The Tennessee government at one point reported to get as many as 400,000 coronavirus vaccine doses from the Trump administration's supposed vaccine reserve, which would've been a windfall for a state with untapped distribution capacity and limited supply. Tennessee's top health official confirmed.

Instead, state leaders were stunned earlier this month when it was revealed the federal reserve was empty. Tennessee got no surge of doses from the release of the reserve and, separately, is still waiting for increased vaccine supplies that federal officials promised would start this week, said Health Commissioner Dr. Lisa Piercey.

"We were all under the impression there was this big reserve and they were going to flood the market with it," Piercey told USA TODAY NETWORK - Tennessee. "We had calculated internally, [not informal estimations, that we could get up to 400,000 – like this big [inflat

State 'unconquerable' amid virus, disasters says Reeves

BY EMILY WAGSTER PETTUS
Associated Press

JACKSON

Mississippi is "unconquerable" after a year dominated by the coronavirus pandemic and natural disasters including tornadoes that cut wide paths of destruction last Easter Sunday, Republican Gov. Tate Reeves said in his State

Tate Reeves

of the State speech Tuesday.

Speaking on the south steps of the Capitol, Reeves made a few policy proposals. He renewed his call for eliminating the state's personal income tax and said he would sign a bill to increase teachers' pay. He called on legislators to make "wise investments" in workforce training, although he did not offer specific proposals.

And he vowed that Mississippi will vaccinate people against the coronavirus as quickly as possible.

"We need to crush this virus and get back to our way of life," Reeves said, according to a prepared text of his speech. "The virus is still here, and it cannot be solved by ignoring it. We have to defeat it, because Mississippians are done. We're done burying loved ones who were lost to this virus. We're done with stressed hospitals. We're done with the fearful talk of lockdowns and shutdowns. We're ready for economic again."

Reeves served eight years as state treasurer and eight as lieu-

Brent Myers, a CVS pharmacist, second from left, spoke with residents at the Mississippi State Veterans Home in Jackson on Jan. 9 about receiving the Pfizer COVID-19 vaccination.

Updates on the Federal Retail Pharmacy Program for COVID-19 Vaccination

The initial phased implementation of the program will begin with select retail pharmacies administering COVID-19 vaccine across the country as early as Thursday, February 11. The program will be implemented incrementally, based on the available supply of COVID-19 vaccines. As the vaccine supply increases, the program aims to expand the number of participating pharmacy locations ultimately providing COVID-19 vaccines in all 40,000 retail pharmacy locations nationwide. Allocations to support the Federal Retail Pharmacy Program are separate from weekly allocations provided to jurisdictions. What jurisdictions see in their weekly allocation will remain stable.

Eligibility Criteria for Vaccination

The Federal pharmacy partners will administer vaccine to individuals according to state-selected eligibility criteria. Pharmacy partners have developed screening questionnaires specific to each jurisdiction's criteria and will finalize them based on the survey results to help ensure eligibility prior to vaccination. After launch, immunization program managers will be able to update eligibility criteria weekly using an application in Tiberius, the centralized system used by the federal government to support vaccine distribution efforts. Information about how to use this new Tiberius application will be sent to immunization programs this week.

Program Data and Monitoring

By Friday, CDC will provide a list of the retail locations that will be providing COVID-19 vaccine in each jurisdiction as part of the initial phased implementation of the program.

All pharmacy partners enrolled in the Federal Retail Pharmacy Program are required to report inventory daily to VaccineFinder and patient administration information to the jurisdiction's IIS as well as directly to CDC's Data Clearing House. Jurisdictions will have access to patient administration data submitted by all pharmacies in their jurisdiction. Jurisdictions will also have access to information in Tiberius-specific to pharmacy programs.

Information will include details on stores that will be receiving vaccine, store-level supply information, and administration/uptake information as it becomes available. Jurisdictions will also be provided points of contacts for pharmacy partners to facilitate coordination with partners.

Communications Support

CDC has developed a **toolkit of materials** to help jurisdictions and partners describe and

communicate about the implementation of the Federal Retail Pharmacy Program. We hope these materials will assist in providing clear and consistent information about the program goals and parameters.

The toolkit includes the attached materials for your use and reference:

- Frequently Asked Questions about the Program for Jurisdictions and Pharmacy Partners
- Key communication messages for jurisdictions and pharmacy partners
- A One-Page Fact Sheet on the Federal Retail Pharmacy Program (to share with partners or members of the community)

Upcoming Trainings/Webinars/Jurisdictional Calls

- Below is a link to a series of accredited education about COVID-19 vaccine in general, safety, and administration considerations.
    - Vaccine Courses, Broadcasts, Webcasts and Self Study Training | CDC
- Tiberius users can access the training video on submitting transfer requests at the following link: https://protect-ows.hhs.gov/workspace/compass/view/ri.compass.main.folder.c95b290c-2561-4cd1-85f7-e31dac51d34b [protect-ows.hhs.gov

Upcoming NACCHO Webinars:

Tuesday, February 9 at 12 pm ET: COVID-19 Action in the Biden Era: A Fireside Chat with Dr. Fauci

Upcoming CDC Foundation Webinar:

February 24 at 1:00-2:00 pm EST - Updates and Resources from CDC and Ad Council

During this session,

- Anne Schuchat, principal deputy director at the CDC, will provide an update on vaccine distribution.
- A representative from the Ad Council will present messaging content and guidance for local public health officials
- Judy Monroe, president, and CEO of the CDC Foundation, will moderate an audience Q&A.

Georgia Tech Center for Design and Inclusive Innovation Webinar:

February 10 at 2:00 pm EST

- Guidance for Businesses and Employers Considering the Needs of People with Disabilities during COVID-19

CDC COVID-19 Partner Update Webinar

- COVID-19 Information for Essential Workplaces
- February 8 at 3:00 PM ET

NEW Pharmacy/LTCF Office Hours

- Office Hours will now be held twice a week on Tuesdays and Fridays from 4 - 4:30 pm ET. Please find the call-in information below:

Upcoming National Vaccine Advisory Committee (NVAC) Meeting

- February 4-5, 1:00-5:45 PM
- Live webcast link and agenda found here

COVID-19 Resources

- Vaccine Confidence Consultations from Vaccine Task Force
  - This email serves as an entry point to many vaccine confidence consultation options offered by CDC. Vaccine confidence and communications experts will receive emails from providers and public health professionals and then set up brief calls to understand needs, tailor support, and provide further technical assistance in data collection, creation of communication products and more to promote community vaccine confidence for COVID-19 vaccines. They can be contacted at confidenceconsults@cdc.gov
- ELC Enhancing Detection Expansion FAQ (attached)
  - Developed by the ELC Team, this FAQ answers common questions about Enhancing Detection Expansion funding for jurisdictions. More information can be found on the ELC Website.
- Factsheet: 12 Things Jurisdictions Need to Know about VAERS (attached)
  - A factsheet developed by VTF on how to report adverse events following vaccination to the Vaccine Adverse Events Reporting System (VAERS)
- The COVID State-Profiles Report (aka Governors Report) is now posted publicly at COVID Data Tracker, and will be updated weekly. As a reminder, Community Profile Report has been posted publicly since December, and is updated daily. There is also a public facing version of the **T**herapeutics Distribution Location Tool**.**
- COVID-19 Vaccination Communication Toolkits for Community- Based Organizations and Essential Workers
  - COVID-19 vaccines will be available to essential workers and other community members soon. CDC has designed two toolkits to help build confidence in this new vaccine. The toolkits will help community-based organizations (CBOs) and employers to educate community members and workers about COVID-19 vaccines, raise awareness about the benefits of vaccination, and address common questions and concerns.

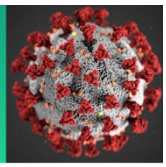
COVID-19 Science Update



From the Office of the Chief Medical Officer, CDC COVID-19 Response, and the CDC Library, Atlanta, GA.
Intended for use by public health professionals responding to the COVID-19 pandemic.

***** Available on-line at https://www.cdc.gov/library/covid19 *****

Section headings in the COVID-19 Science Update align with the CDC Science Agenda for COVID-19.

Detection, Burden, and Impact

PEER-REVIEWED

Antigen-based testing but not real-time polymerase chain reaction correlates with severe acute respiratory syndrome coronavirus 2 viral culture. Pekosz *et al.* Clinical Infectious Diseases (January 20, 2021).

Key findings:

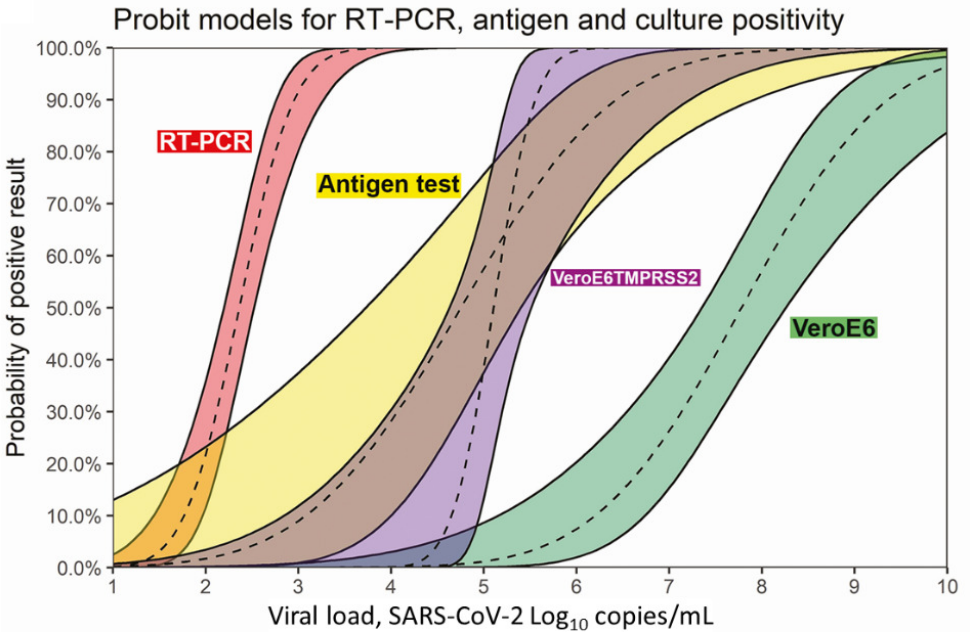
- The BD Veritor antigen test had a higher positive predictive value (PPV) (90.0%, 95% CI 76.3%-97.6%) than the Quidel Lyra RT-PCR SARS-CoV-2 test (73.7%, 95% CI 60.8%-85.3%) relative to positive viral culture.
- Viral culture using VeroE6TMPRSS2 cells, which are susceptible to infection by influenza and coronaviruses, correlated better with antigen tests compared with VeroE6 cells (Figure).

Methods: RT-PCR and antigen tests were compared with SARS-CoV-2 viral cultures from 38 adult patients sampled within 7 days of symptom onset across 21 US localities in June 2020. Probability of positivity and viral loads were fit with probit models for each testing method. *Limitations*: Correlations may be valid only for samples taken within 7 days from symptom onset; small sample of symptomatic adults.

Implications: Point-of-care antigen tests might minimize the spread of SARS-CoV-2 by identifying infectious adults in areas of high community transmission.

MS-DOH-21-1816-A-001578

Figure.



Note: Adapted from Pekosz *et al.* Modelled probability distributions of each SARS-CoV-2 test type, **RT-PCR**, **antigen**, and viral cultures (**VeroE6TMPRSS2** and **VeroE6**), across log-transformed viral load. As viral load increases, the probability of any test producing a positive result increases. Licensed under CC BY-NC-ND 4.0.

PREPRINT (NOT PEER-REVIEWED)

Predictive power of SARS-CoV-2 wastewater surveillance for diverse populations across a large geographical range. Melvin *et al.* medRxiv (January 25, 2021).

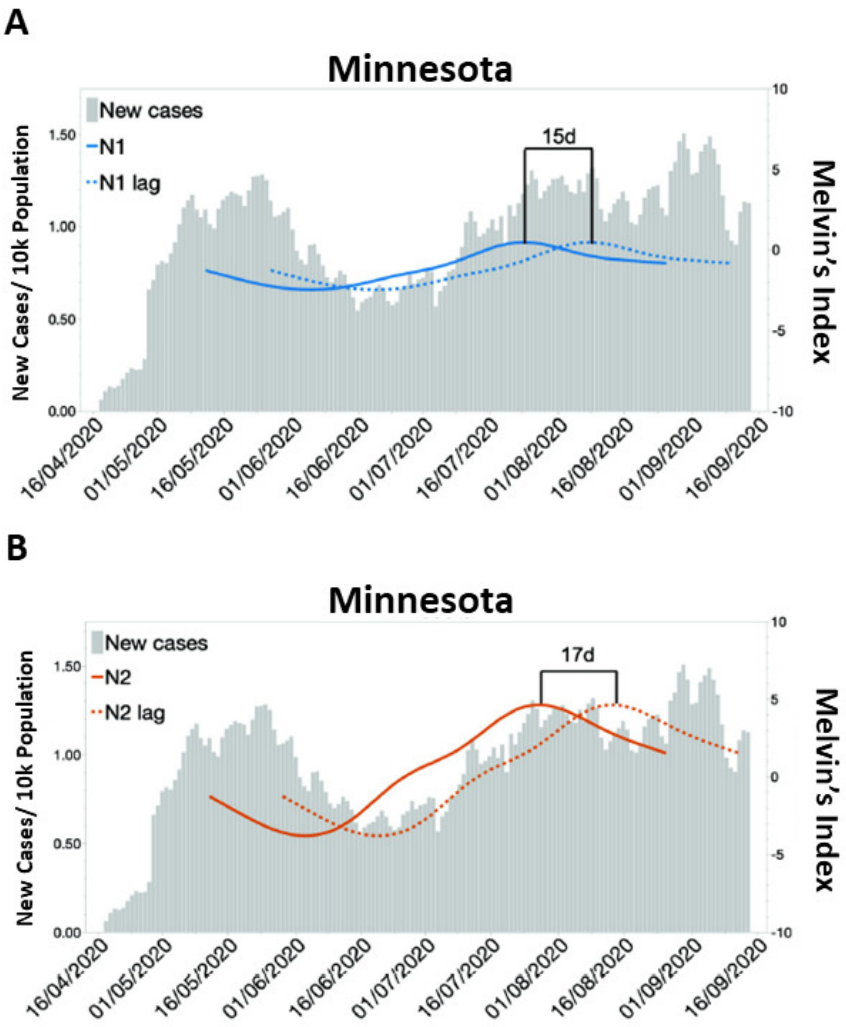
Key findings:

- In Minnesota, wastewater SARS-CoV-2 RNA levels, using RT-PCR to amplify 2 nucleocapsid gene targets (N1 and N2), predicted new clinical cases with a lag of 15 days for N1 ($r = 0.73$, $p < 0.001$) and 17 days for N2 ($r = 0.77$, $p < 0.001$) (Figure).

Methods: Compared Minnesota Department of Health COVID-19 case data with indexed SARS-CoV-2 RNA levels in municipal wastewater from 19 Minnesota cities in summer 2020. Developed a novel index (Melvin's Index) of wastewater SARS-CoV-2 viral load, standardized based on a plant virus that is abundant in human feces, to control for factors such as treatment facility capacity, flow rate, and population size. Successively lagged Melvin's Index values in 1-day increments to find the lag time (between observing an increase in SARS-CoV-2 RNA in wastewater and the appearance of confirmed new COVID-19 positive tests) that maximized correlation (r) between Melvin's Index and new confirmed cases. *Limitations*: Variations in clinical SARS-CoV-2 testing might affect correlation with population wastewater viral load.

Implications: Wastewater surveillance for SARS-CoV-2 might allow early detection of local outbreaks, especially where access to healthcare services is limited. A study in Barcelona found SARS-CoV-2 was detected in sewage collected 41 days before the first COVID-19 case.

Figure.



Note: Adapted from Melvin *et al*. Correlation and lag analysis of wastewater SARS-CoV-2 levels with new COVID-19 clinical cases in Minnesota. **A)** Indexed **N1 levels in real time** and **transposed (dotted line)** to show lag (15 days) to clinical case reports **B)** **N2 levels in real time** and **transposed (dotted line)** to show lag (17 days) to clinical case reports. Licensed under CC BY-ND 4.0.

Transmission

PEER-REVIEWED

Resurgence of COVID-19 in Manaus, Brazil, despite high seroprevalence. Sabino *et al.* Lancet (January 27, 2021).

Key findings:

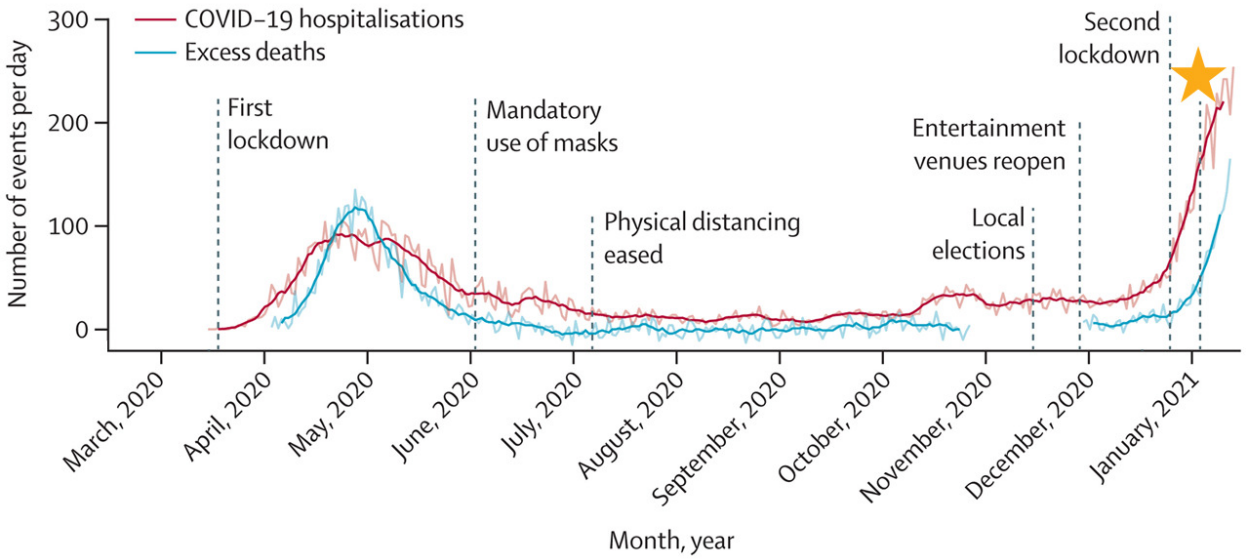
- Manaus, Brazil experienced a sharp rise in COVID-19 hospitalizations in January 2021 despite extensive transmission earlier in the pandemic and rates that had been stable and low for 7 months during relaxed COVID-19 mitigation (Figure).
- There are 4 possible explanations for the surge.
    - Greater mixing of susceptible and infected persons in December 2020.

- Waning immunity in the population.
- Circulating variants, specifically B.1.1.7 (501Y.V1) and P.1 with the E484K mutation, evading immunity.
- New variants being more transmissible.

Methods: COVID-19 hospitalizations, excess deaths, and real-time effective reproductive numbers were assessed from the literature and qualitatively compared monthly from March 2020 to January 2021 in Manaus, Brazil. *Limitations*: Associations were not directly estimated.

Implications: New variants of SARS-CoV-2 might demonstrate changes in transmissibility and/or virulence and could lead to a resurgence of COVID-19 despite high reported seroprevalence. In Rio Grande do Sul, another state in Brazil, da Silva Francisco *et al.* found wide circulation of the B.1.1.28 variant, with the E484K mutation, co-infection of variants, and new emerging variants. These findings stress the importance of tracking circulating viruses and of reaffirming COVID-19 mitigation measures.

Figure.



Note: Adapted from Sabino *et al.* Smoothed COVID-19 **hospitalizations** and **excess deaths** since March 2020 in Manaus, Brazil. Key mitigation events are marked with dotted lines. The gold star indicates the first detection of P.1 variant. Reprinted from The Lancet, Vol. 397 number 10273, Sabino *et al*, Resurgence of COVID-19 in Manaus, Brazil, despite high seroprevalence., Pages 452– 455, Copyright (2021), with permission from Elsevier.

Natural History of SARS-CoV-2 Infection

PREPRINTS (NOT PEER-REVIEWED)

SARS-CoV-2 seropositivity and subsequent infection risk in healthy young adults: a prospective cohort study. Letizia *et al.* medRxiv (January 29, 2021).

Key findings:

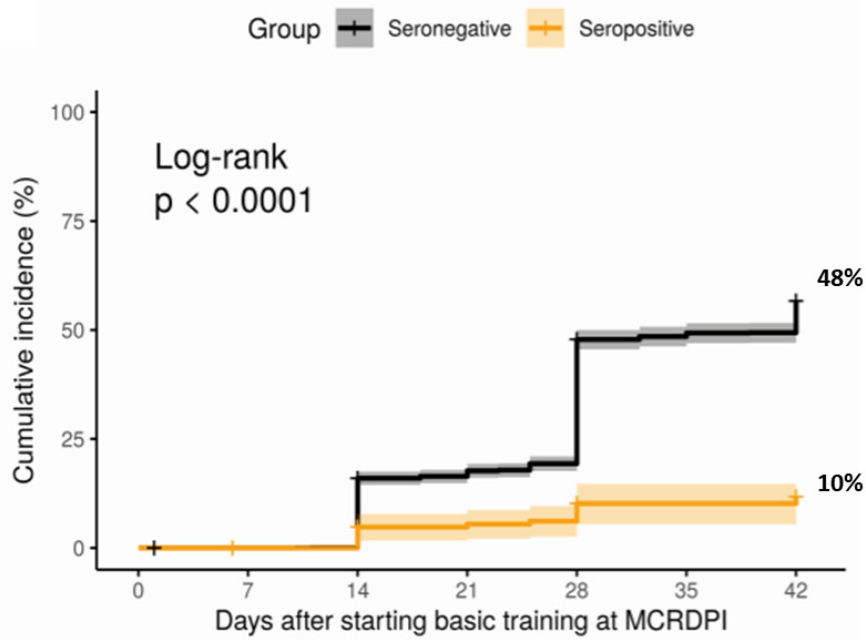
- Although seropositivity conferred an 82% reduced incidence rate, 10.1% of 189 seropositive participants had ≥1 positive RT-PCR test for SARS-CoV-2 (compared with 48.0% of 2,247 seronegative participants) (Figure).

  - Among those infected, seropositive participants had only a modest, approximately 10-fold decrease in nares virus load compared with seronegative participants.
- Among seropositive participants
  - New infection was associated with significantly lower baseline full-length spike protein IgG titers.
  - Baseline neutralizing titers were detected in 83.3% of the first 54 participants who never became PCR positive compared with 31.6% of the 19 infected participants.

Methods: Prospective 6-week observational study of 3,249 predominantly male, 18–20-year-old Marine recruits, who underwent baseline 2-week supervised quarantine and SARS-CoV-2 RT-PCR and IgG antibody testing. Serial RT-PCR testing was conducted and questionnaires on development of symptoms were completed during and after quarantine. *Limitations*: Overall high attack rate might not be generalizable to other populations and settings; unknown when seropositive participants were initially infected.

Implications: Although persons with SARS-CoV-2 antibodies are largely protected, subsequent infection is possible for some persons due to lack of sterilizing immunity. Some re-infected individuals could have a similar capacity to transmit virus as those infected for the first time.

Figure.



Note: Adapted from Letizia *et al*. SARS-CoV-2 PCR positive incidence curves during the six-week follow-up period among baseline **seropositive** and **seronegative** groups. Licensed under CC BY 4.0.

Kinetics and correlates of the neutralizing antibody response to SARS-CoV-2. Vanshylla *et al.* bioRxiv (January 26, 2021).

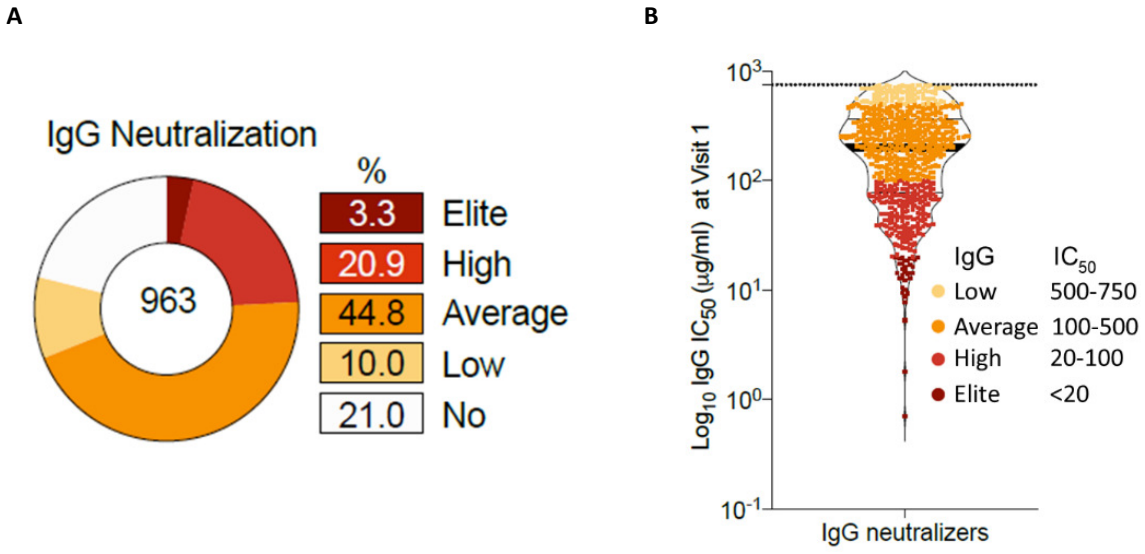
Key findings:

- 82% of individuals developed serum, and 79% IgG, neutralizing antibodies (NAb) to SARS-CoV-2.
- Neutralizing activity was highly variable, ranging from 3% who were initially 'elite' neutralizers, with a 50% Inhibitory Concentration [IC_{50}] of <20 µg/ml of IgG, to 21% who had no neutralizing activity (Figure).
- Higher anti-spike IgG levels, older age, time since disease onset, and fever during acute infection were predictors of SARS-CoV-2 neutralizing activity in mild courses of COVID-19.
- NAb had an initial half-life of 7 weeks in serum and 31 weeks in IgG titer samples.

Methods: NAb responses to SARS-CoV-2 were examined in 963 persons recently recovered from (mostly) mild COVID-19, during up to 4 follow-up visits between April 6 and December 17, 2020. Statistical modeling was used to infer antibody decay rates and to build a prediction model to evaluate how clinical features correlate with NAb titers. *Limitations:* Loss to follow up may bias results.

Implications: Although NAb can persist for up to 10 months after infection, persons who recover from mild COVID-19 illness have a broad spectrum of neutralizing activity which might affect protective immunity at a population level.

Figure.



Note: Adapted from Vanshylla *et al*. **(A)** Donut chart depicts the initial fraction of persons who developed NAb at study visit 1. **(B)** Violin plot depicts IgG IC_{50} values for the persons who developed neutralizing antibodies (n=760), categorized by IgG IC_{50}: **low** (IC_{50} >500-750 µg/ml), **average** (IC_{50} >100-500 µg/ml), **high** (IC_{50} 20-100 µg/ml), **and elite** (IC_{50} <20 µg/ml). Dotted line represents the limit of detection of the assay. Used by permission of authors.

Protection in Healthcare and Non-Healthcare Work Settings

PREPRINT (NOT PEER-REVIEWED)

Strategies to minimize SARS-CoV-2 transmission in classroom settings: combined impacts of ventilation and mask effective filtration efficiency. Rothamer *et al.* medRxiv. (January 4, 2021).

Key findings:

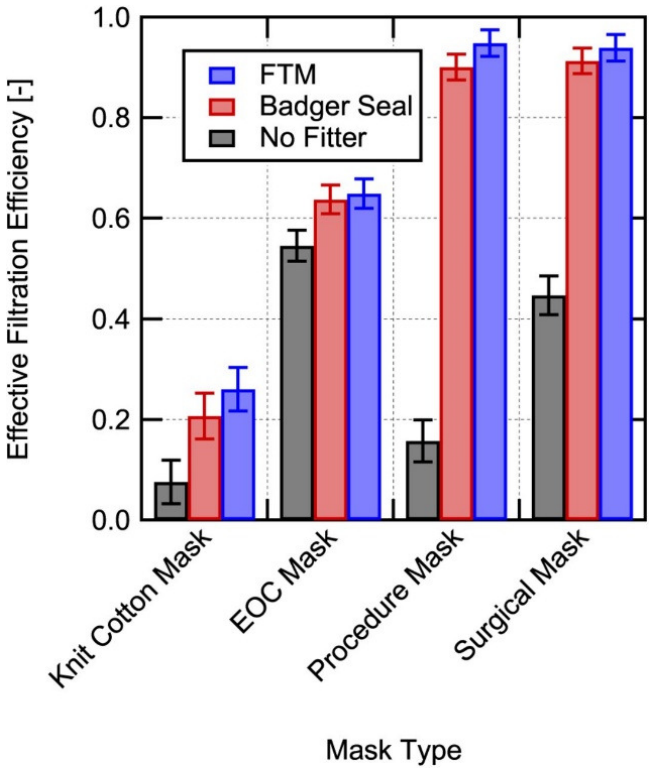
- Filtration efficiencies of four masks tested ranged from 7.5% to 54.5%.
- The addition of mask fitters, devices to improve the seal of a mask, increased filtration efficiency from 20.6% to 91.3% (Figure).
- Ventilation alone did not substantially reduce infection risk.

Methods: A simulation study to evaluate ventilation and mask filtration efficiency of non-medical grade masks, with and without mask fitters, on aerosol transmission in a classroom setting using CPR manikins fitted with aerosol-releasing tubing. Two mask fitters were tested, Badger Seal and Fit the Mask (FTM), using 4 masks: 1) a commercial 4-ply knit cotton mask, 2) a 3-ply polypropylene mask, 3) a 3-ply disposable procedure mask, and 4) a

surgical mask. *Limitations*: Potential overestimation of mask efficacy because manikins were fitted to minimize leakage; simulation might not represent real-world settings.

Implications: All non-medical grade masks are prone to leakage; however, the use of mask fitters can significantly reduce aerosol transmission of SARS-CoV-2 in a classroom setting. Gandhi *et al.* hypothesized that the use of multi-layered, well-fitting masks could achieve >90% efficiency at reducing aerosol transmission.

Figure.



Note: Adapted from Rothamer *et al*. Overall effective filtration efficiency for inhalation for 4 masks by fitter status (with **no mask fitter**, with the **Badger Seal mask fitter**, with the **Fit the Mask (FTM) mask brace**). Licensed under CC BY-ND 4.0.

Prevention, Mitigation and Intervention Strategies

PEER-REVIEWED

Model-informed COVID-19 vaccine prioritization strategies by age and serostatus. Bubar *et al.* Science (January 21, 2021).

Key findings:

- Prioritizing adults ≥60 years old shows the greatest reduction in mortality and years of life lost (YLL) after accounting for country-specific age structure, age-contact structure, infection fatality rates, seroprevalence, and age-varying efficacy of vaccine.
- Prioritizing adults aged 20–49 years old minimizes cumulative incidence but is only superior at minimizing deaths when R_0 = 1.15 and vaccine efficacy is ≥80% or vaccine rollout is ≤0.2%, or when vaccine efficacy is lower in older adults (≥60 years old) compared to individuals <60 years.
- Prioritizing seronegative individuals provides the greatest benefit where seroprevalence is high.

Methods: A mathematical model quantified the impact of five age-stratified COVID-19 vaccine prioritization strategies on cumulative incidence, mortality and YLL. *Limitations*: Model assumptions limit generalizability; disease severity is considered by age only.

Implications: Pairing vaccination with serological testing of individuals may be a useful strategy for prioritization of limited vaccine supplies and to reach vulnerable populations.

PREPRINTS (NOT PEER-REVIEWED)

mRNA-1273 vaccine induces neutralizing antibodies against spike mutants from global SARS-CoV-2 variants. Wu *et al.* bioRxiv (January 25, 2021).

Key findings:

- Moderna mRNA-1273 vaccine was able to neutralize all known strains of SARS-CoV-2.
    - Full neutralization was still achieved despite diminished neutralizing responses against the B.1.351 (South Africa) variant, with the E484K mutation, because neutralizing titers remained relatively high (1:290).
    - No significant differences in neutralizing antibody titers against B.1.1.7 (UK), 20E, 20A.EU2, DG614-N439K, or mink cluster 5, variants were detected.

Methods: Neutralization assays using pseudovirus expressing SARS-CoV-2 spike protein mutations found in major current variants were used to determine the neutralizing capacity of sera from 8 human subjects and 12 non-human primates vaccinated with the Moderna mRNA-1273 vaccine. Neutralization was compared to the neutralization observed against D614G, the dominant strain of 2020. *Limitations*: Small sample size; P.1 variant was not included.

Implications: Moderna mRNA-1273 vaccine appears to be effective against both the UK and South African SARS CoV-2 variants. However, further studies are warranted to substantiate these findings.

The effectiveness of the first dose of BNT162b2 vaccine in reducing SARS-CoV-2 infection 13-24 days after immunization: real-world evidence. Chodick *et al.* medRxiv (January 29, 2021).

Key findings:

- The cumulative incidence of SARS-CoV-2 infection was 0.57% (n=2,484) during days 1-12 and 0.27% (n=614) during days 13-24 following the first dose of the BNT162b2 mRNA COVID-19 vaccine.
- There was a 51.4% reduction in the weighted average daily incidence of SARS-CoV-2 infection at days 13–24 after the first dose (21.8 per 100,000 population), compared to days 1–12 (43.41 per 100,000 population).

Methods: A retrospective cohort study of 503,875 individuals aged ≥16 years old in Israel estimated the effectiveness of the first dose of the BNT162b2 vaccine administered from December 19, 2020 to January 15, 2021. Daily and cumulative infection rates during days 13-14 were compared to days 1-12 after the first dose using generalized linear models. *Limitations*: Unreported vaccinations might bias results.

Implications: Based upon temporal incidence, the BNT162b2 vaccine (Pfizer-BioNTech) is approximately 51% effective at reducing the risk of SARS-CoV-2 infection at 13 to 24 days following the first dose.

In Brief

Detection, Burden, and Impact

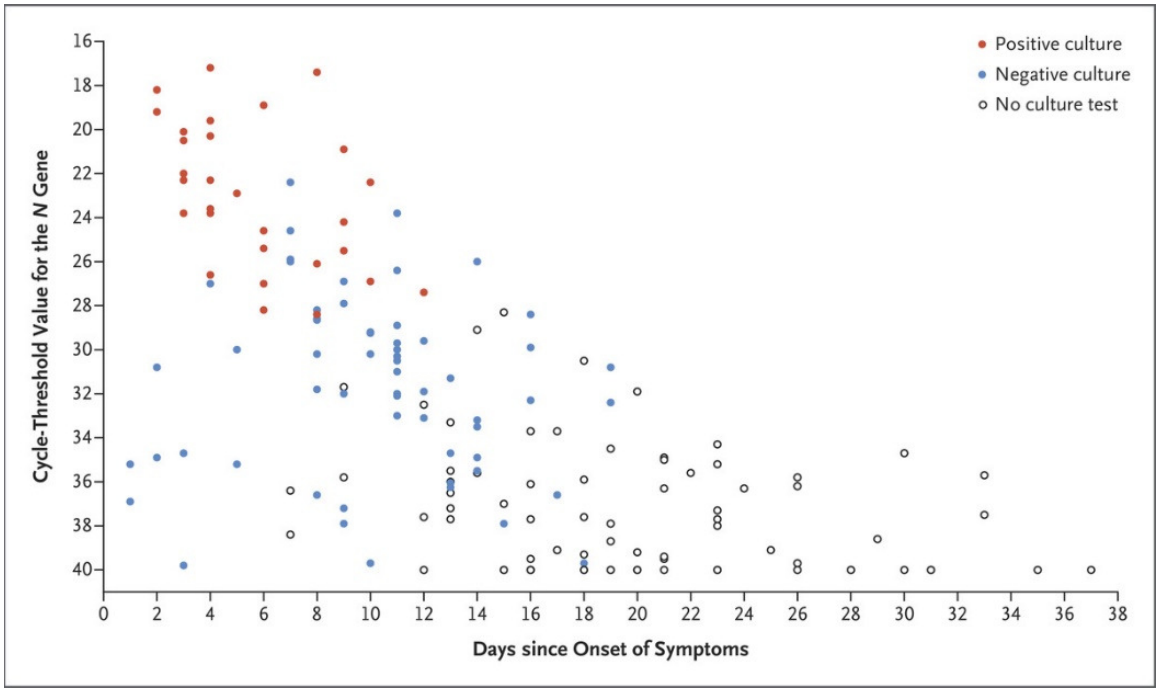
- Lowe *et al.* **Association of smoking and cumulative pack-year exposure with COVID-19 outcomes in the Cleveland Clinic COVID-19 registry.** JAMA Internal Medicine. (January 25, 2021). Of 7,102 adults with COVID-19 in the Cleveland Clinic COVID-19 registry between March 8 and August 25, 2020, 341 persons who smoked >30 pack-years had higher odds of hospitalization and death, although the odds were attenuated with inclusion of comorbidities; these data demonstrate an apparent dose-dependent relationship between smoking and adverse COVID-19 outcomes.

- Ehrenberg *et al.* **Launching a saliva-based SARS-CoV-2 surveillance testing program on a university campus.** medRxiv (Preprint, January 26, 2021). Describes a successful university-based surveillance system using saliva-based testing for SARS-CoV-2 among 3,653 persons to identify asymptomatic and pre-symptomatic cases and prevent outbreaks.

Natural History of SARS-CoV-2 Infection

- Kim *et al.* **Duration of culturable SARS-CoV-2 in hospitalized patients with COVID-19.** NEJM (January 27, 2021). Based on all 2-day RT-PCRs and viral cultures among 21 hospitalized patients with COVID-19, the median duration of shedding of viable virus was approximately 7 days (95% CI 5-10).

Figure.



Adapted from Kim *et al.* Timing of presence or absence of viable SARS-CoV-2 on viral culture and Ct values for 165 serial samples. Viral loads were determined with the Ct value for the *N* gene of SARS-CoV-2. Each circle represents a sample obtained on the specified day. Viral culture was either **positive** or **negative**. DOI: 10.1056/NEJMc2027040. Copyright © (2021) Massachusetts Medical Society. Reprinted with permission from Massachusetts Medical Society.

- Al-Samkari et al. **Thrombosis, bleeding, and the observational effect of early therapeutic anticoagulation on survival in critically ill patients with COVID-19.** Annals of Internal Medicine (January 26, 2021). In a multi-center, observational cohort study of 3,239 critically ill patients admitted between March 4 and April 11, 2020, early therapeutic anticoagulation did not affect in-hospital survival.

- Starr *et al.* **Prospective mapping of viral mutations that escape antibodies used to treat COVID-19.** Science (January 25, 2021). Mapping of viral mutations to SARS-CoV-2 receptor binding domain showed that a single amino acid mutation (E406W) escapes the two monoclonal antibody REGN-CoV2 cocktail.

- Rappazzo *et al.* **Broad and potent activity against SARS-like viruses by an engineered human monoclonal antibody.** Science (January 25, 2021). An engineered human monoclonal antibody demonstrated neutralization potency similar to neutralizing antibodies currently in clinical use providing significant protection against COVID-19 in mouse models.

- Nemani *et al.* **Association of psychiatric disorders with mortality among patients with COVID-19.** JAMA (January 27, 2021). In a retrospective cohort study of 7,348 patients with confirmed COVID-19 at 4 acute care hospitals in New York City from March 3 to May 31, 2020, persons with schizophrenia had significantly increased odds of 45-day mortality.

- Alam *et al.* **An interactive COVID-19 virus mutation tracker (CovMT) with a particular focus on critical mutations in the receptor binding domain (RBD) region of the spike protein.** medRxiv (Preprint, January 25, 2021). As new SARS-CoV-2 variants emerge with increased transmissibility and potential immune escape, it is important to monitor sequencing efforts and evolution of mutations. These authors developed a global mutation tracker that is updated daily and includes clinical data.

Protection in Healthcare and Non-Healthcare Work Settings

- Moghadas *et al.* **Evaluation of COVID-19 vaccination strategies with a delayed second dose.** medRxiv (Preprint, January 29, 2021). Based on an assumed 80% efficacy after the first dose, modelling showed that delaying the second dose of the Moderna vaccine by 9-12 weeks could reduce infections, hospitalizations, and deaths. However, for the Pfizer-BioNTech COVID-19 vaccine, with an assumed 52% efficacy after the first dose, there was no clear advantage to delaying the second dose due to waning immunity.

Prevention, Mitigation, and Intervention Strategies

- Crane *et al.* **Change in reported adherence to nonpharmaceutical interventions during the COVID-19 pandemic, April-November 2020.** JAMA (January 22, 2021). National survey responses from 7,705 participants between April 1 and November 24, 2020, showed a decrease in adherence to nonpharmacological interventions indicating "pandemic fatigue; however, there was in increase in self-reported mask-wearing which may reflect improved public health messaging.

Social, Behavioral, and Communication Science

- Ayers *et al.* **Suicide-related internet searches during the early stages of the COVID-19 pandemic in the US.** JAMA Network Open (January 21, 2021). Google searches related to suicide between January 1 and July 5, 2020, showed a decline after a national emergency was declared in March 2020. This decline was likely due to increased social support, called the "pulling together" phenomenon, often associated with catastrophes.

ELC Enhancing Detection Expansion

Questions & Answers

As of February 2, 2021

All questions are hyperlinked to their respective answers below; click on a question to be brought to its answer. Click on 'ELC Enhancing Detection Expansion' at the bottom of each page to be brought back to the start of the document. Appendices available at the end which include allowable expense comparisons between ELC Enhancing Detection Expansion and Immunization VFC Supplemental Funding.

Budget and Allowable Costs

1. Is there a budget template?
2. What are examples of some costs not allowed in Enhancing Detection (ED) Expansion?
3. Can we use the funds to pay for activities done in months before the grant was awarded?
4. Can funding be used to support providers with Electronic Laboratory Reporting (ELR) or telemedicine technology to enhance testing?
5. Can funding be used to purchase vaccines?
6. When submitting a revised budget as an amendment, do you have to submit other forms?
7. Can resources be used for quarantine/isolation-related costs?
8. When setting up and operating pop-up testing sites, what types of expenses are allowable through ED Expansion?
9. If a recipient's partners and community providers meet the testing goal and need to provide additional supplies/resources for expanded testing, what costs are allowable through ELC Enhancing Detection Expansion?
10. Are funds intended to support activities for the duration of the 30-month period? For example, if a jurisdiction liquidates all their funds prior to the end of the 30 months, are they still required to continue activities in the guidance until the end of the 30 months?
11. If a jurisdiction liquidates most or all funds towards supporting a few activities in the workplan, are they still required to complete the remaining activities?
12. Can ELC ED Expansion funds be used to cover the costs of COVID-19 testing?
13. When reporting the monthly expenses in the REDCap Financial Reporting page, what are 'unliquidated obligations' and how do they differ from expenses?
14. Am I required to have prior approval (redirection/contract approval) before I can use the funds that were placed in the "Other" cost category of my ELC ED Expansion Notice of Award (NOA) for COVID-19 response activities?
15. The Notice of Award for ELC ED Expansion has a budget period from August 1, 2020, to July 31, 2023; does this mean that contracts and other acquisitions using ELC ED Expansion funds cannot go past July 31, 2021?
16. How does expanded authority work for the supplemental COVID-19 funds?
17. May social services be supported with ED Expansion funds?
18. Can ELC ED Expansion funding be used to purchase vehicles, including mobile testing vans?
19. Can ELC ED Expansion funding be used for renovations and minor construction costs?
20. Can recipients request more than the recommended "1 program manager, 1 budget staff" in the budget?
21. With this new funding opportunity, and the allowance of covering existing core staff's percent of work redirected to COVID-19 activities, what happens to our (base) core ELC funding?
22. Are recipients able to start spending funds, before revised budgets are approved?
23. Now that workplans are being combined into ED Expansion for ELC CARES and Enhancing Detection, will financial reporting be bundled as well?

Workforce Capacity:

24. If the health department has previously reached the personnel/hiring cap in their jurisdiction, should this be addressed or acknowledged in the budget?

ELC Enhancing Detection Expansion Testing & Testing Plan Template:

25. Can you confirm that the target coverage for our testing projections is 2% of population each month?

26. What level of continued federal support can recipients expect for laboratory testing (e.g., provision of specimen collection and testing kits) as the COVID-19 response evolves?
27. Is the laboratory test order and reporting activity required?

Advance Electronic Data Exchange at Public Health Labs:

28. Is the laboratory test order and reporting activity required?
29. I cannot find the ED Expansion performance measures, where are they located?
30. What elements are needed in the line level testing data reporting to CDC?
31. Will these expectations for lab test reporting affect current reporting feeds from labs to health departments? If the state feed changes, does the originating reporting feed at the lab have to change?
32. Our jurisdiction is having difficulty with ensuring all laboratories are reporting line-level test data (including negatives); how important is this element to our ELC activities?
33. Can CDC provide additional clarity on what specific activities under "Improve Surveillance and Reporting of Electronic Health Data" are considered to "enable comprehensive, automated, daily reporting to the CDC and others in a machine-readable format"?

Activities:

34. Could you elaborate on what activities are allowable under contact tracing?
35. Are we able to obligate subcontracts before our revised budgets are submitted?
36. If ED Expansion is a copy of ED in REDCap, do we still report milestones and progress updates for ED?

Coordinate and Engage with Partners:

37. If a jurisdiction is largely de-centralized, to what extent is the State Health Department expected to partner at the local level?
38. What are examples of partners to consider funding when addressing health equity needs?

Other projects:

39. We attended the webinar presented by the United States Digital Service (USDS) and are interested in participating. Can the ELC facilitate this?
40. For ELC COVID performance measures, where are measures E23, E24 and E25 located in the REDCap portal?

Appendices

A: Basic Comparison & Examples of Allowable
B: Costs Allowable Expenses At-A-Glance

ELC Enhancing Detection Expansion Answers

Budget & Expenses:

1. Is there a budget template?
    - Yes, the ELC budget workbook (Excel) was provided in a Grant Note in GrantSolutions (GMM). You can also contact your ELC Project Officer. Recipients must complete the budget revision using the Excel budget workbook and adhere to the CDC guidelines (https://www.cdc.gov/grants/documents/Budget-Preparation-Guidance.pdf). The revised budget must then be sent back to CDC through a budget revision amendment in GrantSolutions, along with a cover letter signed by the Authorized Organizational Representative (AOR) of record in GrantSolutions.
2. What are examples of some costs not allowed in Enhancing Detection (ED) Expansion?
    - Research, lobbying, and clinical care (except as may be allowed by law) cannot be supported with funds awarded under ELC Enhancing Detection (ED) Expansion. However, all questions should be submitted as a Grant Note in GMM for review by your Grants Management Specialist (GMS) at CDC's Office of Grant Services (OGS) and your ELC Project Officer.
3. Can we use the funds to pay for activities done in months before the grant was awarded?
    - Legislative language was not included in this appropriation to permit retroactive charges; therefore, only costs associated with activities from time of award issuance are allowable.
4. Can funding be used to support providers with Electronic Laboratory Reporting (ELR) or telemedicine technology to enhance testing?
    - Certain costs not associated with the delivery of clinical care may be allowable. Please email your ELC Project Officer for a more individualized consult to discuss the specifics of your situation.
5. Can funding be used to purchase vaccines?
    - Per OGS, the purchase of vaccines is not permissible using ED Expansion funds. However, certain vaccine related costs may be allowable using ED Expansion funds. This includes storage and administration costs (i.e., injection cost if not covered in question #12). Recipients are encouraged to coordinate with PHEP and Immunization partners within the jurisdiction to effectively plan necessary activities and optimize use of resources.
6. When submitting a revised budget as an amendment, do you have to submit other forms?
    - The following must be part of the submission:
        i. The workplan completed in REDCap (and exported as a PDF);
        ii. The revised ELC budget workbook, using the Excel workbook provided at the time of award issuance;
        iii. A cover letter which is on agency/recipient stationary and signed by the Authorizing Official of record in GrantSolutions;
        iv. The State Testing and Case Investigation & Contact Tracing Plan completed in REDCap (and exported as a PDF); and
        v. The ELC Governance Team support letter.
7. Can resources be used for quarantine/isolation-related costs?
    - Costs associated with quarantine and isolation may be allowable as they relate to one or more activities in the workplan. For example, resources necessary to support testing and monitoring of individuals traveling from high-risk areas (within or outside of the U.S.) may be allowable and within scope of this project (this includes wrap- around services). Resources necessary for quarantine under a legal order (hotel, wraparound services, etc.) may also be allowable; recipients should simply tie these requests to their ELC workplan. ELC Project Officers should be contacted to discuss the specifics of such a request.
8. When setting up and operating pop-up testing sites, what types of expenses are allowable through ED Expansion?
    - Most costs associated with setting up and operating alternate testing sites are allowable under ED Expansion if the workplan reflects these sites in one or more of the activities. Please see question #12 for additional details pertaining to insurance.

