americans died at a rate that was 2.1 times higher than whites Americans. Black Americans died from COVID-19 at a rate that was 1.9 times higher than the rates of deaths among whites. Asian Americans died at a rate that was 0.9 times that of whites.[24,25] In addition, as of mid-November 2021, an estimated

MS-DOH-21-1816-A-000744

167,082 children had lost a parent, guardian, or caregiver due to COVID-19; many of these children were already experiencing significant social and economic adversity.[26]

During the early stages of the pandemic (2020) the federal government lacked an evidence-based leadership role in the pandemic response, and science and public health expertise were often not heeded. In addition, political polarization at the federal and state levels confounded critical public health guidance and contributed to a confusing spectrum of responses across the country, from some areas issuing mask mandates to other jurisdictions limiting public health authorities. An October 2020 Columbia University report concluded that earlier implementation of lockdowns, a national mask-wearing mandate, and federal guidance on social distancing could have saved between 130,00 and 210,000 American lives.[27] Similarly, Peterson-Kaiser Family Foundation reported in October 2021 that between June and December 2021, approximately 163,000 U.S. COVID-19 deaths could have been prevented through vaccination.[28]

Social media platforms were (and still are) greenhouses for misinformation about the virus and vaccines. The Global Health Security Index found that, despite strong health security capacity, the United States had the lowest possible score on public confidence in the government, a factor that has been common in countries with higher rates of COVID-19 cases and deaths.[29]

Public health leaders Daniel Dawes, executive director of the Satcher Health Leadership Institute, and Dr. Brian Castrucci, president and CEO of the de Beaumont Foundation, wrote in their February 2021 op-ed in *STAT* that while COVID-19 does not discriminate by race, it undeniably exposed the "devastating inequities that come with being a person of color in America."[30] Structural racism impacts people of color in nearly every facet of their lives, from where they live and work to their access to healthcare. Racism is often at the root of conditions that drive poor health outcomes in communities of color. The disproportionate impact of COVID-19—higher rates of infection, hospitalization, and death—in communities of color were stark illustrations of this fact according to Dawes and Castrucci. A baseline goal in public health must be increasing the health status (and therefore the strength and resilience) of every community. In order to improve the health status within communities of color, long-standing racist policies and practices, and their legacies, in employment, housing, education, and healthcare must be changed. Dawes and Castrucci write that America's pre-COVID-19 "normal" "was not equitable or just"; therefore, a return to pre-COVID normal would allow the inequities that fueled the pandemic to persist.

What's needed?

Increased, flexible, and sustained funding. Funding for public health must be increased, flexible, and sustained over time. The pattern of public health funding in this country has long been that money is found (often borrowed from other public health priorities like chronic disease prevention) to fund needed response during an emergency. Once the emergency has passed, governments return to a pattern of inadequate levels of funding for public health. Without increased, predictable, and sustained funding—for personnel, equipment, training, and data systems—the next public health emergency response will be less effective than it needs to be, putting lives and livelihoods at risk.

MS-DOH-21-1816-A-000745

It is also important to note that while the pandemic response and recovery funding authorized in 2020 and 2021 were critical to meet the urgent needs of the pandemic response, those resources were one-time appropriations. What's needed to protect all Americans from the next public health emergency is year-in, year-out sustained, predictable funding.

Editor's note: In November 2021, the U.S. House of Representatives passed the $1.75 trillion Build Back Better Act, including approximately $10 billion for public health—about $7 billion over five years for public health infrastructure and about $3 billion for other pandemic preparedness.[31] These funds, if ultimately appropriated, would be an important down payment toward rebuilding the nation's public health system.

Federal leadership. In an event as large and complex as a pandemic, there is no substitute for a strong, coordinated federal response. TFAH has made a number of policy recommendations designed to ensure strong federal leadership during future public health emergencies, including the creation of a White House Health Security Directorate.[32]

Editor's note: The Biden Administration created a National Security Council Directorate on Global Health Security and Biodefense, led by a senior director for global health security and biodefense, in January 2021.[33] Future administrations should strengthen this senior-level advisory structure at the White House.

A diverse and highly skilled public health workforce. According to an October 2021 report released by the de Beaumont Foundation and the Public Health National Center for Innovations, a division of the Public Health Accreditation Board, state and local public health departments need approximately 80 percent more full-time staff to meet the nation's basic public health needs. According to the report, years of budget cuts have reduced essential state and local public health staff by 15 percent over the last decade. These reductions in the size of the workforce make local and state health departments less able to meet community health needs, including responding to emergencies. The report concludes that the nation needs to hire an additional 80,000 full-time public health staff to ensure that basic community health needs are met in all jurisdictions.[34]