9. If a recipient's partners and community providers meet the testing goal and need to provide additional supplies/resources for expanded testing, what costs are allowable through ELC Enhancing Detection Expansion?
    - Most costs, in particular supplies and resources, are allowable so long as they relate to one or more of the activities in the workplan. However, testing costs, even for the uninsured would not be allowable when any/all of the associated costs are being reimbursed in any fashion. Please see question #12 for additional details pertaining to insurance.
10. Are funds intended to support activities for the duration of the 30-month period? For example, if a jurisdiction liquidates all their funds prior to the end of the 30 months, are they still required to continue activities in the guidance until the end of the 30 months?
    - The expected timeframe for completion of all required activities under ELC ED Expansion is 30 ½ months. It is possible that certain activities may be completed in a shorter period (e.g., 24 months); however, the overall project period is 30 ½ months to allow sufficient time to conduct the range of activities. As this award builds on the ELC ED award, it is important to gauge progress based on the achievement of the required expansion of activities, not the spending of funds. Expenditures that are not aligned with the commensurate level of completion of the approved activities will be scrutinized. Should it be found that resources were not utilized in the manner consistent with grant regulations, the award terms and conditions and/or approved work plans and budget submissions, the jurisdiction may be found to be noncompliant and could be required to reimburse the federal government. Additionally, as indicated in the Guidance associated with this award (https://www.cdc.gov/ncezid/dpei/elc/resources.html), if required tasks and activities in the Guidance are not addressed, funds may be restricted in the Payment Management System (PMS). It is highly recommended that recipients continue to engage their ELC Project Officer and the OGS GMS as funds are activities are undertaken and funds are expended to ensure appropriate progress during the ED Expansion project period.
11. If a jurisdiction liquidates most or all funds towards supporting a few activities in the workplan, are they still required to complete the remaining activities?
    - The ELC ED Expansion Guidance sets out the required activities in furtherance of the purpose and use of the funds and the award. Budgets should align to the workplans and are intended to support the breadth of all required activities.
12. Can ELC ED Expansion funds be used to cover the costs of COVID-19 testing?
    - Yes, COVID-19 testing can be covered using ELC Enhancing Detection Expansion funds in the following ways:
        i. Uninsured: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing for the uninsured.
        ii. Unable to bill: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing when billing is not feasible. While not an exhaustive list, some examples are the following: mobile testing sites; non-traditional testing sites; state/local laboratories not having the authority or ability to bill insurance; etc.
        iii. Billing serves as a real or perceived barrier to timely test delivery: ELC Enhancing Detection Expansion funds can cover costs associated with COVID-19 testing when establishing billing services (directly or through a contractual agreement) would delay testing and/or reduce the jurisdiction's ability to rapidly increase testing capacity to meet needs.
        iv. Payor of last resort when billing insurance: In situations where COVID-19 testing is billed to insurance and is either not covered or partially covered by a third-party payor (e.g., private insurance, CMS, etc.), after the claim is rejected or partial reimbursement occurs, the outstanding balance can be covered by ELC Enhancing Detection Expansion funds.
13. When reporting the monthly expenses in the REDCap Financial Reporting page, what are 'unliquidated obligations' and how do they differ from expenses?
    - The funds awarded fall into one of three categories:
        i. Unobligated: Funds in a budget or spend plan that are available for use, but not yet encumbered or committed.

ii. Unliquidated obligations (ULOs): Funds that have been encumbered/committed but have not yet been paid out. Examples include: (1) executing a $100K contract and having to pay 10% upfront would result in $10K in 'expenditures' and $90K in 'unliquidated obligations'; (2) using a purchase order to acquire a piece of equipment for $50K would result in $50K in 'unliquidated obligations' until the equipment is delivered, the agency is invoiced, and the invoiced is paid.
iii. Expenditures: Funds that have been drawn down from the account and paid out.

- Note: It is important to remember that once an unliquidated obligation is paid, the following monthly reporting should transfer the amount paid from 'unliquidated obligations' to 'expenditures' as the obligation has now been liquidated.

14. Am I required to have prior approval (redirection/contract approval) before I can use the funds that were placed in the "Other" cost category of my ELC ED Expansion Notice of Award (NOA) for COVID-19 response activities?
    - All awarded funds were placed in the 'Other' cost category as an initial means to obligate and award funding. This action allowed CDC to expedite your award and facilitate your emergency response. Based on the emergency, you have been authorized to use these funds consistent with the issued Guidance and terms of the award set out therein, including entering into contracts as required to address the needs of COVID-19. Please ensure that such funds are expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75. All costs must also be reflected in the budget and workplan you are preparing for submission by March 18, 2021. You are not required to wait until your budget is submitted and approved to execute any needed contracts or other obligations. We do however require that this information is incorporated in the budget and that the contract(s) are in alignment with the issued CDC Guidance, applicable terms and conditions, and your internal procurement policies. This ability to use the funds prior to the budget submission and approval is an exception that applies solely to COVID-19 awards within ELC.
15. The Notice of Award for ELC ED Expansion has a budget period from August 1, 2020, to July 31, 2023; does this mean that contracts and other acquisitions using ELC ED Expansion funds cannot go past July 31, 2021?
    - The ELC ED Expansion awards were issued in ELC Budget Period 2. There was specific guidance in the Terms and Conditions of the Notice of Award that provided an extended fiscal period (i.e., extending past the end of the budget period in which funds were awarded) for these special COVID-19 funds. The 30 ½ -month fiscal period for the ELC Enhancing Detection Expansion awards means that contracts can extend past the July 31, 2021, end of Budget Period 2, by exercising option years. Additionally, other costs (e.g., purchasing equipment, supplies, etc.) can also occur after July 31, 2021, in accordance with the terms and conditions of this award.
16. How does expanded authority work for the supplemental COVID-19 funds?
    - Unlike funding in ELC (base) core awards, the supplemental ELC ED Expansion COVID-19 awards are issued with an expanded budget period; therefore, expanded authority is not needed to extend use of COVID supplemental funds from one ELC budget period to the next.
    - During the regular ELC budget period closeout (i.e., October 30), when submitting the annual FFRs, one FFR will need to be submitted for each document number that ELC awards were made on. The special COVID-19 document numbers will be reported on separate FFRs from the (base) core ELC award for Budget Periods 1 & 2. For base (core) funding only, whatever funds remain unobligated at time of submitting the annual FFR should be noted in Section #12 along with the intended use of Expanded Authority.
    - Given the ELC ED Expansion award has an extended fiscal period, the account will continue to be active in the Payment Management System (PMS) and can have funds drawn down to cover expenses through the end of the ED Expansion award budget period.
17. May social services be supported with ED Expansion funds?
    - Social services that are critical to facilitating the detection, prevention, and control of COVID-19 may be allowable. For example, those services that help facilitate compliance with isolation and quarantine and/or case investigation and contact tracing efforts may be allowable expenses and may be a part of recipient workplans (e.g., health educators, counselors, etc.). ELC Project Officers should be contacted to

discuss the specifics of such a request. Recipients are reminded that funds are to be expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.

18. Can ELC ED Expansion funding be used to purchase vehicles, including mobile testing vans?
    - Yes, but recipients must include three (3) quotes and/or a blanket purchasing agreement along with a justification for leasing/purchasing in the revised budgets that are due by March 18, 2021. For situations where the acquisition needs to occur before the revised NOA is issued, please submit the request and associated quotes in GrantSolutions via Grant Note. This information must also be included in the revised budget once submitted.
    - For redirecting funds to purchase vehicles, including mobile testing vans, that were not in the approved budgets, please work with your ELC Project Officer to submit a redirection request. The request will need to include a cost analysis between lease versus purchase options and quote. For mobile testing vans, due to the nature of having to customize the vehicle, it is understood that a lease versus purchase analysis might not be applicable.
19. Can ELC ED Expansion funding be used for renovations and minor construction costs?
    - Yes, but recipients must include the quotes and justification for renovations and/or minor construction in the revised budgets that are due by March 18, 2021. For situations where the alterations need to occur before the revised NOA is issued, please submit the request and associated quotes in GrantSolutions via Grant Note.
    - For redirecting funds to conduct renovations and/or minor construction that were not in the approved budgets, please work with your ELC Project Officer to submit a redirection request. The request will need to include:
        i. A description of the renovation or minor construction,
        ii. The justification of how the renovations or minor construction will relate to activities in the approved workplan, and
        iii. A quote or bid justifying the cost that is being requested in the redirection.
20. Can recipients request more than the recommended "1 program manager, 1 budget staff" in the budget?
    - Yes, this is a minimum recommendation for basic management of this project. Recipients may also need to increase overall administrative staff support to accommodate the demands of managing their portfolio.
21. With this new funding opportunity, and the allowance of covering existing core staff's percent of work redirected to COVID-19 activities, what happens to our (base) core ELC funding?
    - Recipients' (base) core dollars should be reserved for non-COVID programmatic activities. As numerous health department staff are working on COVID-19 currently, it is understandable if (base) core funding spending is lower than usual. These programmatic activities can be extended into Budget Period 3.
    - ELC staff who are typically supported through (base) core funding but are working all or a portion of their time on the COVID-19 response should have their associated personnel costs charged to the ELC CARES, ELC Enhancing Detection, and/or ELC ED Expansion COVID accounts as appropriate.
22. Are recipients able to start spending funds, before revised budgets are approved?
    - Yes, funds are available for use now. In the interim (before revised budgets are accepted), make sure your expenses align with activities described in the ELC Guidance (https://www.cdc.gov/ncezid/dpei/elc/resources.html). Also, please see response to #14 above. Also, recipients are reminded that funds are to be expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.
23. Now that workplans are being combined into ED Expansion for ELC CARES and Enhancing Detection, will financial reporting be bundled as well?
    - No, each COVID-19 supplemental award requires its own, monthly financial report due to the nature of being awarded on separate accounts in the Payment Management System (PMS) and the need to track and account for spending by each separate supplemental appropriation.

Workforce Capacity:

24. If the health department has previously reached the personnel/hiring cap in their jurisdiction, should this be addressed or acknowledged in the budget?
    - Increased staffing (e.g., contractual, temporary, term staff, etc.) may be essential to achieve the targets and requirements of this award, but we understand expanding human resources in your jurisdictions may not be in your control. If you anticipate insurmountable challenges with hiring or starting new contracts, please let your ELC Project Officer know immediately. Direct assistance and technical assistance can be discussed on a case-by-case basis, and major challenges will also be proactively communicated to the Department of Health and Human Services (HHS).

ELC Enhancing Detection Expansion Testing & Testing Plan Template:

25. Can you confirm that the target coverage for our testing projections is 2% of population each month?
    - Yes, and 2% is the minimum threshold as recommended by HHS/Office of the Assistant Secretary for Health (OASH).
26. What level of continued federal support can recipients expect for laboratory testing (e.g., provision of specimen collection and testing kits) as the COVID-19 response evolves?
    - The ELC can only speak to the funding that CDC administers. Questions regarding the monthly allocations of Viral Transport Medium (VTM) and swabs should be directed to your regional HHS/OASH representative. Of note: the published Jurisdictional Testing Plans may be found at: https://www.hhs.gov/coronavirus/testing-plans/index.html. Any questions should be directed to your HHS/OASH representative.

Advance Electronic Data Exchange at Public Health Labs:

27. Can recipients accelerate previously on-going activities to improve laboratory informatics, for example, more rapid interfacing diagnostic equipment to improve the automation of reporting?
    - Yes, ELC expects all funded jurisdictions will make measurable progress in improving the efficiency of laboratory management and operations, as well as improving the analytic capacity within the laboratory settings. This may include improving automation of reporting with increased test volumes to efficiently manage throughput and staffing, or new analytic capacity to better inform the jurisdictional response efforts.
28. Is the laboratory test order and reporting activity required?
    - Yes, all activities included in the Guidance document (https://www.cdc.gov/ncezid/dpei/elc/resources.html) should be considered required with the ELC ED Expansion award.
29. I cannot find the ED Expansion performance measures, where are they located?
    - At the time the Guidance was published, the performance measures were not yet finalized. Recipients should anticipate their performance under the ED Expansion award will continue to be measured by and monitored as was done with the ELC Enhancing Detection award. Once changes are finalized for the ELC ED Expansion award, information will be shared via the ELC mailbox and a webinar will be held.
30. What elements are needed in the line level testing data reporting to CDC?
    - This includes all RT-PCR, antigen, and antibody tests and results (positives, negatives, and indeterminants), patient demographics, as well as reporting, performing and ordering facilities. For more detailed guidance please refer to standard CSV file, which ELC will share.
    - Critical data elements should be the primary focus for lab data reporting to CDC for COVID-19:
        i. Test ordered – use harmonized LOINC codes provided by CDC
        ii. Device Identifier – use if LOINC codes do not indicate device/test kit
        iii. Test result
        iv. Test Result date
        v. Accession #/Specimen ID
        vi. Age (or DOB)
        vii. Patient race

viii. Patient ethnicity
ix. Patient gender
x. Patient residence zip code
xi. Patient residence county
xii. Ordering provider name and NPI or CLIA (as applicable)
xiii. Ordering provider zip
xiv. Performing Lab name and CLIA number, if known
xv. Performing Lab zip code
xvi. Specimen Source - use appropriate LOINC, SNOMED-CT, SPM4 codes, or equivalently detailed alternative codes
xvii. Date test ordered (date format)
xviii. Date specimen collected (date format)

- "Ask On Order" questions that are highly desired are shown below. These are secondary in importance to the critical data elements above:
  i. First test (Y/N/U)
  ii. Employed in healthcare? (Y/N/U)
  iii. Symptomatic? Y/N/U and then Date of Symptom Onset (mm/dd/yy)
  iv. Hospitalized? (Y/N/U)
  v. ICU? (Y/N/U)
  vi. Resident in a long-term care facility (including skilled nursing facilities, nursing homes, long-term care for the developmentally disabled, and assisted living homes): (Y/N/U)
  vii. Pregnant? (Y/N/U)

31. Will these expectations for lab test reporting affect current reporting feeds from labs to health departments? If the state feed changes, does the originating reporting feed at the lab have to change?
    - It is possible reporting fields or feeds will be expanded to accommodate for this reporting, but please defer to your local and state health department guidance. It should result in laboratories collecting and sending more complete data, though laboratories should continue to report the most complete data they have to their jurisdictional health departments. States should include the more complete data they receive to CDC. Any changes with reporting to CDC will be handled and managed through the epidemiology and informatics sections of your health departments.
32. Our jurisdiction is having difficulty with ensuring all laboratories are reporting line-level test data (including negatives); how important is this element to our ELC activities?
    - The public health response to COVID-19 depends on having comprehensive laboratory testing data - at scale, in near real-time, and including critical geographic and demographic information, to the fullest extent as feasible and with sufficient granularity. These data will contribute to understanding disease incidence and testing coverage and may contribute to the identification of testing issues and/or supply shortages. Additionally, the ELC has several performance measures that rely on the reporting of these data. The ELC has elected to reduce the burden placed on recipients by utilizing data sources and elements where states/jurisdictions are already reporting. Without the successful line-level test data reported (see: https://www.cdc.gov/coronavirus/2019-ncov/lab/reporting-lab-data.html), the ELC would need to institute a separate reporting process for laboratory data.
33. Can CDC provide additional clarity on what specific activities under "Improve Surveillance and Reporting of Electronic Health Data" are considered to "enable comprehensive, automated, daily reporting to the CDC and others in a machine-readable format"?
    - This suite of activities is intended to improve the health department's access to and interoperability of many relevant data sources for visibility on the spread of disease and to increase the usefulness of all data sources. Health departments should be able to receive all data message types and have the systems, processing ability, and staffing to consume and analyze new feeds alongside existing data, such as: increased testing volumes from new sites, death registry reports, and ADT data feeds from emergency departments and urgent care clinics. Linked data should be accessible to local public health

(and the public, where possible), in a format that can be easily uploaded into commonly used analysis and visualization tools, such as ESRI, Tableau, and PowerBI.

Activities:

34. Could you elaborate on what activities are allowable under contact tracing?
    - Activities allowable under contact tracing may include:
        i. Temporary staff used for incremental tracing
        ii. Public education/awareness campaign
        iii. Contracted vendor for contact tracers and monitors
        iv. Management and supervision of trainers, as well as the conducting of training
        v. Data and software platforms needed to support the training programs
35. Are we able to obligate subcontracts before our revised budgets are submitted?
    - Yes, you are able to grant subawards at this time, so long as the activity is undertaken consistent with the Guidance and the terms of the award. Please see response to #14 above.
36. If ED Expansion is a copy of ED in REDCap, do we still report milestones and progress updates for ED?
    - We are in the midst of Quarter 2 workplan milestone progress reporting for ED. Once that ends, we will close the ED workplan monitoring portal. Starting with Quarter 3 reporting, the Community-based Surveillance, ELC CARES, and ELC Enhancing Detection workplan milestone progress reporting will cease. Recipients will only be required to report the workplan milestone progress for ELC ED Expansion as these activities cover the other prior COVID awards.

Coordinate and Engage with Partners:

37. If a jurisdiction is largely de-centralized, to what extent is the State Health Department expected to partner at the local level?
    - CDC encourages State Health Departments to continue working collaboratively with city, county, and local health departments, and other partners (e.g., academic, regional organizations) to improve capacity for addressing gaps in addressing COVID-19 within their communities (e.g., testing, outbreak investigation, infection prevention and control (IPC) practices, etc.). Providing financial resources to local health departments is strongly encouraged, where possible, to build local public health capacity.
38. What are examples of partners to consider funding when addressing health equity needs?
    - Examples of partners may include but are not limited to:
        i. Tribal affiliates and community-based organizations colleges and universities
        ii. Occupational health settings for large employers
        iii. Churches or religious or faith-based institutions
        iv. Federally Qualified Health Centers (FQHCs), including Community Health Centers (CHCs)
        v. Pharmacies
        vi. Long-term care facilities (LTCFs), including independent living facilities, assisted living centers, and nursing homes
        vii. Organizations and businesses that employ critical workforce
        viii. First responder organizations
        ix. Non-traditional providers and locations that serve high-risk populations
        x. Other partners that serve underserved populations

Other Projects:

39. We attended the webinar presented by the United States Digital Service (USDS) and are interested in participating. Can the ELC facilitate this?
    - The USDS webinar provided an overview of the three projects which will be piloted in interested jurisdictions to help with better, faster data to public health departments. The ELC is not directly involved with the projects or the decision-making process for pilot selection. It is ELC's understanding that any products developed through the pilots will be open source and available for all jurisdictions to

adopt. While you may utilize ELC resources to support a project, you will need to tie the project back to your workplan and ensure successful completion of all the required ELC Enhancing Detection Expansion activities. If you have any questions about USDS-CDC collaboration or any specific projects, please email USDS@cdc.gov.

40. For ELC COVID performance measures, where are measures E23, E24 and E25 located in the REDCap portal?
    - Measures E23, E24 and E25 are collected by the HAI/AR program via their performance measure REDCap site "HAI/AR Performance Measures 2019 - 2020 (BP1)". Recipients will be notified directly by the HAI/AR program when these measures are available on REDCap.

Appendices

A: Basic Comparison & Examples of Allowable
B: Costs Allowable Expenses At-A-Glance

ELC Enhancing Detection Expansion & Immunization CoAg COVID-19 Funding Supplementals

A: Basic Comparison & Examples of Allowable Costs

Please ensure that such funds are expended in accordance with your organization's policies and procedures and are reasonable, allocable, allowable, and necessary as per 2 CFR Part 200 and 45 CFR Part 75.

All costs must alignment to the workplan and the impact to the overall ability to complete required activities.

	ELC Enhancing Detection (ED) Expansion	Immunization & VFC Cooperative Agreement
Purpose	Provide critical resources to state, local, & territorial health departments in support of a broad range of COVID- 19/SARS-CoV-2 testing & epidemiologic surveillance related activities. Activities intended to complement activities covered through other ELC COVID resources and explicitly expand upon those strategies and activities in ELC Enhancing Detection Expansion.	Provide resources to support and strengthen critical COVID-19 immunization planning and implementation requirements and activities to ensure effective and efficient vaccination in phases 1 (a, b, and c), 2, and 3 for state, local, and territorial awardees.
Funding appropriation	Coronavirus Response and Relief Act, 2020 (P.L. 116-260)	Coronavirus Response and Relief Supplemental Appropriations Act of 2021 (P.L. 116-260)
Key Activities	All Activities are required: 1. Enhance Laboratory, Surveillance, Informatics, and other Workforce Capacity (5 Activities) 2. Strengthen Laboratory Testing (3 Activities) 3. Advance Electronic Data Exchange at Public Health Labs (1 Activity) 4. Improve Surveillance and Reporting of Electronic Health Data (6 Activities) 5. Use Laboratory Data to Enhance Investigation, Response, and Prevention (3 Activities) 6. Coordinate and Engage with Partners (2 Activities)	1. Increase COVID-19 vaccination capacity across the jurisdiction, including among high-risk and underserved populations 2. Ensure high-quality and safe administration of COVID-19 vaccines 3. Ensure equitable distribution and administration of COVID-19 vaccines 4. Increase vaccine confidence through education, outreach, and partnerships 5. Develop and implement community engagement strategies to promote COVID-19 vaccination efforts 6. Support high vaccination uptake in tribal nations 7. Use immunization information systems to support efficient COVID-19 vaccination
Amount	$19.11 billion	$3 billion
Previous COVID funding	Over $11 billion and 15 projects represented. Of this, $10.25 billion was for ELC Enhancing Detection—the guidance upon which ED Expansion builds	This is the 3rd IP19-1901 COVID supplement during budget year 2 (July 2020 - June 2021) and the 4th total IP19-1901 COVID supplement. In total between all the supplements, approximately $3.48 billion in COVID funding has been awarded to the 64 immunization jurisdictions.
Funding period	1/15/2021 - 7/31/2023	7/1/2020 - 6/30/2024
Number of recipients	64	64
Funding strategy	PHEP formula (per legislation)	PHEP formula (per legislation)
Project director	Project Directors largely from Epi and Lab	Immunization and VFC CoAg Principal Investigator which is largely the immunization program manager

	ELC Enhancing Detection (ED) Expansion	Immunization & VFC Cooperative Agreement
Engagement with local health departments	While no formula exists for the advisable level of funding to local health departments (LHD), LHD needs should be reflected within budgets. Workplans should indicate how LHD engagement will take place to successfully complete the activities. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.	Allowable and encouraged. LHD needs should be reflected within budgets. Workplans should indicate how LHD engagement will take place to successfully complete the activities. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.
Mandate to support local health departments at a specified level	No, however, budgets and workplans should reflect how LHD needs will be addressed through these resources. Recipients should also be able to estimate the resources provided to LHDs for quarterly reporting and highlight any barriers to relaying this support.	No, however, LHD and partners work plans must include activities and deliverables to meet vaccination needs of their community.
Financial reporting	Monthly reporting via REDCap & GrantSolutions	Monthly reporting via REDCap & GrantSolutions
Progress on activities reporting	Quarterly reporting via REDCap. Includes updates to Jurisdictional Testing and Contact Tracing/Case Investigation plans	Quarterly through REDCap
Performance measure reporting	Quarterly, through REDCap, but reporting frequency may be adjusted	Quarterly, through REDCap, but reporting frequency may be adjusted
Reimbursement of allowable costs	Officially allowable but activities supported would largely fall upon award/post-award. Prior incurred costs would need to be associated with activities in the workplan. Charges not related to the workplan activities may result in the health department having to pay the money back.	Allowable
Restrictions	Research as defined by CDC, clinical care (except as may be allowed by law), purchasing vaccines, and major construction (e.g., new building, modification of more than 50% of structure, etc.) are not allowed. Renovations and minor construction (e.g., modification of less than 50% of structure, concrete slabs for modular labs/generators, etc.) are allowable.	Research as defined by CDC, clinical care (except as may be allowed by law), purchasing vaccines, and major construction (e.g., new building, modification of more than 50% of structure, etc.) are not allowed. Renovations and minor construction (e.g., modification of less than 50% of structure, concrete slabs for modular labs/generators, etc.) are allowable.
Of note: Allowable, allocable, reasonable; and consistent with the appropriation, grant regulations, grant terms and conditions	Resources to complement, but not duplicate, other CDC vaccine delivery efforts (e.g., those activities covered under IP19-1901). Costs can include infrastructure needs (e.g. staff, contractors, call centers, storage, space, etc.) that support testing as well as vaccination operations.	Resources to complement, but not duplicate, other CDC vaccine delivery efforts (e.g., those activities covered under IP19-1901). Costs can include infrastructure needs (e.g., staff, contractors, call centers, storage, space, etc.) that support testing as well as vaccination operations.

ELC Enhancing Detection Expansion & Immunization CoAg COVID-19 Funding Supplementals

B: Allowable Expenses At-A-Glance

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Personnel (term, temporary, students, overtime, contract staff, etc.)	**Laboratorians**	Yes	No
	Informaticians	Yes	Yes
	Epidemiologists	Yes	Yes
	Data Entry Clerks, managers/analysists	Yes	Yes
	Data Visualization Specialists	Yes	Yes
	Vaccine registry data manager	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Health Communicators (including those specializing in risk comms.)	Yes	Yes
	Health Educators	Yes	Yes
	Management, budget, & administrative support	Yes	Yes
	Infection Prevention & control staff	Yes	Yes, may be allowable if the position is responsible for vaccine-related work
	Community Health Workers & organizations working with populations at higher risk for COVID-19	Yes	Yes
	Security staff (for personnel and clinic settings)	Yes	Yes
	Nurses or other staff used to administer vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
Equipment	**Laboratory equipment & necessary maintenance contracts at PHL (includes state PHLs that are affiliated with clinical or academic institutions)**	Yes	May be allowable if support is not available through the ELC CoAg.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Equipment	**Laboratory equipment & necessary maintenance contracts at local or regional PHLs**	Yes, to the extent that equipment is necessary to successfully complete the Activities listed in the guidance, resources (e.g. equipment) may be purchased. Disposition of these items, including any reporting on their location/condition, is the responsibility of the prime recipient of funds & must be in accordance with grant regulations and OGS policies.	Yes, to the extent that equipment is necessary to successfully complete the Activities listed in the guidance, resources (e.g. equipment) may be purchased. Disposition of these items, including any reporting on their location/condition, is the responsibility of the prime recipient of funds and must be in accordance with grant regulations and OGS policies. Equipment may include items such as vaccine storage units.
	General equipment (generators, freezers, computers)	Yes	Yes, may be allowable as they support COVID- 19 vaccine administration & reporting
	Vaccine storage equipment & necessary maintenance contracts	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Hardware/software necessary for robust implementation of electronic laboratory & surveillance data exchange between recipient & other entities (e.g. healthcare entities, jurisdictional public health, & CDC)	Yes	Yes
	Hardware/software that may be used to assist with case investigation & contact tracing	Yes	No
	Equipment necessary to ensure safety of laboratory workers (e.g. BSCs, HVAC, etc.)	Yes	No
Supplies	**Collection supplies, test kits, reagents, consumables & other necessary supplies for existing testing or onboarding new platforms**	Yes	May be allowable if support is not available through the ELC CoAg.
	Collection supplies, test kits, reagents, consumables & other testing or onboarding new platforms at regional or local health departments	Yes	May be allowable if support is not available through the ELC CoAg.
	Ancillary supplies & consumables necessary to perform testing for SARS-CoV-2 within or outside of traditional PHL setting	Yes	May be allowable if support is not available through the ELC CoAg.
	PPE for laboratorians or other staff conducting sample collection or	Yes	May be allowable if support is not available through the ELC CoAg.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Supplies	**processing. Also includes PPE for general staff as needed & deemed necessary by the work conditions**		
	PPE for use during vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
Software	**Software or systems to assist with laboratory resource management (e.g. software for inventory management, temperature notifications, etc.), quality management, biosafety, or training needs**	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Software/hardware necessary for robust implementation of electronic laboratory and surveillance data exchange between recipients and other entities, jurisdictional public health & CDC	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Tools that assist in the rapid identification, electronic reporting, monitoring, analysis, & evaluation of control measures to reduce the spread of disease (e.g. GIS software, visualization dashboards, cloud services, etc.)	Yes	Yes, as it applies to vaccine management and Immunization Information Systems
	Software or applications that allow for more efficient case investigation & contact tracing	Yes	No
	Software associated with vaccine registries or tracking of vaccine	Case-by-case only. May be allowable if support is not available through the Immunization CoAg (IP19-1901)	Yes
	Vaccine Registry enhancements	Enhancements to registries already initiated with ELC resources may be completed if it does not interfere with the successful completion of all required activities; however, these should be considered one-time system improvements. The ELC will not be able to maintain the costs of these systems or upgrades.	Yes
Construction & Renovation	**Renovations & minor construction (e.g. alteration of less than 50% total square footage of an existing structure, installation of a concrete**	Yes, may be considered for unique cases where conditions do not currently allow for safe or effective testing and/or delivery of effective public health services.	Yes, on a case by case basis and as it relates to vaccines or vaccination activities.

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
	slab for modular laboratory units, etc.)		
Vehicles	**Leasing/purchasing vehicles (e.g. mobile testing, providing public health services in underserved areas, etc.)**	Yes, recipients will need to submit quotes with their revised budgets that are due within 60 days of award issuance and receive prior approval from OGS. After the revised NOA is issued, any further request for leasing/purchasing must be made through GrantSolutions and include the necessary quotes. Vehicles already purchased or leased for the purpose of testing may also be utilized for vaccine delivery	Leasing and rentals allowable, however, purchase is not
Quarantine & Isolation	**Quarantine & isolation support necessary for preventing the spread of COVID-19 (including wraparound services such as hoteling, food, laundry, mental health services, etc.)**	Yes, and may include wraparound services but not medical costs associated with treatment.	No
	Medication & patient treatment	No	No
Outreach & Education	**Expenses associated with outreach & assistance (e.g. support provided through community-based organizations) for those at higher risk of COVID-19**	Yes, these may include but are not limited to organizations that work with tribes, individuals experiencing homelessness, and racial and ethnic minority populations.	Yes, these may include but are not limited to organizations that work with tribes, individuals experiencing homelessness, and racial and ethnic minority populations.
	Health communications materials & health education services to inform & protect communities	Yes, health communications materials & health education services to inform & protect communities are allowable, if they do not duplicate activities covered by other CDC funding mechanisms (e.g., IP21-2106, IP21-2107). Recipients are reminded to be cognizant of the statutory & policy requirements for acknowledging the HHS/CDC funding when issuing statements, press releases, publications, requests for proposal, bid solicitations & other documents. In accordance with CDC General Terms & Conditions for Non-research Awards - Acknowledgement of Federal Funding, in your base award.	Yes, health communications materials & health education services to inform & protect communities are allowable, if they do not duplicate activities covered by other CDC funding mechanisms (e.g., IP21-2106, IP21-2107). Recipients are reminded to be cognizant of the statutory & policy requirements for acknowledging the HHS/CDC funding when issuing statements, press releases, publications, requests for proposal, bid solicitations & other documents. In accordance with CDC General Terms & Conditions for Non-research Awards - Acknowledgement of Federal Funding, in your base award.
	Support for social services & health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts	Yes	Yes, as it relates to vaccination activities
	Mass vaccination campaigns	Aspects of this activity may be supported if not already covered by another source.	Yes

Category	Expense	ELC Enhancing Detection Expansion	Immunization & VFC Cooperative Agreement
Stipends & Incentives	**Incentives to encourage participation by individuals (e.g., have testing done) or by a facility (e.g., onboard ELR for timely reporting of results)**	Stipends/incentives may be considered to encourage participation in testing and/or vaccination coverage for those put at higher risk for COVID-19 (individual level) or for facilities/agencies to enroll and/or report data to the health department (institutional level). Recipients interested in exploring this option (individual and/or institutional) must submit a plan that covers all of the following elements: (a) justification, (b) cost savings [e.g., how it will defray costs or have a positive return on investment], (c) defined amount, (d) qualifications for issuance, & (e) method of tracking. When submitting the revised budget within 60 days of award issuance, stipend/incentive plans must be included in the 'budget justification' section of the ELC budget workbook and receive CDC approval before implementation. After the revised NOA is issued, any subsequent requests for using funds to support stipends/incentives must be made in GrantSolutions, including the stipend/incentive plan, and receive CDC approval before implementation.	No, but please also speak with your POB Project Officer.
Contracts	**Contracts with academic institutions, private laboratories, other non-commercial healthcare entities, and/or commercial entities**	Yes	Yes, as it relates to vaccines or vaccination activities
	Contracts (or mini grants) with local or regional health departments	Yes	Yes
	Courier service (new or expansion of existing agreements)	Yes	Yes
	Contracts to support testing at non-traditional testing sites or POC tests	Yes	No
	Contracts to support testing at clinical, private, or academic institutions	Yes	No
Social Services	**Support for social services and health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts**	Support for social services & health education efforts that will facilitate compliance with isolation & quarantine and/or case investigation & contact tracing efforts.	Support for social services & education efforts that support vaccination activities.

12 Things States Need to Know about the Vaccine Adverse Event Reporting System (VAERS)

The federal government takes all reports of vaccine adverse events seriously, and CDC and the U.S. Food and Drug Administration (FDA) are actively engaged in safety monitoring of COVID-19 vaccines. CDC uses numerous vaccine safety monitoring systems, including VAERS, to watch for adverse events (possible side effects) after vaccination.

Q. What is the Vaccine Adverse Event Reporting System?

After a vaccine has been authorized or approved by the FDA, post-approval monitoring using VAERS begins. VAERS is a national system used by FDA and CDC to collect reports of adverse events that happen after vaccination. VAERS can provide vaccine safety experts with valuable information to assess possible safety concerns. VAERS is especially useful for quickly detecting unusual or unexpected patterns of adverse event reporting that might signal a possible safety problem with a vaccine.

Q. Who can report post-vaccination adverse events to VAERS?

Anyone can submit a report to VAERS. Healthcare professionals, health departments, vaccine manufacturers, vaccine recipients, and parents or family members of people who have received a vaccine are encouraged to submit a VAERS form if they experience any adverse events after getting any vaccine.

Q. What do CDC and FDA do when a VAERS report is submitted?

Experts from CDC and FDA monitor VAERS reports to identify adverse events that need to be studied further. All serious reports are reviewed daily by vaccine safety experts. Scientists at CDC and FDA use statistical models to help understand whether there are any safety signals for a vaccine product and compare them with safety signals for other vaccines to determine if further investigation is needed.

Helpful Hints for States:

- Work with your communications team when considering developing statements about reporting adverse events after COVID-19 vaccination.
- Each state has a vaccine safety coordinator who can serve as a liaison with local health departments, providers, and partners on vaccine safety issues.
- CDC staff is available to provide state and local health departments with technical support and communications around adverse events after COVID-19 vaccination.
- Contact COVID19VaxSafety@cdc.gov to reach CDC for non-urgent matters. For urgent matters, call **(770) 488-7100** to reach the CDC Emergency Operations Center.

Q. When does CDC follow up on reports submitted to VAERS?

VAERS staff obtains follow-up medical records for reports classified as serious. A serious report describes an event that resulted in permanent disability, hospitalization, life-threatening illness, or death. VAERS staff may also obtain follow-up medical records for adverse events of interest, like anaphylaxis. Reviewing these records can help CDC and FDA medical staff better understand cases.

www.cdc.gov/coronavirus/vaccines

MS-DOH-21-1816-A-001606

CS322534-A 02/03/21

Q. Will CDC follow up with people who submit VAERS reports?

The person who submits a VAERS report will receive a confirmation that VAERS has received the report or a reminder if important information was left out of the initial report. If additional information is needed, CDC may reach out to healthcare providers relevant to the case.

Q. What happens when a death is reported to VAERS?

When a death is reported to VAERS, CDC obtains medical records about the person's death, including an autopsy report, if available. If no autopsy was performed, CDC will obtain a death certificate and other relevant medical records. VAERS scientists will **not** reach out to the person who submitted the report, unless the name of the hospital or vaccination provider is **not** included.

Q: Do CDC and FDA provide VAERS reporters with an assessment following reports of serious adverse events, including death?

No. One of the limitations of VAERS is that VAERS generally cannot assess causality. However, as a hypothesis-generating system, VAERS is valuable for identifying potential vaccine safety concerns that can be studied further.

Q. Who are vaccine safety coordinators?

Vaccine safety coordinators are public health officials at jurisdiction health departments that serve as CDC's "eyes and ears" on vaccine safety issues and coordinate with CDC on incident response. They also serve as primary educators for vaccine safety reporting at the state and local level and coordinate local efforts to report vaccine adverse events to VAERS.

Q. What information from VAERS does CDC make available to vaccine safety coordinators each week?

Each week, CDC makes available via Epi-X a summary of VAERS reports received within the jurisdiction in the last week and a summary of VAERS data from other jurisdictions. CDC also sends a daily email notification whenever VAERS receives death reports from the jurisdiction. These reports are available via Epi-X.

Q. Do we need to follow up on VAERS reports filed in our jurisdiction?

Public health jurisdiction staff does **not** need to follow up on VAERS reports. VAERS staff will routinely follow up to obtain medical records for all reports of serious adverse events or death.

Q. When should we consider contacting CDC about COVID-19 vaccine adverse event reports?

Vaccine safety coordinators, immunization program managers, and other health department staff are welcome to contact CDC about vaccine safety issues at any time. Consider contacting CDC about:

- Unusual or unexpected vaccine adverse event reports
- Clusters of adverse events
- Vaccine administration errors
- Events that may impact public confidence in vaccination programs
- CDC laboratory and/or pathology support
- Requests for investigation by high-ranking state or local health officials
- Adverse event reports that may generate an increased level of media attention

Q. How can we contact CDC if there is an emergency relating to COVID-19 vaccine safety?

For public health emergencies, jurisdictions and providers may call the CDC Emergency Operations Center at **(770) 488-7100**.
For non-urgent concerns, jurisdictions and providers may email covid19vaxsafety@cdc.gov. For medical emergencies call **911**.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- TODAY: Webinar - ELC Reopening Schools [Link]
  - CDC's Epidemiology and Laboratory Capacity (ELC) Program will host a webinar **TODAY**, Thursday, **April 1** at **4:00 pm EDT** regarding funding to enable and expand school-based screening testing. Attendees can expect a review of the *Reopening Schools* guidance (*attached), subject matter expert perspectives, and a Q&A session. The webinar will be recorded and a link to download will be made available afterwards, in addition to a copy of slides.
  - Call information is below:
    - Weblink: https://www.mymeetings.com/nc/join/
      Conference Number: PWXW2102397
      Direct link: https://www.mymeetings.com/nc/join.php?i=PWXW2102397&p=9125099&t=c
    - Telephone: 1-415-228-4882 or 800-369-2098
      Passcode: 9125099

HHS Press Release: "HHS to Expand Access to COVID-19 Vaccines for Older Adults and People with Disabilities" [Link]

- On **Monday, March 29**, HHS announced a partnership between CDC and the Administration for Community Living (ACL) to provide nearly $100 million in funding to help increase vaccinations among older adults and people with disabilities. From the announcement: *"With funding from CDC, ACL will issue nearly $93 million in grants to the aging and disability networks in every state and territory. These funds will help provide critical services to overcome barriers that are preventing millions of those most at risk for serious illness and death from COVID-19 from receiving vaccines. This partnership also will provide an additional $5 million in funding for national hotlines to assist older adults and people with disabilities in registering for a vaccination and to connect them with local disability and aging agencies that can provide services and supports necessary to access them."*
- The full press release is available on HHS' website here.

- NIOSH Resources: "Safe and Proper Sharps Disposal During the COVID-19 Mass Vaccination Campaign" [Attachments, Link]
  - The National Institute for Occupational Safety and Health (NIOSH) recently released a new suite of communications products aimed at preventing needlesticks at mass vaccination sites, as well as promoting proper sharps disposal. Please see attached for two printouts that can be posted for staff and office use. An accompanying webpage is available on CDC's website here.
- MMWR Early Release: "Provisional Mortality Data — United States, 2020" [Attachment, Link]
  - From the summary: *"The age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics."*
- MMWR Early Release: "Death Certificate–Based ICD-10 Diagnosis Codes for COVID-19 Mortality Surveillance — United States, January–December 2020" [Attachment, Link]
  - From the summary: *"Among 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both."*

Standing Updates

- CDC Partner Update – March 31 [Attachment]
  - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Updates – March 29, 30, & 31 [Attachments]
  - Please see attached for the latest COVID-19 updates from the HHS Office of

Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.

- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
  - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

ELC REOPENING SCHOOLS: SUPPORT FOR SCREENING TESTING TO REOPEN & KEEP SCHOOLS OPERATING SAFELY

GUIDANCE

PROJECT E: EMERGING ISSUES

BACKGROUND AND PURPOSE

To support safe, in-person instruction in kindergarten through grade 12 (K-12) schools, screening testing can provide another layer of prevention to protect students, teachers, and staff and slow the spread of SARS-CoV-2, the virus that causes Coronavirus Disease 2019 (COVID-19). While it is critical for schools to open as soon as possible (and remain open) for academic and social, emotional benefits, it is equally important to do so safely (see: https://www.cdc.gov/coronavirus/2019-ncov/community/schools-childcare/operation-strategy.html)

To enable schools to establish COVID-19 screening testing programs to support and maintain in-person learning, the federal government is providing financial resources to enable and expand school-based screening testing. Screening guidance should be implemented in ways consistent with CDC guidance; however, it is recognized that there may be practical or resource limitations in some school districts that make adherence to this guidance difficult at the start of this initiative.

Approximately $30 billion has already been awarded to public health departments to support activities, including screening testing, through the *ELC Enhancing Detection* (ED) and *ELC ED Expansion* supplements. Using those supplemental funds, public health departments increased their ability to provide screening testing broadly to their communities, including congregate settings, like schools. However, few have set up comprehensive programs of weekly test screening in K-12 schools (public and private) across an entire jurisdiction (i.e., state, local, and territorial), which is the goal of this new effort.

Awarding $10 billion from the *American Rescue Plan Act of 2021*, P.L. 117-2, under the *ELC Reopening Schools* award, will afford recipients the ability to support comprehensive screening testing for K-12 schools (public and private). A key goal of this initiative is to establish screening testing programs in schools around the country in April 2021, extending through the end of the school year and into summer activities and subsequent school year, as funds allow. This approach also encourages continuity and enhancement of existing COVID-related activities, maintains the health department's integral role in the screening testing ecosystem, builds upon the work already begun under *ELC Enhancing Detection* (ED) and *ELC ED Expansion* supplements, and ensures a holistic assessment and monitoring of disease burden within any given community. Recipients should ensure equitable access to the support being provided by this opportunity and where appropriate, coordinate with other initiatives that may already be targeting areas with high SVI.

FUNDING STRATEGY & SUPPORT TO SCHOOL DISTRICTS

The $10 billion, under the *ELC Reopening Schools* award, will be awarded to the current 64 ELC recipients according to a population-based formula.

The objectives and goals of this funding are primarily focused on providing needed resources to implement screening testing programs in schools aligned with the CDC recommendations for K-12 (https://www.cdc.gov/coronavirus/2019-ncov/community/schools-childcare/operation-strategy.html). Therefore, a minimum of 85% of the award must be allocated to directly fund school districts or provide materials (e.g., test kits, PPE, staffing, etc.) and services (e.g., sample collection, laboratory testing, etc.) to increase screening testing in all K-12 schools (public or private) within the recipient's jurisdiction. Recipients may use a combination of approaches (examples follow below) to successfully provide the necessary support to schools.

Up to 15% may be used by recipients for coordination, management, technical assistance, monitoring, and data collection and reporting activities to support K-12 screening testing programs. These funds may not be applied to expenditures incurred before the date of award. However, recipients can use previously awarded funds for any school screening testing activities that are consistent with those awards and in a way that is not a duplication of effort but an enhancement or complementary effort. School screening testing is an allowable activity under the prior two supplemental awards: *ELC Enhancing Detection* and *ELC Enhancing Detection Expansion*.

Examples of providing funding directly to support school districts and private/charter schools **include, but are not limited to:**

1. Contracting with testing companies to directly implement programs in K-12 schools and school districts.
2. Partnering with local or chain pharmacies to provide screening testing for K-12 schools and school districts (e.g., contract or fee-for-service model).
3. Partnering directly with laboratories with or without established regional footprints.
4. Directly contracting with K-12 schools and school districts within a recipient's jurisdiction for the completion of the activities in this guidance.
5. Establishing an account to allow K-12 schools and school districts to be reimbursed for costs associated with screening testing.
6. Coordinating with the State Department of Education to facilitate financial support for K-12 schools and school districts.
7. Sub-awarding to Local Health Departments to support school screening testing directly

8. Supporting IT systems to monitor screening testing in K-1 K-12 schools and school districts and ensure positive results are linked to public health action.

   ** Each jurisdiction is different; it is assumed that any proposed approach will align with existing jurisdictional laws, regulations, and business practices, while remaining consistent with this award.*

Examples of providing materials and services to school districts and private/charter schools **include, but are not limited to:**

1. Recipient using purchasing authorities to obtain screening testing kits, and necessary supplies, and providing them to school districts and private/charter schools within their jurisdiction.
2. Providing courier services to improve turn-around time for results.
3. Providing Personal Protection Equipment (PPE).
4. Providing laboratory support.
5. Personnel support, onsite, such as a screening testing coordinator, for sample collection, or other additional staff needed to implement testing programs, etc.
6. Logistical and operational support, including IT systems and data management, as needed.

Financial expenditures will be monitored and assessed with recipients monthly.

ALLOWABLE COSTS

Recipients should consider requesting the following when developing the *ELC Reopening Schools* budgets. The financial resources provided are required, by law, to support school-based screening testing activities intended to reopen schools at the kindergarten through 12-grade level that were closed (partially or fully) due to COVID-19.

1. Personnel (term, temporary, students, overtime, contract staff, etc.).
2. Laboratory equipment used for COVID-19 testing and necessary maintenance contracts.
3. Collection supplies, test kits, reagents, consumables, and other necessary supplies for existing screening testing or onboarding new platforms to support school screening testing.
4. Personal Protective Equipment (PPE) (e.g., masks, gloves, gowns) for those (e.g., teachers and school staff) collecting samples and/or conducting screening testing.
5. Courier service contracts (new or expansion of existing agreements).
6. Hardware and software necessary for reporting to public health and communication and coordination of follow up on any positive cases detected.
7. Tools that assist in the rapid identification, electronic reporting, monitoring, analysis, and evaluation of control measures to reduce the spread of COVID-19, that may be translatable to other diseases (e.g., GIS software, visualization dashboards, cloud services).
8. Contracts with academic institutions, private laboratories, other non-commercial healthcare entities, and/or commercial entities that may provide all or part of the screening testing needs. This may include contracts with companies that offer comprehensive support for screening testing in K-12 (e.g., sample collection, screening testing, and reporting).
9. Software or systems to assist with laboratory resource management (e.g., software for inventory management, temperature notifications, etc.), quality management, biosafety, or training needs.
10. Leasing/purchasing vehicles (e.g., mobile screening testing, providing K-12 screening testing services in underserved areas, etc.). Note: Recipients will need to submit quotes with their revised budgets and receive prior approval from the Office of Grant Services (OGS). If need arises before or after the revised Notice of Grant Award (NOA) is issued, requests for leasing/purchasing must be made through GrantSolutions and include the necessary quotes.

11. Program incentives may be considered to encourage individuals to participate in screening testing. Recipients interested in exploring this option must submit a plan that covers all of the following elements: (a) justification, (b) cost savings [e.g., how it will defray costs or have a positive return on investment], (c) defined amount (not to exceed $25 per instance), (d) qualifications for issuance, and (e) method of tracking. When submitting the revised budget within 60 days of award issuance, the program incentive plan must be included in the 'budget justification' section of the ELC budget workbook and receive CDC approval before implementation. After the revised NOA is issued, any subsequent requests for using funds to support program incentives must be made in GrantSolutions, including the program incentive plan, and must receive CDC approval before implementation.
12. Wrap-around (e.g., hoteling, food, laundry, mental health services, etc.) services for those who test positive.
13. Expenses associated with outreach and assistance (e.g., support provided through community-based organizations).
14. Expenses associated with technical assistance to establish school-based screening testing programs (NGOs, academic institutions, foundations, etc.).

*ELC Reopening School*s funds can be used to cover screening testing costs (e.g., administration, etc.) fully. Recipients should follow all appropriate federal laws and regulations pertaining to testing reimbursements, including assuring that charges are not covered both by ELC funds and other reimbursement sources.

The above list covers the anticipated, most relevant costs associated with achieving the activities in this guidance. This list does not represent a full list of allowable costs. Recipients are referred to the cost principles regulation found at 45 CFR Part 75 Subpart E – Cost Principles.

In determining if costs are allowable, consideration must be given to applicable regulations; the overall underlying cooperative agreement (CK19-1904); be considered necessary and reasonable; and be considered allocable (see: 45 CFR 75.403). Any questions about specific budget items should be directed to the OGS and the ELC Project Officer.

Please also note, the CDC is not prescribing the tests that may be used for screening; however, they must have received an emergency use authorization (EUA).

COVID-19 TERMS AND CONDITIONS

Coronavirus Disease 2019 (COVID-19) Funds: A recipient of a grant or cooperative agreement awarded by the Department of Health and Human Services (HHS) with funds made available under the Coronavirus Preparedness and Response Supplemental Appropriations Act, 2020 (P.L. 116-123); the Coronavirus Aid, Relief, and Economic Security Act, 2020 (the "CARES Act") (P.L. 116-136); the Paycheck Protection Program and Health Care Enhancement Act (P.L. 116-139); the Consolidated Appropriations Act and the Coronavirus Response and Relief Supplement Appropriations Act, 2021 (P.L. 116-260) and/or the American Rescue Plan of 2021 [P.L. 117-2] agrees, as applicable to the award, to: 1) comply with existing and/or future directives and guidance from the Secretary regarding control of the spread of COVID-19; 2) in consultation and coordination with HHS, provide, commensurate with the condition of the individual, COVID-19 patient care regardless of the individual's home jurisdiction and/or appropriate public health measures (e.g., social distancing, home isolation); and 3) assist the United States Government in the implementation and enforcement of federal orders related to quarantine and isolation.

In addition, to the extent applicable, Recipient will comply with Section 18115 of the CARES Act, with respect to the reporting to the HHS Secretary of results of tests intended to detect SARS–CoV–2 or to diagnose a possible case of COVID–19. Such reporting shall be in accordance with guidance and direction from HHS and/or CDC. HHS laboratory

reporting guidance is posted at: https://www.hhs.gov/sites/default/files/covid-19-laboratory-data-reporting-guidance.pdf.

Further, consistent with the full scope of applicable grant regulations (45 C.F.R. 75.322), the purpose of this award, and the underlying funding, the recipient is expected to provide to CDC copies of and/or access to COVID-19 data collected with these funds, including but not limited to data related to COVID-19 testing. CDC will specify in further guidance and directives what is encompassed by this requirement.

This award is contingent upon agreement by the recipient to comply with existing and future guidance from the HHS Secretary regarding control of the spread of COVID-19. In addition, recipient is expected to flow down these terms to any subaward, to the extent applicable to activities set out in such subaward.

To achieve the public health objectives of ensuring the health, safety, and welfare of all Americans, Recipient must distribute or administer testing without discriminating on non-public-health grounds within a prioritized group.

Acknowledgement of Federal Funding: When issuing statements, press releases, publications, requests for proposal, bid solicitations and other documents --such as tool-kits, resource guides, websites, and presentations (hereafter "statements")--describing the projects or programs funded in whole or in part with U.S. Department of Health and Human Services (HHS) federal funds, the recipient must clearly state:

1. The percentage and dollar amount of the total costs of the program or project funded with federal money; and,

2. The percentage and dollar amount of the total costs of the project or program funded by non-governmental sources.

When issuing statements resulting from activities supported by HHS financial assistance, the recipient entity must include an acknowledgement of federal assistance using one of the following or a similar statement.

If the HHS Grant or Cooperative Agreement is NOT funded with other non-governmental sources:

> This **[project/publication/program/website, etc.]** [**is/was**] supported by the [**full name of the OPDIV/STAFFDIV**] of the U.S. Department of Health and Human Services (HHS) as part of a financial assistance award totaling **$XX** with 100 percent funded by [**OPDIV/STAFFDIV**]/HHS. The contents are those of the author(s) and do not necessarily represent the official views of, nor an endorsement, by [**OPDIV/STAFFDIV]/**HHS, or the U.S. Government. For more information, please visit [**OPDIV/STAFFDIV website, if available**].

The HHS Grant or Cooperative Agreement IS partially funded with other nongovernmental sources:

> This [**project/publication/program/website, etc**.] [**is/was**] supported by the [full name of the **OPDIV/STAFFDIV**] of the U.S. Department of Health and Human Services (HHS) as part of a financial assistance award totaling **$XX** with **XX** percentage funded by **[OPDIV/STAFFDIV**]/HHS and **$XX** amount and **XX** percentage funded by non-government source(s). The contents are those of the author(s) and do not necessarily represent the official views of, nor an endorsement, by [**OPDIV/STAFFDIV**]/HHS, or the U.S. Government. For more information, please visit [**OPDIV/STAFFDIV website, if available**].

The federal award total must reflect total costs (direct and indirect) for all authorized funds (including supplements and carryover) for the total competitive segment up to the time of the public statement.

Any amendments by the recipient to the acknowledgement statement must be coordinated with the HHS Awarding Agency.

If the recipient plans to issue a press release concerning the outcome of activities supported by HHS financial assistance, it should notify the HHS Awarding Agency in advance to allow for coordination.

Termination

This award may be terminated in whole or in part consistent with 45 CFR 75.372.

CDC may impose other enforcement actions in accordance with 45 CFR 75.371- Remedies for Noncompliance, as appropriate.

SUPPORTING MANAGEMENT OF ACTIVITIES AND RESOURCES

Recipients will need to ensure proper oversight of the use of funds under this award. Please note that 85% of the awarded amount is expected to directly support K-12 screening testing in school districts and private/charter schools within a jurisdiction. Up to 15% may be used by recipients for coordination, management, technical assistance, monitoring, and data collection and reporting activities to support K-12 screening testing programs.

Additionally, there are special reporting requirements (see 'Summary of Reporting Requirements' in the 'Performance Measures and Reporting' section) which will likely require dedicated personnel resources to ensure timeliness and completeness of data being reported.

Examples of support in the form of coordination, management, technical assistance, monitoring and reporting, include but are not limited to:

1. Contracting for the development of a web-based platform, linking school districts and private/charter schools with testing service providers, with a program overview, toolkit and resources, and communication materials (e.g., https://covidedtesting.com/).
2. Adapting, modifying or implementing testing program toolkits or playbooks to support school districts and private/charter schools in program design (https://www.rockefellerfoundation.org/wp-content/uploads/2021/02/The-RockefellerFoundation-Covid-19-K-12-Testing-Playbook-for-Educators-and-Leaders.pdf).

PROCESS FOR WORKPLAN AND BUDGET SUBMISSION

Within five (5) business days of receipt of this guidance, the recipient's Authorized Official is required to acknowledge receipt of this guidance by submitting a Grant Note in GrantSolutions. The acknowledgement must be submitted on the recipient's official agency letterhead and utilize the 'Acknowledgement Letter for CK19-1904 – COVID Supplemental Funds' template provided at the end of this guidance document.

This funding will be awarded in the ELC Budget Period 2 (BP2) (i.e., August 1, 2020 – July 31, 2021) under CK19-1904. However, recipients should note that this supplemental funding is for a sixteen (16) month project period and will end on July 31, 2022. The expanded project period coincides with the end of Budget Period 3 (BP3) (i.e., August 1, 2021 – July 31, 2022) of the ELC Cooperative Agreement (CK19-1904).

To reduce burden on recipients, given the multiple ELC COVID awards, the workplan will be streamlined for this award. Please see the 'Activities' section of this guidance for details pertaining to the three (3) required activities under this award.

To allow recipients to focus efforts on initiating activities (i.e. getting at least 85% of the award to support school districts and private/charter schools to increase screening testing, begin screening testing, etc.), recipients are given sixty (60) days from time of award for the submission of a revised budget in GrantSolutions via budget revision amendment. During this period, all funds will be available and recipients are expected to use funding expeditiously to conduct activities consistent with this guidance.

In cases of recipients entering into contractual agreements for school district support, to meet the OGS requirement for prior approval, submission of contract details can be made via Grant Note until the revised budget is officially submitted as a budget revision amendment in GrantSolutions.

Given this award has a 16-month funding period, revised budgets should reflect activities and associated costs that will end on July 31, 2022. Recipients are reminded that expanded authority[1] applies, in terms of carryover of unobligated from one budet period to the next budget period to cover the approved workplan activities.

REQUIRED TASKS

Note: If a recipient does not meet the below required tasks and has not received written approval for an extension from CDC, recipient may have their funds restricted in the Payment Management System (PMS) for specific costs/activities. Recurring or repeat non-compliance may result in additional restrictions or other actions being taken, consistent with applicable grant regulations.

In addition to the programmatic activities noted below in further detail, recipient responsibilities include but are not limited to:

1. Within **five (5) business days** of receipt of this guidance the Authorized Official is required to acknowledge receipt of this guidance by submitting a Grant Note in GrantSolutions. The acknowledgement must be submitted on the recipient's official agency letterhead and utilize the 'Acknowledgement Letter for CK19-1904 – COVID Supplemental Funds' template provided at the end of this guidance document.
2. Regular participation in calls with CDC/HHS for technical assistance and monitoring of activities supported through this cooperative agreement.
3. On-time submission of all requisite reporting. This may include but is not limited to reporting of performance measures, progress on milestones, and/or financial updates within REDCap.
4. Report expenditures and unliquidated obligations (ULOs) on a monthly basis. On the 5th day of the month, the expenditures and ULOs from the prior month shall be reported in the REDCap 'ELC ED Expansion Financial Reporting' page.

[1] Expanded Authority is provided to recipients through 45 CFR Part 75.308, which allows carryover of unobligated balances from one budget period to a subsequent budget period. Unobligated funds may be used for purposes within the scope of the project as originally approved. Recipients will report use, or intended use, of unobligated funds in Section 12 "Remarks" of the annual Federal Financial Report.

5. Documentation of any necessary budget change/reallocation through GrantSolutions and REDCap.
6. Within ten (10) business days after receipt of the Notice of Award recipients shall report on the below via REDCap. After June, reporting for the remainder of the project period will be adjusted, at the recipient level, based on the school calendar and school district progress.
    a. Brief narrative that describes the methods used to provide support to schools;
    b. Budget estimates for providing up to the 85% of total award in support to schools;
    c. List of school districts and private/charter schools and estimated enrollment number for K-12 that are receiving support; and
    d. Frequency of testing.
7. **Weekly reporting**, within fifteen (15) business days from issuance of the award and until the end of June 2021, recipients shall report on the below via REDCap. After June, reporting for the remainder of the project period will be adjusted, at the recipient level, based on the school calendar and school district progress.
    a. The number of tests conducted by school district;
    b. Test type; and
    c. Cases identified.

ACTIVITIES

This award has three (3) required overarching activities that are designed to meet the immediate needs to safely reopen schools and the ongoing efforts to keep schools operating safely.

Activity 1: Rapid deployment of screening testing resources

The focus for Activity 1 is to jumpstart the ability for jurisdictions to implement school testing (estimated timeframe April to June). A minimum of 85% (direct and indirect) of the award must be allocated to support schools (public or private) that cover all or some K-12 grades within the recipient's jurisdiction. Recipients may use a combination of mechanisms to successfully provide the necessary support to schools. While not exhaustive, examples of mechanisms to provide financial support are listed in the 'Funding Strategy' section above. Additionally, examples of types of support may be found under the 'Allowable Costs' section. Recipients will need to support school district implementation with technical assistance and monitoring, as well as identifying public health actions needed based on school screening testing information. Recipients should assure that school districts and private/charter schools have adequate plans for action when they identify a positive test result.

Recipients may also plan and implement support for screening programs in school-affiliated summer programs, including camps and summer instruction. Recipients can also consider summer programs outside of schools that focus on providing equitable access to educational and recreational activities.

Initial reporting requirements

Within ten (10) business days after receipt of the Notice of Award and until the end of June 2021, recipients shall provide weekly reports on the below via REDCap. After June, reporting for the remainder of the project period will be adjusted, at the recipient level, based on the school calendar and school district progress.

1. A brief narrative that describes the method(s) that will be used to provide support to schools (e.g., partnerships with pharmacies, contracts for comprehensive screening testing services, reimbursable accounts with school districts and private/charter schools , or any combination of mechanisms).
2. Budget estimates for each method of support being provided up to the 85% of the total award.
3. A list of all school districts and private/charter schools supported with these funds and estimated enrollment numbers of K-12 students in each district and private/charter schools implementing screening testing programs.

Activity 2: Development of K-12 screening testing implementation plan

Recipients will develop a comprehensive screening testing plan[2] to support SARS-CoV-2 screening testing in K-12 schools across their communities for the 2021-2022 school year. In developing the plan, the information collected and lessons learned from Activity 1 (e.g., any limits in ability to conduct this program whether legal or practical, etc.) should inform planning for the 2021-2022 school year. The plan should include the approach(es) utilized to provide screening testing support to K-12 schools and a timeline for implementation that is consistent with CDC testing guidance and K-12 operational planning guidance (https://www.cdc.gov/coronavirus/2019-ncov/community/schools-childcare/operation-strategy.html). Existing plans may also be used or modified where appropriate. The plan is intended to be used by the jurisdiction, therefore not collected by CDC, and should address the specific needs within that jurisdiction.

Activity 3: Implementation screening testing action plan

Using the screening testing plan as a guide, recipients will progress through the stepwise implementation of the plans to support schools safely opening/remaining open for the 2021-2022 school year. The implementation plan should include methods to monitor effectiveness and integrate modifications as needed based on lessons learned over time.

Please note that additional supplemental guidance may be released to recipients based on information collected from performance measures, milestone progress reporting, and/or additional scientific understanding of SARS-CoV-2.

PERFORMANCE MEASURES

As noted above, within 10 business days of receipt of this guidance, recipients must provide a list of all school districts and private/charter schools implementing screening testing programs, that are supported with these funds, which will be used for weekly reporting. This list should include the number of K-12 students enrolled in each. This list will be utilized for the subsequent performance measure reporting.

Reporting to ELC via REDCap will commence within 15 business days after receipt of the Notice of Award and until the end of June 2021. Recipients shall provide weekly reports on the below via REDCap. After June, reporting for the remainder of the project period will be adjusted, at the recipient level, based on the school calendar and school district progress. It is expected that a substantial portion of the resources provided through this opportunity will be focused on establishing screening programs (April to June).

[2] For schools that host school-affiliated summer programs (in-person learning or summer camp), action plans should include details about screening testing over the summer months. Recipients can also consider summer programs outside of schools that focus on providing equitable access to educational and recreational activities.

1. Number of tests conducted by school districts and private/charter schools
2. Test type (e.g. antigen vs PCR)
3. Cased identified

ELC Reopening Schools Metrics for Week #1 for Recipient: X				
School District	Enrollment	Tests Conducted PCR	Tests Conducted Antigen	Cases (All test types)
District A				
District B				
District ….				

The ELC Program Office will utilize existing data sources whenever possible to reduce the reporting burden on recipients and, where appropriate, existing ELC performance measures may be used.

School districts and private/charter schools will not report test results directly to CDC under this award. For purposes of programmatic support to screening efforts, schools should be required by the recipient to report all positive results to the health department for public health action. Funds may be used to support data reporting by schools and their implementing partners. This project must be conducted in accordance with existing laws.

SUMMARY OF REPORTING REQUIREMENTS

The following is a summary of the reporting requirements for the ELC Reopening Schools award.

1. Within five (5) business days of receipt of this guidance, the Authorized Official is required to acknowledge receipt of this guidance by submitting a Grant Note in GrantSolutions.
2. Within ten (10) business days after receipt of the Notice of Award recipients shall provide the below via REDCap.
    a. Brief narrative that describes the methods used to provide support to schools;
    b. Budget estimates for providing up to the 85% of total award in support to schools;
    c. List of school districts and private/charter schools and estimated enrollment number for K-12 that are receiving support; and
    d. Frequency of testing.
3. Within fifteen (15) business days from issuance of the award and until the end of June 2021, recipients shall provide weekly reports on the below via REDCap. After June, reporting for the remainder of the project period will be adjusted, at the recipient level, based on the school calendar and school district progress.
    a. The number of tests conducted by school districts and private/charter schools;
    b. Test type; and
    c. Cases identified.
4. Weekly reporting, in REDCap, on the financial support to school districts and private/charter schools until end of June 2021.
5. Monthly fiscal reports, entered in REDCap with final report in GrantSolutions via Grant Note, beginning 30 days after NOAs are issued.
6. Performance measure data.
7. CDC may require recipients to develop annual progress reports (APRs). CDC will provide APR guidance and optional templates should they be required.

ACKNOWLEDGEMENT LETTER: DUE WITHIN FIVE (5) DAYS OF NOA RECEIPT

ELC Reopening Schools: Support for Screening testing to Reopen & Keep Schools Operating Safely

Date:

Organization Name:

Subject: Acknowledgement Letter for CK19-1904 – COVID-19 Supplemental Funds – ELC Reopening Schools

Reference: Guidance for the use of supplemental funding (April 2021) for CK19-1904 *ELC Reopening Schools: Support for Screening Testing to Reopen & Keep Schools Operating Safely* through the American Rescue Plan Act of 2021.

This is to acknowledge that I have received, reviewed, and understand the requirements in the attached programmatic guidance.

The federal funding received will be in support of the supplemental funding referenced herein and will be spent in accordance with the legislation and programmatic guidance.

To: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Subject: HHS COVID-19 Update - 3/29

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for March 29, 2021:

President Biden's remarks on Monday on the COVID-19 Response and State of Vaccinations:

- **New Vaccination Goal:** Last week we set a goal of 200 million shots by day 100 of our administration, double the original goal that I had set. To make that progress, over the last three days, we've had a record number of shots in arms with over 10 million shots recorded over the weekend. No other country has come close: 100 million shots in less than 60 days, and now we're moving on to the next 100 million shots in just 40 days. Nearly 75 percent of Americans over the age of 65 have received at least one vaccination shot. At least 90 percent of all adults in this country will be eligible to be vaccinated by April 19th, and the remaining 10 percent will be eligible no later than May 1 st. Moreover, 33 million doses of vaccine will be available to vaccinators this week.
- **Importance of Avoiding a Surge:** This is not the time to lessen our efforts, and if we let our guard down now, we could see the virus getting worse, not better. I am reiterating my call for every governor, mayor, and local leader to maintain and reinstate the mask mandate. Mask up. It's a patriotic duty, and it's the only way we ever get back to normal.
- **Increasing Vaccine Availability - 90/90 Initiative:** I am directing my COVID team to ensure there is a vaccine site within five miles of 90 percent of all Americans by April 19th. This is part of the Administration's "90/90" Initiative: by April 19 th, three weeks from today, 90 percent of adults — people over 18 and over — will be eligible get vaccinated and 90 percent of all Americans will be living within five miles of a place they can get a shot. We will also increase the current 17,000 pharmacies giving out vaccines to nearly 40,000 pharmacies within the next three weeks. We will also add 12 more federally-run mass vaccination sites, where currently, over 60 percent of the shots given at the existing sites goes to minorities communities. Lastly, I am directing millions of dollars, through the Department of Health and Human Services, to provide assistance, including transportation, to more vulnerable seniors and people with disabilities to help them get their shots.

Highlights from Friday and Monday's White House COVID-19 Response Team briefings:

Jeff Zients:

- **Increasing the Vaccine Supply:** The Administration has taken aggressive action to accelerate the production timelines of Pfizer, Moderna, and Johnson & Johnson, including using the Defense Production Act to expedite critical supplies, equipment, and materials, and brokering the historic partnership between Merck and Johnson & Johnson. J&J appears on track to deliver 20 million doses by the end of March, delivering 11 million doses this week, and both Pfizer and Moderna appear on track to meet their first-quarter targets.
- **Increasing the Number of Vaccinators:** The Administration has deployed over 6,500 federal personnel to serve as vaccinators and to support vaccinations, including calling on FEMA, retired doctors and nurses, and active-duty military to administer shots. In the coming weeks, at the President's direction, we will increase the 2,900 active-duty military men and women in the field to over 6,000 active-duty troops.
- **Increasing the Number of Places to get Vaccinated:** Across the country, there are nearly 50,000 sites where Americans can go to get a shot. We will continue to increase the number of local pharmacies administering the vaccine and expand community health centers providing the vaccine in the coming weeks. Importantly, over 65 percent of the shots administered at these community health centers have been to people of color. In addition to pharmacies and community health centers, there are over 650 federally supported community vaccination sites across the country. The Administration has also committed to deploying more than 500 mobile clinics as well as a program to get vaccines directly to dialysis centers.
- **Vaccine Eligibility Expansions:** Forty-six states and the District of Columbia have already announced plans to open up eligibility no later than May 1st. Fourteen states have already opened eligibility to all adults or will open eligibility in the next week. Twelve additional states are opening up eligibility to all adults by April 15th. In total, about half the states will have opened up eligibility to all adults by mid-April.

Andy Slavitt:

- **Number of People Vaccinated:** The U.S. is now averaging 2.7 million vaccinations over the last seven days. As of today, 73 percent of seniors have now received their first dose. Thirty-six percent — more than one in three adults — have received their first dose. Overall, more than 50 million Americans — approaching one in five adults — are fully vaccinated.
- **Federal Vaccination Sites:** Two new federally run mass vaccination sites will open: the first is at America's Center Convention Complex in St. Louis, Missouri, and the second is at Roosevelt High School in Gary, Indiana. These sites will join the 21 operational sites the administration has opened, which have already administered a combined 1.7 million shots.
- **Vaccine Passports:** The government is not viewing its role as the place to create a passport, nor a place to hold the data of citizens. We view this as something that the private sector is doing and will do. We are leading an interagency process right now to ensure that some important criteria are met with these credentials. Number one, that there is equitable access, including access to technology. It is also important that we recognize that there are still many millions of Americans that have not yet been vaccinated, which is a fundamental equity issue. Privacy of information, security of information, and a marketplace of solutions are all things that are part of what we believe in, as is the ability for people to access this for free and in multiple languages.

Dr. Walensky:

- **Case Update:** Yesterday, the US surpassed 30 million cases of COVID-19. CDC's most recent data show that the seven-day average of new cases is slightly less than 60,000 cases per day. This is a 10 percent increase compared to the prior seven-day period. Hospitalizations have also increased, with the most recent seven-day average at about 4,800 admissions per day. Deaths have increased nearly 3 percent to a seven-day average of approximately 1,000 deaths per day.
- **Avoiding a Surge:** The trajectory of the pandemic in the United States looks similar to many other countries in Europe, including Germany, Italy, and France looked like just a few weeks ago. And since that time, those countries have experienced a consistent and worrying spike in cases. Similarly, while the United States was stagnated at around 40,000 to 50,000 cases a day for a couple of weeks, we

now see a steady rise of cases towards 60,000 to 70,000 cases a day. Many states are opening up at levels that we wouldn't necessarily recommend, and we have also seen an uptick in travel. We also know that about 25 percent of all sequenced virus is now the B.1.1.7 variant, which is more transmissible and accounts for 8,000 cases in 51 jurisdictions. I will be speaking with many governors tomorrow, and I would encourage the public to follow the public health prevention strategies consistently, while we work to get the American public vaccinated.

- **Real World Effectiveness of Vaccine:** An MMWR study was released (see more info below) which found that the risk of infection was reduced by 90 percent after individuals received the two recommended doses of the Pfizer and Moderna vaccines. The study also found that people started to get a protective effect, even after the first dose, the risk of infection decreased by 80 percent after two weeks. Findings of this are all consistent with the clinical trial data. Importantly, people in the study received self-collected nasal swabs each week for laboratory testing, allowing CDC to look at evidence of COVID-19 infection whether or not people had symptoms. This study also demonstrates that two vaccines can reduce the risk of COVID-19 infections, not just in symptomatic infections but also in asymptomatic or pre-symptomatic infections. These findings underscore the importance of getting both of the recommended doses of the vaccine in order to get the greatest level of protection against COVID-19, especially as our concerns about variants escalate.
- **Updated Underlying Conditions:** After a thorough review of the evidence, we have simplified the list of underlying conditions for consumers and created a new page for healthcare providers. This will make it easier for patients and the public and providers to understand the important information related to their underlying medical conditions and its potential impact on COVID-19 severity. We've also updated the list of underlying medical conditions to include substance use disorders, based on evidence that having these conditions can increase risk of severe illness or death from COVID-19.
- **CDC's Commitment to Health Equity:** CDC will provide $3 billion from the CARES Act and the American Rescue Plan to 64 jurisdictions to support broad-based vaccine distribution, access, and administration efforts. 75 percent of the funding must focus on specific programs and initiatives intended to increase vaccine access, acceptance, and uptake among racial and ethnic minority communities. In addition, 60 percent of the funding must go to support local health departments, community-based organizations, and community health centers. In addition, CDC announced a separate investment of $300 million that will train, deploy, and engage more community health workers to help communities and individuals hardest hit by the pandemic.

Dr. Fauci:

- **Effects of COVID-19:** While the most important and common manifestation of COVID-19 is the acute respiratory distress syndrome, we now know there are neurological disorders, cardiac dysfunction, acute kidney injury, and hypercoagulability that can occur if contracting the virus. The bottom line: This is a very, very bad disease.
- **New Clinical Trial Among College Students:** This is a randomized, open-label, controlled study involving 12,000 college kids between 18 and 26 years of age at more than 20 universities; these students will be followed over five months. The students are going to be randomized into two groups: 6,000 will receive the Moderna vaccine immediately and another 6,000 will be vaccinated with a delay of four months later, serving as a control cohort. Importantly, about 25,000 individuals will be identified by the participants in the main study as "close contacts" and they will provide periodic blood samples along with the students in the study. The purpose of this study is to determine whether vaccinated people get infected asymptomatically, and if they do, do they transmit the infection to other.

Vaccine Updates

Vaccine Eligibility and Proximity: Today, President Biden unveiled new actions to get more people vaccinated quickly and announced that by April 19, 90% of adults in the U.S. will be eligible for vaccination and 90% will have a vaccination site within 5 miles of where they live. This announcement builds on last week's historic $10 billion investment to expand access to COVID-19 vaccines in the hardest-hit and highest-risk communities.

Developing Vaccines Quickly: Bringing a new vaccine to the public involves many steps including vaccine development, clinical trials, US Food and Drug Administration (FDA) authorization or approval, manufacturing, and distribution. Many different public organizations and private companies have worked together to make COVID-19 vaccines available to the public. While COVID-19 vaccines have been developed rapidly, all steps have been taken to ensure their safety and effectiveness.

Vaccinating People in Dialysis Clinics: The federal government is partnering with dialysis organizations, local and state jurisdictions to increase access to COVID-19 vaccines for patients and healthcare personnel in outpatient dialysis clinics. This partnership complements existing jurisdictional efforts to ensure equitable and effective access to COVID-19 vaccines and will increase availability of COVID-19 vaccines for patients in dialysis clinics. These patients are disproportionately affected by COVID-19 and are at high risk of severe illness from COVID-19.

Connecticut First State to Open COVID -19 Vaccine Mobile Unit: In the ongoing effort to bring the COVID vaccine to communities and people in socially vulnerable areas, Connecticut will open the country's first Mobile Vaccination Unit (MVU) on March 29, 2021 at the Beardsley Zoo in Bridgeport, Connecticut. The MVU will travel throughout Connecticut for 60 days to reach populations in 17 communities. Destinations were targeted based on the CDC's Social Vulnerability Index, U.S. Census Bureau's Community Resilience Estimates, low vaccine coverage, metrics and other barriers to vaccine access. The MVU will be used to complement ongoing efforts of local public health departments, health care providers, pharmacies, community and faith-based organizations, employers, private sector vaccinators and other federal resources.

Medical Reserve Corps Volunteers Aid COVID-19 Vaccination Efforts: More than 300 Medical Reserve Corps (MRC) units are assisting with COVID-19 vaccination efforts in 43 states, Puerto Rico, American Samoa, and the Northern Mariana Islands. Additional MRC units are preparing to activate to support vaccinations as more doses become available. MRC is sponsored nationally by HHS Office of the Assistant Secretary for Preparedness and Response (ASPR) and the agency provides the MRC network with technical assistance, strategy and policy development, training, and other related services. The units are managed and deployed at the state, territorial or local level, often by local health departments and emergency management agencies.

Baltimore Fait Community Promoting COVID-19 Vaccine Confidence: The African American faith community in Baltimore has been integral to educating the public about the risks posed by flu and the importance of vaccination. This work now provides immunization partners with lessons learned for the COVID-19 vaccination program.

Testing

EUA for Twist Bioscience Corporation: The FDA issued an emergency use authorization (EUA) to the Twist Bioscience Corporation for their SARS-CoV-2 NGS Assay. The SARS-CoV-2 NGS Assay is a next-generation sequencing (NGS) based test for the identification of SARS-CoV-2 RNA from respiratory samples, such as nose or throat swabs and washes, from people who are suspected of having COVID-19. This is the second whole genome sequencing diagnostic test for the qualitative detection of SARS-CoV-2 RNA authorized by the FDA. The test can be performed in laboratories certified under the Clinical Laboratory Improvement Amendments of 1988 (CLIA) that meet the requirements to perform high-complexity testing.

Automated Antigen Detection Assay for Acute COVID-19: BARDA is expanding its existing partnership with DiaSorin SpA on the development of a COVID-19 immunoassay. This new test detects the presence of SARS-CoV-2 in nasal swabs or nasopharyngeal swabs to diagnose acute COVID-19 disease. DiaSorin intends to develop, validate, manufacture, market, and obtain regulatory authorization in the United States and worldwide for this new, fully automated, chemiluminescent, antigen assay for the qualitative detection of the SARS-CoV-2 virus using nasal swabs or nasopharyngeal swabs. This assay will allow testing of nasal swabs in addition to traditional nasopharyngeal swabs, thereby expanding the utility of the assay by simplifying collection and enhancing patient comfort and safety.

Performing Broad-Based Testing: This tool is intended to help public health departments, healthcare providers, and administrators of congregate settings prepare for broad-based viral testing in correctional facilities and homeless service settings, after known or suspected exposure to the virus that causes COVID-19 or when there is moderate to substantial transmission in the community.

Testing Updates: As of Friday, 348 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 258 molecular tests and sample collection devices, 74 antibody and other immune response tests, and 16 antigen tests. There are 42 molecular authorizations that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home tests, one over-the-counter (OTC) at-home antigen test, and one OTC molecular test.

Funding

Access to COVID-19 Vaccines for Older Adults and People with Disabilities As part of President Biden's announcement today that the Administration will take further action to expand access to COVID-19 vaccines, HHS, through a partnership between the CDC and the Administration for Community Living (ACL), will provide nearly $100 million to help increase vaccinations among older adults and people with disabilities. This effort will help advance the key goals of protecting those most vulnerable and advancing equity within President Biden's National Strategy for the COVID-19 Response and Pandemic Preparedness.

Health Equity Funding: The Centers for Medicare & Medicaid Services Office of Minority Health (CMS OMH) is excited to release a notice of funding opportunity for the Minority Research Grant Program (MRGP), which provides up to $250,000 in funding to health equity researchers at minority-serving institutions. The MRGP allows researchers at minority-serving institutions (MSIs) to build their portfolios while conducting studies pertinent to the health care needs of racial and ethnic minorities, people with disabilities, sexual and gender minorities, and rural populations. Those interested in applying are encouraged to review the notice of funding opportunity CMS-1W1-21-002. The deadline to submit applications is Friday, June 11, 2021, at 3:00 p.m. ET.

Information for Specific Populations

Underlying Medical Conditions Associated with High Risk for Severe COVID-19: This webpage provides an evidence-based resource for healthcare providers caring for patients with underlying medical conditions who are at higher risk of developing severe outcomes of COVID-19. Severe outcomes are defined as hospitalization, admission to the intensive care unit (ICU), intubation or mechanical ventilation, or death. View CDC's page on scientific evidence for conditions that increase risk of severe illness.

Older Adults: The risk of severe illness from COVID-19 increases with age. This is why CDC recommends that adults 65 years and older are one of the first groups to receive COVID-19 vaccines. Getting a COVID-19 vaccine is an important step to help prevent getting sick from COVID-19. That said, it might take time before enough vaccines are made for everyone who wants to be vaccinated.

Infection Control for Nursing Homes: Given their congregate nature and resident population served (e.g., older adults often with underlying chronic medical conditions), nursing home populations are at high risk of being affected by respiratory pathogens like SARS-CoV-2 and other pathogens, including multidrug-resistant organisms (e.g., carbapenemase-producing organisms, Candida auris). As demonstrated by the COVID-19 pandemic, a strong infection prevention and control (IPC) program is critical to protect both residents and healthcare personnel (HCP). Even as nursing homes resume more normal practices and begin relaxing restrictions, nursing homes must sustain core IPC practices and remain vigilant for SARS-CoV-2 infection among residents and HCP in order to prevent spread and protect residents and HCP from severe infections, hospitalizations, and death.

People with Certain Medical Conditions: CDC updated their page for people with certain medical conditions. This page includes conditions such as liver disease, cancer, and more.

Drug Use & Substance Use Disorder: Having a substance use disorder can make you more likely to get severely ill from COVID-19. People who use drugs may also have underlying medical conditions that put them at increased risk for severe illness from COVID-19, and they may have concerns and questions related to their risk.

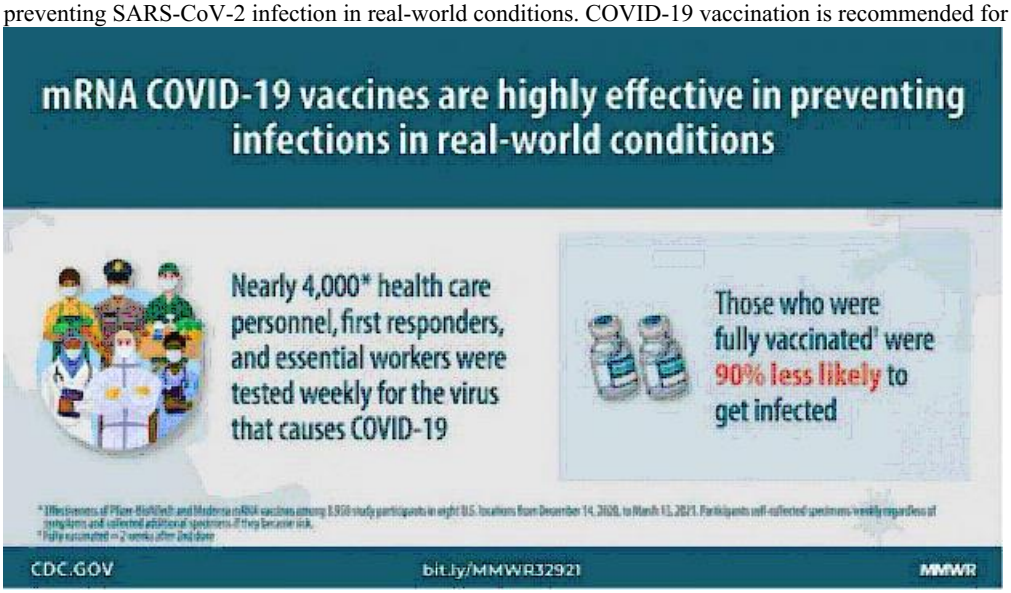
State Vets & Animal Health Officials: CDC updated their resources for state vets and animal health officials.

Temporary Halt in Residential Evictions: CDC Director Dr. Rochelle Walensky signed a declaration determining that the evictions of tenants could be detrimental to public health control measures to slow the spread of SARS-Cov-2, the virus that causes COVID-19.

Research

Use of Mental Health Care during the COVID-19 Pandemic: CDC released an MMWR on symptoms of anxiety or depressive disorder and use of mental health care among adults during the COVID-19 pandemic. During August 2020–February 2021, the percentage of adults with recent symptoms of an anxiety or a depressive disorder increased from 36.4% to 41.5%, and the percentage of those reporting an unmet mental health care need increased from 9.2% to 11.7%. Increases were largest among adults aged 18–29 years and those with less than a high school education. Trends in mental health can be used to evaluate the impact of strategies addressing adult mental health status and care during the pandemic and to guide interventions for disproportionately affected groups.

Effectiveness of COVID-19 Vaccines in Preventing SARS-CoV-2: CDC released an MMWR on interim estimates of v accine effectiveness of BNT162b2 and mRNA-1273 COVID-19 vaccines in preventing SARS-CoV-2 infection among health care personnel, first responders, and other essential and frontline workers**.** Prospective cohorts of 3,950 health care personnel, first responders, and other essential and frontline workers completed weekly SARS-CoV-2 testing for 13 consecutive weeks. Under real-world conditions, mRNA vaccine effectiveness of full immunization (≥14 days after second dose) was 90% against SARS-CoV-2 infections regardless of symptom status; vaccine effectiveness of partial immunization (≥14 days after first dose but before second dose) was 80%. Authorized mRNA COVID-19 vaccines are effective for preventing SARS-CoV-2 infection in real-world conditions. COVID-19 vaccination is recommended for all eligible persons.



Benefits of mRNA COVID-19 Vaccines: A new CDC study provides strong evidence that mRNA COVID-19 vaccines are highly effective in preventing SARS-CoV-2 infections in real-world conditions among health care personnel, first responders, and other essential workers. These groups are more likely than the general population to be exposed to the virus because of their occupations. The study looked at the effectiveness of Pfizer-BioNTech and Moderna mRNA vaccines in preventing SARS-CoV-2 infections among 3,950 study participants in six states over a 13-week period from December 14, 2020 to March 13, 2021. Results showed that following the second dose of vaccine (the recommended number of doses), risk of infection was reduced by 90 percent two or more weeks after vaccination. Following a single dose of either vaccine, the participants' risk of infection with SARS-CoV-2 was reduced by 80 percent two or more weeks after vaccination.

Marvin Figueroa, Director
Office of Intergovernmental and External Affairs
U.S. Department of Health and Human Services
Washington, D.C.

Subject: HHS COVID-19 Update - 3/30

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for March 30, 2021:

Case Update

New Cases (based on 7-day rolling average)
- **30,085,827** US cases
- **13.2% increase** in new cases (7-day average), as of March 30th; (was 1.8% increase last week)

Testing
- **364,465,712** tests completed (3/30)
- **5.0% positive test rate** as of the week of 3/23 – 3/30 (was 4.7% last week)

Hospitalizations
- **1,936,304** total COVID hospital admissions
- The 7-day average (3/23-3/30) number of new confirmed COVID-19 admissions **increased by 1.1%** week on week (from 4,517 to 4,693 admissions per day)

Deaths
- **546,704** total US deaths
- The 7-day average (3/23-3/29) number of reported deaths **increased by 6.7%** week on week (from 928 to 985 deaths per day)

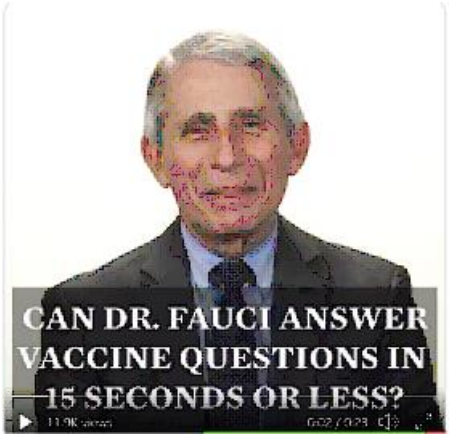
Vaccines
- **147,602,345** vaccine doses **administered** (3/30)
- **28.9%** (96 million people) of the population has received **1 or more doses** and **16.1%** (53.4 million people) of the population have been **fully vaccinated**
- **73.1%** of adults 65 and older have received **at least 1 dose** and **49.8%** have been **fully vaccinated**

Vaccine Updates

Fact Sheet on Johnson & Johnson Janssen Vaccine: CDC updated their general information on the Johnson & Johnson Vaccine. The J&J/Janssen vaccine is recommended for people aged 18 years and older. Learn more about how CDC is making COVID-19 vaccine recommendations and CDC's vaccine rollout recommendations.

Reported Adverse Events After COVID-19 Vaccination: Over 145 million doses of COVID-19 vaccines were administered in the United States from December 14, 2020, through March 29, 2021. During this time, the Vaccine Adverse Event Reporting System (VAERS) received 2,509 reports of death (0.0017%) among people who received a COVID-19 vaccine. CDC and FDA physicians review each case report of death as soon as notified and CDC requests medical records to further assess reports. A review of available clinical information including death certificates, autopsy, and medical records revealed no evidence that vaccination contributed to patient deaths. CDC and FDA will continue to investigate reports of adverse events, including deaths, reported to VAERS.

Dr. Fauci on Getting Vaccinated: In a brief video, Dr. Fauci explains why everyone should get vaccinated.



Testing and Treatment

COVID-19 Response at a Glance: FDA has updated its FDA COVID-19 Response At-A-Glance Summary, which provides a quick look at facts, figures and highlights on the FDA's response efforts.

New Drug Application Approved to Assist with Intubation: On March 29, the FDA approved an abbreviated new drug application for succinylcholine chloride injection USP 200 mg/10 mL, which is indicated, in addition to general anesthesia, to facilitate tracheal intubation and to provide skeletal muscle relaxation during surgery or mechanical ventilation. Side effects of succinylcholine chloride injection include anaphylaxis, hyperkalemia, and malignant hyperthermia. The FDA recognizes the increased demand for certain products during the COVID-19 public health emergency, and we remain deeply committed to facilitating access to safe and effective medical products to help address critical needs of the American public.

Strategies for Safe Sharps Disposal: The CDC offered strategies for how to protect yourself from needlestick injuries while administering COVID-19 vaccines or while helping at vaccination sites. Additionally, a shortage in the supply of FDA-cleared sharps disposal containers may occur during the COVID-19 mass vaccination campaign or as a result of other causes. Healthcare facilities and COVID-19 vaccination sites must use sharps disposal containers that meet Occupational Safety and Health Administration (OSHA) Bloodborne Pathogens standard requirements to dispose of contaminated needles and other sharps. Use FDA-cleared containers whenever possible. Conserve your FDA-cleared sharps disposal containers to help avoid a potential supply shortage. If FDA-cleared sharps disposal containers are unavailable, then consider using alternative containers that meet the OSHA requirements after checking your state's specific disposal requirements at SafeNeedleDisposal.org and discussing disposal options with your medical waste vendors.

COVID-19 Electronic Laboratory Reporting Implementation by State: CDC has been rapidly onboarding state and jurisdictional health departments to a more detailed form of COVID-19 electronic laboratory reporting (CELR). As of Tuesday, March 30th, 53 jurisdictions have converted to electronic laboratory reporting, representing approximately 92% of the total laboratory testing volume in the country.

FDA Testing Update: As of today, 349 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 258 molecular tests and sample collection devices, 74 antibody and other immune response tests, and 17 antigen tests. There are 42 molecular authorizations that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home test, one over-the-counter (OTC) at-home antigen test, and one OTC molecular test.

Information for Specific Populations

CDC Update on COVID-19 in Pets: A small number of pets worldwide, including cats and dogs, have been reported to be infected with the virus that causes COVID-19. The virus that causes COVID-19 can spread from people to animals in some situations, mostly during close contact. This is monitored frequently, and updates will continue to be posted.

CDC Recommendations for Managing Malaria and COVID-19: Ministries of Health and National Malaria Control Programs (NMCPs) need to ensure that malaria prevention and treatment activities are implemented while also protecting patients, health care providers, and public health officials from COVID-19 exposure. The CDC put forth key considerations for continuing essential malaria prevention and control activities safely and effectively, supplementing country Ministry of Health guidance.

CMS Updates

MIPS Application Extension: CMS has re-opened the 2020 extreme and uncontrollable circumstances application for the Merit-based Incentive Payment System (MIPS) eligible clinicians, groups, virtual groups, and APM entities who are unable to submit data due to COVID-19. For the 2020 performance year, we will be using our Extreme and Uncontrollable Circumstances policy to allow clinicians, groups, and virtual groups to submit an application requesting reweighting of one or more Merit-based Incentive Payment System (MIPS) performance categories due to the current COVID-19 public health emergency. To provide additional support to clinicians during this time, we are extending the deadline to submit a COVID-19 related extreme and uncontrollable circumstances application for PY 2020 to Wednesday, March 31, 2021 at 8 p.m. ET.

Research

Measles Vaccine Used as Base for Experimental COVID-19 Vaccine: Scientists developed a SARS-CoV-2 vaccine by adding a key coronavirus gene to the measles vaccine. The experimental vaccine protected against COVID-19 in animal studies, supporting further development. The vaccine prevented the virus from replicating in the lungs and nasal passages, produced a strong T cell response, and produced levels of neutralizing antibodies in rodents higher than those found in recovered COVID-19 patients. This vaccine candidate could potentially be used against both COVID-19 and measles.

T-Cells Recognize Recent SARS-CoV-2 Variants: In a study of recovered COVID-19 patients, researchers from the NIAID, NIH, and colleagues determined that SARS-CoV-2-specific CD8+ T-cell responses remained largely intact and could recognize virtually all mutations in the B.1.1.7 (U.K.), B.1.351 (South Africa), and B.1.1.248 (Brazil) variants. While larger studies are needed, the researchers note that their findings suggest that the T-cell response in convalescent individuals, and most likely in vaccines, are largely not affected by the mutations found in these variants and should offer protection against emerging variants. Optimal immunity to SARS-Cov-2 likely requires strong multivalent T-cell responses in addition to neutralizing antibodies and other responses to protect against current SARS-CoV-2 strains and emerging variants. The authors stress the importance of monitoring the anti-SARS-CoV-2 T-cell responses in order to determine if booster vaccinations are needed.

Increased Mortality Rate from the 'U.K. Variant' B.1.1.7: NIH Director, Dr. Francis Collins, examines studies conducted by Nicholas Davies, Karla Diaz-Ordaz, and Ruth Keogh, London School of Hygiene and Tropical Medicine, regarding the increased mortality rate from 'U.K. Variant' B.1.1.7. The researchers' estimates suggest that B.1.1.7 infection was associated with 55 percent greater mortality compared to other SARS-CoV-2 variants over this time period. This finding is in line with another recent study reported in the *British Medical Journal*, which found that the B.1.1.7 variant was associated with a 64 percent greater chance of death compared to earlier variants.

Subject: HHS COVID-19 Update - 3/31

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for March 31, 2021:

Highlights from the White House COVID-19 Response Team briefing:

Andy Slavitt:

- **Increasing Vaccination Sites:** The President committed to opening at least 12 more federally run mass vaccination sites, adding to the existing total of 25 sites. Three new sites will open next week in Memphis, Tennessee, Milwaukee, Wisconsin, and Greenbelt, Maryland, in addition to the two we announced on Monday in St. Louis, Missouri, and Gary, Indiana. Each of these sites is the first federally run mass vaccination site in its respective state, and each can administer 3,000 vaccinations a day.
- **Mask Mandates:** We need every governor, mayor, and local leader to maintain or reinstate mask mandates. And we need every American to do their part so that we can win this race and save lives.