Modernized health data and disease tracking systems, including disaggregated data collection and reporting. Improved response to public health emergencies requires 21st-century data collection and management, including real-time data on the social determinants of health. Achieving health equity is rooted in understanding health disparities and what causes them. Such understanding begins with a health data systems infrastructure that is able to surveil, collect, disaggregate, interpret, and share data in a timely fashion, including on race, ethnicity, income, disability, social determinants, other demographic factors, and the drivers of health. These capacities and these data are often missing from many federal and state data sets that currently provide data on white, Black, and Hispanic people but lack data on other groups, such as American Indians, Alaska Natives, Asian Americans, and Native Hawaiians or other Pacific Islanders, or treat these groups as one homogeneous population.[35]

The Robert Wood Johnson Foundation created the National Commission to Transform Public Health Data Systems to review how public health data are collected, shared, and used, as well as to make recommendations to ensure that such data are comprehensive and create a blueprint for health equity. Among the recommendations included in its October 2021 report was to ensure that public health measurement captures race and ethnicity information at the individual level whenever person-level data is collected, and addresses structural racism and other inequities.[36]

Also released in October 2021, a report from Grantmakers in Health and the National Committee for Quality Assurance stated that having more complete data will require action across multiple sectors, including changes in data standards and systems; regulations, including a clear and sufficient federal standard for data completeness; and a roadmap for collecting and reporting on data in ways that will reduce health inequities and provide incentives, requirements, resources, and technical assistance as needed.[37]

Editor's note: Congress has allocated over $1 billion through the Coronavirus Aid, Relief, and Economic Security (CARES) Act (P.L. 116-136), the America Rescue Plan Act (P.L. 117-2), and annual appropriations to support rapid public health data modernization.[38] In August 2021, CDC announced plans to use some of this funding for a new analytics center to better forecast and track disease outbreaks.[39]

Modernize public health labs and increase their surge capacity. Congress must sufficiently fund CDC to support sustained modernization of state and local public health laboratories, so they are better connected and ready to meet public health threats.[40] Also needed is better coordination between public health and private laboratories, including clinical and academic settings. Public and private laboratories both

played critical roles during the pandemic response. (See interview: pg. 15.)

Strengthen public health departments' emergency response functioning by providing sufficient funding and requiring plans in order to allow for execution of rapid hiring, rapid procurement, and project scale-up and management in response to a public health emergency.

Combat misinformation and increase the public's trust in science and government. U.S. Surgeon General Dr. Vivek Murthy has identified health misinformation as a serious threat to Americans' health. In July 2021, the Surgeon General issued an advisory, *Confronting Health Misinformation: The Surgeon General's Advisory on Building a Healthy Information Environment,* including ways in which institutions in education, media, medicine, research, social media and technology companies, and government stakeholders can address the issue.[41] Distrust of government and science was at the root of at least some vaccine hesitancy. Addressing this distrust will be critical to being prepared to respond to future public health emergencies.

Invest in the social determinants of health and anti-poverty programs to support the public's health and promote resilience. Key drivers of everyone's health are the conditions in which they are born, grow, live, work, and age. These health drivers, also known as "social determinants of health," in large part determine if a population group or community has the resources and resilience to weather and recover from a public health emergency. In an emergency, every community needs access to healthcare, food, clean water, and transportation. Communities without these resources tend to have poorer health outcomes at the individual and population level and are more vulnerable during an emergency.

A 2017 report from the National Academies of Sciences, Engineering, and Medicine stated that "health inequities are in large part a result of poverty, structural racism, and discrimination."[42] In addition, as illuminated and exacerbated by COVID-19, structural racism has contributed to a public health crisis in the United States—rates of illness are higher and life expectancy is lower for people of color, including Black people and American Indian people, than for white people.[43]

COVID-19 HEALTH EQUITY TASK FORCE REPORT ADDRESSES HEALTH INEQUITIES

The Biden Administration created the Presidential COVID-19 Health Equity Task Force in January 2021. The October 2021 *COVID-19 Health Equity Task Force Report* and proposed implementation plan made recommendations to the President for mitigating the health inequities caused or exacerbated by the pandemic and for preventing such inequities in the future.[44] The task force, chaired by Dr. Marcella Nunez-Smith, included multisector experts and people with lived experience concerning communities suffering disproportionate rates of illness and death from COVID-19.

In its report, the task force made 55 recommendations to address and eliminate health disparities, many of which mirrored TFAH policy recommendations. Among the report's five high-level recommendations to the President were:

1. Invest in community-led solutions to address health equity.
2. Enforce a data ecosystem that promotes equity-driven decision making.
3. Increase accountability for health equity outcomes.
4. Invest in a representative healthcare workforce, and increase equitable access to quality healthcare for all.
5. Lead and coordinate implementation of the COVID-19 Health Equity Task Force's recommendations from a permanent health equity infrastructure in the White House.

Within those areas, the task force recommended increased and sustained funding for the public health workforce and emergency response, investment in modernized public health data systems and equity-centered public health data collection, and systems to address the social determinants of health and increase access to behavioral healthcare.

In a statement applauding the report, TFAH President and CEO Dr. J. Nadine Gracia, said: "The COVID-19 Health Equity Task Force has laid out a road map for reducing inequities during the pandemic and before the next public health emergency. As the report acknowledges, we must engage in a multisector effort to address the upstream factors that contribute to underlying health inequities in order to promote optimal health and build resilience in all communities."

The Critical Role of Public Health Laboratories During COVID-19 and Beyond

An Interview with Scott Becker, MS, CEO of the Association of Public Health Laboratories

TFAH: How did public health laboratories perform during the pandemic?

Becker: Public health laboratories have performed remarkably well despite a number of challenges. Performance issues with the initial CDC assay presented significant hurdles and delays at the beginning of the pandemic. The laboratories were resilient, though, quickly notifying CDC and the Association of Public Health Laboratories (APHL) of assay issues and identifying solutions, such as using their own laboratory-developed tests. For instance, Wadsworth Center, New York State Department of Health, secured an emergency-use authorization for its real-time PCR assay. Other ongoing challenges included the limited national supply chain for reagents and consumables.

Typically, public health laboratories identify novel threats, perform initial testing, and then hand off to the private sector for high-throughput surge testing. The state public health laboratory traditionally maintains ongoing responsibility for testing in high-priority or potential outbreak situations, as well as for regional surveillance. In the case of COVID-19, public health laboratories have been in response mode for an extended period, providing sustained surge capacity for their jurisdictions and, in some locations, serving as the primary test provider. We are almost at the two-year mark for the COVID-19 pandemic, and during this time public health laboratories have tested more than 21 million specimens for SARS-CoV-2. All of APHL's member public health laboratories—that is, most laboratories nationwide—are meeting the testing demands within their jurisdictions.

The emergence of the Omicron variant created an increase in demand for COVID-19 testing for all public health laboratories. Many of these same laboratories are also sequencing SARS-CoV-2 samples to monitor for Omicron and other variants, and they report cases to CDC for surveillance purposes.

TFAH: What lessons—on lab performance/capacity and beyond—should the nation learn as a result of the pandemic?

Becker: There are significant lessons from this pandemic as well as previous responses to Zika and Ebola viruses. First, we must look at the coordination, or lack thereof, of the U.S. national laboratory system and how this limits our ability to respond to novel threats. APHL believes that we need to develop a national laboratory system that better integrates public and private laboratories, including large commercial facilities, hospitals, and academic institutions. We also need to transform the public health laboratory system to be more agile and interconnected to respond to all threats.

MS-DOH-21-1816-A-000748

Another area of concern is the shrinking public health workforce and lack of diversity within its ranks. A key place to address this is by building and supporting a diverse, equitable, and inclusive public health laboratory workforce. The fundamental purpose of public health laboratories is to serve their communities, so it is vital that lab staff represent the diverse communities in which they are working. A representative workforce not only creates a better work environment for all staff, but it also allows a public health lab to better serve the community's health needs.

Finally, there are lessons on the use of various technologies for screening and testing. For instance, point-of-care diagnostics and at-home testing play a pivotal role in reducing the testing burden on laboratories. Such technologies also ensure access to testing for underserved communities. Understanding the quality of these screening tools and sharing results with public health agencies will be critical for surveillance and contact tracing for future pandemics.

TFAH: Does the nation have the needed level of lab capacity for when another pandemic happens?

Becker: Responding to a pandemic is complex and encompasses the actual laboratory test (assay), instruments, supplies (reagents), test results (electronic laboratory reporting), safe and secure facilities, personal protective equipment, and trained personnel.

Whether or not we are ready for the next threat will vary. We often prepare for what we have experienced instead of preparing for a true unknown. We may have instrument capacity, but we still need to collaborate with the private sector and other governmental agencies, beyond CDC, to develop and pre-position tests in laboratories. We also need to rebuild and strengthen the laboratory workforce as well as the broader public health workforce.

TFAH: What's the role of public health labs in overall healthcare? Has that relationship worked during the COVID-19 pandemic?

Becker: The quintessential role of public health laboratories is to monitor the diseases and health status of populations. This role has evolved over time, especially given increasing threats such as natural disasters, human-caused incidents, emerging and pandemic infectious diseases, and acts of terrorism. In executing their 11 core functions, public health laboratories engage the entire healthcare community to varying degrees in the state public health laboratory system. While there were some initial bumps in the response, overall, public health laboratories worked well with healthcare—including commercial laboratories and other private institutions including in nontraditional testing sites, such as prisons and nursing homes.

Public health and healthcare take different yet equally important approaches to serving and protecting the nation's health. At the foundation of both approaches is laboratory testing, which is necessary for health departments to monitor disease in the population and identify novel threats, and for healthcare providers to make decisions to treat patients. The interdependency of public- and private-sector testing has never been more important than as seen with the COVID-19 response. These two systems must work together to provide timely and accurate testing, covering a significant portion of the U.S. population. As is the case with novel infectious threats, prompt and quality testing is critical as it shapes treatment options and epidemiological actions such as contact tracing, and as it influences larger public health decisions, including quarantine.

TFAH: Are rapid, self-administered tests, followed by a lab test if positive, part of the right approach to ending the pandemic?