Dr. Walensky:

- **Case Update:** CDC's most recent data show that the seven-day average of new cases is slightly less than 62,000 cases per day. We continue to see an increase, and this is almost a 12 percent increase from the seven-day period prior. Hospitalizations also continue to increase. The most recent seven-day average — about 4,900 admissions per day — is up from 4,600 admissions per day in the prior seven-day period. The seven-day average of deaths remains slightly above 900 deaths per day.
- **Inequities in COVID-19 Deaths:** COVID-19 deaths were highest for older adults and males, and were higher, as we previously saw, among American Indian and Alaska Natives, Hispanics, non-Hispanic Blacks, and non-Hispanic Native Hawaiian and Pacific Islander persons compared to non-Hispanic whites. In fact, among nearly all these ethnic and racial minority groups, the COVID-19-related deaths were more than double the death rate of non-Hispanic white persons. Based on the current state of the pandemic, these impacts have remained in 2021, where we continue to see that communities of color account for an outsize portion of these deaths.
- **Number of People Vaccinated:** This week, we will reach 100 million people who have received at least one dose of the COVID-19 vaccine in the United States — a remarkable feat in such a short period of time. Further, over 70 percent of people over age 65, our most vulnerable group, have received at least one vaccine dose. In addition to increasing the number of mass vaccination sites across the country with FEMA, expanding the Federal Retail Pharmacy Program, and ensuring that all Americans have a vaccine site within five miles of their home, we are also activating mobile vaccination units and clinics. CDC is also excited to partner with the Administration for Community Living to support their efforts to get older, at-risk adults and those with disabilities vaccinated.
- **Guidance for Adult Day Service Centers:** CDC updated COVID-19 guidance for adult day service centers. These populations are at high risk for severe COVID-19 disease, and this guidance will help center administrators and staff protect themselves and adults receiving their services by promoting and engaging in preventive behaviors that reduce COVID-19 spread and help maintain healthy operations and environments of these facilities.
- **B.1.1.7 Variant:** We now have B.1.1.7 (U.K. variant) as 26 percent of the circulating variant across the United states, and it is the predominant strain in at least five regions of the United States. The variant is more transmissible – somewhere between 50 and 70 percent more transmissible than the wild-type strain. Therefore, to the extent that people are not practicing those standard mitigation strategies, we do think that more infections will result because of B.1.1.7. We believe that the current mitigation strategies of masking and distancing would work just as well against the current, the wild-type strain, as they do the B.1.1.7 strain.

Dr. Fauci:

- **Importance of Getting Vaccinated:** We are seeing now immune protection against COVID-19 variants when individuals are vaccinated against the wild-type strain, namely the common virus in society, on two mechanisms: the antibody response that has a spillover effect and the cross-reactivity. Vaccination is not only going to protect us against the common COVID-19 virus in society, but it has the potential, to a greater or lesser degree, to also protect against a range of variants. So, when vaccination becomes available, get vaccinated.

Vaccine Updates

Federal Retail Pharmacy Program: CDC updated their general information on the Federal Retail Pharmacy Program for COVID-19 Vaccination. As the program expands and supply becomes more readily available, the allocation may be adjusted to reflect partner size (number of store locations nationwide), reach (percent of the total US population living within 5 miles of a store location), and ability to vaccinate (throughput). The program, which will scale up to eventually include COVID-19 vaccination at all 40,000+ retail locations, will make it easier for individuals to access free COVID-19 vaccine at a pharmacy in their community, and improve vaccine uptake while decreasing the logistical and operations burden on state, local, and territorial health departments.

Johnson & Johnson Janssen Vaccine: CDC updated their general information on the Johnson & Johnson Vaccine. The J&J/Janssen vaccine is recommended for people aged 18 years and older. Learn more about how CDC is making COVID-19 vaccine recommendations and CDC's vaccine rollout recommendations.

FEMA Vaccination Sites: FEMA announced that it will open a COVID-19 vaccination site in Greenbelt, Maryland on April 7th. The center's capacity is expected to be up to 3,000 shots per day. President Biden also committed to opening sites in Memphis, TN and Milwaukee, WI. These sites join many new FEMA vaccination sites recently announced, including in Boston, Massachusetts; Essex, New Jersey; Norfolk, Virginia; and Yakima, Washington, all of which open today. In the next week, federal communication vaccination center pilot sites in Gary, Indiana and St. Louis, Missouri are scheduled to open, as well. The agency has provided more than $4.47 billion for expenses related to COVID-19 vaccination at 100% federal cost share.

Peace Corps Assistance in COVID-19 Response: FEMA and the Peace Corps announced a historic partnership to combat the COVID-19

pandemic, marking only the second time in the Peace Corp's history where volunteers will serve a domestic deployment. The Peace Corps will soon begin recruiting for the special domestic deployment through Peace Corps Response, a program that sends in individuals with specialized experienced to short-term service assignment of up to 12 months. Assignments will focus on urgent needs as identified by FEMA and on communities that have been traditionally under-served.

Evaluating Moderna COVID-19 Variant Vaccine: An investigational vaccine designed to protect against the B.1.351 SARS-CoV-2 variant has been administered as part of a new Phase 1 clinical trial evaluating the vaccine candidate's safety and immunogenicity in adult volunteers. The vaccine, known as mRNA-1273.351, was developed by the biotechnology company ModernaTX, Inc., based in Cambridge, Massachusetts. The trial is led and funded by the National Institute of Allergy and Infectious Diseases (NIAID), part of the National Institutes of Health. The trial will enroll approximately 210 healthy adult volunteers at four clinical research sites in the United States that are part of the NIAID-funded Infectious Diseases Clinical Research Consortium (IDCRC).

HHS Podcast: HHS's new podcast, *COVID-19 Immunity in Our Community*, features top medical experts to answer questions on COVID-19 vaccines. Today's episode, "Building Vaccine Trust Within the Black Community," discusses how we can start to rebuild the Black community's trust in the vaccines, in order to achieve herd immunity and, hopefully, regain some sense of normalcy in our everyday lives.

Testing and Treatment

Covid-19 Precautions: CDC updated their COVID-19 page, reiterating that it is critical to keep taking precautions to prevent COVID-19. Learn more about how to protect yourself and others from CDC's recommendations.

COVID-19 Self Testing: CDC and NIH launched an innovative community health initiative called "Say Yes! COVID Test" starting in two locales, Pitt County, North Carolina, and coming soon to Chattanooga/Hamilton County, Tennessee. As many as 160,000 residents across the two communities will have access to free, rapid antigen tests that they can administer themselves to use three times a week for one month. NIH will provide the tests (also called a home-test or at-home test) and evaluate the effectiveness of the initiative, which aims to determine if frequent self-administered COVID-19 testing helps residents reduce community transmission of SARS-CoV-2, the virus that causes COVID-19 disease.

$147 Million to Expand Production of Swabs: DOD and HHS awarded $146.7 million to Puritan Medical Products on March 26 for renovations in the company's Orlinda, Tenn. facility to increase production capacity of foam tip swabs used in COVID-19 diagnostic tests. Funded through HCEA, the award will help the company boost total production capacity of the swabs to 250 million per month by February 2022.

Monoclonal Antibody Treatments: 3 EUAs for monoclonal antibody (mAb) treatments for mild-to-moderate COVID-19 in at-risk patients: bamlanivimab, casirivimab/imdevimab, and bamlanivimab/etesevimab. Learn more about FDA-authorized monoclonal treatments that can help at-risk patients fight the disease.

HHS Innovative Challenge for Masks: The U.S. Department of Health and Human Services launches $500,000 innovation challenge competition today encouraging American inventors to aid the nation's COVID-19 response by designing effective, comfortable face masks for personal use that resolve the common complaints people have about wearing masks. The contest taps into the nation's creativity and entrepreneurial spirit to help curb the spread of SARS-CoV-2, the virus that causes COVID-19.

Information for Specific Populations

Healthcare Workers: CDC updated their guidance for managing patients with COVID-19, including clinical guidance, home and hospital care, care for special populations, disease severity, and more.

Guidance for Adult Day Services Centers: CDC released guidance for administrators and staff to prevent the spread of COVID-19. Adult Day Services Centers (ADSCs) provide social or health services to community-dwelling adults aged 65 and over and adults of any age living with disability. Older adults and persons with disabilities are at highest risk for severe illness from COVID-19 including hospitalization, intensive care, and death. ADSC administrators and staff can help protect themselves and program participants (that is, adults attending ADSCs) from COVID-19 by promoting and engaging in preventive behaviors that reduce spread and maintain healthy operations and environments at ADSC facilities. This guidance is meant to supplement — not replace — any Federal, state, tribal, local, or territorial public health and safety laws, rules, and regulations with which adult day services center programs must comply. CDC has also developed recommendations for participants at ADSCs and their caregivers.

Suggestions for Youth and Summer Camps: CDC offers suggestions for ways in which camp administrators can help protect campers, staff, and communication, and prevent the spread of COVID-19. Camp administrators can determine, in collaboration with state and local health officials, whether and how to implement these considerations, making adjustments to meet the unique needs and circumstances of the local community. Implementation should be guided by what is feasible, practical, acceptable, and tailored to the needs of each community. These suggestions are meant to supplement— not replace —any state, local, territorial, or tribal health and safety laws, rules, and regulations with which camps must comply.

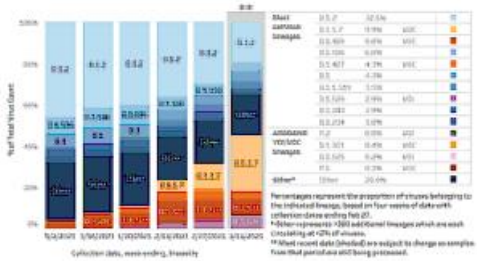
Essential Services for Malaria: CDC updated their key considerations for continuing essential malaria prevention and control activities safely and effectively. These considerations should supplement country Ministry of Health guidance.

CMS Updates

Medicare Fee-for-Service Billing: CMS updated their COVID-19 Frequently Asked Questions on Medicare Fee-for-Service (FFS) Billing. The policies set out in this FAQ are effective for the duration of the public health emergency unless superseded by future legislation. The FAQs in this document supplement the previously released FAQs, 1135 Waiver FAQs.

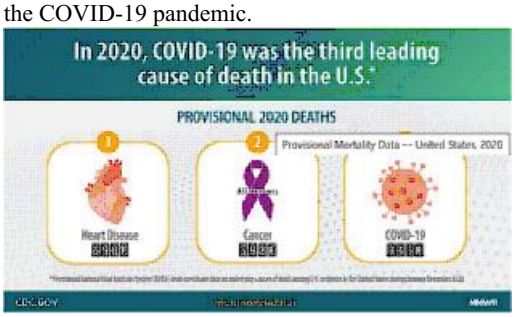
Research

Variant Proportions in the U.S: CDC's national genomic surveillance program identifies new and emerging SARS-CoV-2 variants to determine implications for COVID-19 diagnostics, treatments, or vaccines authorized for use in the United States. Monitoring the spread of emerging variants in the United States relies on widespread, rapid sequencing. To accelerate sequencing in the United States, CDC has contracted with commercial diagnostic laboratories, and, in partnership with the Association of Public Health Laboratories (APHL), has implemented the National SARS-CoV-2 Strain Surveillance (NS3) program to provide a comprehensive and population-based US surveillance system. This data, along with data from many other sources, are used to inform national and state public health actions related to variants.



COVID-19 2020 Mortality Surveillance: The Morbidity and Mortality Weekly Report (*MMWR*) on death certificate-based ICD-10 diagnosis codes for COVID-19 mortality surveillance addresses that among the 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record.

Provisional 2020 Mortality Data: The Morbidity and Mortality Weekly Report (*MMWR*) on provisional mortality data in the United States in 2020 addresses that the age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics. Provisional death estimates provide an early indication of shifts in mortality trends. Timely and actionable data can guide public health policies and interventions for populations experiencing higher numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic.



Case Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 cases will remain stable or have an uncertain trend over the next 4 weeks, with 223,000 to 723,000 new cases likely reported in the week ending April 24, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of new reported cases per week will likely decrease in 4 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported cases are uncertain or predicted to remain stable in the other states and territories. View previous case forecasts.

Hospitalization Forecasts: This week's national ensemble predicts that the number of new daily confirmed COVID-19 hospital admissions will remain stable or have an uncertain trend over the next 4 weeks, with 2,300 to 8,700 new confirmed COVID-19 hospital admissions likely reported on April 26, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of daily confirmed COVID-19 hospital admissions will likely increase in 6 jurisdictions and decrease in 12 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported hospital admissions are uncertain or predicted to remain stable in the other states and territories. View previous hospitalization forecasts.

Death Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 deaths will remain stable or have an uncertain trend over the next 4 weeks, with 3,100 to 10,200 new deaths likely reported in the week ending April 24, 2021. The national ensemble predicts that a total of 565,000 to 585,000 COVID-19 deaths will be reported by this date. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of newly reported deaths per week will likely decrease in 8 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported deaths are uncertain or predicted to remain stable in the other states and territories. View previous death forecasts.

Death Certificate–Based ICD-10 Diagnosis Codes for COVID-19 Mortality Surveillance — United States, January–December 2020

Adi V. Gundlapalli, MD, PhD[1]; Amy M. Lavery, PhD[1]; Tegan K. Boehmer, PhD[1]; Michael J. Beach, PhD[1]; Henry T. Walke, MD[1]; Paul D. Sutton, PhD[2]; Robert N. Anderson, PhD[2]

Approximately 375,000 deaths during 2020 were attributed to COVID-19 on death certificates reported to CDC (*1*). Concerns have been raised that some deaths are being improperly attributed to COVID-19 (*2*). Analysis of *International Classification of Diseases, Tenth Revision* (ICD-10) diagnoses on official death certificates might provide an expedient and efficient method to demonstrate whether reported COVID-19 deaths are being overestimated. CDC assessed documentation of diagnoses co-occurring with an ICD-10 code for COVID-19 (U07.1) on U.S. death certificates from 2020 that had been reported to CDC as of February 22, 2021. Among 378,048 death certificates listing U07.1, a total of 357,133 (94.5%) had at least one other ICD-10 code; 20,915 (5.5%) had only U07.1. Overall, 97.3% of 357,133 death certificates with at least one other diagnosis (91.9% of all 378,048 death certificates) were noted to have a co-occurring diagnosis that was a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), a significant contributing condition (e.g., hypertension or diabetes), or both. Overall, 70%–80% of death certificates had both a chain-of-event condition and a significant contributing condition or a chain-of-event condition only; this was noted for adults aged 18–84 years, both males and females, persons of all races and ethnicities, those who died in inpatient and outpatient or emergency department settings, and those whose manner of death was listed as natural. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of co-occurring diagnoses on the death certificate is essential for a comprehensive and authoritative public record. Continued messaging and training (*3*) for professionals who complete death certificates remains important as the pandemic progresses. Accurate mortality surveillance is critical for understanding the impact of variants of SARS-CoV-2, the virus that causes COVID-19, and of COVID-19 vaccination and for guiding public health action.

Death certificates were processed using standard CDC protocols to convert all written text and diagnoses to ICD-10 codes (*4*). Individual data elements were extracted for analysis from death certificates that had the ICD-10 code for COVID-19 (U07.1) listed in Part I (the section for reporting chain of events leading directly to death, the immediate cause of death, and the underlying cause of death) or Part II (the section for reporting all other significant conditions that contributed to death) of the death certificate for deaths that occurred during the calendar year 2020 (Supplementary Figure, https://stacks.cdc.gov/view/cdc/104571) (*3*) and had been reported to CDC by February 22, 2021. First, the location of ICD-10 diagnoses in relation to the COVID-19 diagnosis was used to categorize the co-occurring diagnoses as being in the chain of events that directly caused the death (chain-of-event conditions) or a significant condition contributing to death (significant contributing conditions). Any co-occurring ICD-10 code that appeared on the same line or above U07.1 in Part I was considered to be a chain-of-event condition. Any ICD-10 code that appeared on a line below U07.1 in Part I or in Part II was considered to be a contributing condition. Second, the highest-frequency ICD-10 codes noted in ≥1% of all death certificates with COVID-19 listed in Part I and at least one diagnosis other than COVID-19 were reviewed for consistency and plausibility with conditions known to be associated with severe outcomes in patients with COVID-19 (*5*–*8*). Conditions consistent with those known to be associated with severe COVID-19 outcomes were coded as chain-of-event or significant contributing conditions regardless of their location on the death certificate. For example, a death certificate with an ICD-10 code for respiratory failure listed below U07.1 would be coded as a chain-of-event condition

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-001635

because respiratory failure caused by COVID-19 led directly to the death. Third, less frequently appearing ICD-10 codes that were determined to be consistent with those associated with severe COVID-19 outcomes were also coded as chain-of-event or significant contributing conditions. Finally, death certificates were categorized into five mutually exclusive categories according to the ICD-10 codes recorded on the death certificate 1) only the ICD-10 code for COVID-19; 2) at least one other co-occurring ICD-10 code for a chain-of-event condition; 3) at least one other co-occurring ICD-10 code for a significant contributing condition; 4) an ICD-10 code for both a chain-of-event and significant contributing condition; or 5) an ICD-10 code that could not be categorized as a plausible chain-of-event or significant contributing condition based on current knowledge. Results were stratified by age, sex, race/ethnicity, and setting of death reported on the death certificate. All analyses were conducted using SAS (version 9.4; SAS Institute) and Stata (version 15.0; StataCorp).

Among 378,048 death certificates with the ICD-10 code U07.1, 94.5% (357,133) had at least one other ICD-10 code, whereas 5.5% (20,915) listed only U07.1 (Table 1); 330,198 (87%) listed COVID-19 in Part I. Death certificates with only U07.1 and no other diagnosis accounted for 2.9%–6.6% of death certificates for decedents across all age, sex, and racial/ethnic categories (Table 1). Having only COVID-19 listed on the death certificate was slightly more frequent for death certificates that listed "dead on arrival" (34; 10%) or "decedent's home" (2,006; 8.6%) as the place of death or "pending" (seven; 13.5%) as the manner of death.

Overall, 97.3% of 357,133 death certificates with at least one other diagnosis (91.9% of all 378,048 death certificates) were noted to have a co-occurring diagnosis that was a plausible chain-of-event condition (e.g., pneumonia, respiratory failure, adult respiratory distress syndrome, cardiac arrest, or sepsis), or significant contributing condition (e.g., hypertension, diabetes, dementia, or chronic obstructive pulmonary disease) (*5*), or both. The most frequent chain-of-event ICD-10 diagnosis codes on 330,198 death certificates that listed COVID-19 on Part I of the death certificate were J18.9 (pneumonia) (45%) and J96.0 (acute respiratory failure) (20%) (Table 2); the most frequent significant contributing condition ICD-10 codes were I10 (essential hypertension) (18%) and E14.9 (diabetes mellitus) (10%). Nearly 75% of all death certificates had a chain-of-event condition, alone or in combination with a significant contributing condition; this finding was noted for adults aged 18–84 years, males and females, persons of all races and ethnicities, those who died in inpatient and outpatient or emergency department settings, and those whose manner of death was listed as natural (Table 1).

Nearly 18% of death certificates had a co-occurring significant contributing condition only (Table 1). This finding was more frequent for death certificates indicating that the death occurred in the decedent's home (38.3%), a nursing home or long-term care facility (38.5%), or hospice facility (23.2%). A small proportion (9,638; 2.5%) of death certificates had co-occurring diagnosis codes that could not be plausibly categorized as either a chain-of-event or significant contributing condition. This finding was more frequent among decedents aged <18 years (64; 35.2%) and 18–29 years (145; 10.2%); these age groups represented only 0.4% (1,608) of all death certificates. This was recorded more frequently among decedents who died at home (1,259; 5.4%), were declared "dead on arrival" (15; 4.4%), or whose manner of death was self-inflicted (39; 63.9%), homicide (13; 43.8%), "could not determine" (18; 26.5%), or accidental (417; 20.0%).

Deaths reported from inpatient settings accounted for 240,770 (64%) of all death certificates; 86% of these had co-occurring diagnoses identified as chain-of-event and significant contributing conditions (104,250; 43%) or chain-of-event conditions only (103,475; 43%). A higher proportion of deaths reported from nursing homes or long-term care facilities (22% of all death certificates) listed contributing conditions only (39%) on the death certificate. Contributing conditions were also noted in a larger proportion of death certificates listing the decedent's home as the location of death (38%); these death certificates were less likely to have co-occurring chain-of-event diagnoses listed on the death certificate.

Discussion

Among death certificates from calendar year 2020 listing COVID-19 and at least one other co-occurring diagnosis, the documentation is consistent with these deaths being attributable to COVID-19. Specifically, in 97% of 357,133 death certificates with COVID-19 and at least one other diagnosis, the documented chain-of-event and significant contributing conditions were consistent with those reported in clinical and epidemiologic studies to occur among patients with severe COVID-19–associated outcomes (*5*,*9*). Only 5.5% of death certificates had COVID-19 without any other conditions listed. Attributability of death to COVID-19 could not be evaluated for these death certificates and represents an opportunity for improvement in documentation.

A small proportion (2.5%) of death certificates documented conditions that have not currently been described to be associated with COVID-19 critical illness or death. This was noted more often among those who died at home, declared dead on arrival, and whose manner of death was not natural. In particular, a higher percentage of decedents aged <18 years (35.2%) and 18–29 years (10.2%) did not have a chain-of-event or

MS-DOH-21-1816-A-001636

TABLE 1. Distribution of death certificates with COVID-19 diagnosis* across five mutually exclusive categories defined by presence and classification of co-occurring diagnoses, by demographic characteristics, setting of death, and manner of death characteristics — National Center for Health Statistics, United States, January–December 2020

Characteristic	No. of death certificates	No. (row %)				
		COVID-19 only	COVID-19 and ≥1 chain-of-event condition only	COVID-19 and ≥1 significant contributing condition only	COVID-19 and ≥1 chain-of-event and ≥1 significant contributing condition	COVID-19 with no plausible chain-of-event or significant contributing condition
Total	**378,048**	**20,915 (5.5)**	**128,603 (34.0)**	**67,184 (17.8)**	**151,708 (40.1)**	**9,638 (2.5)**

significant contributing condition listed on the death certificate, even though their death certificates did have at least one other diagnosis code along with COVID-19 in Part I or II. Although these age categories constituted a very small proportion of the entire decedent group, the information on the death certificate provides a starting point for identification of other conditions that might contribute to mortality in younger persons. Detailed evaluation of death certificates might provide insights into rare and lesser known conditions that are not yet understood to be associated with or contribute to death from COVID-19.

The findings in this report are subject to at least two limitations. First, the accuracy of documentation of chain-of-event and significant contributing conditions on death certificates is known to be suboptimal (*10*); the effect of COVID-19 on

MS-DOH-21-1816-A-001637

TABLE 2. Highest-frequency *International Classification of Diseases, Tenth Revision* (ICD-10) codes listed in death certificates with COVID-19 in Part I of death certificate and at least one diagnosis other than COVID-19 (330,198) — National Center for Health Statistics, United States, January–December 2020

Multiple sclerosis (G35)	124 (0.0)

* A total of 330,198 death certificates had COVID-19 listed in Part I of death certificate and at least one other diagnosis listed on the death certificate.
† COVID-19 diagnosis listed in Part I of the death certificate; chain-of-event conditions listed on the same line or above the COVID-19 diagnosis in Part I of the death certificate.
§ COVID-19 diagnosis listed in Part I of the death certificate; significant contributing conditions listed below the COVID-19 line in Part I or in Part II of the death certificate.
¶ COVID-19 diagnosis listed in Part I of the death certificate; co-occurring conditions listed anywhere on the death certificate and not identified as known chain-of-event or significant contributing conditions.

completion of death certificates merits further study, with an emphasis on variation by time, jurisdiction in which the death occurred, age group, race, ethnicity, and setting of death. Second, CDC was unable to compare death certificate data with decedent's medical records or autopsy reports for end-of-life events and co-occurring diagnoses. Medical record review is needed to confirm findings from this study and elucidate more information for decedents with only COVID-19 listed on their death certificate or those that could not be plausibly categorized as attributable to COVID-19 based on death certificate data alone.

These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of co-occurring diagnoses on the death certificate is essential for a comprehensive and authoritative public record. Continued messaging to and training of professionals who complete death certificates (*3*) remains important as the pandemic progresses. Accurate mortality surveillance is critical for understanding the impact of SARS-CoV-2 variants and of COVID-19 vaccinations and for guiding public health action.

MS-DOH-21-1816-A-001638

Summary

What is already known about this topic?

During 2020, approximately 375,000 U.S. deaths were attributed to COVID-19.

What is added by this report?

Among 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both.

What are the implications for public health practice?

These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record.

Death Certificate–Based ICD-10 Diagnosis Codes for COVID-19 Mortality Surveillance — United States, January–December 2020

Adi V. Gundlapalli, MD, PhD[1]; Amy M. Lavery, PhD[1]; Tegan K. Boehmer, PhD[1]; Michael J. Beach, PhD[1]; Henry T. Walke, MD[1]; Paul D. Sutton, PhD[2]; Robert N. Anderson, PhD[2]

Approximately 375,000 deaths during 2020 were attributed to COVID-19 on death certificates reported to CDC (*1*). Concerns have been raised that some deaths are being improperly attributed to COVID-19 (*2*). Analysis of *International Classification of Diseases, Tenth Revision* (ICD-10) diagnoses on official death certificates might provide an expedient and efficient method to demonstrate whether reported COVID-19 deaths are being overestimated. CDC assessed documentation of diagnoses co-occurring with an ICD-10 code for COVID-19 (U07.1) on U.S. death certificates from 2020 that had been reported to CDC as of February 22, 2021. Among 378,048 death certificates listing U07.1, a total of 357,133 (94.5%) had at least one other ICD-10 code; 20,915 (5.5%) had only U07.1. Overall, 97.3% of 357,133 death certificates with at least one other diagnosis (91.9% of all 378,048 death certificates) were noted to have a co-occurring diagnosis that was a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), a significant contributing condition (e.g., hypertension or diabetes), or both. Overall, 70%–80% of death certificates had both a chain-of-event condition and a significant contributing condition or a chain-of-event condition only; this was noted for adults aged 18–84 years, both males and females, persons of all races and ethnicities, those who died in inpatient and outpatient or emergency department settings, and those whose manner of death was listed as natural. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of co-occurring diagnoses on the death certificate is essential for a comprehensive and authoritative public record. Continued messaging and training (*3*) for professionals who complete death certificates remains important as the pandemic progresses. Accurate mortality surveillance is critical for understanding the impact of variants of SARS-CoV-2, the virus that causes COVID-19, and of COVID-19 vaccination and for guiding public health action.

Death certificates were processed using standard CDC protocols to convert all written text and diagnoses to ICD-10 codes (*4*). Individual data elements were extracted for analysis from death certificates that had the ICD-10 code for COVID-19 (U07.1) listed in Part I (the section for reporting chain of events leading directly to death, the immediate cause of death, and the underlying cause of death) or Part II (the section for reporting all other significant conditions that contributed to death) of the death certificate for deaths that occurred during the calendar year 2020 (Supplementary Figure, https://stacks.cdc.gov/view/cdc/104571) (*3*) and had been reported to CDC by February 22, 2021. First, the location of ICD-10 diagnoses in relation to the COVID-19 diagnosis was used to categorize the co-occurring diagnoses as being in the chain of events that directly caused the death (chain-of-event conditions) or a significant condition contributing to death (significant contributing conditions). Any co-occurring ICD-10 code that appeared on the same line or above U07.1 in Part I was considered to be a chain-of-event condition. Any ICD-10 code that appeared on a line below U07.1 in Part I or in Part II was considered to be a contributing condition. Second, the highest-frequency ICD-10 codes noted in ≥1% of all death certificates with COVID-19 listed in Part I and at least one diagnosis other than COVID-19 were reviewed for consistency and plausibility with conditions known to be associated with severe outcomes in patients with COVID-19 (*5*–*8*). Conditions consistent with those known to be associated with severe COVID-19 outcomes were coded as chain-of-event or significant contributing conditions regardless of their location on the death certificate. For example, a death certificate with an ICD-10 code for respiratory failure listed below U07.1 would be coded as a chain-of-event condition

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-001640

because respiratory failure caused by COVID-19 led directly to the death. Third, less frequently appearing ICD-10 codes that were determined to be consistent with those associated with severe COVID-19 outcomes were also coded as chain-of-event or significant contributing conditions. Finally, death certificates were categorized into five mutually exclusive categories according to the ICD-10 codes recorded on the death certificate 1) only the ICD-10 code for COVID-19; 2) at least one other co-occurring ICD-10 code for a chain-of-event condition; 3) at least one other co-occurring ICD-10 code for a significant contributing condition; 4) an ICD-10 code for both a chain-of-event and significant contributing condition; or 5) an ICD-10 code that could not be categorized as a plausible chain-of-event or significant contributing condition based on current knowledge. Results were stratified by age, sex, race/ethnicity, and setting of death reported on the death certificate. All analyses were conducted using SAS (version 9.4; SAS Institute) and Stata (version 15.0; StataCorp).

Among 378,048 death certificates with the ICD-10 code U07.1, 94.5% (357,133) had at least one other ICD-10 code, whereas 5.5% (20,915) listed only U07.1 (Table 1); 330,198 (87%) listed COVID-19 in Part I. Death certificates with only U07.1 and no other diagnosis accounted for 2.9%–6.6% of death certificates for decedents across all age, sex, and racial/ethnic categories (Table 1). Having only COVID-19 listed on the death certificate was slightly more frequent for death certificates that listed "dead on arrival" (34; 10%) or "decedent's home" (2,006; 8.6%) as the place of death or "pending" (seven; 13.5%) as the manner of death.

Overall, 97.3% of 357,133 death certificates with at least one other diagnosis (91.9% of all 378,048 death certificates) were noted to have a co-occurring diagnosis that was a plausible chain-of-event condition (e.g., pneumonia, respiratory failure, adult respiratory distress syndrome, cardiac arrest, or sepsis), or significant contributing condition (e.g., hypertension, diabetes, dementia, or chronic obstructive pulmonary disease) (*5*), or both. The most frequent chain-of-event ICD-10 diagnosis codes on 330,198 death certificates that listed COVID-19 on Part I of the death certificate were J18.9 (pneumonia) (45%) and J96.0 (acute respiratory failure) (20%) (Table 2); the most frequent significant contributing condition ICD-10 codes were I10 (essential hypertension) (18%) and E14.9 (diabetes mellitus) (10%). Nearly 75% of all death certificates had a chain-of-event condition, alone or in combination with a significant contributing condition; this finding was noted for adults aged 18–84 years, males and females, persons of all races and ethnicities, those who died in inpatient and outpatient or emergency department settings, and those whose manner of death was listed as natural (Table 1).

Nearly 18% of death certificates had a co-occurring significant contributing condition only (Table 1). This finding was more frequent for death certificates indicating that the death occurred in the decedent's home (38.3%), a nursing home or long-term care facility (38.5%), or hospice facility (23.2%). A small proportion (9,638; 2.5%) of death certificates had co-occurring diagnosis codes that could not be plausibly categorized as either a chain-of-event or significant contributing condition. This finding was more frequent among decedents aged <18 years (64; 35.2%) and 18–29 years (145; 10.2%); these age groups represented only 0.4% (1,608) of all death certificates. This was recorded more frequently among decedents who died at home (1,259; 5.4%), were declared "dead on arrival" (15; 4.4%), or whose manner of death was self-inflicted (39; 63.9%), homicide (13; 43.8%), "could not determine" (18; 26.5%), or accidental (417; 20.0%).

Deaths reported from inpatient settings accounted for 240,770 (64%) of all death certificates; 86% of these had co-occurring diagnoses identified as chain-of-event and significant contributing conditions (104,250; 43%) or chain-of-event conditions only (103,475; 43%). A higher proportion of deaths reported from nursing homes or long-term care facilities (22% of all death certificates) listed contributing conditions only (39%) on the death certificate. Contributing conditions were also noted in a larger proportion of death certificates listing the decedent's home as the location of death (38%); these death certificates were less likely to have co-occurring chain-of-event diagnoses listed on the death certificate.

Discussion

Among death certificates from calendar year 2020 listing COVID-19 and at least one other co-occurring diagnosis, the documentation is consistent with these deaths being attributable to COVID-19. Specifically, in 97% of 357,133 death certificates with COVID-19 and at least one other diagnosis, the documented chain-of-event and significant contributing conditions were consistent with those reported in clinical and epidemiologic studies to occur among patients with severe COVID-19–associated outcomes (*5*,*9*). Only 5.5% of death certificates had COVID-19 without any other conditions listed. Attributability of death to COVID-19 could not be evaluated for these death certificates and represents an opportunity for improvement in documentation.

A small proportion (2.5%) of death certificates documented conditions that have not currently been described to be associated with COVID-19 critical illness or death. This was noted more often among those who died at home, declared dead on arrival, and whose manner of death was not natural. In particular, a higher percentage of decedents aged <18 years (35.2%) and 18–29 years (10.2%) did not have a chain-of-event or

MS-DOH-21-1816-A-001641

TABLE 1. Distribution of death certificates with COVID-19 diagnosis* across five mutually exclusive categories defined by presence and classification of co-occurring diagnoses, by demographic characteristics, setting of death, and manner of death characteristics — National Center for Health Statistics, United States, January–December 2020

Characteristic	No. of death certificates	No. (row %)				
		COVID-19 only	COVID-19 and ≥1 chain-of-event condition only	COVID-19 and ≥1 significant contributing condition only	COVID-19 and ≥1 chain-of-event and ≥1 significant contributing condition	COVID-19 with no plausible chain-of-event or significant contributing condition
Total	**378,048**	**20,915 (5.5)**	**128,603 (34.0)**	**67,184 (17.8)**	**151,708 (40.1)**	**9,638 (2.5)**
Age group, yrs						
<18	182	8 (4.4)	70 (38.5)	18 (9.9)	22 (12.1)	64 (35.2)
18–29	1,426	77 (5.4)	636 (44.6)	167 (11.7)	401 (28.1)	145 (10.2)
30–39	4,161	275 (6.6)	1,712 (41.1)	550 (13.2)	1,371 (32.9)	253 (6.1)
40–49	11,053	660 (6.0)	4,551 (41.2)	1,408 (12.7)	3,982 (36.0)	452 (4.1)
50–64	55,719	2,911 (5.2)	22,788 (40.9)	6,693 (12.0)	21,666 (38.9)	1,661 (3.0)

significant contributing condition listed on the death certificate, even though their death certificates did have at least one other diagnosis code along with COVID-19 in Part I or II. Although these age categories constituted a very small proportion of the entire decedent group, the information on the death certificate provides a starting point for identification of other conditions that might contribute to mortality in younger persons. Detailed evaluation of death certificates might provide insights into rare and lesser known conditions that are not yet understood to be associated with or contribute to death from COVID-19.

The findings in this report are subject to at least two limitations. First, the accuracy of documentation of chain-of-event and significant contributing conditions on death certificates is known to be suboptimal (*10*); the effect of COVID-19 on

MS-DOH-21-1816-A-001642

TABLE 2. Highest-frequency *International Classification of Diseases, Tenth Revision* (ICD-10) codes listed in death certificates with COVID-19 in Part I of death certificate and at least one diagnosis other than COVID-19 (330,198) — National Center for Health Statistics, United States, January–December 2020

Condition (ICD-10 code)	No. (% of 330,198*)
Conditions listed as chain-of-event conditions on ≥1% of death certificates†	
Pneumonia, unspecified (J18.9)	148,530 (45.0)
Acute respiratory failure (J96.0)	66,609 (20.2)
Respiratory failure, unspecified (J96.9)	47,045 (14.2)
Cardiac arrest, unspecified (I46.9)	36,983 (11.2)
Adult respiratory distress syndrome (J80)	36,297 (11.0)
Sepsis, unspecified (A41.9)	20,117 (6.1)
Viral pneumonia, unspecified (J12.9)	12,421 (3.8)
Asphyxia (R09.0)	10,641 (3.2)
Respiratory arrest (R09.2)	7,009 (2.1)
Conditions listed as significant contributing conditions on ≥1% of death certificates§	
Essential (primary) hypertension (I10)	58,930 (17.8)
Unspecified diabetes mellitus without complications (E14.9)	34,038 (10.3)
Unspecified dementia (F03)	32,189 (9.7)
Chronic obstructive pulmonary disease, unspecified (J44.9)	24,678 (7.5)
Atherosclerotic heart disease (I25.1)	22,162 (6.7)
Type 2 diabetes mellitus without complications (E11.9)	21,038 (6.4)
Atrial fibrillation and flutter (I48)	19,784 (6.0)
Congestive heart failure (I50.0)	16,841 (5.1)
Tobacco use (F17.9)	16,424 (5.0)
Chronic kidney disease, unspecified (N18.9)	14,525 (4.4)
Alzheimer disease, unspecified (G30.9)	11,220 (3.4)
Hypertensive heart disease without (congestive) heart failure (I11.9)	9,881 (3.0)
Hyperlipidemia, unspecified (E78.5)	9,330 (2.8)
Other specified disorders of kidney and ureter (N28.8)	8,958 (2.7)
Obesity, unspecified (E66.9)	8,913 (2.7)
Chronic kidney disease, stage 5 (N18.5)	7,955 (2.4)
Stroke, not specified as hemorrhage or infarction (I64)	6,494 (2.0)
Heart failure, unspecified (I50.9)	6,436 (1.9)
Conditions listed on ≥0.5% of death certificates and not identified as known chain-of-event conditions or significant contributing conditions¶	
Other specified general symptoms and signs (R68.8)	1,124 (0.3)
Other lack of normal physiologic development, underweight (R62.8)	734 (0.2)
Dyspnea (R06.0)	363 (0.1)
Senility (R54)	331 (0.1)
Other and unspecified infectious disease (B99.9)	247 (0.1)
Gastrointestinal hemorrhage (K92.2)	213 (0.1)
Unspecified protein energy deficiency (E46)	204 (0.1)
Influenza due to unidentified influenza virus (J11.1)	174 (0.1)
Urinary tract infection (N39.0)	150 (0.0)
Malaise and fatigue (R53)	145 (0.0)
Unspecified fall (W19)	139 (0.0)
Multiple sclerosis (G35)	124 (0.0)

* A total of 330,198 death certificates had COVID-19 listed in Part I of death certificate and at least one other diagnosis listed on the death certificate.
† COVID-19 diagnosis listed in Part I of the death certificate; chain-of-event conditions listed on the same line or above the COVID-19 diagnosis in Part I of the death certificate.
§ COVID-19 diagnosis listed in Part I of the death certificate; significant contributing conditions listed below the COVID-19 line in Part I or in Part II of the death certificate.
¶ COVID-19 diagnosis listed in Part I of the death certificate; co-occurring conditions listed anywhere on the death certificate and not identified as known chain-of-event or significant contributing conditions.

completion of death certificates merits further study, with an emphasis on variation by time, jurisdiction in which the death occurred, age group, race, ethnicity, and setting of death. Second, CDC was unable to compare death certificate data with decedent's medical records or autopsy reports for end-of-life events and co-occurring diagnoses. Medical record review is needed to confirm findings from this study and elucidate more information for decedents with only COVID-19 listed on their death certificate or those that could not be plausibly categorized as attributable to COVID-19 based on death certificate data alone.

These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of co-occurring diagnoses on the death certificate is essential for a comprehensive and authoritative public record. Continued messaging to and training of professionals who complete death certificates (*3*) remains important as the pandemic progresses. Accurate mortality surveillance is critical for understanding the impact of SARS-CoV-2 variants and of COVID-19 vaccinations and for guiding public health action.

MS-DOH-21-1816-A-001643

Summary

What is already known about this topic?

During 2020, approximately 375,000 U.S. deaths were attributed to COVID-19.

What is added by this report?

Among 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both.

What are the implications for public health practice?

These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record.

Provisional Mortality Data — United States, 2020

Farida B. Ahmad, MPH[1]; Jodi A. Cisewski, MPH[1]; Arialdi Miniño, MPH[1]; Robert N. Anderson, PhD[1]

CDC's National Vital Statistics System (NVSS) collects and reports annual mortality statistics using data from U.S. death certificates. Because of the time needed to investigate certain causes of death and to process and review data, final annual mortality data for a given year are typically released 11 months after the end of the calendar year. Daily totals reported by CDC COVID-19 case surveillance are timely but can underestimate numbers of deaths because of incomplete or delayed reporting. As a result of improvements in timeliness and the pressing need for updated, quality data during the global COVID-19 pandemic, NVSS expanded provisional data releases to produce near real-time U.S. mortality data.* This report presents an overview of provisional U.S. mortality data for 2020, including the first ranking of leading causes of death. In 2020, approximately 3,358,814 deaths† occurred in the United States. From 2019 to 2020, the estimated age-adjusted death rate increased by 15.9%, from 715.2 to 828.7 deaths per 100,000 population. COVID-19 was reported as the underlying cause of death or a contributing cause of death for an estimated 377,883 (11.3%) of those deaths (91.5 deaths per 100,000). The highest age-adjusted death rates by age, race/ethnicity, and sex occurred among adults aged ≥85 years, non-Hispanic Black or African American (Black) and non-Hispanic American Indian or Alaska Native (AI/AN) persons, and males. COVID-19 death rates were highest among adults aged ≥85 years, AI/AN and Hispanic persons, and males. COVID-19 was the third leading cause of death in 2020, after heart disease and cancer. Provisional death estimates provide an early indication of shifts in mortality trends and can guide public health policies and interventions aimed at reducing numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic.

CDC analyzed provisional NVSS death certificate data for deaths occurring among U.S. residents in the United States during January–December 2020. The numbers and rates of overall deaths and COVID-19 deaths were assessed by age, sex, and race/ethnicity (categorized as Hispanic, non-Hispanic White [White], Black, non-Hispanic Asian, non-Hispanic AI/AN, non-Hispanic Native Hawaiian or other Pacific Islander [NH/PI], non-Hispanic multiracial, and unknown). Causes of death were coded according to the *International Classification of Diseases, Tenth Revision* (ICD-10), which describes disease classification and the designation of underlying cause of death (*1*,*2*). Numbers and rates of COVID-19 deaths include deaths for which COVID-19 was listed on the death certificate as a confirmed or presumed underlying cause of death or contributing cause of death (ICD-10 code U07.1). COVID-19 was the underlying cause of approximately 91% (345,323) of COVID-19–associated deaths during 2020 (*3*). Leading underlying causes of death were calculated and ranked (*4*). Deaths that occurred in the United States among residents of U.S. territories and foreign countries were excluded.§ Age was unknown for 86 (<0.01%) decedents, and race/ethnicity was unknown for 9,135 (0.27%). There were no records with unknown sex. To describe the trend in deaths during 2020, the number of deaths from all causes and from COVID-19 were calculated for each week. Midyear U.S. Census Bureau population estimates (July 1, 2020) were used to calculate estimated death rates per 100,000 standard population (*5*). Age-adjusted death rates were calculated for deaths by sex and race/ethnicity, and crude death rates were calculated by age. Age-adjusted death rates for 2020 were also compared with those from 2019 (*6*).

In 2020, approximately 3,358,814 deaths occurred in the United States (Table). The age-adjusted rate was 828.7 deaths

* https://www.cdc.gov/nchs/nvss/deaths.htm

† Based on death records received and processed as of March 21, 2021, for deaths occurring in the United States among U.S. residents. Data included in this analysis include >99% of deaths that occurred in 2020.

§ At the time of analysis, 1.1% of total NVSS deaths and 0.6% of COVID-19 deaths that occurred in the United States were among residents of U.S. territories and foreign countries.

Hispanic	304,488 (724.1)	68,469 (164.3)
White, non-Hispanic	2,467,419 (827.1)	228,328 (72.5)
Black, non-Hispanic	443,116 (1,105.3)	59,871 (151.1)
Asian, non-Hispanic	90,519 (457.9)	13,334 (66.7)
American Indian or Alaska Native, non-Hispanic	24,279 (1,024.0)	4,504 (187.8)
Native Hawaiian or other Pacific Islander, non-Hispanic	4,424 (828.4)	679 (122.3)
Multiracial, non-Hispanic	15,434 (378.8)	1,125 (31.8)
Unknown	9,135 (—)	1,573 (—)

* National Vital Statistics System provisional data are incomplete. Data from December are less complete due to reporting lags. These data exclude deaths that occurred in the United States among residents of U.S. territories and foreign countries.

† Deaths per 100,000 standard population. Age-adjusted death rates are provided by sex and race/ethnicity.

§ Deaths with confirmed or presumed COVID-19 as an underlying or contributing cause of death, with *International Classification of Diseases, Tenth Revision* code U07.1.

per 100,000 population, an increase of 15.9% from 715.2 in 2019. The highest overall numbers of deaths occurred during the weeks ending April 11, 2020, (78,917) and December 26, 2020 (80,656) (Figure 1). Death rates were lowest among persons aged 5–14 years (13.6) and highest among persons aged ≥85 years (15,007.4); age-adjusted death rates were higher among males (990.5) than among females (689.2).

During 2020, COVID-19 was listed as the underlying or contributing cause of 377,883 deaths (91.5 per 100,000 population). COVID-19 death rates were lowest among children aged 1–4 years (0.2) and 5–14 years (0.2) and highest among those aged ≥85 years (1,797.8). Similar to the rate of overall deaths, the age-adjusted COVID-19–associated death rate among males (115.0) was higher than that among females (72.5).

Age-adjusted death rates differed by race/ethnicity. Overall age-adjusted death rates were lowest among Asian (457.9 per 100,000 population) and Hispanic persons (724.1) and highest among Black (1,105.3) and AI/AN persons (1,024.0). COVID-19–associated death rates were lowest among multiracial (31.8) and Asian persons (66.7) and highest among AI/AN (187.8) and Hispanic persons (164.3). COVID-19 was listed as the underlying cause of 345,323 deaths during 2020 and was the third leading underlying cause of death, after heart disease (690,882 deaths) and cancer (598,932) (Figure 2).

Summary

What is already known about this topic?

The COVID-19 pandemic caused approximately 375,000 deaths in the United States during 2020.

What is added by this report?

The age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics.

What are the implications for public health practice?

Provisional death estimates provide an early indication of shifts in mortality trends. Timely and actionable data can guide public health policies and interventions for populations experiencing higher numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic.

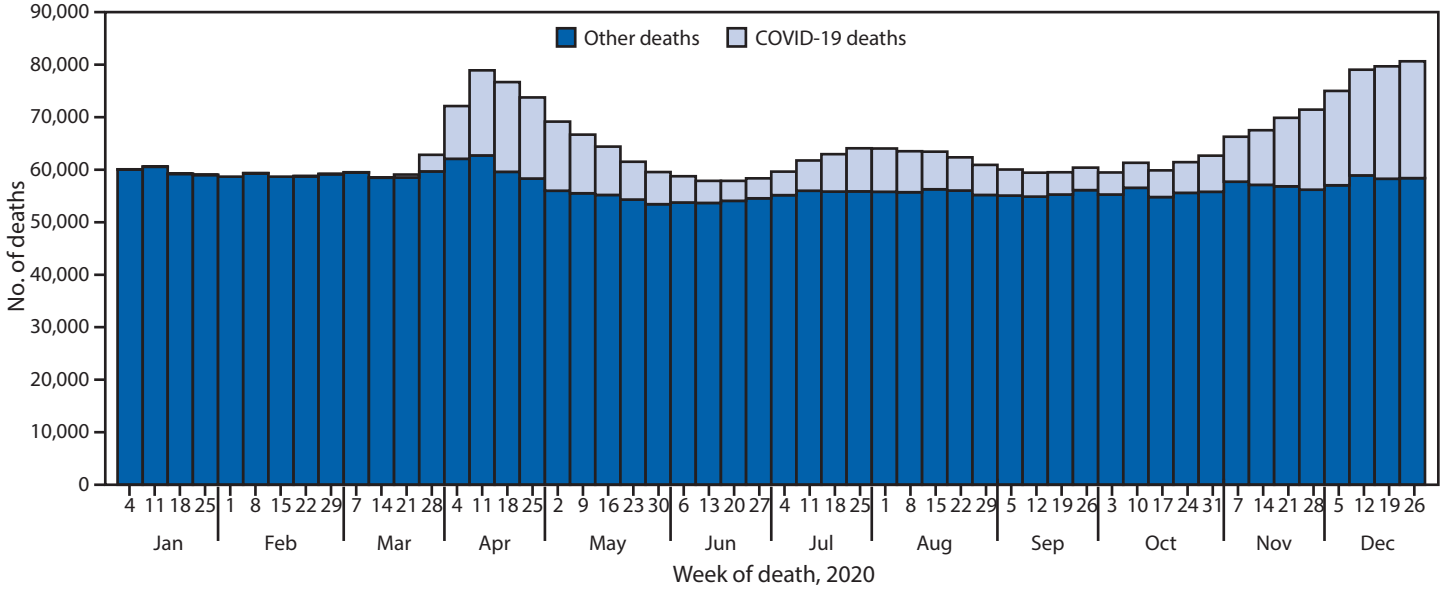
Discussion

During January–December 2020, the estimated 2020 age-adjusted death rate increased for the first time since 2017, with an increase of 15.9% compared with 2019, from 715.2 to 828.7 deaths per 100,000 population. COVID-19 was the underlying or a contributing cause of 377,883 deaths (91.5 deaths per 100,000). COVID-19 death rates were highest among males, older adults, and AI/AN and Hispanic persons. The highest numbers of overall deaths and COVID-19 deaths occurred during April and December. COVID-19 was the third leading underlying cause of death in 2020, replacing suicide as one of the top 10 leading causes of death (*6*).

The findings in this report are subject to at least four limitations. First, data are provisional, and numbers and rates might change as additional information is received. Second, timeliness of death certificate submission can vary by jurisdiction. As a result, the national distribution of deaths might be affected by the distribution of deaths from jurisdictions reporting later, which might differ from those in the United States overall. Third, certain categories of race (i.e., AI/AN and Asian) and Hispanic ethnicity reported on death certificates might have been misclassified (*7*), possibly resulting in underestimates of death rates for some groups. Finally, the cause of death for certain persons might have been misclassified. Limited availability of testing for SARS-CoV-2, the virus that causes COVID-19, at

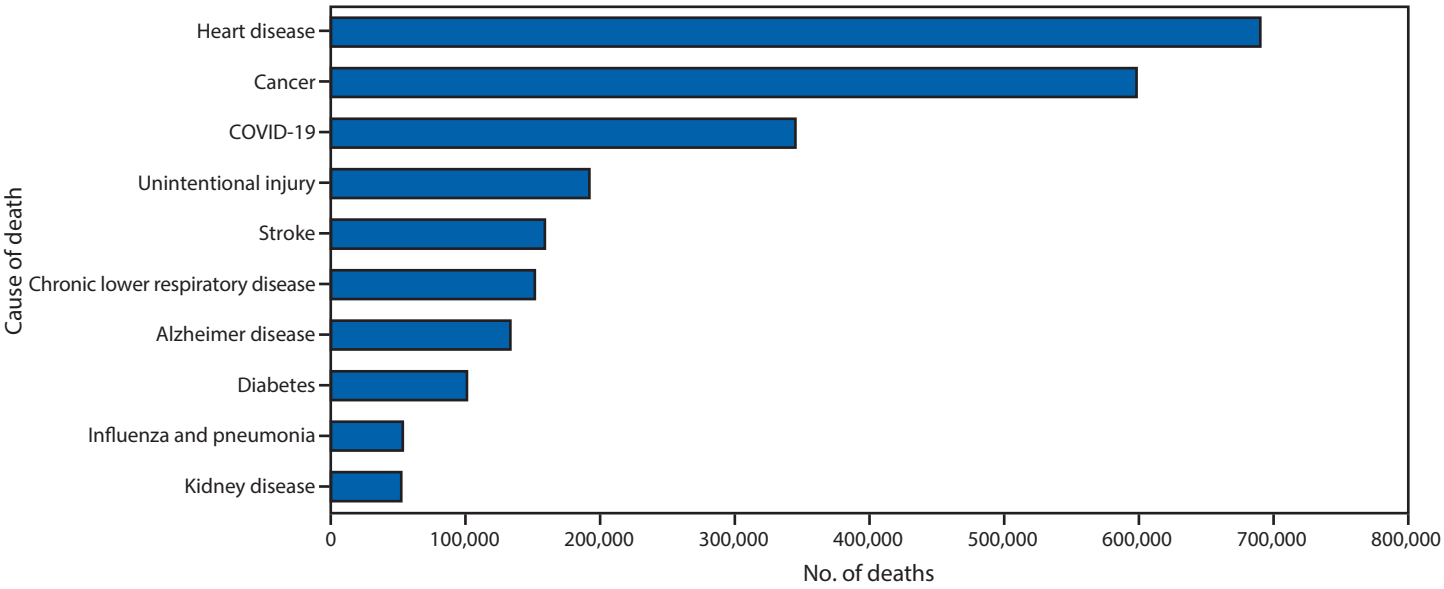
MS-DOH-21-1816-A-001646

FIGURE 1. Provisional* number of COVID-19–related deaths† and other deaths, by week — National Vital Statistics System, United States, 2020



* National Vital Statistics System provisional data are incomplete. Data from December are less complete due to reporting lags. Deaths that occurred in the United States among residents of U.S. territories and foreign countries were excluded.
† Deaths with confirmed or presumed COVID-19 as an underlying or contributing cause of death, with *International Classification of Diseases, Tenth Revision* code U07.1.

FIGURE 2. Provisional* number of leading underlying causes of death† — National Vital Statistics System, United States, 2020



* National Vital Statistics System provisional data are incomplete. Data from December are less complete due to reporting lags. Deaths that occurred in the United States among residents of U.S. territories and foreign countries were excluded.
† Deaths with confirmed or presumed COVID-19 as an underlying or contributing cause of death, with *International Classification of Diseases, Tenth Revision* code U07.1.

the beginning of the COVID-19 pandemic might have resulted in an underestimation of COVID-19–associated deaths.

This report provides an overview of provisional U.S. mortality data for 2020. Provisional death estimates can give researchers and policymakers an early indication of shifts in mortality trends and provide actionable information sooner than the final mortality data that are released approximately 11 months after the end of the data year. These data can guide public health policies and interventions aimed at reducing numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic and among persons most affected, including those who are older, male, or from disproportionately affected racial/ethnic minority groups.

PROTECTING AMERICA'S SAFETY, HEALTH, AND SECURITY

March 31, 2021

CDC Resources

- **Guidance for Adult Day Services Centers:** Updated guidance and strategies for administrators and staff to prevent the spread of COVID-19 in Adult Day Services has been recently released. Adult Day Services Centers (ADSCs) are professional care settings where community-dwelling adults receive social or health services for some part of the day. ADSCs often serve adults age 65 years or older who may require supervised care and adults (of any age) living with dementia, cognitive decline, or disability. ADSCs are designed to provide a safe, community-based group setting where specific needs are addressed and individualized therapeutic, social, or health services are delivered. These centers provide needed services to participants and also support caregiver employment and provide respite, which benefits the mental health of both participants and caregivers.
- **Vaccine resources:** Below are resources to help emerging issues of misinformation, disinformation, and provide information to places where intervention efforts can positively impact vaccine confidence across the U.S
    - COVID-19 Vaccine Community Features
    - Updated COVID-19 Vaccination for Communities
    - How to Talk about COVID-19 Vaccines with Friends and Family
    - COVID Data Tracker Weekly Review
    - Communications Resources for COVID-19
    - Vaccine Social Media Toolkit
    - Audience-specific COVID-19 Vaccination Toolkits
    - Frequently Asked Questions about COVID-19 Vaccination
    - Content Syndication
- **ELC Guidance for School Testing:** To enable schools to establish COVID-19 screening testing programs to support and maintain in-person learning, the federal government is providing financial resources to enable and expand school-based screening testing. Screening guidance should be implemented in ways consistent with CDC guidance; however, it is recognized that there may be practical or resource limitations in some school districts that make adherence to this guidance difficult at the start of this initiative.

MMWR Resources

- **Provisional Mortality Data — United States, 2020**: Provisional death estimates provide an early indication of shifts in mortality trends. Timely and actionable data guide public health policies and interventions for populations experiencing higher numbers pf deaths that are directly or indirectly associated with the COVID-19 pandemic.
- **Death Certificate–Based ICD-10 Diagnosis Codes for COVID-19 Mortality Surveillance — United States, January–December 2020:** Approximately 375,000 deaths during 2020 were attributed to COVID-19 on death certificates reported to CDC. Concerns have been raised that some deaths are being improperly attributed to COVID-19. Analysis of International Classification of Diseases, Tenth Revision diagnoses on official death certificates might provide an expedient and efficient method to demonstrate whether reported COVID-19 deaths are being overestimated.

Upcoming Meetings

- **CDC's COVID-19 Related Response Strategies:** Thursdays from 2:00-3:00 PM EDT. CDC's 2019 Novel Coronavirus (COVID-19) response team hosts a **Response Strategies call** series to provide state and local partners with once weekly national technical assistance calls to share science-based mitigation strategies, lessons learned, and state-to-state information sharing. **To be added to this weekly series, please email** eocevent424@cdc.gov.
- **FEMA Funeral Assistance Program:** With FEMA participation, The International Association of Coroners & Medical Examiners (IACME) will host a webinar to provide information on the Funeral Assistance program, including death certificate requirements for program eligibility on **Thursday, April 1, 2021, at 12 PM PST/3 PM EDT**. There will be a brief question and answer session. To register, click here.

Additional Resources

- **Federal Emergency Management Agency (FEMA) to Help Pay Funeral Costs for COVID-19-Related Deaths:** In early April, FEMA will begin providing financial assistance financial assistance for funeral expenses incurred after Jan. 20, 2020 for deaths related to coronavirus (COVID-19) to help ease some of the financial stress and burden caused by the pandemic. FEMA is now moving rapidly to implement this funeral assistance program nationwide.

Safe and Proper Sharps Disposal During the COVID-19 Mass Vaccination Campaign

Sharps are objects that can pierce the skin (for example, contaminated syringes and needles, lancets, scalpels, infusion needle sets, connection needles, auto injectors), as defined in the Occupational Safety and Health Administration (OSHA) Bloodborne Pathogens standard. This fact sheet reenforces how you can protect yourself from needlestick injuries while administering COVID-19 vaccines or while helping at vaccination sites.

Protect Yourself From a Needlestick Injury

- Place sharps disposal containers as close as possible to you or within arm's reach. When a wall mount is not possible, set the container on a table or a cart in an upright position (preferably secured). Do not place sharps disposal containers on the floor or the ground.
- Immediately after you use a sharp, engage any safety feature, and place it in a sharps disposal container that is closable, puncture-resistant, leakproof on the sides and bottom, and biohazard-labeled or color-coded.
- Do not remove, recap, break, or bend contaminated needles or separate contaminated needles from syringes before discarding them into a sharps disposal container as this increases the risk of a needlestick injury and a bloodborne pathogen exposure. Best practice is to immediately place the connected needle and syringe into the sharps disposal container.
- Use sharps containers to dispose of needles and other sharps contaminated with blood or other potentially infectious material.
- Close the container when it is filled to the clearly marked fill line or when it is ¾ full if it has no fill line.
- Do not overfill sharps disposal containers—even during supply shortages—as this increases the risk of a needlestick injury and a bloodborne pathogen exposure.

Sharps Disposal Containers are for Needles and Sharps Only

- Place only needles and sharps in sharps disposal containers.
- Do not put anything in sharps disposal containers that can be placed in regular waste containers (such as uncontaminated trash, gauze, alcohol pads, needle caps, and gloves).
- Place non-sharp, contaminated material, such as gauze contaminated with blood or other potentially infectious material, in a red biohazard waste disposal bag.
- Follow your local guidelines for proper disposal methods. Visit https://safeneedledisposal.org

If you experience a needlestick from a used or contaminated needle, seek immediate evaluation and treatment.

Call the PEP (post-exposure prophylaxis) hotline at 1–888–448–4911 immediately for guidance on treating exposures.

Strategies for Sharps Disposal Container Use During Supply Shortages

For Managers and Purchase Agents

A shortage in the supply of Food and Drug Administration (FDA)-cleared sharps disposal containers may occur during the COVID-19 mass vaccination campaign or as a result of other causes. Healthcare facilities and COVID-19 vaccination sites must use sharps disposal containers that meet Occupational Safety and Health Administration (OSHA) Bloodborne Pathogens standard requirements to dispose of contaminated needles and other sharps. Use FDA-cleared containers whenever possible.

Conserve your FDA-cleared sharps disposal containers to help avoid a potential supply shortage. If FDA-cleared sharps disposal containers are unavailable, then consider using alternative containers that meet the OSHA requirements after checking your state's specific disposal requirements at SafeNeedleDisposal.org and discussing disposal options with your medical waste vendors.

FIRST, conserve your FDA-cleared sharps disposal containers by doing the following:

- Place only sharps (as defined in OSHA's Bloodborne Pathogens standard, for example, contaminated syringes, needles, lancets, scalpels, infusion needle sets, connection needles, auto-injectors) in sharps disposal containers.
- Do not remove, recap, break, or bend contaminated needles or separate contaminated needles from syringes before discarding them into a sharps disposal container. Best practice is to immediately place the connected needle and syringe into the sharps disposal container.
- Place contaminated dressings, gauze, cotton materials, tubing, and contaminated cleanup items in biohazard waste disposal bags.
- Place uncontaminated non-sharps in a standard trash can. Always place sharps in sharps disposal containers, not in the trash.
- Consider using reusable FDA-cleared sharps disposal containers. These can be reused after being picked up, processed, and disinfected by a regulated medical waste removal service according to state and local regulations.
- Ensure containers are filled to the recommended capacity prior to removal, but do not overfill. Filling above the fill line or more than ¾ full of the alternative container can increase the risk of a needlestick injury and a bloodborne pathogen exposure.
- Follow the manufacturer's instructions for use.

SECOND, follow these procedures when FDA-cleared sharps disposal containers are scarce or unavailable:

NOTE: Once the availability of FDA-cleared sharps disposal containers returns to normal, healthcare facilities and COVID-19 vaccination sites should promptly resume usual practices.

- Consider avoiding timed sharps container disposal, where containers are removed at set intervals regardless of fill level. Removing and replacing sharps disposal containers based on set time intervals rather than when they are at the recommended capacity can waste valuable container space during a shortage.
- Ask your distributors about all types of FDA-cleared sharps disposal containers that are available. For example, using an FDA-cleared sharps disposal container that does not fit within the wall brackets at your facility is better than not having a sharps disposal container at all.
- Consider using alternative containers, after checking your state's specific disposal requirements at SafeNeedleDisposal.org and discussing disposal options with your medical waste vendors.
- Acceptable alternative containers must meet OSHA's Bloodborne Pathogens standard requirements:
  - » Made of heavy-duty, puncture-resistant plastic or metal
  - » Leakproof on the sides and bottom
  - » Have an opening large enough to accommodate a sharp but not large enough for a hand to enter
  - » Have a tight-fitting and puncture-resistant lid
  - » Remain upright and stable during use and handling
  - » Are clearly labeled or color-coded in accordance with OSHA labeling standards:
    - to warn of biohazardous sharps waste inside the container,
    - to indicate what should and should not be placed into the container, and
    - to indicate that it is not an FDA-cleared sharps disposal container

>>> See the back for ideas

CDC OSHA

cdc.gov/coronavirus

MS-DOH-21-1816-A-001652

CS 323144-A 03/26/2021

Alternative sharps disposal containers must meet OSHA requirements and may include the following items:

Heavy-duty plastic household containers, such as empty plastic laundry detergent, windshield wiper fluid, cat litter, or bleach containers that have been emptied and thoroughly rinsed

New, never used, heavy-duty paint or chemical buckets with a secure lid and a removeable spout large enough for sharps to be inserted but too small for a hand to enter

New, never used, heavy-duty plastic or metal gas or diesel fuel containers with tight caps

New, never used, heavy-duty plastic chemical-dispensing containers (2.5 or 5 gallon) with tight caps

Report supply shortages to the FDA

The FDA encourages health care facilities to report any supply disruptions of sharps disposal containers to the device shortages mailbox deviceshortages@fda.gov. This mailbox is monitored closely and is a valuable resource to augment FDA efforts to detect and mitigate potential supply chain disruptions.

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC COCA Call: Johnson & Johnson/Janssen COVID-19 Vaccine and Cerebral Venous Sinus Thrombosis with Thrombocytopenia – Update for Clinicians on Early Detection and Treatment [Attachment, Link]
    - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **tomorrow**, Thursday, **April 15** at **2:00 pm EDT** to present the latest evidence on cerebral venous sinus thrombosis (CVST) with thrombocytopenia associated with the administration of the Johnson & Johnson/Janssen COVID-19 vaccine. Speakers will discuss what is known about CVST, the importance of early detection, and updated vaccine recommendations. Call information is below:
        - Weblink: https://www.zoomgov.com/j/1614336614?pwd=ZVhQUHoyaG4zVFdua2czcE9EU20wUT09
          Telephone: (669) 254 5252 or (646) 828 7666
          Webinar ID: 161 433 6614
          Passcode: 160026
          Post-Event
          Recording: https://emergency.cdc.gov/coca/calls/2021/callinfo_041521.asp
- MMWR Early Release: "Laboratory Modeling of SARS-CoV-2 Exposure Reduction Through Physically Distanced Seating in Aircraft Cabins Using Bacteriophage Aerosol — November

2020" [Attachment, Link]
    - From the report: *"Based on laboratory modeling of exposure to SARS-CoV-2 on single-aisle and twin-aisle aircraft, exposures in scenarios in which the middle seat was vacant were reduced by 23% to 57%, compared with full aircraft occupancy, depending upon the model."*
- CDC Partner Update Call: "When to Clean, When to Disinfect, and What Science Says about SARS-CoV-2 on Surfaces" [Link]
    - CDC will host the next installment of its weekly partner call **Monday, April 19** at **3:00 pm EDT**. Dr. Cynthia Ogden will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Dr. Vincent Hill will discuss how SARS-CoV-2 impacts cleaning and disinfecting surfaces.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 4/19" in the subject line. The call will be recorded and posted to CDC's website here.
- AMCHP CBO and Tribal Government Conference Scholarships [Attachment, Link]
    - The Association of Maternal & Child Health Programs (AMCHP) is offering approximately 16 need-based scholarships to its annual conference taking place May 24–27, 2021. These scholarships are intended for community-based organizations or tribal governments. To apply, complete this survey by May 7. Questions may be sent to evidence@amchp.org.

Council of State and Territorial Epidemiologists
Emergency Preparedness & Response Mailbox
preparedness.cste.org

Do you work at a community-based organization or one representing a tribal government? Interested in attending the AMCHP Conference?

AMCHP invites you to apply for our

Community-Based Organization (CBO) and Tribal Government Conference Scholarships

What are the Conference Scholarships?

AMCHP recognizes the value in having community members, those working at community-based organizations, and those representing tribal governments participate in the annual conference as a way to share their expertise and insights while learning from and networking with others. At the same time, AMCHP acknowledges that attending the conference can be cost prohibitive. To help reduce this barrier, AMCHP will be offering approximately 16 need-based scholarships.

What Can I Use the Scholarship For?

You are welcome to use the scholarship for one of the following options:

1) Full conference registration
2) Participation stipend of $300 which can be used for but is not limited to:

- Childcare support
- Compensation for time used to participate in the conference that would otherwise not be paid through work

How Do I Know If I'm Eligible to Apply?

Anyone representing a community-based organization (CBO) or tribal government is welcome to submit a request. AMCHP defines a CBO as a public or private non-profit organization, or other organization such as an LLC, that is representative of a community or a significant segment of a community and works to meet community needs.

We will consider requests based on the following criteria:

- The size of your organization.
- Whether this is your first time attending the AMCHP conference.
- Whether an organization is led by or directly supporting Black, Indigenous, People of Color (BIPOC) communities; others experiencing systemic oppression including but not limited to the disability community, the LGBTQI+ community, etc.; or those representing groups that have been historically oppressed. This is directly aligned with AMCHP's commitment to living by its "All-In" Statement.

I'm Interested. How Do I Apply?

- Please complete the following **brief survey** to submit a request for the scholarship.
- You may submit a request until **Friday, May 7th**.

What is the Selection Process Like?

- Requests will be reviewed on a rolling basis based on the criteria outlined above.
- All decisions will be communicated by **May 14th**.

Once I'm Approved, What Next?

- If approved for **registration support or reimbursement**, you will be provided with a special registration link. No additional documentation is required.
- If approved for a **participation stipend**, you will be asked to complete a brief form.

AMCHP is currently accepting applications via

https://www.surveymonkey.com/r/AMCHPScholarshipSurvey

Have questions? Please contact **evidence@amchp.org**

- **Health Alert: Cases of Venous Sinus Thrombosis with Thrombocytopenia after Receipt of the Johnson & Johnson COVID-19 Vaccine:** Published April 13, 2021. Please see the following official CDC Health Alert for a detailed explanation for the medical reasoning behind the pausing of Johnson & Johnson COVID-19 vaccines being administered.
- **Strategies for Optimizing the Supply of N95 Respirators:** This guidance has been updated as of April 9. Acknowledged that the supply and availability of NIOSH-approved respirators have increased significantly over the last several months. Includes guidance for conventional, contingency, and crisis capacity strategies.
- **Summary for Healthcare Facilities: Strategies for Optimizing the Supply of N95 Respirators during Shortages:** This guidance has been updates as of April 9. This summary is intended to help healthcare facilities optimize supplies of disposable N95 filtering facepiece respirators when there is limited supply during the COVID-19 pandemic. The strategies are categorized in a continuum of care and further organized according to the hierarchy of controls.
- **Health Equity in Action:** CDC has launched a new web page, Health Equity in Action, for visitors to learn more about CDC's collaborative efforts to address health disparities among populations at higher risk for COVID-19. CDC and its partners are committed to reducing the disproportionate burden of COVID-19 among populations at increased risk for infection, severe illness, and death. Health Equity in Action highlights some of the multiple CDC efforts in place related to COVID-19 from across CDC's COVID-19 response and partnerships.

Morbidity and Mortality Weekly Report (MMWR)

- **April 14, Laboratory Modeling of SARS-CoV-2 Exposure Reduction Through Physically Distanced Seating in Aircraft Cabins Using Bacteriophage Aerosol — November 2020:** Link to the article here. A laboratory study modelling spread of COVID-19 in occupied aircrafts tested multiple seating scenarios and found vacant middle seats were associated with reduced exposure to the virus that causes COVID-19 compared with full occupancy. When paired with correct and consistent mask use and cabin ventilation, increasing physical distance between passengers, and lowering passenger density could help prevent COVID-19 spread during air travel.

Upcoming Meetings

- **Meeting of the Advisory Committee on Immunization Practices (ACIP):** Wednesday, April 14, 1:30 – 4:30 PM EST. ACIP will hold an emergency meeting on Wednesday, April 14 from 1:30-4:30 pm ET to discuss the reports and evidence to make any further recommendations. Agenda for this meeting is here.
- **Lessons from the Field: Guidance for Early Childhood Education Programs and Providers:** Wednesday, April 14, 3:00 – 4:00 EST. This webinar features a panel of practitioners who have worked to ensure the safety and wellbeing of the children and families they serve by implementing CDC guidance while providing early childhood education and childcare. Following a brief overview of the latest guidance from the CDC related to mitigation guidance in early childhood care, practitioners will share lessons learned and challenges overcome to sustain safe operations Register for the event here.

- **Community of Practice Call:** 2:00-3:00 PM EDT, Thursday, April 15, 2021. CDC invites partners to attend this week's Community of Practice call, the link to which can be foundhere.
- **COVID-19 Partner Update: When to Clean, When to Disinfect, and What Science Says about SARS-CoV-2 on Surfaces:** Monday, April 19, 3:00 – 4:00 PM EST. Dr. Cynthia Ogden will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Dr. Vincent Hill will discuss how SARS-CoV-2 impacts cleaning and disinfecting surfaces. Register for the event here.
- **Protecting Children's Environmental Health During COVID-19: Supporting Daycares and Other Early Childcare Settings:** April 28, 3:00 – 4:00 PM EST. The novel coronavirus (COVID-19) has highlighted new opportunities and challenges to protecting children's environmental health. This webinar will cover unique considerations for children's environmental health in underserved communities, success strategies, and coordination strategies among states, local health departments, and daycares and other early childcare settings during COVID-19. Register for the webinar here.

Additional Resources

- **Frequently Asked Questions for Vaccine Adverse Event Reporting System:** The Vaccine Adverse Event Reporting System (VAERS) is a national early warning system to detect possible safety problems in U.S. licensed vaccines.This FAQ page will help answer many questions you may have about how adverse reactions to vaccines are reported to the CDC and HHS.
- **National Institute of Health materials on Thrombocytopenia:** The NIH maintains a website on what is thrombocytopenia. The page also includes information on causes, risk factors, screening, prevention, signs, symptoms, diagnosis, and treatment.

COVID-19 Healthcare Quality and Worker Safety Information

CDC Health Alert

Cases of Cerebral Venous Sinus Thrombosis with Thrombocytopenia after Receipt of the Johnson & Johnson COVID-19 Vaccine

As of April 12, 2021, approximately 6.85 million doses of the Johnson & Johnson (J&J) COVID-19 vaccine (Janssen) have been administered in the United States. The Centers for Disease Control and Prevention (CDC) and the U.S. Food and Drug Administration (FDA) are reviewing data involving six U.S. cases of a rare type of blood clot in individuals after receiving the J&J COVID-19 vaccine that were reported to the Vaccine Adverse Events Reporting System (VAERS). COVID-19

In these cases, a type of blood clot called cerebral venous sinus thrombosis (CVST) was seen in combination with low levels of blood platelets (thrombocytopenia). All six cases occurred among women aged 18–48 years. The interval from vaccine receipt to symptom onset ranged from 6–13 days. One patient died. Providers should maintain a high index of suspension for symptoms that might represent serious thrombotic events or thrombocytopenia in patients who have recently received the J&J COVID-19 vaccine. When these specific type of blood clots are observed following J&J COVID-19 vaccination, treatment is different from the treatment that might typically be administered for blood clots. Based on studies conducted among the patients diagnosed with immune thrombotic thrombocytopenia after the AstraZeneca COVID-19 vaccine in Europe, the pathogenesis of these rare and unusual adverse events after vaccination may be associated with platelet-activating antibodies against platelet factor-4 (PF4), a type of protein. Usually, the anticoagulant drug called heparin is used to treat blood clots. In this setting, the use of heparin may be harmful, and alternative treatments need to be given.

CDC will convene an emergency meeting of the Advisory Committee on Immunization Practices (ACIP) on Wednesday, April 14, 2021, to further review these cases and assess potential implications on vaccine policy. FDA will review that analysis as it also investigates these cases. Until that process is complete, CDC and FDA are recommending a pause in the use of the J&J COVID-19 vaccine out of an abundance of caution. The purpose of this Health Alert is, in part, to ensure that the healthcare provider community is aware of the potential for these adverse events and can provide proper management due to the unique treatment required with this type of blood clot.

View the CDC Health Alert

Updated **Post-COVID Conditions: Information for Healthcare Providers —** CDC has updated our information for healthcare providers related to health conditions that may persist or recur following infection with SARS-CoV-2, the virus that causes COVID-19. More information is included about what is currently known about these post-COVID conditions (previously referred

to as “Late Sequelae of COVID-19”), an umbrella term for the wide range of health consequences present for more than four weeks after infection. This webpage includes information about multiorgan system effects of COVID-19, the effects of COVID-19 treatment and hospitalizations, and the condition known as “long COVID.” CDC continues active investigation of post-COVID conditions and will provide updates as new data emerge. To learn more, please visit Post-COVID Conditions: Information for Healthcare Providers

Updated **Strategies for Optimizing the Supply of N95 Respirators** — This guidance has been updated to include the following:

- Acknowledged that the supply and availability of NIOSH-approved respirators have increased significantly over the last several months

- For conventional capacity strategies
    - Added language on extended use of N95 respirators as source control
    - Added language on use of respirators with exhalation valves
- For contingency capacity strategies
    - Added a strategy to prioritize respirators for HCP who are using them as PPE over those HCP who are only using them for source control
    - For extended use of N95 respirators as PPE, clarified that N95 respirators should be discarded immediately after being removed
- For crisis capacity strategies
    - Removed the strategy of using non-NIOSH approved respirators developed by manufacturers who are not NIOSH-approval holders
    - Highlighted that the number of reuses should be limited to no more than five uses (five donnings) per device by the same HCP to ensure an adequate respirator performance
    - Removed decontamination of respirators as a strategy with limited re-use
    - Emphasized that facemasks for caring for a patient with suspected or confirmed SARS-CoV-2 infection should only be used for certain scenarios as a last resort if respirators are severely limited
    - Removed the table “Suggested well-fitting facemask or respirator use, based upon distance from a patient with suspected or confirmed SARS-CoV-2 infection and use of source control”

To learn more, please visit Strategies for Optimizing the Supply of N95 Respirators: COVID-19

Updated **Summary for Healthcare Facilities: Strategies for Optimizing the Supply of N95 Respirators during Shortages —** This summary is intended to help healthcare facilities optimize supplies of disposable N95 filtering facepiece respirators when there is limited supply during the COVID-19 pandemic. The strategies are categorized in a continuum of care and further organized according to the hierarchy of controls. To learn more, please visit Summary for Healthcare Facilities: Strategies for Optimizing the Supply of N95 Respirators during Shortages

Additional Resources

COVID-19 Science Update — To help inform CDC's COVID-19 Response, as well as to help CDC staff stay up to date on the latest COVID-19 research, the Response's Office of the Chief Medical Officer has collaborated with the CDC Office of Library Science to create a series called *COVID-19 Science Update*

***Morbidity and Mortality Weekly Report (MMWR)* — Factors Associated with Participation in Elementary School–Based SARS-CoV-2 Testing — Salt Lake County, Utah, December 2020–January 2021** — CDC, in collaboration with the University of Utah Health and Economic Recovery Outreach Project, Utah Department of Health (UDOH), Salt Lake County Health Department, and one Salt Lake county school district, offered free, in-school, real-time reverse transcription–polymerase chain reaction (RT-PCR) saliva testing as part of a transmission investigation of SARS-CoV-2 in elementary school settings. Among 856 unique student contacts at 20 elementary schools, 594 who were exposed to 33 index patients at 13 elementary schools were analyzed. Compared with non-Hispanic White students, participation in the testing program was higher among students identifying as Hispanic/Latino White (PR = 1.21) and among members of a racial minority group (PR = 1.19). In-school specimen collection could be a useful strategy for facilitating SARS-CoV-2 testing among those at higher risk for infection, who might also have limited access to testing. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – Community Transmission of SARS-CoV-2 Associated with a Local Bar Opening Event – Illinois, February 2021** — Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred during February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – COVID-19 Incidence and Mortality Among American Indian/Alaska Native and White Persons — Montana, March 13–November 30, 2020** — Aggregate analyses of data from selected U.S. states indicate that COVID-19 incidence and mortality are higher among American Indian or Alaska Native (AI/AN) persons than they are among White persons. COVID-19 incidence and mortality rates among AI/AN persons in Montana were 2.2 and 3.8 times, respectively, those among White persons. The case-fatality rate among AI/AN persons was 1.7 times that among White persons. These findings reinforce importance of using state-level surveillance to develop state and tribal COVID-19 vaccine allocation strategies and to inform local implementation of culturally appropriate public health measures that might help reduce COVID-19 incidence and mortality in AI/AN communities. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – Use of Stay-at-Home Orders and Mask Mandates to Control COVID-19 Transmission — Blackfeet Tribal Reservation, Montana, June–December 2020** – Community mitigation measures (e.g., stay-at-home orders and mask use), coupled with case investigation and contact tracing with immediate isolation or quarantine, are primary approaches to preventing and controlling community SARS-CoV-2 transmission. In the Blackfeet Tribal Reservation, enforcement of stay-at-home orders and mandated use of face coverings in public, with potential fines and jail for noncompliance, were associated with a thirty-three-fold reduction in COVID-19 incidence from its peak of 6.40 cases per 1,000 residents per day on October 5 to 0.19 on November 7, 2020. Enforcement of stay-at-home orders and mask use mandates, coupled with robust public health investigations, have been shown to reduce COVID-19 incidence. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – Provisional Mortality Data — United States, 2020** — The COVID-19 pandemic caused approximately 375,000 deaths in the United States during 2020. The age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics. Provisional death estimates provide an early indication of shifts in mortality trends. Timely and actionable data can guide public health policies and interventions for populations experiencing higher numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – Death Certificate–Based ICD-10 Diagnosis Codes for COVID-19 Mortality Surveillance — United States, January–December 2020** — During 2020, approximately 375,000 U.S. deaths were attributed to COVID-19. Among 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – Notes from the Field: COVID-19 Case Investigation and Contact Tracing Program — Spirit Lake Tribe, North Dakota, September–November 2020** — In late September 2020, the incidence of confirmed COVID-19 in North Dakota began increasing rapidly, from approximately 300 new cases per day to approximately 2,260 cases on November 13, 2020 (1). On October 20, the North Dakota Department of Health reported that contact tracing notification efforts were delayed. Because of the delay, COVID-19 patients were asked to notify their own contacts about potential exposure and encourage them to seek testing for SARS-CoV-2, the virus that causes COVID-19 (2). The Spirit Lake sovereign

nation in east central North Dakota is home to approximately 7,500 members of the Spirit Lake Tribe. In response to increasing incidence of COVID-19 on the Spirit Lake Reservation, CDC assisted the Spirit Lake Tribe in building a tribally managed program for comprehensive COVID-19 case investigations, case notification, contact tracing, contact testing, and contact management to ensure timely implementation of these critical epidemic control measures. You can learn more here: *Morbidity and Mortality Weekly Report*

***Morbidity and Mortality Weekly Report (MMWR)* – COVID-19 Stats: College and University COVID-19 Student Testing Protocols, by Mode of Instruction (N = 1,849) — United States, Spring 2021** — As of March 17, 2021, a total of 899 (49%) of 1,849 public and private, nonprofit 4-year U.S. colleges and universities provided some type of COVID-19 testing for asymptomatic students, including 548 (30%) institutions conducting classes in-person or in a hybrid format. Among institutions providing testing for asymptomatic students, 389 (43%) had protocols that required periodic testing for various subgroups (e.g., athletes, fraternity and sorority activity participants, and a random sample of students); 287 (32%) mandated that all students receive testing (ranging from every other day to once every other week), which did not vary by public or private, nonprofit status or by mode of instruction. Among institutions, 18% (338 of 1,849) did not mention a COVID-19 testing protocol on their websites, including 146 with in-person or hybrid instruction. Although asymptomatic transmission is estimated to account for approximately one half of SARS-CoV-2 transmission, a majority (950; 51%) of institutions did not publish a testing protocol for screening asymptomatic students in spring 2021. You can learn more here: *Morbidity and Mortality Weekly Report*

Subject: HHS COVID-19 Update - 4/13

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 13, 2021:

Highlights from Today's White House Briefing with Jeff Zients and Dr. Fauci

Jeff Zients

- **Johnson & Johnson:** As you all know, the FDA and CDC announced earlier today that out of an abundance of caution, they've recommended a pause in the use of Johnson & Johnson vaccine as they review data involving six reported U.S. cases of a rare and severe type of blood clot in individuals after receiving the Johnson & Johnson vaccine. Let me start by saying that this announcement will not have a significant impact on our vaccination program. The J&J vaccine makes up less than 5% of the more than 190 million recorded shots in arms in the United States to date.
- **Pfizer and Moderna Distribution:** The President took action earlier this year, before the J&J vaccine was even authorized, to secure enough Pfizer and Moderna doses for 300 million Americans by the end of July. Over the last few weeks, we have made available more than 25 million doses of Pfizer and Moderna each and every week. In fact, this week we will make available 28 million doses of these two vaccines. As we've done since we took office, we will continue to get the supply out the door as soon as it's available. We have more than enough supply of Pfizer and Moderna vaccines to continue the current pace of about three million shots per day. That puts us well on pace to meet the President's goal with 200 million shots by his 100th day in office and continue to reach every adult who wants to get vaccinated. We're now working with our state and federal partners to get anyone scheduled for a J&J vaccine quickly rescheduled for a Pfizer or Moderna vaccine.
- **Leading with Science:** The President has committed to the American people that his administration will always lead with science, tell the truth, and give Americans the facts as we know them. CDC and FDA will continue to do just that and provide regular updates to the public, and they will do so as they continue their investigation. The White House was notified last night that there would be an announcement this morning and therefore had no other involvement other than knowing last night that there would be an announcement this morning from the FDA and the CDC.

Dr. Fauci

- **Reasoning for the Pause:** This pause allows both the FDA and the CDC to further investigate these cases to try and understand some of the mechanisms of the situation, and some more details about the history of the individuals who were involved that might shed light on what we will do. It also makes physicians aware of what is going on. For example, if someone comes in with this really rather rare syndrome of thrombotic thrombocytopenia, where you get thrombosis, and the most common way to treat that is with Heparin, that would be a mistake in this situation, because it could be dangerous and make the situation much worse. When individuals, particularly younger women, who might come to a physician with a particular thrombotic phenomenon, which is something that happens for other reasons all the time, we want to alert physicians to take a history of a recent vaccination. The pause not only allows us to take a look at the cases and learn more, but it is also a signal out there to help the physicians. What I heard from the previous press discussion was the pause is going to be more like days to weeks, rather than weeks to months.
- **Effects on People Previously Vaccinated:** We know that there have been 6.85 million doses of J&J distributed in the United States thus far. So, someone who had it a month or two ago would say, "What does this mean for me?" It really doesn't mean anything. You're okay, because if you look at the time frame when this occurs, it's pretty tight from a few days, six to 13 days from the time of the vaccination. If someone was recently vaccinated, within days, I would tell them to, first of all, don't get an anxiety because, remember, it's less than one in a million. However, having said that, pay attention. Do you have symptoms? Headache? Do you have shortness of breath? Chest discomfort? Do you have anything that resembles a neurological syndrome? Obviously, if you have something as serious as a seizure, I mean, that's pretty clear. Headache is the very common component of it because the sinus thrombosis that they have is the draining of the blood in the brain and it will cause enough symptomatology to make you notice it. Just tell people to just watch out for not feeling very well.
- **Vaccine Confidence:** There have been now a 120 million people that have received at least one dose of a vaccine. Most of that, subtract the 6.85 million, is in the mRNA from Pfizer and Moderna. There have been no red flags signals from those. So, you're talking about tens and tens and tens of millions of people who've received vaccine with no adverse effect. This is a really rare event. If you look at what we know so far, there have been six out of the 6.85 million doses, which is less than one in a million. This pause is out of an abundance of caution to give us a time to take a good look at it and see if we can get further information.
- **Abundance of Caution:** Well, our FDA is internationally known for their capability of making sure that we have the safest products out there. That's what I meant when I said, "an abundance of caution." You want to make sure that safety is the important issue here. We are totally aware that this is a very rare event. We want to get this worked out as quickly as we possibly can, and that's why you see the word pause. In other words, we want to hold off for a bit and very well may go back to that, maybe with some conditions or maybe not. We want to leave that up to the FDA and the CDC to investigate this carefully. I don't think it was pulling the trigger too quickly.

Case Update

New Cases (based on 7-day rolling average)

- **31,076,891** US cases
- **6.5% increase** in new cases (7-day average), as of April 11th; (was 3.0% increase last week)

Testing

- **389,636,919** tests completed (4/13)
- **6.0%** positive test rate as of the week of 4/3 – 4/9 (was 5.7% last week)

Hospitalizations

- **2,009,551** total COVID hospital admissions
- The 7-day average (4/4 – 4/10) number of new confirmed COVID-19 admissions **increased** week on week (from 4,843 to 5,246

admissions per day)

Deaths

- **559,172** total US deaths
- The 7-day average (4/5 – 4/11) number of reported deaths **decreased** week on week (from 781 to 678 deaths per day)

Vaccines

- **192,282,781** vaccine doses **administered** (4/13)
- **36.8%** (122.3 million people) of the population has received **1 or more doses** and **22.7%** (75.3 million people) of the population have been **fully vaccinated**
- **79.2%** of adults 65 and older have received **at least 1 dose** and **62.5%** have been **fully vaccinated**

Vaccine Updates

Joint CDC and FDA Statement on Johnson & Johnson COVID-19 Vaccine: As of April 12, more than 6.8 million doses of the Johnson & Johnson (Janssen) vaccine have been administered in the U.S. CDC and FDA are reviewing data involving six reported U.S. cases of a rare and severe type of blood clot in individuals after receiving the J&J vaccine. CDC will convene a meeting of the Advisory Committee on Immunization Practices (ACIP) on Wednesday to further review these cases and assess their potential significance. FDA will review that analysis as it also investigates these cases. Until that process is complete, we are recommending a pause in the use of this vaccine out of an abundance of caution. Right now, these adverse events appear to be extremely rare. COVID-19 vaccine safety is a top priority for the federal government, and we take all reports of health problems following COVID-19 vaccination very seriously. Listen to the joint media briefing with the FDA and CDC here. CDC has updated the following pages with the announcement of the pause: Johnson & Johnson General Information, Reported Adverse Events, Viral Vector Vaccines, Different Vaccines, Vaccines for COVID-19, Frequently Asked Questions about Vaccination, Key Things to Know, Vaccine Safety and Monitoring (including v-safe), and Coronavirus Disease 2019 (COVID-19).

Statement from Jeff Zients on Johnson & Johnson Vaccine: Jeff Zients, White House COVID-19 Response Coordinator, released a statement on Johnson & Johnson Vaccine. As FDA and CDC announced earlier today, out of an abundance of caution, they have recommended a pause in the use of the Johnson & Johnson vaccine as they review data involving six reported U.S. cases of a rare and severe type of blood clot in individuals after receiving the Johnson & Johnson vaccine. This announcement will not have a significant impact on our vaccination plan: Johnson & Johnson vaccine makes up less than 5 percent of the recorded shots in arms in the United States to date. Based on actions taken by the President earlier this year, the United States has secured enough Pfizer and Moderna doses for 300 million Americans. Over the last few weeks, we have made available more than 25 million doses of Pfizer and Moderna each week, and in fact this week we will make available 28 million doses of these vaccines. This is more than enough supply to continue the current pace of vaccinations of 3 million shots per day and meet the President's goal of 200 million shots by his 100th day in office—and continue on to reach every adult who wants to be vaccinated. We are working now with our state and federal partners to get anyone scheduled for a J&J vaccine quickly rescheduled for a Pfizer or Moderna vaccine.

Vaccines by Jurisdiction: CDC updated their report on COVID-19 vaccine distribution, delivery, and administration by jurisdiction. The report provides an overview of the multiple channels being used to ensure all Americans have access to COVID-19 vaccine. Jurisdictional delivery and administration portfolios vary across the United States because of population variability.

V-Safe Pregnancy Registry: CDC updated their information on the v-safe COVID-19 Vaccine Pregnancy Registry. If you are pregnant, you might choose to be vaccinated when it's available to you. There is currently no evidence that antibodies formed from COVID-19 vaccination cause any problem with pregnancy, including the development of the placenta. However, data are limited about the safety of COVID-19 vaccines for people who are pregnant. The registry is collecting health information from people who received COVID-19 vaccination in the periconception period (within 30 days before last menstrual period) or during pregnancy. The information is critical to helping individuals and their healthcare providers make informed decisions about COVID-19 vaccination. Participation is voluntary, and participants may opt out at any time.

Addressing COVID-19 Health Disparities Among Racial and Ethnic Minority Communities: The FDA reaffirmed their commitment to addressing COVID-19 health disparities among racial and ethnic minority communities. The FDA's Center for Biologics Evaluation and Research (CBER) is working hand-in-hand with the FDA's Office of Minority Health and Health Equity (OMHHE) to address concerns about vaccines among diverse communities. OMHHE is in turn committed to protecting and promoting the health of diverse populations by focusing its efforts on research and outreach and communication strategies that address health disparities.

Testing and Treatment

FDA Testing Update: As of today, 358 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 262 molecular tests and sample collection devices, 75 antibody and other immune response tests, and 21 antigen tests. There are 45 molecular authorizations and one antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home tests, four over-the-counter (OTC) at-home antigen tests, and two OTC molecular tests. The FDA has authorized 7 antigen tests and 2 molecular tests for serial screening programs.

Reopening Guidance

Crew Disembarkations Through Commercial Travel: CDC updated their guidance for cruise ships and their crew members. CDC is committed to helping cruise lines provide for the safety and well-being of their crew members while onboard cruise ships and as they disembark. CDC is allowing crew members to disembark from all cruise ships in U.S. waters with certain precautions. Cruise lines with complete and accurate response plans are able to use commercial travel to disembark crew members from certain ships if the ships meet certain criteria set by CDC. CDC outlines which cruise ships operating or planning to operate in U.S. waters during the initial phases of the Framework for Conditional Sailing Order have met surveillance reporting requirements.

Information for Specific Populations

Long-term Care Facility Residents: CDC updated their information for long-term care facility (LTCF) residents on how to get a COVID-19 vaccine. If you have not already been vaccinated against COVID-19, you can: talk to the LTCF staff to determine if a vaccine can be made available to you on site and/or ask a family member or friend to help you schedule a vaccination appointment if a vaccine is not available on site. Studies show that COVID-19 vaccines are safe and effective, a COVID-19 vaccine cannot make you sick with COVID-19, and depending on the kind of COVID-19 vaccine you get, you might need a second shot 3 or 4 weeks after your first shot. After getting vaccinated, some people have side effects; these are normal signs that your body is building protection against COVID-19. You will not need to pay for a COVID-19 vaccine and the CDC recommends all LTCF residents to get vaccinated against COVID-19.

Temporary Halt in Residential Evictions: CDC updated their information on the temporary halt in residential evictions to prevent the further spread of COVID-19. Director Dr. Rochelle Walensky signed a declaration determining that the evictions of tenants could be detrimental to public health control measures to slow the spread of SARS-Cov-2, the virus that causes COVID-19.

COVID-19 Vaccines Available in Baltimore for Native Americans in DMV Area: Today, the Indian Health Service, Native American Lifelines of Baltimore, and the University of Maryland, Baltimore are announcing the availability of COVID-19 vaccines for American Indians and Alaska Natives living and working in and near the Baltimore and Washington, D.C., areas. Vaccines are being provided by the IHS Nashville Area and will be administered by the University of Maryland, Baltimore, in coordination with Native American Lifelines of Baltimore. Beginning Friday, April 16, 2021, vaccines will be available for tribal members and employees of Indian agencies and tribal organizations, as well as their spouses or partners and other household members. Appointments can be booked now here.

Vaccine Guidance and Resources for People with Disabilities and Older Adults: As part of a shared commitment to President Biden's National Strategy - PDF and Executive Order to ensure an equitable COVID-19 response, the Office for Civil Rights (OCR), the Administration for Community Living (ACL), and the Office of the Assistant Secretary for Planning and Evaluation (ASPE) at HHS have published several new resources to help states, vaccination providers, and others leading COVID-19 response activities improve access to vaccines for people with disabilities and older adults. These resources clarify legal requirements, illustrate some of the barriers to vaccine access faced by people with disabilities and older people, and provide strategies – and examples of how the aging and disability network can help employ them – to ensure accessibility. The Office for Civil Rights released new guidance - PDF outlining legal standards under the federal civil rights laws prohibiting disability discrimination and providing concrete examples of the application of the legal standards in the context of COVID-19 vaccine programs and how to implement them. OCR also issued a fact sheet - PDF setting out specific steps that those involved in the planning and distribution of vaccines to combat the COVID-19 pandemic may wish to consider to promote compliance with disability rights laws and provide access to vaccination programs for people with disabilities. Earlier COVID-19 guidance from OCR addressed civil rights protections prohibiting discrimination on the basis of race, color, national origin - PDF, and civil rights of persons with limited English proficiency - PDF.

Research

Post-Acute COVID-19: The National Institute of Allergy and Infectious Disease (NIAID), in collaboration with other institutes and centers of the

National Institutes of Health, led a virtual "Workshop on Post-Acute Sequelae of COVID-19." A paper published recently in *Annals of Internal Medicine* describes the workshop. Over 1,200 registered participants including researchers, clinicians, and affected community members discussed what is known about sequelae after COVID-19 and the knowledge gaps that need to be addressed in future research.

NIH Trial of Anti-CD14 Antibody to Treat COVID-19 Respiratory Disease Begins: A clinical trial testing the safety and efficacy of an investigational monoclonal antibody for treating people who are hospitalized with respiratory disease and low blood oxygen due to infection with SARS-CoV-2, the virus that causes COVID-19, has begun. The Phase 2 trial, called the COVID-19 anti-CD14 Treatment Trial (CaTT), is sponsored and funded by the National Institute of Allergy and Infectious Diseases (NIAID), part of the National Institutes of Health. The main goal of the CaTT study is to determine whether treatment with IC14 decreases the time it takes people with COVID-19 respiratory disease to recover such that they no longer need ongoing medical care in the hospital. Secondary goals are to determine the safety of IC14 in the study population and the efficacy of the drug at reducing the severity of COVID-19 respiratory disease. If the results of the CaTT study are promising, then IC14 may be tested in a larger Phase 3 efficacy trial.

Mapping Severe COVID-19 in the Lungs at Single-Cell Resolution: A team of NIH-funded researchers captured changes in the lungs over the course of a COVID-19 infection at unprecedented, single-cell resolution. The imaging data adds evidence that SARS-CoV-2, the coronavirus that causes COVID-19, primarily infects cells at the surface of the air sacs. Their findings also offer valuable clues for treating the most severe consequences of COVID-19, suggesting that a certain type of scavenging immune cell might be driving the widespread lung inflammation that leads to acute respiratory distress syndrome (ARDS), in which fluid and cellular infiltrates build up in the lung's air sacs, called alveoli, keeping them from exchanging oxygen with the bloodstream.

Immune Response to Vaccination After COVID-19: NIH released a study regarding the immune response to vaccination after COVID-19. Researchers found that after a single dose of the Pfizer-BioNTech vaccine, people with a prior COVID-19 infection had antibody levels similar to those of people without prior infection after two vaccine doses. The results, which need to be confirmed in large, diverse populations, may point to a strategy to stretch the currently limited supply of vaccines against COVID-19.

College and University COVID-19 Stats: CDC updated an *MMWR* on COVID-19 student testing protocols by mode of instruction at colleges and universities during the spring of 2021.

Non-COVID-19 Updates

Addressing the Black Maternal Health Crisis: Today—during Black Maternal Health Week—the Biden-Harris Administration is announcing initial actions it has taken to address the maternal health crisis in the United States. President Biden issued the first-ever presidential proclamation calling on all Americans to recognize the importance of addressing the crisis of Black maternal mortality and morbidity in this country, an executive order to implement a comprehensive approach to advancing racial equity, and an executive order to establish the White House Gender Policy Council to take a whole-of-government approach to gender equity. The Administration has taken the following actions to strengthen health equity and address racial disparities in maternal health through increased investment in reducing maternal mortality and morbidity; approval of the first Medicaid Section 1115 Waiver to broadly extend postpartum coverage; and $12 million in additional funds for maternal obstetrics care in rural communities

Laboratory Modeling of SARS-CoV-2 Exposure Reduction Through Physically Distanced Seating in Aircraft Cabins Using Bacteriophage Aerosol — November 2020

Watts L. Dietrich[1]; James S. Bennett, PhD[1]; Byron W. Jones, PhD[2]; Mohammad H. Hosni, PhD[2]

Aircraft can hold large numbers of persons in close proximity for long periods, which can increase the risk for transmission of infectious disease.* Current CDC guidelines recommend against travel for persons who have not been vaccinated against COVID-19, and a January 2021 CDC order requires masking for all persons while on airplanes.[†,§] Research suggests that seating proximity on aircraft is associated with increased risk for infection with SARS-CoV-2, the virus that causes COVID-19 (*1*,*2*). However, studies quantifying the benefit of specific distancing strategies to prevent transmission, such as keeping aircraft cabin middle seats vacant, are limited. Using bacteriophage MS2 virus as a surrogate for airborne SARS-CoV-2, CDC and Kansas State University (KSU) modeled the relationship between SARS-CoV-2 exposure and aircraft seating proximity, including full occupancy and vacant middle seat occupancy scenarios. Compared with exposures in full occupancy scenarios, relative exposure in vacant middle seat scenarios was reduced by 23% to 57% depending upon the modeling approach. A 23% exposure reduction was observed for a single passenger who was in the same row and two seats away from the SARS-COV-2 source, rather than in an adjacent middle seat. When quantifying exposure reduction to a full 120-passenger cabin rather than to a single person, exposure reductions ranging from 35.0% to 39.4% were predicted. A 57% exposure reduction was observed under the vacant middle seat condition in a scenario involving a three-row section that contained a mix of SARS-CoV-2 sources and other passengers. Based on this laboratory model, a vacant middle seat reduces risk for exposure to SARS-CoV-2 from nearby passengers. These data suggest that increasing physical distance between passengers and lowering passenger density could help reduce potential COVID-19 exposures during air travel. Physical distancing of airplane passengers, including through policies such as middle seat vacancy, could provide additional reductions in SARS-CoV-2 exposure risk.

The study consisted of three components. The first involved analysis of data on virus aerosol dispersion in aircraft cabin mock-ups from a previous study conducted at KSU during July–August 2017 as part of a pandemic influenza research initiative (*3*). Next, these data were used to create a regression model to estimate the reduction in aerosol concentration as distance from a source increased. Finally, these regression models were applied to conceptual aircraft seating scenarios to simulate the reduction in exposure resulting from vacant middle seats in an aircraft cabin. Laboratory experiments were performed with bacteriophage MS2 virus obtained from the American Type Culture Collection.[¶] Bacteriophage MS2 has frequently been used as a surrogate for pathogenic viruses in aerosolization studies (*4*) and was used to approximate the airborne dispersion of SARS-CoV-2. During the aerosol dispersion study at KSU, mannequins with realistic passenger heat emission were seated in the cabin mock-ups, and then MS2 aerosol was introduced from a source location and collected at six different sample locations in the cabin. This process was repeated four times: twice in a single-aisle cabin and twice in a twin-aisle cabin (Figure 1), resulting in 24 total samples.** Because these data were collected before the COVID-19 pandemic, the effects of passengers wearing masks on the aerosol dispersion behavior were not measured. These viral aerosol data were then used to create a nonlinear regression model[††] which assesses the association between the number of plaque-forming

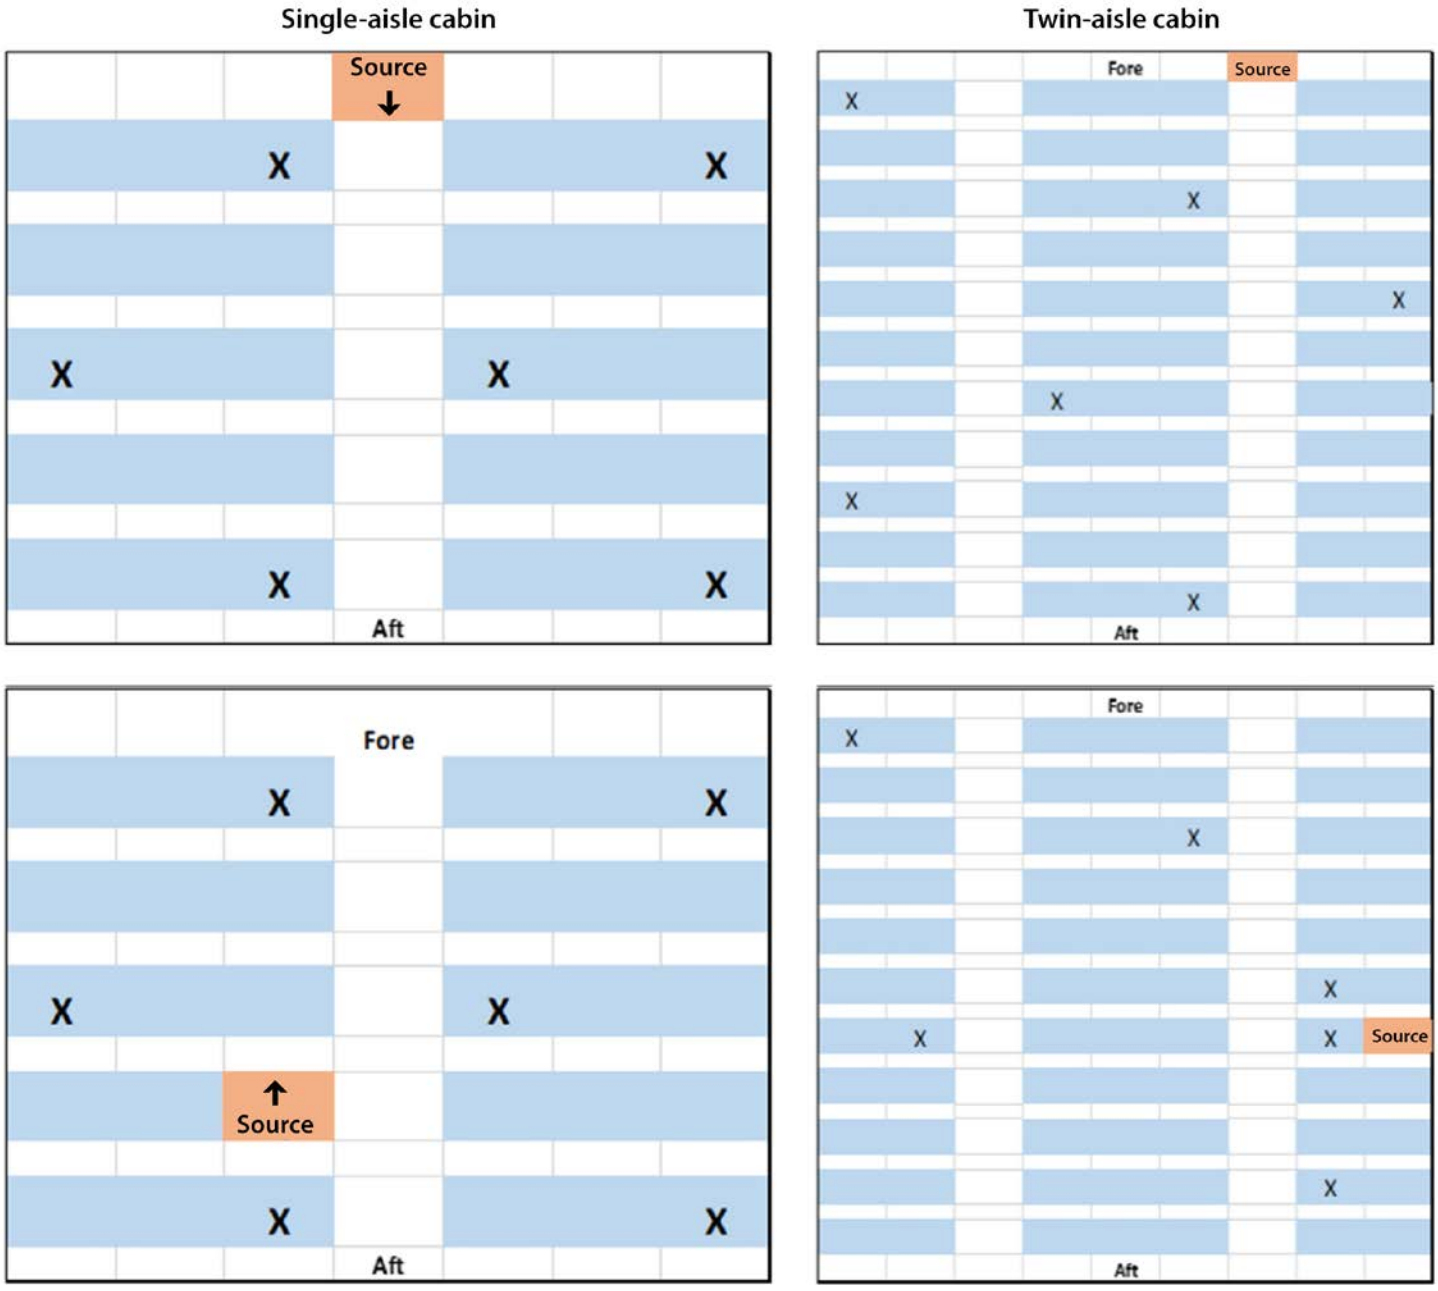
units (PFUs) (evidence of the presence of viable virus) and the distance between source and sample locations. For both single-aisle and twin-aisle scenarios, findings from the nonlinear regression model indicate that the number of PFUs declined exponentially with increasing distance (Supplementary Figure, https://stacks.cdc.gov/view/cdc/104935).

In November 2020, CDC applied this data-driven model to simulate the protective effect of a vacant middle seat versus full aircraft occupancy. Two analytical approaches were used. Both approaches analyzed reductions in relative exposures (the number of PFUs divided by the maximum predicted value) rather than absolute exposure.

FIGURE 1. Diagram of aircraft cabin configurations and source and sampling locations to assess exposure to aerosolized bacteriophage MS2 virus as a surrogate for airborne SARS-CoV-2 exposure in single-aisle and twin-aisle cabins* — Kansas State University, July–August 2017†



Source: Modified with permission from Lynch JA, Bennett JS, Jones B, Hosni MH. Viral particle dispersion and viability in commercial aircraft cabins. In: 2018 American Society of Heating, Refrigerating and Air-Conditioning Engineers Annual Conference Proceedings; June 23–27, 2018; Houston, TX; 2018.
Abbreviations: aft = back of the plane; fore = front of the plane; source = aerosol source; X = sampling location.
* For both single-aisle and twin-aisle cabin scenarios, two different source configurations were assessed for placement of infectious passengers: one with the source at the front of the plane in an aisle and one with the source in a seat. Each configuration consisted of six total sampling locations, for a total of 24 samples.
† Data were collected at Kansas State University during July–August 2017 as part of a pandemic influenza research initiative.

MS-DOH-21-1816-A-001672

The first approach considered only the extra distance between passengers created by the vacant middle seat. The regression model estimated exposure as a function of distance to assess the exposure reduction of moving an adjacent passenger one seat further away from an infectious passenger, leaving an empty middle seat between them. The distance effect was explored further to simulate the total exposure reduction for groups of passengers up to and including a full simulated cabin of 120 seats.[§§] A total of 300 simulations were tested using Monte Carlo methods, where the number (one to three) and placement of infectious passengers were varied. The total exposure reduction for all passengers in the cabin was predicted by placing a source at an arbitrary seat location and applying the regression model to calculate relative exposure at all other seat locations, which were summed to obtain a total exposure for the cabin.

The second approach combined the distance effect predicted by the regression model and the reduced occupancy effect predicted by simple probability estimation, as these are inseparable in realistic arrangements of infectious passengers and other passengers. When simply defining exposure risk as reduced occupancy, a vacant middle seat reduced exposure by an estimated 33% compared with full occupancy, in single-aisle, three-seats-per-side cabins, because there are 33% fewer potentially infectious passengers.

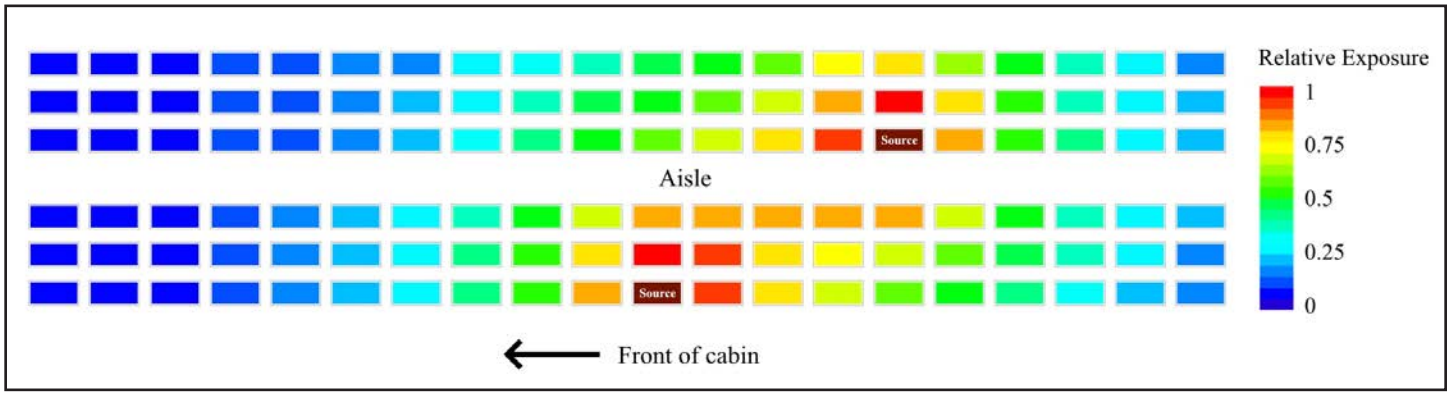
The first approach predicted a 23% exposure reduction by moving an adjacent passenger one seat further away from an infectious passenger. The total reduction in relative exposure for a full 120-seat cabin yielded reduction of 35.0%–36.4%, 35.1%–38.2%, and 35.9%–39.4% for one, two, and three infectious passengers, respectively, depending on their seating pattern. All sources were placed in window or aisle seats such that the potential reduction in number of infectious passengers onboard from vacant middle seating was not considered (Figure 2). The second approach was applied to a cluster of nine infectious passengers (including three in middle seats) among 18 total passengers in three rows (Figure 3). When the infectious and other passengers who would have had middle seats were removed, leaving six infectious passengers out of 12 total passengers remaining in the window and aisle seats, a 57% exposure reduction was observed.

** The laboratory cabin environments were a five-row section of an actual Boeing 737 fuselage and an 11-row section of a geometrically accurate mock-up, including original equipment seats, of a Boeing 767 cabin. Ventilation systems used actual Boeing 737 (single aisle) and 767 (twin aisle) equipment where practical, but with no jet engine, so that supply ventilation came from conditioned air in the laboratory rather than from a jet engine. Bacteriophage MS2 virus aerosol was introduced by spray bottle from a source location using three closely timed, consecutive sprays, totaling approximately 3.7 mL. For both single-aisle and twin-aisle cabin scenarios, two different source configurations were assessed: one with the source at the front of the plane and one with the source at the back. Each configuration consisted of six total seat locations; a total of 24 samples were evaluated. Viral aerosol samples were collected in bioaerosol liquid (10% glycerol in 1× phosphate buffered saline) impingers. These devices collected aerosol by drawing air though a small volume of liquid for 5 minutes; samplers were held in place with clamp and stand assemblies on seats, with the impinger intake facing forward to approximate seated head-height for an average adult. Collection fluid aliquots were evaluated for viral particle presence by plaque assay, and the number of plaque-forming units (PFUs) was considered proportional to the airborne concentration references of viable virus.

†† The virion data were fitted to exponential regression equations of the form, $C = Ae^{BD}$, with number of PFUs (C) as the dependent variable and the distance between spray and sampling locations (D) as the independent variable. A and B are constants determined by regression analysis, as was the coefficient of determination, R^2.

§§ This simulated cabin was single-aisle, with 20 rows and three seats per side, for a total of 120 seats; the distance between rows was 3 ft (0.9 m); the distance between adjacent seat centers was 1.6 ft (0.5 m). This number of rows is on the lower end of a typical Boeing 737 coach cabin, depending on the specific design. The total exposure reduction for all passengers in the cabin was predicted by placing a source at an arbitrary seat location and applying the regression model to calculate relative exposure at all other seat locations, which were summed to obtain a total exposure for the cabin.

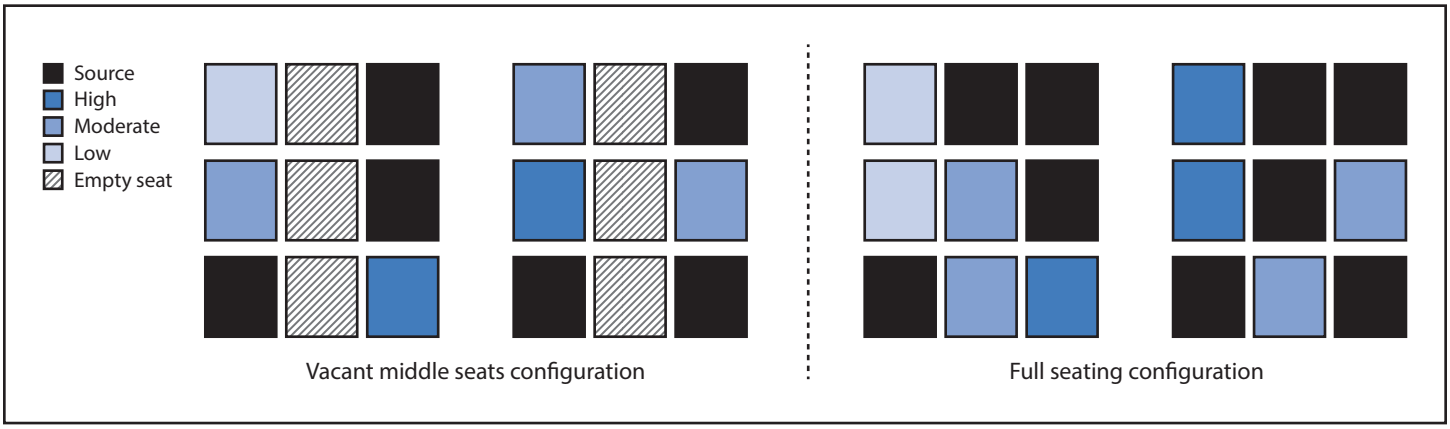
FIGURE 2. Estimated reduction in relative exposure to aerosolized bacteriophage MS2 as a surrogate for SARS-CoV-2 through physically distanced seating in a single-aisle, 20-row simulated aircraft cabin* — November 2020



* A total of 300 simulations in which the number (one, two, or three) and placement of infectious passengers varied were tested using Monte Carlo methods. The simulated cabin had a single aisle, with 20 rows and three seats per side (120 total seats); the distance between rows was 3 ft (0.9 m); the distance between adjacent seats was 1.6 ft (0.5 m). In the source configuration shown here, the total reduction in exposure with vacant middle seats was calculated to be 35.4%.

MS-DOH-21-1816-A-001673

FIGURE 3. Relative estimated reduction in exposure to bacteriophage MS2 as a surrogate for SARS-CoV-2 through physically distanced seating in a single-aisle, three-row section of an aircraft cabin with full occupancy* compared with vacant middle seats† — November 2020



* A cluster of nine infectious passengers (including three in middle seats) among 18 total passengers in three rows. Removing the infectious and other passengers who would have had middle seats, leaving six infectious passengers out of 12 total passengers remaining in the window and aisle seats, resulted in an estimated 57% reduction in SARS-CoV-2 exposure. Exposures were as follows: 21.1 for six noninfectious passengers in the configuration with no middle seats; 48.7 for the nine noninfectious passengers with full occupancy.

† The local prevalence (the percentage of passengers in the three rows who are infectious) was held constant in the comparison to reasonably account for the fact that keeping middle seats vacant is expected to prevent both infectious and noninfectious passengers from sitting there.

Discussion

This laboratory-based model predicts a 23% to 57% reduction in exposure to viable virus particles when middle seats on an airline are kept vacant. This range is comparable to that reported in another study that used computational fluid dynamics simulation and considered cabin ventilation rates per passenger to show that keeping middle seats vacant reduced the risk for airborne infection by 45%.¶¶ Studies of tracer gas/particle dispersion generally indicate that distance is an important determinant of contaminant exposure on aircraft (*5*,*6*), including showing that airborne concentration decay with distance is similar for various contaminant types and closely mirrors infection patterns on aircraft; this finding supports the use of bacteriophage MS2 as a surrogate for SARS-CoV-2 exposure.*** Further, a recent investigation of SARS-CoV-2 transmission on an international flight found that seating proximity was strongly associated with infection risk: 75% of infected passengers were seated within two rows of the symptomatic passenger who likely originated the outbreak (*1*).

Aircraft cabin environmental control systems (ventilation systems) are designed to deliver amounts of clean air per occupant that conform to various standards.††† When these standards are adhered to, most virus particles are removed within several seat rows from a source on an aircraft, and the recirculated portion of the air supplied to each passenger has passed through high efficiency particle air (HEPA) filters.§§§ As aircraft ventilation removes airborne contaminants, it also causes some turbulent dispersion. This spreading effect of aerosols is larger than transient flows created by passenger or crew movement in the aisles under typical cruise conditions (*7*). Physical distancing is difficult on crowded flights, and sitting within 6 ft of others, sometimes for hours, might increase risk for SARS-CoV-2 exposure. To reduce this risk, the CDC order issued in January 2021 requires the wearing of masks by travelers to prevent spread of COVID-19, including all passengers on aircraft traveling into, within, or out of the United States, and recommends against travel for all unvaccinated persons.

It is important to recognize that the current study addresses only exposure and not transmission.¶¶¶ The impact of masking also was not considered in the current aerosol analysis because

¶¶ https://www.sae.org/publications/technical-papers/content/2021-01-0036/

*** MS2 virus when collected in SKC BioSamplers (as in the current study) showed similar resistance to sampling and environmental stresses as does Newcastle disease virus but greater resistance than influenza A and MHV coronavirus. However, the relative exposure method of the current study might diminish the importance of sampling resistance. In addition, the airborne transport behavior of virus aerosols depends on the aerodynamic diameter of the evaporated droplet nuclei and not on biologic properties of individual viruses.

††† Including requirements set by the Federal Aviation Administration (https://www.faa.go) and recommendations from the Environmental Protection Agency (https://www.epa.go), and American Society of Heating, Refrigeration, and Air-Conditioning Engineers (https:www.ashrae.org). Additional information is available at https://www.faa.gov/data_research/research/med_humanfacs/cer/media/In-FlightOnboardMonitoring.pdf and https://www.nap.edu/catalog/10238/the-airliner-cabin-environment-and-the-health-of-passengers-and-crew/FlightOnboardMonitoring.pdf

§§§ https://www.epa.gov/indoor-air-quality-iaq/what-hepa-filter-1

¶¶¶ Applicability to COVID-19 transmission would involve two steps: MS2 phage exposure relating to SARS-CoV-2 exposure and SARS-CoV-2 exposure being large enough to cause COVID-19 transmission in a person. Relative exposure removes the importance of source specifics, making MS2 aerosol experiments a reasonable substitute in terms of transport physics. Importantly, the threshold behavior of COVID-19 transmission depends on factors related to in vivo respiratory droplets typically associated with SARS-CoV-2 and host characteristics such as individual susceptibility and is beyond the scope of this study.

MS-DOH-21-1816-A-001674

masks are more effective at reducing fomite and droplet exposures than aerosol exposures (*8*,*9*). A case study of COVID-19 transmission on a flight with mandated mask wearing (*10*) suggests that some virus aerosol is emitted from an infectious masked passenger, such that distancing could still be useful. The findings in these studies indicate that masking seems to not eliminate all airborne exposures to infectious droplets and aerosols and support the importance of multicomponent prevention strategies as good practices; combining the effects of masking and distancing is more protective than either by itself.

The findings in this report are subject to at least four limitations. First, data were collected under higher relative humidity conditions in the laboratory than would be present during flight. Droplet evaporation into aerosol is more rapid under lower relative humidity. Because aerosols travel farther than droplets, the current study might underpredict the aerosol spread in an actual cabin environment. The slower evaporation in the current study might then overpredict the observed effect of distancing because this more rapid decrease makes estimated distance effects larger. Second, in the data used to build the regression models, most of the variability was within approximately 5 ft of the infection source. Although this near-zone variability weakens the quantification of the effect of short distances, the equations were the statistical best fit and had coefficient of determination (R^2) values (the percentage of the response variable variation explained by a model) above 70%, suggesting that the distance model explained most of the observed virus concentration behavior. Third, the use of spray bottles to emit droplets, followed by 5 minutes of air sampling, might not fully represent the variety of respiratory events that could transmit virus (e.g., exhalation, talking, coughing, and sneezing). Mandated mask use further alters the human respiratory source, making the relative exposure approach used here an important way to diminish bias related to release volume. Finally, the study only assessed aerosols, not fomites and droplets. Exposures decrease more rapidly with distance for these exposure paths; therefore, distancing would have an even larger protective effect than that observed in this study.

Based on a data-driven model, approaches to physical distancing, including keeping middle seats vacant, could reduce exposure to SARS-CoV-2 on aircraft. The extent to which exposure reduction might decrease transmission risk is not yet understood. Current CDC guidelines recommend against travel for persons who have not been vaccinated and require masking for all persons while on aircraft. Physical distancing of aircraft passengers, including through policies such as middle seat vacancy, could provide additional reductions in SARS-COV-2 exposure risk. This study could help inform future modeling of transmission risk, which might encompass determinants that were not fully explored here such as mask use, virus characteristics, and host characteristics, such as vaccination status.

Summary

What is already known about this topic?

Aircraft can hold large numbers of persons in close proximity for long periods, which are conditions that can increase the risk for transmitting infectious diseases.

What is added by this report?

Based on laboratory modeling of exposure to SARS-CoV-2 on single-aisle and twin-aisle aircraft, exposures in scenarios in which the middle seat was vacant were reduced by 23% to 57%, compared with full aircraft occupancy, depending upon the model.

What are the implications for public health practice?

Physical distancing of airplane passengers, including through policies such as middle seat vacancy, could provide additional reductions in risk for exposure to SARS-CoV-2 on aircraft.

Acknowledgment

Johnson & Johnson/Janssen COVID-19 Vaccine and Cerebral Venous Sinus Thrombosis with Thrombocytopenia – Update for Clinicians on Early Detection and Treatment

You may participate in this COCA Call via Zoom

Overview

This COCA Call will present the latest evidence on cerebral venous sinus thrombosis (CVST) with thrombocytopenia associated with the administration of the Johnson & Johnson/Janssen COVID-19 vaccine. Speakers will discuss what is known about CVST, the importance of early detection, and updated vaccine recommendations.

If you are unable to attend the live COCA Call, the recording will be available for viewing on theCOCA Call webpage a few hours after the live event ends.

The slide set will be available under "Call Materials" on theCOCA Call webpage the day of the call.

Continuing Education (CE) will not be provided for this call.

Advanced registration is not required.

Date: Thursday, April 15, 2021

Time: 2:00 pm - 3:00 pm (ET)

A few minutes before the webinar starts, please click on the Zoom link below to join:https://www.zoomgov.com/j/1614336614?pwd=ZVhQUHoyaG4zVFdua2czcE9EU20wUT09

COCA Call Objectives

At the conclusion of the session, the participant will be able to accomplish the following—

1. Cite background information on the topic covered during the presentation.
2. Discuss CDC's role in the topic covered during the presentation.
3. Describe the topic's implications for clinicians.
4. Discuss concerns and/or issues related to preparedness for and/or response to urgent public health threats.
5. Promote health improvement, wellness, and disease prevention in cooperation with patients, communities, at-risk populations, and other members of an interprofessional team of healthcare providers.

Overview

This COCA Call will present the latest evidence on cerebral venous sinus thrombosis (CVST) with thrombocytopenia associated with the administration of the Johnson & Johnson/Janssen COVID-19 vaccine. Speakers will discuss what is known about CVST, the importance of early detection, and updated vaccine recommendations.

If you are unable to attend the live COCA Call, the recording will be available for viewing on theCOCA Call webpage a few hours after the live event ends.

The slide set will be available under "Call Materials" on theCOCA Call webpage the day of the call.

Continuing Education (CE) will not be provided for this call.

Advanced registration is not required.

Date: Thursday, April 15, 2021

Time: 2:00 pm - 3:00 pm (ET)

A few minutes before the webinar starts, please click on the Zoom link below to join:https://www.zoomgov.com/j/1614336614?pwd=ZVhQUHoyaG4zVFdua2czcE9EU20wUT09

COCA Call Objectives

At the conclusion of the session, the participant will be able to accomplish the following—

1. Cite background information on the topic covered during the presentation.
2. Discuss CDC's role in the topic covered during the presentation.
3. Describe the topic's implications for clinicians.
4. Discuss concerns and/or issues related to preparedness for and/or response to urgent public health threats.
5. Promote health improvement, wellness, and disease prevention in cooperation with patients, communities, at-risk populations, and other members of an interprofessional team of healthcare providers.

Presenters

Sara Oliver, MD
LCDR, U.S. Public Health Service
Co-lead, Advisory Committee for Immunization Practices COVID-19 Vaccines Work Group
COVID-19 Response
Centers for Disease Control and Prevention

Tom Shimabukuro, MD, MPH, MBA
CAPT, U.S. Public Health Service
Vaccine Safety Team Lead
COVID-19 Response
Centers for Disease Control and Prevention

The Emergency Risk Communication Branch in the Division of Emergency Operations, Center for Preparedness and Response is responsible for the management of all COCA products.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- ELC K-12 Reopening Schools Deliverables [Attachment]
  - Please see attached for a message from CDC's Epidemiology and Laboratory Capacity (ELC) Team. This message aims to clarify two deliverables due **Friday, April 23**:
    1. Validation/correction of the 'School District Weekly Reporting Template', pre-populated with school districts in your jurisdiction.
    2. A brief narrative of how you plan to partner and provide resources to the districts in your jurisdiction.
  - Full instructions are available in the attached PDF. From the message: *"We do not expect that every district in every jurisdiction will be ready to adopt screening testing immediately. During Phase 2/Activity 2, we will ask you to describe your plan for working with the jurisdictions in more specific terms. [...] We will be sharing FAQs in coming days to provide additional clarity; in the meantime, please don't hesitate to reach out to your ELC Project Officer or leadership with any questions or clarifications."*
- CDC ACIP Emergency Meeting [Link]
  - CDC's Advisory Committee on Immunization Practices (ACIP) will hold another virtual

emergency meeting **Friday, April 23** from **11:00 am–5:00 pm EDT** regarding safety in the use of the Johnson & Johnson (Janssen) vaccine.
    - Registration is *not* required. The meeting will be broadcast on uStream here.
- CDC Partner Update Call: Keeping Up with Critical Diabetes Care and Prevention During COVID-19 [Link]
    - CDC will host the next installment of its weekly partner call **Monday, April 26** at **3:00 pm EDT**. Dr. Kyle Bernstein will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Dr. Beth Bigman will discuss how to maintain critical diabetes care and prevention during the pandemic.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 4/26" in the subject line. The call will be recorded and posted to CDC's website here.
- MMWR Early Release: "Postvaccination SARS-CoV-2 Infections Among Skilled Nursing Facility Residents and Staff Members — Chicago, Illinois, December 2020–March 2021" [Attachment, Link]
    - From the summary: *"Twenty-two possible breakthrough SARS-CoV-2 infections occurred among fully vaccinated persons ≥14 days after their second dose of COVID-19 vaccine. Two thirds of persons were asymptomatic. A minority of persons with breakthrough infection experienced mild to moderate COVID-19–like symptoms; two COVID-19–related hospitalizations and one death occurred. No facility-associated secondary transmission was identified."*
- MMWR Early Release: "COVID-19 Outbreak Associated with a SARS-CoV-2 R.1 Lineage Variant in a Skilled Nursing Facility After Vaccination Program — Kentucky, March 2021" [Attachment, Link]
    - From the summary: *"In a COVID-19 outbreak at a Kentucky SNF involving a newly introduced variant to the region, unvaccinated residents and health care personnel (HCP) had 3.0 and 4.1 times the risk of infection as did vaccinated residents and HCP. Vaccine was 86.5% protective against symptomatic illness among residents and 87.1% protective among HCP."*

Standing Updates

- CDC Partner Update – April 21 [Attachment]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Updates – April 19 & 20 [Attachments]
    - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]

- The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.

- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

From: Epidemiology and Laboratory Capacity for Infectious Diseases (CD (CDC) <elc@cdc.gov>
Sent: Wednesday, April 21, 2021 2:54 PM
To: Epidemiology and Laboratory Capacity for Infectious Diseases (CD (CDC) <elc@cdc.gov>
Subject: Important information regarding ELC K-12 Reopening Schools- Friday Deadline
Importance: High

This message is being sent via BCC to all ELC Governance Team members and partner organizations of ELC

Greetings,

To respond to questions we have received regarding *ELC Reopening Schools*, we wanted to provide additional clarity on the **two** deliverables due this Friday, April 23rd. These items are:

1. Validation/correction of the 'School District Weekly Reporting Template', pre-populated with school districts in your jurisdiction.
    - This list will be used for reporting starting on April 30th and every week thereafter until June 7th (when reporting requirements will be adjusted).
    - Recipients are not required to submit *any* testing data on April 23rd – just the updated/verified template.
    - The School District Weekly Reporting Template:
        - May be changed, as necessary, to reflect any corrections that need to be made. If no corrections are necessary, no adjustments are required.
        - May list all out non-public institutions separately or rolled up under the "Other" category. This choice is at the discretion of the jurisdiction.
    - To access and submit your template:
        - Go into the 'ELC Reopening Schools: COVID Award' portal;
        - In the 'ELC Reopening Schools Reporting' page;
        - In the 'Reporting Spreadsheet' section;
        - Upload the 'School District Weekly Reporting Template' into the 'Upload Current Reporting Spreadsheet Here' field.
2. A brief narrative of how you plan to partner and provide resources to the districts in your jurisdiction. We realize that everyone is at different stages and is dealing with different environments when it comes to instituting K-12 screening tests. With that in mind, please note that:
    - This narrative should be brief and may be very high-level (i.e., 1 paragraph may be sufficient to broadly describe how districts will be engaged/resourced).
    - The narrative should highlight any real or perceived barriers you anticipate as you roll out screening testing for K-12. Some challenges may be experienced state/jurisdiction-wide, or they may be isolated to particular districts. This information is important for the ELC to collate and provide to leadership.
    - This brief narrative is what is referenced in the guidance in terms of weekly reporting regarding support to school districts. The intent of the weekly reporting is to acknowledge that recipients may not have all the details of their implementation plan in the first 10 day after award issuance.

    - Weekly reporting offers recipients the opportunity to add details and/or modify their approach until the implementation plan is finalized.
    - If there are no subsequent changes, then the plan submitted on April 23rd will be automatically used to meet the weekly reporting requirement.
- To submit your narrative:
    - Go into the 'ELC Reopening Schools: COVID Award' REDCap portal;
    - In the 'ELC Reopening Schools Financial Reporting' page;
    - There are two blank, open-ended boxes for your narrative.

We do not expect that every district in every jurisdiction will be ready to adopt screening testing immediately. During Phase 2/Activity 2, we will ask you to describe your plan for working with the jurisdictions in more specific terms. Recipients will then provide more detailed plans, which can include how they will employ different approaches for different districts, for example, or specific strategies such as incentivizing test (e.g., "test to play/stay/or sway"). We will be evaluating the information we receive regularly and will implement changes to our approach as necessary. As a reminder, these funds should cover the required costs for school districts to run a screening testing program, including follow up on positives.

We may reach out directly or via our partners at CSTE, APHL, ASTHO, and NACCHO to receive input from you along the way.

We appreciate the ongoing partnership with all of you and we understand this is yet another large lift. We are here to help in whatever way we can. We will be sharing FAQs in coming days to provide additional clarity; in the meantime, please don't hesitate to reach out to your ELC Project Officer or leadership with any questions or clarifications.

All the very best,
-The ELC Team

Subject: HHS COVID-19 Update - 4/19

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 19, 2021:

Renewal of Determination That a Public Health Emergency Exists: As a result of the continued consequences of the Coronavirus Disease 2019 (COVID-19) pandemic, on this date (April 15, 2021) and after consultation with public health officials as necessary, I, Xavier Becerra, Secretary of Health and Human Services, pursuant to the authority vested in me under section 319 of the Public Health Service Act, do hereby renew, effective April 21, 2021, the January 31, 2020, determination by former Secretary Alex M. Azar II, that he previously renewed on April 21, 2020, July 23, 2020, October 2, 2020, and January 7, 2021, that a public health emergency exists and has existed since January 27, 2020, nationwide.

Highlights from Friday and Monday's White House COVID-19 Response Team Briefing

Andy Slavitt

- **Vaccine Availability:** Over 80 percent of seniors have had at least their first shot. Fifty percent of adults in the U.S. have had at least one shot. We now have one thing on our mind: making sure that the other 50 percent know how easy it is to get a shot. If you still think it's too difficult your vaccine, here's what you need to know: the lack of supply, the shortage of locations, the confusing rules are all in the past. That cannot be said enough. There are thousands of more people ready to help you get vaccinated. There are now millions more vaccine doses available and waiting. There are now more than 60,000 safe and convenient places for you to get your shot.
- **Expanded Vaccine Eligibility:** If you are 16 or over, it is your turn to get vaccinated no matter where you live. There's a nine out of ten chance that you are located within five miles of your vaccine shot. For those of you who can't get to a vaccine site, we're helping community-based organizations connect vulnerable Americans with shots. And now, to get resources to healthcare providers serving at-risk populations and to promote equitable distribution of vaccines, today HHS is making $150 million available to community-based healthcare providers to strengthen their efforts to get shots in arms and care for patients with COVID-19.
- **Get Vaccinated:** Join the more than 130 million Americans who have already gotten at least one shot, that's half of all adults. Here's my direct plea to everyone listening: If you haven't already made an appointment to get vaccinated, make one right now. You are eligible. Then, reach out to your family, friends, and neighbors to make sure they can make an appointment too. See what help you can offer them to help those who might need extra assistance.
- **American Rescue Plan:** We are announcing a $1.7 billion investment to bolster the ability of the CDC and state and local public health departments to monitor, track, and defeat emerging threats — whether it's COVID-19 variants today or other viruses in the future — through a process known as genomic sequencing. This significant investment, which is made possible due to the American Rescue Plan President Biden signed into law last month, is critical in our fight against the new and potentially dangerous variants of COVID-19. Right now, these variants account for nearly half of all COVID-19 cases in the United States, and we need more capacity in our public health system to identify and track these mutations. This funding will enable CDC and states to do more genomic sequencing as we activate the nation's great research capabilities to detect variants earlier and increase our visibility into emerging threats. This investment will give public health officials the chance to react more quickly to prevent and stop the spread. Today's investment also builds on the major investments in testing and genomic sequencing that we made earlier this year. That includes $10 billion of American Rescue Plan funding to support COVID-19 testing in schools, another $2.5 billion to help state and local public health agencies increase testing capacity in underserved and high-risk communities, and nearly $200 million to begin to increase genomic sequencing capacity that this investment comes on top of.

Dr. Walensky

- **Case Update:** Yesterday, CDC reported nearly 60,950 cases of COVID-19. Our seven-day average is up to over 67,440 per day. For context, one month ago, our seven-day average of cases was just over 53,000 per day. The seven-day average of hospital admissions is about 5,460. Sadly, the seven-day average of daily deaths are now increasing, with six consecutive days of increases, to about 695 deaths per day. Sunday, we again saw almost 700 deaths in a single day.
- **Vaccination Update:** So far, we have administered 209 million vaccine doses, with an average daily administration of more than 3 million doses. This brings us to 192.8 million doses in the first 100 days — 96 percent of our goal in 88 days. This means that almost 40 percent of the total population has received at least one dose of a COVID-19 vaccine, and one out of every four people is fully vaccinated. More than 65 percent of people age 65 and older and more than 25 percent of people are fully vaccinated.
- **Vaccine Effectiveness:** First, among nearly 4,000 healthcare personnel, first responders, and essential workers who received the Pfizer and Moderna vaccines, the risk of any infection, asymptomatic and symptomatic, was reduced by 90 percent after receiving the two recommended doses of the vaccine. This study was yet additional evidence that these vaccines are working. The efficacy we saw in clinical trials is now being shown in the real world. Second, last week, we released data on the number of so-called "breakthrough infections," of people who, despite being vaccinated, still tested positive for COVID-19 more than 14 days after they're getting their second vaccine dose. With any vaccine, we expect such rare cases. But so far, out of more than 84 million people who are fully vaccinated, we have only received reports of less than 6,000 breakthrough cases. Although this number is from 43 states and territories and likely an underestimate, it still makes a really important point: These vaccines are working. Of the nearly 6,000 cases, approximately 30 percent had no symptoms at all. Based on these data, here's the bottom line: Getting a vaccine will help protect you, it will help protect others, and it will help us end this pandemic.
- **Rising Cases and Variants:** Some of these increases are as a result of relaxed prevention efforts in states across the country, such as relaxed mask mandates or loosened restrictions on indoor restaurant seating. Another reason for these increases is the continued spread of highly transmissible variants — more than 50 to 70 percent more transmissible — which makes the race to stop the transmission even more challenging and threatens to overwhelm our healthcare system again in parts of this country. CDC data show that the B117 variant — the variant originally identified in the United Kingdom — represents 44 percent of the virus circulating during the week of March 27th.
- **Johnson & Johnson Update:** After the press briefing on Wednesday (4/14), the Advisory Committee on Immunization Practices — or

ACIP — met to discuss the six cases and provide recommendations. I want to thank the ACIP for their thoughtful discussion and their commitment to the science. The recommendation from this group of independent experts for a continued pause will allow additional time to review any additional cases that might come in, and for them to conduct a complete risk assessment and to evaluate the emerging science. ACIP will meet again this Friday, April 23rd, from 11:00 to 5:00 to provide further recommendations.

Dr. Fauci

- **Vaccine Efficacy in Clinical Trials:** This is work that has been done in tens of thousands of people in clinical trials, has been peer reviewed independently, and published in scientific journals. Pfizer and Moderna's efficacy are shown in the New England Journal of Medicine papers. The same holds true for J&J. All three are highly efficacious in clinical trials.
- **Vaccine Efficacy in Real-World Settings:** In over 23,000 employees at the University of Texas, the infection rate was miniscule among vaccinated employees: 0.05 percent. The CDC — looking, again, at the real-world effectiveness — showed that in almost 80,000 person-days with full immunization, 0.04 per 1,000 person-days.
- **Vaccine Safety:** We have an extraordinary capability to monitor safety, as an extremely rare adverse event of 6 individuals among 7,000 was picked up by the surveillance system. Those surveillance systems include ones that follow up on clinical trials, monitoring systems by the CDC, by the FDA, and other monitoring systems. When we say a vaccine is safe, you're talking about an exquisitely sensitive monitoring system.
- **NIH-sponsored Coronavirus Disease 2019 Treatment Guidelines Panel:** This is a panel of individuals co-chaired by Dr. Cliff Lane, who is the Deputy Director of NIAID, but also the Clinical Director of the Institute; Henry Masur, who is the Director of the Critical Care Medicine Unit at NIH; and Roy "Trip" Gulik, who is the Chief of Infectious Diseases at Weill Cornell Medicine in New York City. This panel was established to be able to work, literally in real time, updating guidelines for clinicians and healthcare providers throughout the country and the world on the latest information.

Dr. Murthy

- **American Indians and Alaska Natives:** According to a recent CDC report, American Indians and Alaska Natives were 3.5 times more likely to get COVID than a non-Hispanic, white population. Native people are also more than four times likely to be hospitalized as a result of COVID-19. Despite these challenges, our colleagues working in the Indian health system have heroically administered more than 1 million doses of COVID-19 vaccines. That is a remarkable achievement and a testament to their dedication. Today, the Biden administration is doubling down on this critical work with a — with a $4 billion investment from the American Rescue Plan to the Indian Health Service Tribal and urban Indian health programs. Specifically, these funds will support the following: expanded COVID-19 vaccinations, including mobile efforts, large-scale vaccination events, and public education and outreach campaigns; expanded testing, contact tracing, PPE access, and treatment; increased preventive health services for those at higher risk for COVID-19; and increased support for telehealth, the healthcare workforce, and the broader Indian healthcare system, which has been a hard hit during the pandemic due to lost reimbursements for care for both public and private insurance.
- **Increasing Access and Increasing Confidence:** The more people see those around and get vaccinated, particularly family and friends, the more comfortable they become with getting vaccinated themselves. The easier we make it to get vaccinated, the more people will get vaccinated, and that means more people around them would feel comfortable with getting vaccine themselves. That's why access and confidence go hand in hand, and so does safety. This brings me to the second topic. This week you've heard a lot from us about the pause with administering the Johnson & Johnson COVID-19 vaccine. These decisions are never simple, and this one was taken after a very careful assessment of the risks and benefits of calling for such a pause. However, the actions taken by CDC and the FDA this week should give Americans confidence that our safety system is working for them. For some members of the public, uncertainty about getting vaccinated stems from questions about how safe the vaccines are. This week is a reminder that safety is our top priority. Even when an extremely rare safety occurs, our scientific agencies will act with thoroughness and transparency so people can remain confident in the vaccines that are recommended to them.

Vaccine Updates

Vaccine Eligibility: CDC updated the following COVID-19 information pages to include that everyone 16 years of age and older is now eligible to get a COVID-19 vaccine: Vaccine FAQs, How Vaccines Get to You, Key Things to Know, and Vaccine Rollout Recommendations. CDC also updated the following information pages for specific communities to include the expanded eligibility of the COVID-19 vaccine: persons with disabilities, essential workers, healthcare personnel, older adults, and those high risk for severe illness. Get a COVID-19 vaccine as soon as you can. Moreover, CDC updated their general vaccination resources, including information on preparing for your vaccine.

Moderna Vaccine Update: The FDA updated their Moderna COVID-19 Vaccine Frequently Asked Questions page. On December 18, 2020, the U.S. Food and Drug Administration issued an emergency use authorization for the second vaccine for the prevention of coronavirus disease 2019 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). The emergency use authorization allows Moderna COVID-19 Vaccine to be distributed in the U.S for use in individuals 18 years of age and older.

Johnson & Johnson Update: On April 13, 2021, CDC and FDA recommended a pause in the use of Johnson & Johnson's Janssen COVID-19 Vaccine. Of the nearly 7 million doses administered so far in the United States, a small number of reports of a rare and severe type of blood clot have been reported in people after receiving the J&J/Janssen COVID-19 Vaccine. All reports occurred among women between the ages of 18 and 48, and symptoms occurred six to 13 days after vaccination. As of April 13, 2021, of the more than 180 million doses administered so far of the Pfizer-BioNTech or Moderna vaccines, no reports matching those associated with the J&J/Janssen vaccine have been received.

FEMA's J&J Update: In alignment with the recommendation from the CDC and FDA to pause the use of the Johnson & Johnson vaccine, FEMA immediately ceased administration of these doses at our federal community vaccination center pilot sites and mobile vaccine units. This pause will continue until further guidance is received from CDC and FDA. We are working with our state partners to determine the path forward and find alternative vaccine options for these sites.

FEMA Vaccination Sites: There are 31 active or temporarily closed federal community vaccination center pilot sites and 20 mobile pop-up sites in 22 states. Additionally, there are 10 mobile vaccination units deployed to eight states. These centers and units have administered more than 3.4 million vaccinations. Working with state governments FEMA will open additional federal community vaccination center pilot sites, which include federal support and supplemental vaccine allocation: this week, federal community vaccination center pilot sites are scheduled to open in Bessemer, Alabama; Tulsa, Oklahoma; and Central Point, Oregon. Last week, FEMA transitioned management of the federal community vaccination center pilot sites in Los Angeles and Oakland to the state. FEMA continues to support both sites with federal personnel. Additionally, FEMA has obligated more than $936 million to support the state's vaccination efforts. These sites administered more than 671,000 shots since they opened on Feb. 16. FEMA mobile vaccination units have begun operations. These vehicles can bring vaccinations to hard-to-reach and high-risk populations who cannot access services from fixed sites. Ten mobile vaccination units are currently deployed to Connecticut, Maine, Maryland, Nebraska, Nevada, New Mexico, Oregon and South Dakota.

DoD Response to J&J Pause: In a press briefing on Friday, Pentagon Press Secretary John F. Kirby stated that while the DoD intended to use the Johnson & Johnson vaccine to support overseas personnel and their families, the vaccine distribution planners on our COVID task force developed a plan to reallocate doses of the Moderna vaccine to our overseas commands. Each service will now direct a total of approximately 30,000 additional doses of Moderna throughout the month of May. That's around roughly 10,000 per week, beginning May 10th, to overseas locations in European Command, Indo-Pacific Command and Central Command. This will help keep the vaccination efforts right on pace to provide initial doses to over 70 percent of our overseas personnel and their families by the end of May.

COVID-19 Illness After Vaccination: CDC released information regarding what you should know about the possibility of COVID-19 illness after vaccination. COVID-19 vaccines are effective. However, a small percentage of people who are fully vaccinated will still get COVID-19 if they are exposed to the virus that causes it. These are called "vaccine breakthrough cases." This means that while people who have been vaccinated are much less likely to get sick, it may still happen. Experts continue to study how common these cases are.

CDC Weekly Review: On Friday, CDC released their weekly review on the COVID-19 pandemic, including updated numbers of reported cases, SARA-CoV-2 variants, testing, vaccinations, hospitalizations, and deaths. Nationally, COVID-19-related emergency department visits as well as both hospital admissions and current hospitalizations have risen among patients ages 18 to 64 years in recent weeks. The good news is that emergency department visits and hospitalizations among people ages 65 years and older have decreased, likely demonstrating the important role vaccination plays in protecting against COVID-19. As access to vaccines for all Americans increases, we have reason to be hopeful. However, until more of the U.S. population is fully vaccinated, consistent use of prevention strategies, such as universal and correct use of masks, social distancing, and hand washing, will help to limit the spread of SARS-CoV-2, the virus that causes COVID-19. Even if you have been fully vaccinated against COVID-19, you should keep taking these everyday precautions in public places. For more information, view the CDC's data on vaccinations, vaccination demographics, and vaccination trends.

Operational Considerations for Jurisdictions Planning to Operate COVID-19 Vaccination Clinics: CDC released guidance for jurisdictions planning to operate COVID-19 vaccinations clinics. Safe and effective COVID-19 vaccines have been developed and authorized and are being manufactured. Jurisdictions are presently vaccinating people in their target populations. Currently, vaccine is available in growing quantities, with even more vaccine slated to become available soon. Most jurisdictions can provide access to vaccination using a combination of usual vaccination providers (pharmacies and medical providers/community health centers) and a limited number of public health clinics. Many jurisdictions are planning for and operating multiple, temporary, large- and small-scale vaccination sites, both fixed location and mobile, as strategies to vaccinate more of the population rapidly. The Federal Emergency Management Agency (FEMA) is working with jurisdictions to establish Community Vaccination Centers (CVCs). These CVCs can be established as fixed facilities, drive-through facilities, or as mobile vaccination clinics based on a jurisdiction's needs.

ACIP Jurisdictions Estimated Worker Population: CDC updated their information from the Advisory Committee on Immunization Practices (ACIP) regarding vaccination data among different worker populations.

Testing and Treatment

FDA Revokes EUA for Monoclonal Antibody Bamlanivimab: On Friday, the FDA revoked the emergency use authorization (EUA) that allowed for the investigational monoclonal antibody therapy bamlanivimab, when administered alone, to be used for the treatment of mild-to-moderate COVID-19 in adults and certain pediatric patients. Based on its ongoing analysis of emerging scientific data, specifically the sustained increase of SARS-CoV-2 viral variants that are resistant to bamlanivimab alone resulting in the increased risk for treatment failure, the FDA has determined that the known and potential benefits of bamlanivimab, when administered alone, no longer outweigh the known and potential risks for its authorized use. Therefore, the agency determined that the criteria for issuance of an authorization are no longer met and has revoked the EUA. Instead of administering Bamlanivimab alone, health care providers should consider using the other authorized monoclonal antibody therapies expected to retain activity against the viral variants: Casirivimab and imdevimab, administered together, and Bamlanivimab and etesevimab, administered together.

FDA Testing Update: As of Friday, 363 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 266 molecular tests and sample collection devices, 75 antibody and other immune response tests, and 22 antigen tests. There are 46 molecular authorizations and one antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home tests, four over-the-counter (OTC) at-home antigen tests, and two OTC molecular tests. The FDA has authorized 7 antigen tests and 2 molecular tests for serial screening programs. The FDA has also authorized 457 revisions to EUA authorizations.

Funding

$150 Million from ARP to Support Community-Based Health Care Providers: HHS announced the availability of nearly $150 million to community-based health care providers to aid their response to COVID-19. These funds will support approximately 100 Health Center Program look-alikes to respond to and mitigate the spread of COVID-19, strengthen vaccination efforts, and enhance health care services and infrastructure in communities across the country. Health center look-alikes (LALs) are community-based health care providers that provide essential primary care services to underserved communities and vulnerable populations but are not Health Center Program grantees. This funding will be made available through the Health Resources and Services Administration (HRSA) and is part of President Biden's commitment to ensuring equity in the nation's COVID-19 response and vaccination efforts.

Biden Administration Announces $1.7 Billion Investment to Fight COVID-19 Variants: In order to improve the detection, monitoring, and mitigation of COVID-19 variants, the Biden Administration is rapidly investing $1.7 billion from the American Rescue Plan to help states and other jurisdictions more effectively fight these mutations. An essential component of the response to the emerging COVID-19 variants is increasing the country's genomic sequencing — the process by which COVID DNA is decoded and potentially deadly mutations in the virus are detected. With this funding, allocated through the Centers for Disease Control and Prevention (CDC), will help the CDC, states, and other jurisdictions more effectively detect and track variants by scaling genomic sequencing efforts. With the information from sequencing, the CDC and state and local public health leaders can implement known prevention measures to stop the spread.

Biden Administration Invests $4 Billion in ARP Funding to Combat COVID-19 in Indian Country: As part of President Biden's continued efforts to ensure the pandemic response reaches all people and all communities, the Biden Administration is announcing it will invest more than $4 billion to combat COVID-19 in Indian Country. The funding, from the American Rescue Plan, will expand COVID-19 vaccinations, testing, and treatment; increase preventive health services to American Indians and Alaska Natives at higher risk for COVID-19; expand hospitals' and health clinics' ability to serve their communities during the pandemic and beyond; and provide the Indian Health Service (IHS), tribal health programs, and urban Indian health programs with needed funding to make up for lost reimbursements experienced during the pandemic.

FEMA Funeral Assistance Funding: As of today, FEMA has received more than 101,000 funeral assistance applications. Applicants may apply by calling 844-684-6333 (TTY: 800-462-7585) from 9 a.m. to 9 p.m. ET, Monday through Friday. Multilingual services are available. Callers who use a relay service, videophone or captioned telephones should provide their specific number assigned to that service. It is important that FEMA is able to contact applicants. Please note, phone calls from FEMA may come from an unidentified number. FEMA will not contact anyone until they have called FEMA or have applied for assistance.

Reopening Guidance

Personal and Social Activities: CDC updated their information on engaging in personal and social activities. COVID-19 cases, hospitalizations, and deaths are extremely high across the United States. To decrease your chance of getting and spreading COVID-19, CDC recommends that you do not gather with people who do not live with you at this time. Attending events and gatherings increases your risk of getting and spreading COVID-19. Stay home to protect yourself and others from COVID-19.

Travel Health Notices: CDC updated their travel health notices to provide current risk assessment levels for COVID-19 in different countries.

Considerations for Casinos and Gaming Operations: As some casinos and gaming operations resume in some areas of the United States, CDC offers the following considerations for ways in which casino and gaming operators can help protect staff and customers and slow the spread of COVID-19. Casinos and gaming operations can determine, in collaboration with local, state, territorial, federal, or tribal health officials, whether and how to implement these considerations, making adjustments to meet the needs and circumstances of the local community. Implementation should be guided by what is feasible, practical, acceptable, and tailored to the needs of each community. For more information on bars and restaurants within casinos, please see CDC's Considerations for Restaurants and Bars. These considerations are meant to supplement—not replace—any local, state, territorial, federal, or tribal safety laws, rules, or regulations with which businesses must comply.

Community-Based Organizations: CDC updated their guidance for community-based organizations (CBOs). As some CBOs begin to resume or increase their level of activities, CDC offers considerations for ways these organizations can help protect individuals and communities and slow the spread of coronavirus disease 2019 (COVID-19). COVID-19 cases, hospitalizations, and deaths are extremely high across the United States. To decrease your chance of getting and spreading COVID-19, CDC recommends that you do not gather with people who do not live with you at this time. Attending events and gatherings increases your risk of getting and spreading COVID-19. Stay home to protect yourself and others from COVID-19.

Considerations for Institutions of Higher Education: CDC updated their guidance for institutions of higher education (IHEs). As some IHEs prepare to re-open or keep open in-person learning in the United States, IHEs are faced with the challenge of keeping students, faculty, staff, and volunteers safe due to the coronavirus disease 2019 (COVID-19) pandemic. CDC offers the following considerations for ways that IHEs can help protect students and employees (e.g., faculty, staff, and administrators) and slow the spread of COVID-19. This document refers only to risks related to COVID-19. IHEs may consider implementing several strategies to maintain healthy environments.

Information for Specific Populations

USDA Activities to Contain the COVID-19 Pandemic: The United States Department of Agriculture (USDA) updated their fact sheet on activities to contain the COVID-19 pandemic. USDA has deployed 1,064 disaster, public health specialists to assist with federal response.

Guidance for Large or Extended Families Living in the Same Home: CDC released guidance for large or extended families living in the same home. If you or someone in your household is at increased risk for severe illness from COVID-19, then all family members should act as if they are at increased risk. This can be difficult if space is limited for large or extended families living together. While avoiding close contact with others and isolating someone who is sick can feel lonely, these actions are necessary to reduce the spread of COVID-19 and protect yourself and your household.

DoD Force Health Protection Guidance: On Friday, the Department of Defense released the memorandum for Force Health Protection Guidance (Supplement 20) – Department of Defense Guidance for Personnel Traveling During the Coronavirus Disease 2019 Pandemic. This memorandum applies to official and unofficial travel and proves updated pre- and post-travel guidance for purposes of force health protection (FHP) for Service members, DoD family members, DoD civilian employees, and DoD contractor personnel, as well as fully vaccinated individuals.

Staffing Resources: CDC updated their staffing resources and guidance to strengthen the public health workforce. CDC updated their information regarding the number of CDC COVID-19 response staff deployed across America.

Cleaning, Disinfecting, and Ventilation: CDC updated their resources for cleaning, disinfecting, and ventilation, including an updated toolkit for school administrators on cleaning, disinfection, and hand hygiene. Reducing the risk of exposure to SARS-CoV-2, the virus that causes COVID-19, by cleaning and disinfection is an integral part of opening schools that will require careful planning.

Childhood Vaccination Toolkit for Clinicians: CDC released a toolkit for clinicians on getting children caught up on receiving recommended vaccinations. COVID-19 disrupted both in-person learning and routine well-child visits for many children over the last year. As a result, too many children have fallen behind on receiving recommended vaccines. Children need to get caught up now so that they are protected as they go back to in-person learning and summer camps. Healthcare providers can identify families whose children have missed doses and contact them to schedule appointments. Providers can also let families know what precautions are in place for safe delivery of in-person services.

Health Departments and Public Safety Partners: CDC updated their information for health departments and public health partners to help educate communities and promote COVID-19 vaccination.

Manufacturing Workers & Employers: CDC and the Occupational Safety and Health Administration (OSHA) updated their guidance for manufacturing workers and employers.

Acute Care Delivery at Home Tip Sheet: HHS ASPR Technical Resources, Assistance Center, and Information Exchange (TRACIE) released a tip sheet providing an overview of characteristics of various types of acute care delivery at home programs to help healthcare providers better understand this care model. Some healthcare providers and systems have been providing hospital-level care in patient's homes for years; others have implemented acute care delivery at home models in response to overcrowding at hospitals due to COVID-19.

COVID-19 and Healthcare Professional Stress and Resilience: HHS ASPR Technical Resources, Assistance Center, and Information Exchange (TRACIE) released Issue 12 of The Exchange, which examines the impact of COVID-19 on healthcare professionals. The issue focuses

on three categories: understanding acute and chronic stressors in the healthcare worker population, identifying at-risk employees, and promising practices in building resilience.

COVID-19 Healthcare Delivery Impacts: HHS ASPR Technical Resources, Assistance Center, and Information Exchange (TRACIE) updated their tip sheet to help healthcare system planners prepare to mitigate potential healthcare delivery impacts.

Strategies to Help Combat the Coronavirus Blues: The COVID-19 Schools Task Force, FEMA Region VII, and HHS Region 7 released a document summarizing the contents of the Mind Over Matter Resource Guide. This guide can be used to support messaging for college and university campus communities to help combat COVID-19 fatigue and promote general wellness, both during and after the pandemic.

Temporary Halt in Residential Evictions to Prevent the Further Spread of COVID-19: On April 2, 2021, the CDC released a declaration determining that the eviction of tenants could be detrimental to public health control measures to slow the spread of COVID-19. View the posted order, as well as eviction protection declaration forms in English and Spanish. Please visit HUD's COVID-19 Emergency Information for Housing Counselors for additional resources and information.

United States Coast Guard Vaccine FAQs: The United States Coast Guard updated their Frequently Asked Questions page about the vaccine, and specific questions related to Coast Guard administered vaccines.

Older Adults: CDC updated their information for older adults, who are at a greater risk of hospitalization or dying if diagnosed with COVID-19. The risk for severe illness with COVID-19 increases with age, with older adults at highest risk. If you have a family member or friend who lives in a nursing home, assisted living facility, or other type of senior living or retirement community, you may be concerned about COVID-19. To protect friends and family members who live in these communities, CDC has issued updated recommendations for visitations at post-acute facilities. These recommendations align with the Centers for Medicare and Medicaid Services (CMS) guidance for visitations under various circumstances.

Caring for Someone Sick: CDC updated their guidance for caregivers in non-healthcare settings. Cleaning with a household cleaner that contains soap or detergent reduces the amount of germs on surfaces and objects and decreases risk of infection from surfaces. In most situations, cleaning alone removes most virus particles on surfaces.

People at Increased Risk: CDC updated their resources available for people at increased risk, and for other people who need to take extra precautions.

Non-Emergency Transportation for Tribal Communities: CDC updated their guidance on non-emergency transportation for tribal communities. Tribal community members may need to regularly share personal vehicles with members outside of their own households. They may also need to use personal vehicles to transport people who are visibly sick. In addition, tribal organizations may provide medical transportation to their community members using non-emergency vehicles (cars or vans, for example). CDC outlines precautions that can be considered to minimize risk of spreading COVID-19 when sharing personal vehicles.

Implementing Screening and Treatment of Unhealthy Alcohol Use During COVID-19: The Agency for Healthcare Research and Quality (AHRQ) posted an article on implementing screening and treatment of unhealthy alcohol use during COVID-19. Since the onset of the COVID-19 pandemic in March 2020, alcohol sales have increased dramatically in many States across the country and rates of unhealthy alcohol use are rising in parallel. Unhealthy alcohol use, which refers to the full spectrum of alcohol misuse from risky or hazardous drinking to alcohol use disorder, is associated with adverse consequences, including poorer physical and mental health outcomes as well as negative socioeconomic effects. AHRQ's EvidenceNow: Managing Unhealthy Alcohol Use Initiative represents an important opportunity to help clinicians support many patients receive the appropriate diagnosis, counseling, and treatment for unhealthy alcohol use by implementing the best patient-centered outcomes research findings available to improve health.

Sprayers Safety Precautions: CDC updated their information regarding how to select cleaners, disinfectants, and application methods for use in facilities, businesses, and public indoor spaces to ensure that you can clean and disinfect safely and effectively. In most situations, cleaning surfaces (using soap or detergent) is enough to reduce SAR-CoV-2, the virus that causes COVID-19. Clean surfaces before disinfecting.

CMS Updates

Encouraging Latino Consumers to Enroll in Health Insurance Coverage: Today, HHS Secretary Xavier Becerra announced commitments from national organizations to support Latino outreach and enrollment efforts during the current Special Enrollment Period (SEP) made available on HealthCare.gov by President Biden due to the COVID-19 Public Health Emergency (English | Spanish). As part of the Latino Week of Action April 18 - 24, these organizations and HHS will share information with Latino consumers and use social media to encourage them to enroll in affordable, quality health plans through HealthCare.gov. Access to affordable health coverage and care is particularly important for Latinos in the US because 22% of non-elderly Latinos are uninsured, a rate almost 2.5 times that of White Americans. During this week and beyond, HHS and many organizations will send targeted messages, participate in earned media opportunities, and amplify the SEP through social media channels to raise awareness about the coverage options available through HealthCare.gov for the Latino community. The Centers for Medicare & Medicaid Services (CMS) has also launched an outreach and an educational campaign, which includes broadcast and digital advertising and educates through email and text messages in both Spanish and English.

PPE

Guidance for Wearing Masks: CDC updated their guidance for wearing masks. Masks are a simple barrier to help prevent your respiratory droplets from reaching others. Studies show that masks reduce the spray of droplets when worn over the nose and mouth. CDC also updated their information on the different types of masks. CDC recommends that N95 respirators should be prioritized for protection against COVID-19 in healthcare settings. Essential workers and workers who routinely wore respirators before the pandemic should continue wearing N95 respirators. As N95s become available they can be worn in non-healthcare settings.

Research

Large Clinical Trial to Study Repurposed Drugs to Treat COVID-19 Symptoms: The NIH will fund a large, randomized, placebo-controlled Phase 3 clinical trial to test several existing prescription and over-the-counter medications for people to self-administer to treat symptoms of COVID-19. Part of the Accelerating COVID-19 Therapeutic Interventions and Vaccines (ACTIV) public–private partnership, the ACTIV-6 trial aims to provide evidence-based treatment options for the majority of adult patients with COVID-19 who have mild-to-moderate symptoms and are not sick enough to be hospitalized. NIH will provide an initial investment of $155 million in funding for the trial.

Experimental Antiviral for COVID-19 Effective in Hamster Study: The experimental antiviral drug MK-4482 significantly decreased levels of virus and disease damage in the lungs of hamsters treated for SARS-CoV-2 infection, according to a new study from NIH scientists. SARS-CoV-2 is the virus that causes COVID-19. MK-4482, delivered orally, is now in human clinical trials. Remdesivir, an antiviral drug already approved by the U.S. Food and Drug Administration for use against COVID-19, must be provided intravenously, making its use primarily limited to clinical settings. In their study, published in the journal *Nature Communications*, the scientists found MK-4482 treatment effective when provided up to 12 hours before or 12 hours after infecting the hamsters with SARS-CoV-2. These data suggest that MK-4482 treatment potentially could mitigate high-risk exposures to SARS-CoV-2 and might be used to treat established SARS-CoV-2 infection alone or possibly in combination with other agents.

Public Health Investigations of COVID-19 Vaccine Breakthrough Cases: CDC released a case investigation protocol on public health investigations of COVID-19 vaccine breakthrough cases. The U.S. Food and Drug Administration (FDA) has issued Emergency Use Authorization (EUA) for three COVID-19 vaccines. In large, randomized controlled trials, each vaccine was safe and efficacious for preventing symptomatic, laboratory-confirmed COVID-19 disease. There were no statistically significant differences in efficacy by age, gender, race, or comorbidities. Despite the high level of efficacy, a small number of breakthrough cases occurred. The phase 3 studies have not yet identified risk factors for vaccine breakthrough cases; however, approximately 44,000 people received the FDA-authorized vaccines during the clinical trials and follow-up is ongoing. This protocol can be used to guide public health investigations of COVID-19 vaccine breakthrough cases. We aim to capture both symptomatic and asymptomatic infections. Characterization of vaccine breakthrough cases could provide the first indication that a vaccine is less effective in certain demographic groups or that vaccine-induced immunity is waning, and booster doses may be needed. Clustering of cases among vaccinated persons by time, geographic area, or lot could help identify an issue in manufacturing, shipping, handling, or administration. Evaluating SARS-CoV-2 strains that cause vaccine breakthrough cases provides one way to monitor for variant strains that could result in lower vaccine efficacy.

COVID-19 and the Changing Healthcare Delivery Landscape: HHS ASPR Technical Resources, Assistance Center, and Information Exchange (TRACIE) released a study highlighting the impact of COVID-19 on healthcare delivery. The study examines supply chain, patients delaying emergency care, the delay of elective procedures, and financial impacts to the healthcare system.

COVID-19 Science Update: CDC released their weekly COVID-19 Science Update. This week's issue includes, but is not limited to, research on the following: the association of sociodemographic factors and blood group type with risk of COVID-19, increased household secondary attack rates with variants of concern**,** and the epidemiologic evidence for airborne transmission of SARS-CoV-2 during church singing.

Hospitalization and Death by Race/Ethnicity: CDC updated their information on hospitalization and death rates by race/ethnicity. Race and ethnicity are risk markers for other underlying conditions that affect health including socioeconomic status, access to health care, and exposure to the virus related to occupation, e.g., frontline, essential, and critical infrastructure workers.

Marvin Figueroa, Director
Office of Intergovernmental and External Affairs
U.S. Department of Health and Human Services
Washington, D.C.

From: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Sent: Tuesday, April 20, 2021 6:45 PM EDT
To: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Subject: HHS COVID-19 Update - 4/20

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 20, 2021:

Case Update

New Cases (based on 7-day rolling average)
- **31,484,148** US cases
- **3% decrease** in new cases (7-day average), as of April 19; (was 8% increase last week)

Testing
- **399,891,811** tests completed (4/19)
- **6%** positive test rate as of the week of 4/13– 4/19 (was 5.5% last week)

Hospitalizations
- **2,048,742** total COVID hospital admissions
- The 7-day average (4/13-4/19) number of new confirmed COVID-19 admissions **decreased by 3%** week on week (from 5,493 to 5,341 admissions per day)

Deaths
- **564,292** total US deaths
- The 7-day average (4/13-4/19) number of reported deaths **increased by 3%** week on week (from 673 to 692 deaths per day)

Vaccines
- **211,581,309** vaccine doses **administered** (4/19)
- **39.9%** (132.3 million people) of the population has received **1 or more doses** and **25.7%** (85.4 million people) of the population have been **fully vaccinated**
- **80.1%** of adults 65 and older have received **at least 1 dose** and **64.9%** have been **fully vaccinated**

Vaccine Updates

Percent of Doses Administered: CDC updated their information on the percent of COVID-19 vaccine doses administered. The majority of U.S. states and territories have administered at or above 85% of their first vaccine doses delivered. To maintain inventory, some vaccine will always be kept in supply; so percentages are not expected to reach 100%.

Reported Adverse Events: CDC and FDA have recommended a pause in the use of Johnson & Johnson's J&J/Janssen COVID-19 Vaccine in the United States out of an abundance of caution, effective Tuesday, April 13. The Advisory Committee on Immunization Practices (ACIP) will hold its second emergency meeting to discuss J&J/Janssen COVID-19 Vaccine on April 23, 2021. People who have received the J&J/Janssen COVID-19 Vaccine within the past three weeks who develop severe headache, abdominal pain, leg pain, or shortness of breath should seek medical care right away.

ACIP Meeting Recording: CDC released the recording of the Advisory Committee on Immunization Practices (ACIP) meeting that was held on April 14, 2021 following the pause of the Johnson & Jonson COVID-19 vaccine. The meeting provides an overview of safety with Janssen's COVID-19 vaccine (Ad26.COV2.S), an update on thromboembolic events, an update on COVID-19 vaccines safety surveillance, VaST assessments, and work group interpretations.

V-safe Pregnancy Registry: CDC updated their information on the v-safe pregnancy registry. As of April 19, 2021, more than 94 thousand v-safe participants have indicated they were pregnant at the time they received COVID-19 vaccination. CDC is currently enrolling eligible participants and analyzing data to better understand how COVID-19 vaccination affects pregnant people. As CDC learns more about the effects of vaccination during pregnancy, data will be presented at the Advisory Committee on Immunization Practices (ACIP) meetings, which are open to the public, and in published reports.

COVID-19 Community Corps: The HHS COVID-19 public education campaign is a national initiative to increase public confidence in and uptake of COVID-19 vaccines while reinforcing basic prevention measures such as mask wearing and social distancing. Specifically, the COVID-19 Community Corps works to engage with a broad range of groups and individuals, including trusted community organizations, local leaders, and others sharing the goal of increasing vaccine confidence and uptake. Join the COVID-19 Community Corps here, and view their resources, toolkits, and information on how to communicate with others about protecting themselves and their communities.

Testing and Treatment

FDA Testing Update: As of today, 367 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 269 molecular tests and sample collection devices, 75 antibody and other immune response tests, and 23 antigen tests. There are 49 molecular authorizations and one antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home tests, four over-the-counter (OTC) at-home antigen tests, and two OTC molecular tests. The FDA has authorized 8 antigen tests and 2 molecular tests for serial screening programs. The FDA has also authorized 462 revisions to EUA authorizations.

Funding

$12.7 Million to Programs Enhancing Health Care Delivery to Rural Underserved Populations: Today, the Health Resources and Services Administration (HRSA) announced more than $12.7 million in funding to 61 public, private and non-profit entities across 35 states to serve rural

communities and address rural health disparities as part of its community-based Rural Health Care Services Outreach Program (Outreach Program). The Outreach Program expands and improves health services for rural residents by supporting innovative and evidence-based approaches tailored to the specific needs of local communities. For the first time, funds will go toward supporting the Healthy Rural Hometown Initiative (HRHI) to address underlying factors that drive rural health disparities related to the five leading causes of avoidable death (heart disease, cancer, unintentional injury, chronic lower respiratory disease, and stroke).

Reopening Guidance

Personal and Social Activities: CDC updated their information on how to safely go about personal and social activities . The page outlines guidance for visiting a restaurant or bar, hosting gatherings or cook-outs, attending an event or gathering, using gyms or fitness centers, going to a nail salon, visiting a library, traveling overnight, and visiting parks. Attending events and gatherings increases your risk of getting and spreading COVID-19. Stay home to protect yourself and others from COVID-19.

Safer Travel Ideas: CDC recommends delaying travel until you are able to get fully vaccinated. Even if you are fully vaccinated, choose safer travel options to protect yourself, your loved ones, and others from COVID-19.

Communication Resources for Travelers: CDC's public health messaging system offers up-to-date messages to travelers at specific airports, seaports, and land borders where most international travelers enter or leave the United States.

Crew Disembarkations Through Commercial Travel: CDC is committed to helping cruise lines provide for the safety and well-being of their crew members while onboard cruise ships and as they disembark. CDC is allowing crew members to disembark from all cruise ships in U.S. waters with certain precautions. Cruise lines with complete and accurate response plans are able to use commercial travel to disembark crew members from certain ships if the ships meet certain criteria set by CDC. Criteria include no confirmed cases of coronavirus disease 2019 (COVID-19) or COVID-19-like illness onboard the ship within the last 14 days. These ships are also able to lessen certain social distancing restrictions onboard. Cruise lines with complete and accurate COVID-19 response plans but not meeting the above criteria will still be able to disembark their crew members using noncommercial travel. Cruise lines must have measures in place to ensure those involved in transport are not exposed to the virus that causes COVID-19 and follow all CDC requirements to prevent interaction of disembarking crew with the public. Additionally, CDC recommends that all eligible port personnel and travelers (passengers and crew) get a COVID-19 vaccine when one is available to them.

Information for Specific Populations

DoD COVID-19 Vaccine Availability: As of yesterday, any adult in DoD can get a COVID-19 vaccine if they want one. That includes military personnel, adult dependents, retirees and civilians. To help ensure military personnel and their families stationed overseas are taken care of, the military services are getting an additional 31,500 doses of the Moderna vaccine for use at locations within the U.S. European Command. On the other side of the globe, an additional 30,000 doses of the Moderna vaccine are targeted at locations within both the U.S. Indo-Pacific Command and the U.S. Central Command. Pentagon Press Secretary Kirby said that by the end of May, over 80% of overseas personnel should have received initial doses of the COVID-19 vaccine. The Defense Department has outpaced the national average in administration of the vaccine it's received. Of the more than 3 million doses of vaccines it's received, more than 2.5 million have been administered.

DLA Prepared to Increase Overseas Vaccine Distribution: The Defense Logistics Agency (DLA) is helping military health officials prepare for a surge in COVID-19 vaccinations available to the Defense Department starting this month. The department expects to begin receiving about 390,000 doses weekly — up from an average of 155,500 a week — with DLA continuing to receive, pack, ship and track vaccines for individuals outside the continental U.S. or deployed with the Navy.

Considerations for Retirement Communities and Independent Living Facilities: CDC offers considerations for ways in which administrators of retirement communities and independent living facilities can help protect residents, workers, visitors, and communities and slow the spread of COVID-19. These considerations are for administrators of retirement communities and independent living facilities that are not healthcare facilities. Learn more about guidance for long-term care facilities (LTCFs) that offer medical services (e.g., nursing homes, skilled nursing facilities, assisted living facilities, day care programs for older adults).

Talking to Your Close Contacts if You Have COVID-19: CDC updated their information on how to talk to you close contacts if you have COVID-19. People diagnosed with COVID-19 can still spread the virus even if they don't have any symptoms. If you have COVID-19, stay home, wear a mask and socially distance in your home, and notify your close contacts.

People at Increased Risk: CDC updated their guidance for people at increased risk, and other people who need to take extra precautions. Some people are more likely than others to become severely ill. Severe illness means that a person with COVID-19 may need hospitalization, intensive care, a ventilator to help them breathe or they may even die. People at increased risk, and those who live or visit with them, need to take precautions to protect themselves from getting COVID-19.

Elections and Voting: CDC updated their guidance for election polling locations and voters. Specifically, CDC updated their information on cleaning and disinfecting. Cleaning with products containing soap or detergent reduces germs on surfaces and objects by removing contaminants and may also weaken or damage some of the virus particles, which decreases risk of infection from surfaces. Cleaning high touch surfaces and shared objects once a day is usually enough to sufficiently remove virus that may be on surfaces unless someone with confirmed or suspected COVID-19 has been in your facility. For more information on cleaning your facility regularly and cleaning your facility when someone is sick, see Cleaning and Disinfecting Your Facility.

Research

New Streamlined Approach for Serial Testing Programs: Today, the FDA took steps to further facilitate the authorization of molecular tests for screening asymptomatic individuals using pooled anterior nasal respiratory specimens in serial testing programs. The FDA issued an amendment for many molecular diagnostic COVID-19 tests that had received an emergency use authorization (EUA). If a test developer has self-certified it has validated its test for pooling, FDA will add that test to a list of tests that can be used for pooling nasal specimens as part of a serial testing program. Pooling, the process of combining multiple specimens together to more quickly test groups of people for SARS-CoV-2, can be an efficient approach for a serial testing program that tests many people on a routine basis. The flexibility that the FDA has provided developers continues to be a hallmark of our approach to the COVID-19 pandemic and we will continue to prioritize authorization for tests with the ability to increase testing accessibility or to significantly increase testing capacity. The FDA is committed to assisting our schools, workplaces, communities and other entities with establishing effective testing programs as the national response to the COVID-19 pandemic continues to evolve.

One in Ten Healthcare Workers with Mild COVID Have Lasting Symptoms: NIH Director Dr. Francis Collins comments on a recent *JAMA* study which found that just over 1 in 10 healthcare workers who had what at first seemed to be a relatively mild bout of COVID-19 were still coping with at least one moderate to severe symptom eight months later. Those symptoms—most commonly including loss of smell and taste, fatigue, and breathing problems—also negatively affected the work and/or personal lives of these individuals. Their findings show that 26 percent of those who had mild COVID-19 reported at least one moderate to severe symptom that lasted more than two months. That's compared to 9 percent of participants without COVID-19. What's more, 11 percent of the individuals with mild COVID-19 had at least one debilitating symptom that lasted for at least eight months. In the group without COVID-19, any symptoms of feeling unwell resolved relatively quickly.

Lab Publications: CDC updated their collection of lab publications. The publications cover the following topics: diagnostics, epidemiology, research, serology, and treatment.

COVID-19 Outbreak Associated with a SARS-CoV-2 R.1 Lineage Variant in a Skilled Nursing Facility After Vaccination Program — Kentucky, March 2021

Alyson M. Cavanaugh, DPT, PhD[1,2]; Sarah Fortier, MPH[2]; Patricia Lewis[2]; Vaneet Arora, MD[2]; Matt Johnson[2]; Karim George[2]; Joshua Tobias, PhD[2]; Stephanie Lunn, MPH[2]; Taylor Miller, MPH[2]; Douglas Thoroughman, PhD[2,3]; Kevin B. Spicer, MD, PhD[2,4]

Although COVID-19 mRNA vaccines demonstrated high efficacy in clinical trials (*1*), they were not 100% efficacious. Thus, some infections postvaccination are expected. Limited data are available on effectiveness in skilled nursing facilities (SNFs) and against emerging variants. The Kentucky Department for Public Health (KDPH) and a local health department investigated a COVID-19 outbreak in a SNF that occurred after all residents and health care personnel (HCP) had been offered vaccination. Among 83 residents and 116 HCP, 75 (90.4%) and 61 (52.6%), respectively, received 2 vaccine doses. Twenty-six residents and 20 HCP received positive test results for SARS-CoV-2, the virus that causes COVID-19, including 18 residents and four HCP who had received their second vaccine dose >14 days before the outbreak began. An R.1 lineage variant was detected with whole genome sequencing (WGS). Although the R.1 variant has multiple spike protein mutations, vaccinated residents and HCP were 87% less likely to have symptomatic COVID-19 compared with those who were unvaccinated. Vaccination of SNF populations, including HCP, is critical to reduce the risk for SARS-CoV-2 introduction, transmission, and severe outcomes in SNFs. An ongoing focus on infection prevention and control practices is also essential.

Investigation and Epidemiologic Findings

The SNF conducted vaccination clinics using Pfizer-BioNTech mRNA vaccine on January 10, January 31, and February 21, 2021. Among 83 residents and 116 HCP, 75 (90.4%) and 61 (52.6%), respectively, received two vaccine doses. All vaccinated residents and HCP were vaccinated on-site, the majority on January 10 and 31. Four residents and five HCP received their second dose during the third clinic, which was <14 days before the outbreak onset.

Before and during the outbreak, SARS-CoV-2 testing was used for evaluating symptomatic illness in residents and HCP. Symptom screening of residents and HCP had been ongoing since March 2020, and twice-weekly screening testing of all HCP had been occurring since November 2020. A COVID-19 case was defined as a positive SARS-CoV-2 antigen or reverse transcription–polymerase chain reaction (RT-PCR) test result. Possible reinfection was defined as a positive SARS-CoV-2 test result >90 days after a previous laboratory-confirmed infection.

The outbreak was identified during routine HCP antigen testing on March 1.* This was 8 days after the third vaccination clinic. The index case occurred in an unvaccinated, symptomatic HCP. Once the outbreak was identified, daily rapid point-of-care antigen testing of all residents, regardless of symptoms, was added to the twice-weekly HCP testing. Additional specimens were collected the same day for RT-PCR confirmation of positive antigen test results. One week after the outbreak was identified, resident antigen testing was reduced to three times weekly, then to twice weekly after no additional cases were identified for 1 week.

The local health department interviewed HCP and facility staff members to collect information about the cases. Vaccination status was ascertained through immunization registry review and facility interviews. COVID-19–related hospitalizations and deaths were confirmed by medical records reviews. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.†

Relative risks (RRs) were calculated comparing unvaccinated and vaccinated residents and HCP; vaccine effectiveness (VE [1–RR of vaccinated versus unvaccinated x 100]) was

calculated for the following outcomes: SARS-CoV-2 infection, symptomatic COVID-19, hospitalization, and death. Persons who received their second vaccine dose ≥14 days before the outbreak began were considered vaccinated, consistent with CDC postvaccination guidance[§] and breakthrough case definition. Ten persons who had received at least 1 dose but had not received a second vaccine dose ≥14 days before the outbreak were excluded from analyses.

A sensitivity analysis was conducted using a 7-day threshold to classify persons as vaccinated, consistent with the Pfizer-BioNTech vaccine clinical trials (*1*). Four residents and five HCP who received their second vaccine dose 8 days before outbreak identification were classified as vaccinated in this sensitivity analysis. One HCP who received a single vaccine dose remained excluded (Supplementary Table https://stacks.cdc.gov/view/cdc/105235).

KDPH Division of Laboratory Services performed WGS (*2*). Genomes were assembled using the StaPH-B Monroe pipeline,[¶] followed by Nextclade[**] for clade assignment and mutation calling, Pangolin[††] for lineage assignment, and Nextstrain for phylogenetic analysis (*3*).

During the outbreak, 46 COVID-19 cases were identified, including cases in 26 residents (18 fully vaccinated) and 20 HCP (four vaccinated) (Figure) (Table). Two cases occurred in residents who had received their second vaccine dose within 14 days; these two cases were excluded from the primary analysis. Vaccinated residents and HCP were less likely to be infected than were unvaccinated persons. Attack rates in unvaccinated residents (75.0%) were 3 times as high as those in vaccinated residents (25.4%; RR = 3.0; 95% confidence interval [CI] = 1.7–5.2) and in unvaccinated HCP (29.6%) were 4.1 times as high as those in vaccinated HCP (7.1%; RR = 4.1; 95% CI = 1.5–11.6). The estimated VE against SARS-CoV-2 infection among residents was 66.2% (95% CI = 40.5%–80.8%) and among HCP was 75.9% (95% CI = 32.5%–91.4%).

VE against symptomatic COVID-19 was 86.5% (95% CI = 65.6%–94.7%) among residents and 87.1% (95% CI = 46.4%–96.9%) among HCP. VE against hospitalization was 94.4% (95% CI = 73.9%–98.8%) among residents; no HCP were hospitalized. Three residents died, two of whom were unvaccinated (VE = 94.4%; 95% CI = 44.6%–99.4%).

Four possible reinfections were identified (one resident and three HCP); of these, one HCP was vaccinated. All four persons experienced symptomatic illness. One resident was infected 300 days earlier and had nine consecutive negative RT-PCR tests before reinfection, including two within 30 days of the outbreak. This resident was hospitalized and died.

Laboratory and Bioinformatics Findings

WGS was performed for 28 specimens (27 persons, including one who was reinfected); all had >97% genome coverage at a depth of >30x, therefore passing required quality control matrices.[§§] Examination of phylogeny revealed 28 clustered sequences sharing 14 amino acid mutations not present in the reference Wuhan-1 genome: ORF1a:A2584T, ORF1b:P314L, ORF1b:G1362R, ORF1b:P1936H, S:E484K, S:D614G, S:G769V, S:W152L, M:F28L, N:M1X, N:S187L, N:R203K, N:G204R, and N:Q418H. This cluster aligns with the R.1 lineage, which had not previously been identified in Kentucky. Whereas the 28 sequences share spike protein mutations E484K, D614G, G769V, and W152L with the R.1 root, the mutation ORF1a:A2584T places the cluster in a separate group on the phylogenetic tree.

Public Health Response

The local health department, along with the KDPH regional epidemiologist and regional infection preventionist, provided guidance on implementation of infection prevention strategies. These included the use of transmission-based precautions and hand hygiene, ongoing testing to identify new cases, exclusion of symptomatic HCP from work, isolation and quarantine of HCP, and provision of dedicated and separate spaces for care of infected and exposed residents, regardless of vaccination status.[¶¶]

Discussion

In a SNF with 90.4% of residents vaccinated, an outbreak of COVID-19 occurred after introduction from an unvaccinated, symptomatic HCP. WGS identified an R.1 lineage variant, characterized by E484K and other mutations within the spike protein. Attack rates were three to four times as high among unvaccinated residents and HCP as among those who were vaccinated; vaccinated persons were significantly less likely to experience symptoms or require hospitalization.

Although the R.1 variant is not currently identified as a CDC variant of concern or interest,[***] it does have several mutations of importance. The D614G mutation demonstrates evidence

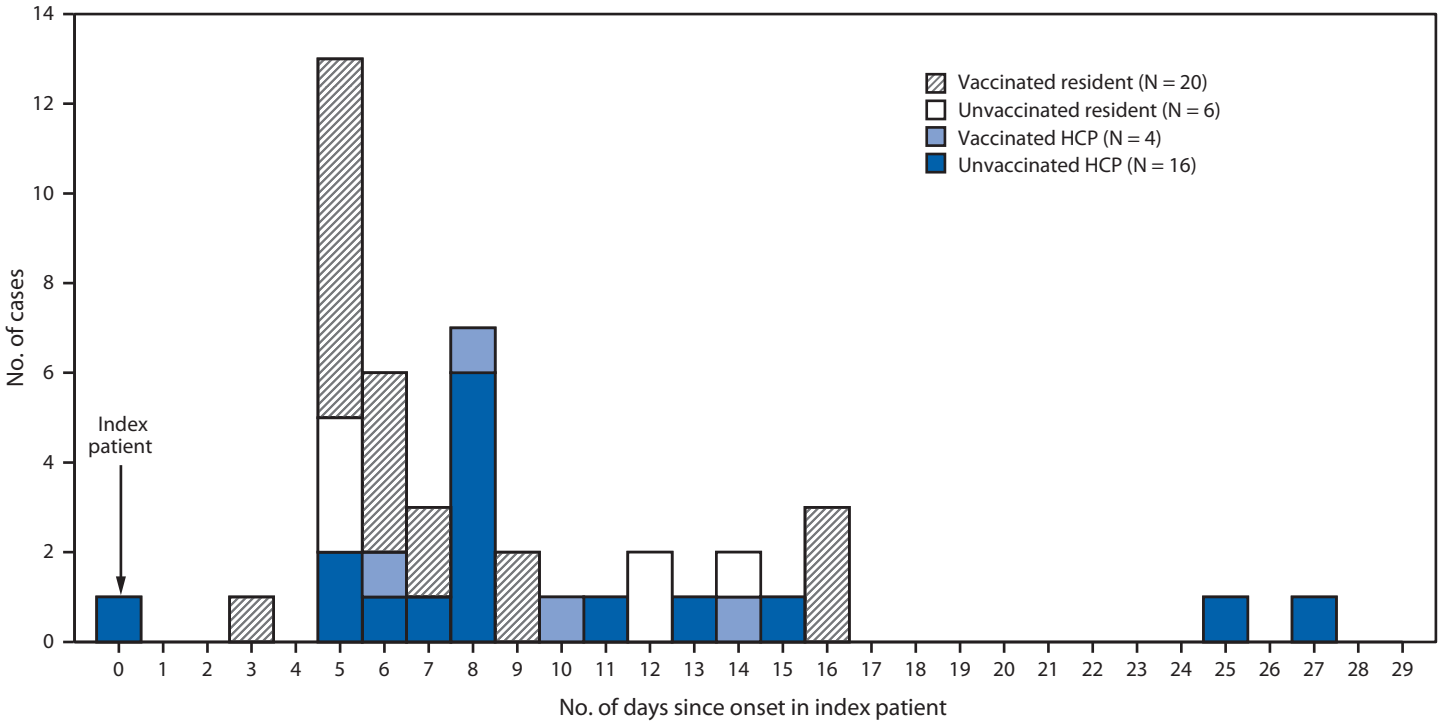
FIGURE. SARS-CoV-2 illness onset* among residents and health care personnel (HCP) in a skilled nursing facility, relative to onset in the index patient, by vaccination status† — Kentucky, March 2021



* Symptom onset date or specimen collection date, if asymptomatic.
† Persons who received 2 doses of Pfizer-BioNTech vaccine are indicated as vaccinated; unvaccinated persons received no vaccine doses. Persons who received a second dose of vaccine <14 days before outbreak onset (four residents and five HCP) and those who received only a single dose of vaccine (one HCP) were excluded from the primary analysis; this resulted in exclusion of two cases that occurred in residents.

of increasing virus transmissibility (*4*). The E484K mutation, found within the receptor-binding domain of the spike protein, is also seen in the variants of concern B.1.351 and P.1, which show evidence of reduced neutralization by convalescent and postvaccination sera (*5*,*6*). Mutation W152L might reduce the effectiveness of neutralizing antibodies (*7*). Although vaccination was associated with decreased likelihood of infection and symptomatic illness, 25.4% of vaccinated residents and 7.1% of vaccinated HCP were infected, supporting concerns about potential reduced protective immunity to R.1. In addition, four possible reinfections were identified, providing some evidence of limited or waning natural immunity to this variant.

Point estimates for VE against SARS-CoV-2 infections were lower than were those reported from Israel's national vaccination program (*8*). Whereas this could reflect reduced protection against R.1, other factors to consider include the smaller sample size in this study and the higher exposure risk associated with an outbreak in a congregate setting. In addition, testing, regardless of symptoms, was performed with high frequency for both residents and HCP, which contrasts with VE studies that use a primary reliance on individual test-seeking behavior. Such differences could influence VE estimates for infection; therefore, caution is urged when comparing these studies. Regardless of VE differences in SARS-CoV-2 infection, the estimated VE for COVID-19 symptom prevention (86.5% for residents; 87.1% for HCP) demonstrates a strong protective effect of vaccination.

The risk for poor outcomes among unvaccinated SNF residents is highlighted by the hospitalization of four of the six unvaccinated, infected residents, and two subsequent deaths, including in one previously infected resident. This underscores the importance of the Advisory Committee on Immunization Practices' recommendation that all persons, including those who have recovered from COVID-19, be vaccinated.†††

Low acceptance of vaccination among SNF HCP might increase the likelihood of SARS-CoV-2 introduction and transmission within a facility. Nationally, a median of 37.5% of HCP working in long-term care facilities had received at least 1 dose of vaccine by mid-January 2021 (*9*). Although the vaccination rate in this SNF surpassed this early national rate, approximately one half of HCP were vaccinated. To protect

Abbreviations: CI = confidence interval; RR = relative risk.

* Receipt of 2 doses of Pfizer-BioNTech vaccine ≥14 days before identification of the SNF outbreak; persons who received a second dose of vaccine <14 days before the outbreak (four residents and five health care personnel) and those who received a single dose of vaccine (one health care worker) were excluded, which resulted in exclusion of two resident cases.

† Receipt of zero doses of COVID-19 vaccine.

§ Calculated as (1−RR of vaccinated versus unvaccinated) x100.

¶ Includes residents and health care personnel.

SNF residents, it is imperative that HCP, as well as SNF residents, be vaccinated. A continued emphasis on strategies for prevention of disease transmission, even among vaccinated populations, is also critical. Timely implementation of infection control strategies after outbreak identification likely contributed to the rapid decline in new cases during the second week of the outbreak.

The findings in this report are subject to at least three limitations. First, the health status of residents who declined vaccination might have differed from those who consented to vaccination. Thus, hospitalization and death outcomes might be biased when comparing the groups without controlling for underlying health conditions. Second, underlying health status and advance directives might affect decisions for resident hospitalization; therefore, association of vaccination with hospitalization in this SNF population might have limited generalizability. Finally, because of the reduced sensitivity of antigen testing in asymptomatic populations,[§§§] it is possible that some asymptomatic cases were not identified. If this introduced differential bias for identification of cases in either the vaccinated or unvaccinated groups, actual VE for the prevention of SARS-CoV-2 infections could differ from measured effectiveness.

Summary

What is already known about this topic?

COVID-19 vaccines have demonstrated high efficacy in clinical trials. Limited data are available on effectiveness in skilled nursing facilities (SNFs) and against emerging variants.

What is added by this report?

In a COVID-19 outbreak at a Kentucky SNF involving a newly introduced variant to the region, unvaccinated residents and health care personnel (HCP) had 3.0 and 4.1 times the risk of infection as did vaccinated residents and HCP. Vaccine was 86.5% protective against symptomatic illness among residents and 87.1% protective among HCP.

What are the implications for public health practice?

Vaccination of SNF residents and HCP is essential to reduce the risk for symptomatic COVID-19, as is continued focus on infection prevention and control practices.

An R.1 lineage variant, not previously detected in Kentucky, was identified in a SNF outbreak where 46 residents and HCP were infected. Compared with unvaccinated persons, vaccinated persons had reduced risk for SARS-CoV-2 infection and symptomatic COVID-19. A continued emphasis on vaccination of SNF populations, including HCP, is essential to reduce the risk for SARS-CoV-2 introduction, transmission, and severe outcomes in SNFs. An ongoing focus on infection prevention and control practices is also critical.

COVID-19 Outbreak Associated with a SARS-CoV-2 R.1 Lineage Variant in a Skilled Nursing Facility After Vaccination Program — Kentucky, March 2021

Alyson M. Cavanaugh, DPT, PhD[1,2]; Sarah Fortier, MPH[2]; Patricia Lewis[2]; Vaneet Arora, MD[2]; Matt Johnson[2]; Karim George[2]; Joshua Tobias, PhD[2]; Stephanie Lunn, MPH[2]; Taylor Miller, MPH[2]; Douglas Thoroughman, PhD[2,3]; Kevin B. Spicer, MD, PhD[2,4]

Although COVID-19 mRNA vaccines demonstrated high efficacy in clinical trials (*1*), they were not 100% efficacious. Thus, some infections postvaccination are expected. Limited data are available on effectiveness in skilled nursing facilities (SNFs) and against emerging variants. The Kentucky Department for Public Health (KDPH) and a local health department investigated a COVID-19 outbreak in a SNF that occurred after all residents and health care personnel (HCP) had been offered vaccination. Among 83 residents and 116 HCP, 75 (90.4%) and 61 (52.6%), respectively, received 2 vaccine doses. Twenty-six residents and 20 HCP received positive test results for SARS-CoV-2, the virus that causes COVID-19, including 18 residents and four HCP who had received their second vaccine dose >14 days before the outbreak began. An R.1 lineage variant was detected with whole genome sequencing (WGS). Although the R.1 variant has multiple spike protein mutations, vaccinated residents and HCP were 87% less likely to have symptomatic COVID-19 compared with those who were unvaccinated. Vaccination of SNF populations, including HCP, is critical to reduce the risk for SARS-CoV-2 introduction, transmission, and severe outcomes in SNFs. An ongoing focus on infection prevention and control practices is also essential.

Investigation and Epidemiologic Findings

The SNF conducted vaccination clinics using Pfizer-BioNTech mRNA vaccine on January 10, January 31, and February 21, 2021. Among 83 residents and 116 HCP, 75 (90.4%) and 61 (52.6%), respectively, received two vaccine doses. All vaccinated residents and HCP were vaccinated on-site, the majority on January 10 and 31. Four residents and five HCP received their second dose during the third clinic, which was <14 days before the outbreak onset.

Before and during the outbreak, SARS-CoV-2 testing was used for evaluating symptomatic illness in residents and HCP. Symptom screening of residents and HCP had been ongoing since March 2020, and twice-weekly screening testing of all HCP had been occurring since November 2020. A COVID-19 case was defined as a positive SARS-CoV-2 antigen or reverse transcription–polymerase chain reaction (RT-PCR) test result. Possible reinfection was defined as a positive SARS-CoV-2 test result >90 days after a previous laboratory-confirmed infection.

The outbreak was identified during routine HCP antigen testing on March 1.* This was 8 days after the third vaccination clinic. The index case occurred in an unvaccinated, symptomatic HCP. Once the outbreak was identified, daily rapid point-of-care antigen testing of all residents, regardless of symptoms, was added to the twice-weekly HCP testing. Additional specimens were collected the same day for RT-PCR confirmation of positive antigen test results. One week after the outbreak was identified, resident antigen testing was reduced to three times weekly, then to twice weekly after no additional cases were identified for 1 week.

The local health department interviewed HCP and facility staff members to collect information about the cases. Vaccination status was ascertained through immunization registry review and facility interviews. COVID-19–related hospitalizations and deaths were confirmed by medical records reviews. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.†

Relative risks (RRs) were calculated comparing unvaccinated and vaccinated residents and HCP; vaccine effectiveness (VE [1–RR of vaccinated versus unvaccinated x 100]) was

Four residents and five HCP who received their second vaccine dose 8 days before outbreak identification were classified as vaccinated in this sensitivity analysis. One HCP who received a single vaccine dose remained excluded (Supplementary Table https://stacks.cdc.gov/view/cdc/105235).

KDPH Division of Laboratory Services performed WGS (*2*). Genomes were assembled using the StaPH-B Monroe pipeline,[¶] followed by Nextclade[**] for clade assignment and mutation calling, Pangolin[††] for lineage assignment, and Nextstrain for phylogenetic analysis (*3*).

During the outbreak, 46 COVID-19 cases were identified, including cases in 26 residents (18 fully vaccinated) and 20 HCP (four vaccinated) (Figure) (Table). Two cases occurred in residents who had received their second vaccine dose within 14 days; these two cases were excluded from the primary analysis. Vaccinated residents and HCP were less likely to be infected than were unvaccinated persons. Attack rates in unvaccinated residents (75.0%) were 3 times as high as those in vaccinated residents (25.4%; RR = 3.0; 95% confidence interval [CI] = 1.7–5.2) and in unvaccinated HCP (29.6%) were 4.1 times as high as those in vaccinated HCP (7.1%; RR = 4.1; 95% CI = 1.5–11.6). The estimated VE against SARS-CoV-2 infection among residents was 66.2% (95% CI = 40.5%–80.8%) and among HCP was 75.9% (95% CI = 32.5%–91.4%).

VE against symptomatic COVID-19 was 86.5% (95% CI = 65.6%–94.7%) among residents and 87.1% (95% CI = 46.4%–96.9%) among HCP. VE against hospitalization was 94.4% (95% CI = 73.9%–98.8%) among residents; no HCP were hospitalized. Three residents died, two of whom were unvaccinated (VE = 94.4%; 95% CI = 44.6%–99.4%).

Four possible reinfections were identified (one resident and three HCP); of these, one HCP was vaccinated. All four persons experienced symptomatic illness. One resident was infected 300 days earlier and had nine consecutive negative RT-PCR tests before reinfection, including two within 30 days of the outbreak. This resident was hospitalized and died.

Laboratory and Bioinformatics Findings

WGS was performed for 28 specimens (27 persons, including one who was reinfected); all had >97% genome coverage at a depth of >30x, therefore passing required quality control matrices.[§§] Examination of phylogeny revealed 28 clustered sequences sharing 14 amino acid mutations not present in the reference Wuhan-1 genome: ORF1a:A2584T, ORF1b:P314L, ORF1b:G1362R, ORF1b:P1936H, S:E484K, S:D614G, S:G769V, S:W152L, M:F28L, N:M1X, N:S187L, N:R203K, N:G204R, and N:Q418H. This cluster aligns with the R.1 lineage, which had not previously been identified in Kentucky. Whereas the 28 sequences share spike protein mutations E484K, D614G, G769V, and W152L with the R.1 root, the mutation ORF1a:A2584T places the cluster in a separate group on the phylogenetic tree.

Public Health Response

The local health department, along with the KDPH regional epidemiologist and regional infection preventionist, provided guidance on implementation of infection prevention strategies. These included the use of transmission-based precautions and hand hygiene, ongoing testing to identify new cases, exclusion of symptomatic HCP from work, isolation and quarantine of HCP, and provision of dedicated and separate spaces for care of infected and exposed residents, regardless of vaccination status.[¶¶]

Discussion

In a SNF with 90.4% of residents vaccinated, an outbreak of COVID-19 occurred after introduction from an unvaccinated, symptomatic HCP. WGS identified an R.1 lineage variant, characterized by E484K and other mutations within the spike protein. Attack rates were three to four times as high among unvaccinated residents and HCP as among those who were vaccinated; vaccinated persons were significantly less likely to experience symptoms or require hospitalization.

Although the R.1 variant is not currently identified as a CDC variant of concern or interest,[***] it does have several mutations of importance. The D614G mutation demonstrates evidence

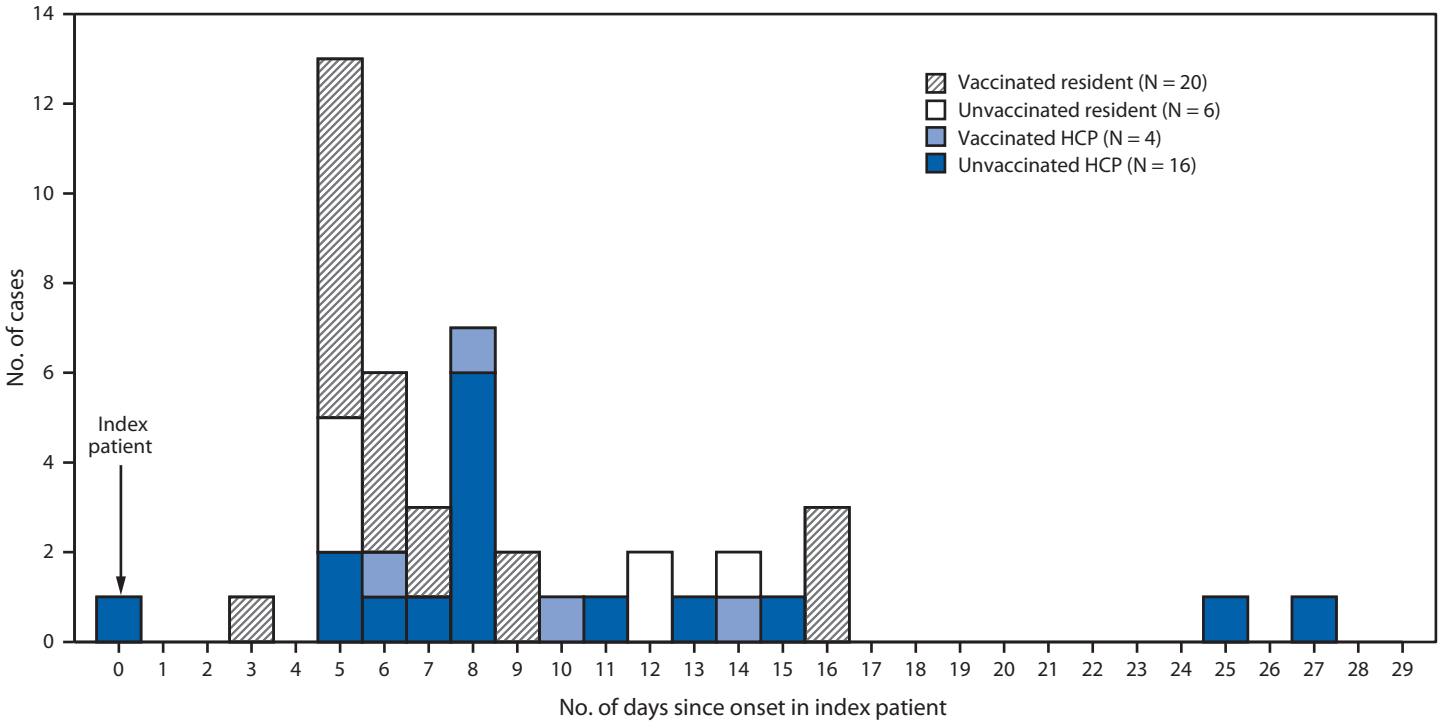
FIGURE. SARS-CoV-2 illness onset* among residents and health care personnel (HCP) in a skilled nursing facility, relative to onset in the index patient, by vaccination status† — Kentucky, March 2021



* Symptom onset date or specimen collection date, if asymptomatic.
† Persons who received 2 doses of Pfizer-BioNTech vaccine are indicated as vaccinated; unvaccinated persons received no vaccine doses. Persons who received a second dose of vaccine <14 days before outbreak onset (four residents and five HCP) and those who received only a single dose of vaccine (one HCP) were excluded from the primary analysis; this resulted in exclusion of two cases that occurred in residents.

of increasing virus transmissibility (*4*). The E484K mutation, found within the receptor-binding domain of the spike protein, is also seen in the variants of concern B.1.351 and P.1, which show evidence of reduced neutralization by convalescent and postvaccination sera (*5*,*6*). Mutation W152L might reduce the effectiveness of neutralizing antibodies (*7*). Although vaccination was associated with decreased likelihood of infection and symptomatic illness, 25.4% of vaccinated residents and 7.1% of vaccinated HCP were infected, supporting concerns about potential reduced protective immunity to R.1. In addition, four possible reinfections were identified, providing some evidence of limited or waning natural immunity to this variant.

Point estimates for VE against SARS-CoV-2 infections were lower than were those reported from Israel's national vaccination program (*8*). Whereas this could reflect reduced protection against R.1, other factors to consider include the smaller sample size in this study and the higher exposure risk associated with an outbreak in a congregate setting. In addition, testing, regardless of symptoms, was performed with high frequency for both residents and HCP, which contrasts with VE studies that use a primary reliance on individual test-seeking behavior. Such differences could influence VE estimates for infection; therefore, caution is urged when comparing these studies. Regardless of VE differences in SARS-CoV-2 infection, the estimated VE for COVID-19 symptom prevention (86.5% for residents; 87.1% for HCP) demonstrates a strong protective effect of vaccination.

The risk for poor outcomes among unvaccinated SNF residents is highlighted by the hospitalization of four of the six unvaccinated, infected residents, and two subsequent deaths, including in one previously infected resident. This underscores the importance of the Advisory Committee on Immunization Practices' recommendation that all persons, including those who have recovered from COVID-19, be vaccinated.†††

Low acceptance of vaccination among SNF HCP might increase the likelihood of SARS-CoV-2 introduction and transmission within a facility. Nationally, a median of 37.5% of HCP working in long-term care facilities had received at least 1 dose of vaccine by mid-January 2021 (*9*). Although the vaccination rate in this SNF surpassed this early national rate, approximately one half of HCP were vaccinated. To protect

TABLE. Relative risk and estimated vaccine effectiveness for prevention of SARS-CoV-2 infection, symptomatic COVID-19, hospitalization, and death for fully vaccinated persons compared with unvaccinated persons during a COVID-19 outbreak in a skilled nursing facility (SNF) — Kentucky, 2021

Population and outcome	No. (% attack rate)		Unvaccinated versus vaccinated RR (95% CI)	Vaccine effectiveness[§] (95% CI)
	Vaccinated*	Unvaccinated†		
Total SNF population[¶]	**(n = 127)**	**(n = 62)**	—	—
SARS-CoV-2 infection	22 (17.3)	22 (35.5)	—	—
Symptomatic	8 (6.3)	20 (32.3)	—	—
Hospitalization	2 (1.6)	4 (6.5)	—	—
Death	1 (0.8)	2 (3.2)	—	—
Residents	**(n = 71)**	**(n = 8)**	—	—
SARS-CoV-2 infection	18 (25.4)	6 (75.0)	3.0 (1.7–5.2)	66.2 (40.5–80.8)
Symptomatic	6 (8.5)	5 (62.5)	7.4 (2.9–18.8)	86.5 (65.6–94.7)
Hospitalization	2 (2.8)	4 (50.0)	17.8 (3.8–82.1)	94.4 (73.9–98.8)
Death	1 (1.4)	2 (25.0)	17.8 (1.8–174.7)	94.4 (44.6–99.4)
Health care personnel	**(n = 56)**	**(n = 54)**	—	—
SARS-CoV-2 infection	4 (7.1)	16 (29.6)	4.1 (1.5–11.6)	75.9 (32.5–91.4)
Symptomatic	2 (3.6)	15 (27.8)	7.8 (1.9–32.4)	87.1 (46.4–96.9)
Hospitalization	0 (—)	0 (—)	—	—
Death	0 (—)	0 (—)	—	—

Abbreviations: CI = confidence interval; RR = relative risk.

* Receipt of 2 doses of Pfizer-BioNTech vaccine ≥14 days before identification of the SNF outbreak; persons who received a second dose of vaccine <14 days before the outbreak (four residents and five health care personnel) and those who received a single dose of vaccine (one health care worker) were excluded, which resulted in exclusion of two resident cases.

† Receipt of zero doses of COVID-19 vaccine.

§ Calculated as (1−RR of vaccinated versus unvaccinated) x100.

¶ Includes residents and health care personnel.

SNF residents, it is imperative that HCP, as well as SNF residents, be vaccinated. A continued emphasis on strategies for prevention of disease transmission, even among vaccinated populations, is also critical. Timely implementation of infection control strategies after outbreak identification likely contributed to the rapid decline in new cases during the second week of the outbreak.

The findings in this report are subject to at least three limitations. First, the health status of residents who declined vaccination might have differed from those who consented to vaccination. Thus, hospitalization and death outcomes might be biased when comparing the groups without controlling for underlying health conditions. Second, underlying health status and advance directives might affect decisions for resident hospitalization; therefore, association of vaccination with hospitalization in this SNF population might have limited generalizability. Finally, because of the reduced sensitivity of antigen testing in asymptomatic populations,[§§§] it is possible that some asymptomatic cases were not identified. If this introduced differential bias for identification of cases in either the vaccinated or unvaccinated groups, actual VE for the prevention of SARS-CoV-2 infections could differ from measured effectiveness.

Summary

What is already known about this topic?

COVID-19 vaccines have demonstrated high efficacy in clinical trials. Limited data are available on effectiveness in skilled nursing facilities (SNFs) and against emerging variants.

What is added by this report?

In a COVID-19 outbreak at a Kentucky SNF involving a newly introduced variant to the region, unvaccinated residents and health care personnel (HCP) had 3.0 and 4.1 times the risk of infection as did vaccinated residents and HCP. Vaccine was 86.5% protective against symptomatic illness among residents and 87.1% protective among HCP.

What are the implications for public health practice?

Vaccination of SNF residents and HCP is essential to reduce the risk for symptomatic COVID-19, as is continued focus on infection prevention and control practices.

An R.1 lineage variant, not previously detected in Kentucky, was identified in a SNF outbreak where 46 residents and HCP were infected. Compared with unvaccinated persons, vaccinated persons had reduced risk for SARS-CoV-2 infection and symptomatic COVID-19. A continued emphasis on vaccination of SNF populations, including HCP, is essential to reduce the risk for SARS-CoV-2 introduction, transmission, and severe outcomes in SNFs. An ongoing focus on infection prevention and control practices is also critical.

Postvaccination SARS-CoV-2 Infections Among Skilled Nursing Facility Residents and Staff Members — Chicago, Illinois, December 2020–March 2021

Richard A. Teran, PhD[1,2*]; Kelly A. Walblay, MPH[2*]; Elizabeth L. Shane, MPH[2]; Shannon Xydis[2]; Stephanie Gretsch, MPH[3]; Alexandra Gagner, MPH[2]; Usha Samala, MPH[2]; Hyeree Choi[2]; Christy Zelinski, MPH[2]; Stephanie R. Black, MD[2]

Early studies suggest that COVID-19 vaccines protect against severe illness (*1*); however, postvaccination SARS-CoV-2 infections (i.e., breakthrough infections) can occur because COVID-19 vaccines do not offer 100% protection (*2*,*3*). Data evaluating the occurrence of breakthrough infections and impact of vaccination in decreasing transmission in congregate settings are limited. Skilled nursing facility (SNF) residents and staff members have been disproportionately affected by SARS-CoV-2, the virus that causes COVID-19 (*4*,*5*), and were prioritized for COVID-19 vaccination (*6*,*7*). Starting December 28, 2020, all 78 Chicago-based SNFs began COVID-19 vaccination clinics over several weeks through the federal Pharmacy Partnership for Long-Term Care Program (PPP).† In February 2021, through routine screening, the Chicago Department of Public Health (CDPH) identified a SARS-CoV-2 infection in a SNF resident >14 days after receipt of the second dose of a two-dose COVID-19 vaccination series. SARS-CoV-2 cases, vaccination status, and possible vaccine breakthrough infections were identified by matching facility reports with state case and vaccination registries. Among 627 persons with SARS-CoV-2 infection across 75 SNFs since vaccination clinics began, 22 SARS-CoV-2 infections were identified among 12 residents and 10 staff members across 15 facilities ≥14 days after receiving their second vaccine dose (i.e., breakthrough infections in fully vaccinated persons). Nearly two thirds (14 of 22; 64%) of persons with breakthrough infections were asymptomatic; two residents were hospitalized because of COVID-19, and one died. No facility-associated secondary transmission occurred. Although few SARS-CoV-2 infections in fully vaccinated persons were observed, these cases demonstrate the need for SNFs to follow recommended routine infection prevention and control practices and promote high vaccination coverage among SNF residents and staff members.

CDPH monitors SNF SARS-CoV-2 infections using a data triangulation method that matches the SARS-CoV-2 test results from nucleic acid amplification tests (NAATs, such as reverse transcription–polymerase chain reaction [RT-PCR]) and antigen tests reported to the Illinois' National Electronic Disease Surveillance System with facility-reported line lists of SARS-CoV-2 test results from routine screening testing.§ In February 2021, CDPH began matching records to Illinois' Comprehensive Automated Immunization Registry Exchange to identify breakthrough infections. After identifying SARS-CoV-2 infection in a SNF resident 16 days after receipt of a second vaccine dose, CDPH initiated an investigation to quantify breakthrough infections across all facilities, evaluate symptoms and clinical outcomes, and assess potential secondary transmission. Vaccine effectiveness was not evaluated.

* These authors contributed equally to this report.

† A public-private partnership among CDC; CVS Pharmacy; Managed Health Care Associates, Inc.; and Walgreens to provide on-site COVID-19 vaccination of residents and staff members at enrolled long-term care facilities, including SNFs. https://www.cdc.gov/vaccines/covid-19/long-term-care/pharmacy-partnerships.html

§ CDPH advises facilities to routinely test residents at least monthly. Staff members were also required to receive testing routinely, with frequency determined based on community positivity rate and other metrics of interest. Staff members at all Chicago-based SNFs were tested at least twice weekly (until February 4, 2021), then weekly (during February 4–March 18, 2021), then biweekly (from March 18, 2021 through the end of investigation period). In response to a facility outbreak (i.e., a resident or staff member with a case within the past 14 days), all staff members and residents (excluding those who received a positive SARS-CoV-2 test <90 days previously) are required to receive testing at least every 3–7 days until no new cases occur for at least 14 days. At the time a breakthrough infection was identified, frequency of resident testing at the 15 SNFs ranged from monthly to twice per week; frequency of staff member testing ranged from weekly to twice weekly.

Summary

What is already known about this topic?

Residents and staff members of skilled nursing facilities (SNFs) are recommended to receive COVID-19 vaccine as a priority group.

What is added by this report?

Twenty-two possible breakthrough SARS-CoV-2 infections occurred among fully vaccinated persons ≥14 days after their second dose of COVID-19 vaccine. Two thirds of persons were asymptomatic. A minority of persons with breakthrough infection experienced mild to moderate COVID-19–like symptoms; two COVID-19–related hospitalizations and one death occurred. No facility-associated secondary transmission was identified.

What are the implications for public health practice?

SNFs should prioritize vaccination and follow recommended COVID-19 infection prevention and control practices, including following work restrictions, isolation, quarantine, testing of residents and staff members, and use of personal protective equipment.

A facility's investigation period started on its first vaccination clinic date and ended March 31, 2021.[¶] A confirmed case of SARS-CoV-2 infection was defined as a positive SARS-CoV-2 NAAT or antigen test result from a respiratory specimen collected from a resident or staff member during the investigation period. Consistent with CDC guidance, a vaccine breakthrough infection in a resident or staff member was defined as a receipt of a positive SARS-CoV-2 NAAT or antigen test result from a respiratory specimen collected ≥14 days after completing the two-dose COVID-19 vaccination series.[**] Infection prevention specialists conducted case investigations to assess symptoms, clinical outcomes, and close contact information.

SARS-CoV-2 incidence during the investigation period was assessed across four groups based on vaccination status at the time a positive respiratory specimen was collected: 1) unvaccinated (never received a COVID-19 vaccine dose); 2) partially vaccinated (received one dose of a two-dose series); 3) vaccinated but not immune (received two doses of a two-dose series but <14 days had elapsed since the second dose); and 4) fully vaccinated (received two doses of a two-dose series and ≥14 days had elapsed since the second dose). In addition to routine facility follow-up, CDPH actively monitored facilities with breakthrough infections for 28 days to identify whether any new cases occurred in close contacts of the person with breakthrough infection.[††] Analyses were completed using SAS (version 9.4; SAS Institute). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[§§]

During the investigation period, an estimated 7,931 SNF residents and 6,834 staff members received two doses of COVID-19 vaccine. A total of 627 confirmed SARS-CoV-2 infections were identified across 75 of the 78 Chicago-based SNFs, including 353 (56%) among residents and 274 (44%) among staff members during the investigation period (Table 1). Three facilities had no confirmed SARS-CoV-2 infections after their first vaccination clinic. Approximately one half (47%) of resident cases occurred in men, 42% were in non-Hispanic Black persons, and the median age was 71 years. More than two thirds (72%) of staff member cases were in women, 38% were in non-Hispanic Black persons, and the median age was 42 years. Among the 627 cases, 447 (71%) occurred in unvaccinated persons, 145 (23%) in partially vaccinated persons, 13 (2%) in vaccinated but not immune persons, and 22 (4%) in fully vaccinated persons (Figure). These breakthrough infections occurred in 12 residents and 10 staff members and accounted for 16% (22 of 136) of SNF-associated cases occurring across all facilities ≥14 days after the second vaccination clinic at the respective facilities. No demographic or clinical differences were observed by vaccination status.

Among the 22 breakthrough infections, 18 (82%) were detected in persons who received testing as part of routine screening, and four (18%) occurred in residents who received testing before a hospital admission or procedure. Among the 18 breakthrough infections identified during routine screening, 14 were detected (across 10 facilities) while residents were receiving weekly testing from the facilities; staff members at all facilities were receiving testing at least weekly. The median interval from second dose to collection of a positive SARS-CoV-2 specimen was 29 days (interquartile range [IQR] = 23–42 days). The median interval between most recent positive NAAT result and last known negative test result was 7 days (IQR = 7–14 days).

[¶] First round vaccination clinics occurred during December 28, 2020–January 18, 2021. Persons were included in the study if infection occurred between the first clinic date at their respective facility and March 31, 2021. Moderna COVID-19 vaccination was exclusively administered at Chicago-based SNFs through the federal PPP. Six residents and two staff members received Pfizer-BioNTech COVID-19 vaccine through Chicago-based vaccine providers not participating in the federal PPP or facilities outside the city of Chicago.

[**] CDC breakthrough infection guidance: https://www.cdc.gov/vaccines/covid-19/health-departments/breakthrough-cases.html. Residents and staff members were excluded from the investigation if they had received 1) a positive SARS-CoV-2 test result from December 28 through the date of their facility's first vaccination clinic or 2) a known initial positive SARS-CoV-2 test result <90 days before their most recent SARS-CoV-2 test result.

[††] For residents, close contact was defined as being within 6 ft of a person for ≥15 minutes over a 24-hour period, regardless of personal protective equipment used. For staff members, close contact was defined as being within 6 ft of a person for ≥15 minutes over a 24-hour period when one or both persons were unmasked.

Abbreviations: I-NEDSS = Illinois' National Electronic Disease Surveillance System; IQR = interquartile range.

* Unvaccinated: received no COVID-19 vaccine doses; partially vaccinated: received one dose; vaccinated but not immune: received two doses but <14 days had elapsed since receipt of second dose; and fully vaccinated with breakthrough infection: received two doses and then received a positive SARS-CoV-2 test result ≥14 days after receipt of the second dose.

† Persons with the following races listed in I-NEDSS as American Indian or Alaska Native, Native Hawaiian or other Pacific Islander, other, or multiracial were categorized as non-Hispanic other.

§ Data on symptoms were extracted from I-NEDSS for unvaccinated, partially vaccinated, and vaccinated but not immune persons. Most COVID-19 case reports are entered into I-NEDSS through electronic laboratory reporting and provide minimal information (e.g., name, date of birth, and laboratory test and results) needed to meet reporting requirements. Data on symptoms in persons with breakthrough infections were supplemented with details from case investigations, which were not completed for nonbreakthrough cases. Symptom status for many persons with nonbreakthrough infection cases is unknown.

¶ Two residents were hospitalized for COVID-19–related reasons. Two additional residents were hospitalized for non-COVID-19–related reasons.

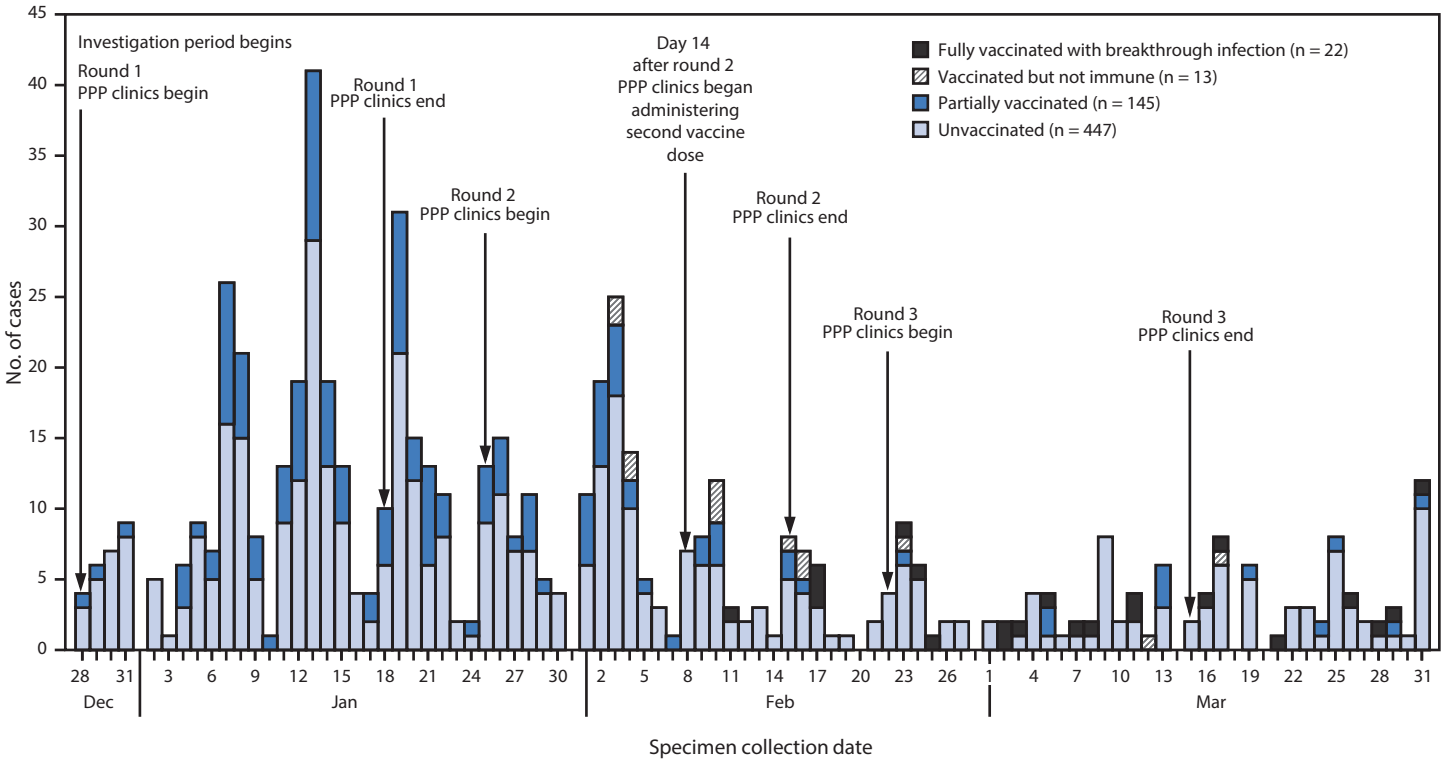
Two-dose vaccination coverage among residents and staff members at facilities with breakthrough infections ranged from 62% to 96% and 18% to 85%, respectively. Among the 15 facilities with breakthrough cases, attack rates[¶¶] for unvaccinated and vaccinated residents were 15% (89 of 604) and 0.8% (15 of 1,781), respectively. Among staff members, attack rates for unvaccinated and vaccinated persons were 6% (62 of 992) and 1% (12 of 1,135), respectively. Eleven facilities reported a total of 41 confirmed cases within 28 days after initial breakthrough infection at a facility (Table 2).[***] No facility-associated secondary transmission was determined to have occurred because the new cases that occurred after the initial breakthrough infection were not close contacts of the persons with breakthrough infections.

[¶¶] To calculate attack rates, residents and staff members who had never received COVID-19 vaccine (i.e., unvaccinated persons) and those who had received one COVID-19 vaccine dose of a two-dose series (i.e., partially vaccinated persons) were categorized as unvaccinated. Residents and staff members who had received two COVID-19 vaccine doses of a two-dose series and <14 days or ≥14 days had elapsed (i.e., vaccinated but not immune and fully vaccinated persons, respectively) were categorized as vaccinated. Aggregate vaccination data were only available for residents and staff members who received two doses of COVID-19 vaccine and did not have a SARS-CoV-2 infection. In the denominator, differentiation between persons who received two doses <14 days or ≥14 days was not possible.

[***] Cases identified within a 28-day monitoring window from the date of specimen collection for the breakthrough infection. For facilities with multiple breakthrough infections, 28-day monitoring windows might overlap, and new facility cases might be listed multiple times. As of April 12, 2021, nine of the 41 cases were breakthrough infections; seven of which are listed (see Table 2) and occurred during the investigation period.

MS-DOH-21-1816-A-001710

FIGURE. Confirmed SARS-CoV-2 infections (n = 627) among residents and staff members at 75* skilled nursing facilities, by specimen collection date and vaccination status† — Chicago, Illinois, December 2020–March 2021



Abbreviation: PPP = Federal Pharmacy Partnership for Long-Term Care Program.

* Among 78 Chicago-based facilities. Three facilities had no confirmed SARS-CoV-2 infections.

† Unvaccinated: received no COVID-19 vaccine doses; partially vaccinated: received one dose; vaccinated but not immune: received two doses but <14 days had elapsed since receipt of second dose; fully vaccinated with breakthrough infection: received two doses and then received a positive SARS-CoV-2 test result ≥14 days after receipt of the second dose.

Among the 22 persons with breakthrough infections, 14 (64%; eight residents and six staff members) were asymptomatic (Table 2). Three symptomatic persons (B3, E10, and G13) had mild, nonspecific symptoms; two (E8 and G12) had mild, specific symptoms; and three (A1, D6, and O22) had diagnosed pneumonia.††† Four residents were hospitalized: two (D6 and O22) for COVID-19–related reasons and two (A1 and D5) for reasons unrelated to COVID-19; one resident (O22) died.

Resident A1 received a diagnosis of pneumonia 9 days after receiving the second COVID-19 vaccine dose and 7 days before receiving a positive SARS-CoV-2 test result (Table 2). Although the timing of the patient's positive SARS-CoV-2 test result met the definition of a breakthrough infection, the clinical history indicated that the infection likely occurred <14 days after the second dose. Resident D6 was hospitalized for weakness and loss of appetite in association with pneumonia. Resident O22 experienced fatigue and respiratory symptoms and received a diagnosis of pneumonia. This patient had a positive SARS-CoV-2 test result on hospital admission and had concomitant group B β-hemolytic streptococcal bacteremia and a *Pseudomonas* urinary tract infection and died 7 days after hospital admission. The death certificate listed complications of COVID-19 infection as primary cause of death; underlying conditions were hypertension, diabetes mellitus, and chronic kidney disease.

Among 12 available specimens from seven patients with breakthrough infections, RT-PCR cycle threshold values were >28, indicating low levels of detectable virus. Six persons with breakthrough infections had a previous positive SARS-CoV-2 test result >90 days before the most recent test, including five persons who had negative test results (range = 1–43 tests) between the positive results (Supplementary Figure, https://stacks.cdc.gov/view/cdc/105130) and at least one negative NAAT result <14 days before the postvaccination positive test result. Five persons were asymptomatic during the second infection. Paired specimens for sequence comparison were unavailable.

††† Symptoms were categorized as nonspecific, mild, or moderate based on the National Notifiable Diseases Surveillance System and Council of State and Territorial Epidemiologists definition of symptomatic COVID-19. https://wwwn.cdc.gov/nndss/conditions/coronavirus-disease-2019-covid-19/case-definition/2020/08/05/

Discussion

Twelve SNF residents and 10 staff members had positive SARS-CoV-2 test results ≥14 days after receiving a second COVID-19 vaccine dose (breakthrough infections). Fourteen (64%) were asymptomatic, available RT-PCR cycle threshold values suggest low viral loads, and no facility-associated secondary transmission was detected. Two residents with breakthrough infections experienced COVID-related hospitalizations, one of whom died because of multiple concurrent infections. Although rare, postvaccination breakthrough infection can occur because COVID-19 vaccines do not offer 100% protection (*2*,*3*). Early studies suggest that COVID-19 vaccines protect against severe illness and might be effective at preventing infection (*1*); however, data on the impact of vaccination on transmission in congregate settings are limited. In addition, some persons whose infections met the case definition of a breakthrough infection might have had persistently positive

MS-DOH-21-1816-A-001712

TABLE 2. (*Continued*) Skilled nursing facility residents and staff members with SARS-CoV-2 breakthrough infections,* by facility and clinical characteristics — Chicago, Illinois, December 2020–March 2021

Abbreviations: Ct = cycle threshold; F = female; HA = headache; M = male; NA = not applicable; NAAT = nucleic acid amplification test; SOB = shortness of breath.

* Receipt of a positive SARS-CoV-2 NAAT (e.g., reverse transcription–polymerase chain reaction) or antigen test result from a respiratory specimen collected ≥14 days after completing the two-dose COVID-19 vaccination series.

† Missing Ct values are for specimens that were discarded by the laboratory and unavailable for sequencing.

§ Cases identified within a 28-day monitoring window from the date of specimen collection for the breakthrough infection. For facilities with multiple breakthrough infections, 28-day monitoring windows might overlap, and new facility cases might be listed multiple times.

¶ When a new case in a facility was identified, infection prevention specialists determined whether the person with the case met criteria to be considered a close contact of the person with the breakthrough infection. Data in this column represent the number of cases in persons that met the definition of a close contact and occurred after identification of the breakthrough infection as of April 12, 2021.

** Resident A1 had a positive SARS-CoV-2 test result 16 days after receiving the second dose of COVID-19 vaccine, which was an incidental finding when admitted to the hospital for new onset of seizures. The positive result might have been related to an episode of pneumonia diagnosed 9 days after the second dose. COVID-19 testing was not associated with compatible symptoms, and this resident was included because the resident's case met the laboratory-based breakthrough infection definition. This resident likely did not experience a breakthrough infection because previous pneumonia onset is suggestive of SARS-CoV-2 infection before full immunization.

†† Resident D5 had a positive preprocedural SARS-CoV-2 test result and was subsequently hospitalized for non-COVID-19–related reasons, including multiple falls and a bloodstream infection related to a midline catheter.

§§ Resident D6 was hospitalized for COVID-19-related reasons because of weakness and loss of appetite in association with pneumonia diagnosed at hospital admission.

¶¶ Based on the symptomatic disease case definition outlined by the Council of State and Territorial Epidemiologists, patient E10 had nonspecific COVID-19 symptoms. Previous testing history was examined using the Illinois' National Electronic Disease Surveillance System. No known previous positive SARS-CoV-2 were identified for this patient.

*** Resident O22 was hospitalized for COVID-19-related reasons because of fatigue, cough, SOB, and difficulty breathing. SARS-CoV-2 test result was positive, and resident received a diagnosis of pneumonia requiring hospital admission and intubation in the intensive care unit for hypoxic respiratory failure. Concomitant infections including group B streptococcal bacteremia and *Pseudomonas* urinary tract infection were also identified. The resident died 7 days after hospital admission.

NAAT results after initial infection; however, most had multiple confirmed negative interim test results. Additional data are needed to differentiate breakthrough infections from sequelae of previous infections and to determine whether persons with breakthrough infections can transmit virus.

The results in this report highlight the importance of COVID-19 vaccination in high-risk congregate settings such as SNFs; most fully vaccinated persons were not infected, did not have COVID-19–like symptoms, and did not have severe illness. Despite the identification of positive NAAT results during the investigation period, breakthrough infections did not lead to secondary transmission at these facilities.

Expanded testing of residents and staff members in these settings in response to clusters or outbreak investigations is also important, regardless of vaccination status, because these persons might have asymptomatic infections.§§§ A previous study found that vaccination has an estimated effectiveness of 63% against SARS-CoV-2 infection among SNF residents >14 days after the first dose through 7 days after the second dose (*8*). Additional studies are needed to assess the impact of full vaccination in SNFs and to understand how vaccination in settings that include older adults, immunocompromised persons, and persons with known history of SARS-CoV-2 infection compares with clinical trial efficacy data. Whether vaccinated asymptomatic persons can transmit SARS-CoV-2 is also unknown; therefore, facilities should continue to require residents to quarantine after close contact with an infected person.¶¶¶

Vaccine effectiveness estimates for prevention of SARS-CoV-2 infection and COVID-19 were not calculated because CDPH does not have access to SNF electronic medical records, limiting the ability to obtain individual-level data from facilities on all residents and staff members and to calculate person-time among vaccinated and unvaccinated persons who were not infected. Facilities did not have the capacity to provide line lists and vaccination information for noninfected residents and staff members.

The findings in this report are subject to at least four limitations. First, confirming whether patients with a breakthrough infection and a previous positive SARS-CoV-2 test result had a true reinfection or represented persons with prolonged shedding from previous infection was not possible. Intermittent prolonged SARS-CoV-2 shedding is well described (*9*). In addition to two SARS-CoV-2 tests ≥90 days apart, paired respiratory specimens are needed so that their genetic sequences can be compared.**** Data such as epidemiologic links to confirmed cases and clinical course can provide supporting evidence for reinfection but do not definitively identify reinfection events. Second, vaccination data in this report are limited to Chicago residents and persons vaccinated in Chicago; data were unavailable for staff members who were not Chicago residents and were vaccinated outside Chicago. Third, data entry errors or delayed surveillance reporting might prevent record matching, leading to an underestimate of breakthrough infections. Finally, although some specimens were submitted for genotyping to evaluate possible variant strains, results are pending and not yet available.

SNFs should continue to follow recommended infection prevention and control practices,†††† including work restrictions, isolation of persons with confirmed cases, quarantine of residents who have had close contact with persons with confirmed cases,

routine and outbreak testing of residents and staff members, and use of personal protective equipment, regardless of vaccination status. Maintaining high vaccination coverage among residents and staff members is also important to reduce opportunities for transmission within facilities and exposure among persons who might not have achieved protective immunity after vaccination.

Postvaccination SARS-CoV-2 Infections Among Skilled Nursing Facility Residents and Staff Members — Chicago, Illinois, December 2020–March 2021

Richard A. Teran, PhD[1,2*]; Kelly A. Walblay, MPH[2*]; Elizabeth L. Shane, MPH[2]; Shannon Xydis[2]; Stephanie Gretsch, MPH[3]; Alexandra Gagner, MPH[2]; Usha Samala, MPH[2]; Hyeree Choi[2]; Christy Zelinski, MPH[2]; Stephanie R. Black, MD[2]

Early studies suggest that COVID-19 vaccines protect against severe illness (*1*); however, postvaccination SARS-CoV-2 infections (i.e., breakthrough infections) can occur because COVID-19 vaccines do not offer 100% protection (*2*,*3*). Data evaluating the occurrence of breakthrough infections and impact of vaccination in decreasing transmission in congregate settings are limited. Skilled nursing facility (SNF) residents and staff members have been disproportionately affected by SARS-CoV-2, the virus that causes COVID-19 (*4*,*5*), and were prioritized for COVID-19 vaccination (*6*,*7*). Starting December 28, 2020, all 78 Chicago-based SNFs began COVID-19 vaccination clinics over several weeks through the federal Pharmacy Partnership for Long-Term Care Program (PPP).† In February 2021, through routine screening, the Chicago Department of Public Health (CDPH) identified a SARS-CoV-2 infection in a SNF resident >14 days after receipt of the second dose of a two-dose COVID-19 vaccination series. SARS-CoV-2 cases, vaccination status, and possible vaccine breakthrough infections were identified by matching facility reports with state case and vaccination registries. Among 627 persons with SARS-CoV-2 infection across 75 SNFs since vaccination clinics began, 22 SARS-CoV-2 infections were identified among 12 residents and 10 staff members across 15 facilities ≥14 days after receiving their second vaccine dose (i.e., breakthrough infections in fully vaccinated persons). Nearly two thirds (14 of 22; 64%) of persons with breakthrough infections were asymptomatic; two residents were hospitalized because of COVID-19, and one died. No facility-associated secondary transmission occurred. Although few SARS-CoV-2 infections in fully vaccinated persons were observed, these cases demonstrate the need for SNFs to follow recommended routine infection prevention and control practices and promote high vaccination coverage among SNF residents and staff members.

CDPH monitors SNF SARS-CoV-2 infections using a data triangulation method that matches the SARS-CoV-2 test results from nucleic acid amplification tests (NAATs, such as reverse transcription–polymerase chain reaction [RT-PCR]) and antigen tests reported to the Illinois' National Electronic Disease Surveillance System with facility-reported line lists of SARS-CoV-2 test results from routine screening testing.§ In February 2021, CDPH began matching records to Illinois' Comprehensive Automated Immunization Registry Exchange to identify breakthrough infections. After identifying SARS-CoV-2 infection in a SNF resident 16 days after receipt of a second vaccine dose, CDPH initiated an investigation to quantify breakthrough infections across all facilities, evaluate symptoms and clinical outcomes, and assess potential secondary transmission. Vaccine effectiveness was not evaluated.

* These authors contributed equally to this report.

† A public-private partnership among CDC; CVS Pharmacy; Managed Health Care Associates, Inc.; and Walgreens to provide on-site COVID-19 vaccination of residents and staff members at enrolled long-term care facilities, including SNFs. https://www.cdc.gov/vaccines/covid-19/long-term-care/pharmacy-partnerships.html

§ CDPH advises facilities to routinely test residents at least monthly. Staff members were also required to receive testing routinely, with frequency determined based on community positivity rate and other metrics of interest. Staff members at all Chicago-based SNFs were tested at least twice weekly (until February 4, 2021), then weekly (during February 4–March 18, 2021), then biweekly (from March 18, 2021 through the end of investigation period). In response to a facility outbreak (i.e., a resident or staff member with a case within the past 14 days), all staff members and residents (excluding those who received a positive SARS-CoV-2 test <90 days previously) are required to receive testing at least every 3–7 days until no new cases occur for at least 14 days. At the time a breakthrough infection was identified, frequency of resident testing at the 15 SNFs ranged from monthly to twice per week; frequency of staff member testing ranged from weekly to twice weekly.

Summary

What is already known about this topic?

Residents and staff members of skilled nursing facilities (SNFs) are recommended to receive COVID-19 vaccine as a priority group.

What is added by this report?

Twenty-two possible breakthrough SARS-CoV-2 infections occurred among fully vaccinated persons ≥14 days after their second dose of COVID-19 vaccine. Two thirds of persons were asymptomatic. A minority of persons with breakthrough infection experienced mild to moderate COVID-19–like symptoms; two COVID-19–related hospitalizations and one death occurred. No facility-associated secondary transmission was identified.

What are the implications for public health practice?

SNFs should prioritize vaccination and follow recommended COVID-19 infection prevention and control practices, including following work restrictions, isolation, quarantine, testing of residents and staff members, and use of personal protective equipment.

A facility's investigation period started on its first vaccination clinic date and ended March 31, 2021.[¶] A confirmed case of SARS-CoV-2 infection was defined as a positive SARS-CoV-2 NAAT or antigen test result from a respiratory specimen collected from a resident or staff member during the investigation period. Consistent with CDC guidance, a vaccine breakthrough infection in a resident or staff member was defined as a receipt of a positive SARS-CoV-2 NAAT or antigen test result from a respiratory specimen collected ≥14 days after completing the two-dose COVID-19 vaccination series.[**] Infection prevention specialists conducted case investigations to assess symptoms, clinical outcomes, and close contact information.

SARS-CoV-2 incidence during the investigation period was assessed across four groups based on vaccination status at the time a positive respiratory specimen was collected: 1) unvaccinated (never received a COVID-19 vaccine dose); 2) partially vaccinated (received one dose of a two-dose series); 3) vaccinated but not immune (received two doses of a two-dose series but <14 days had elapsed since the second dose); and 4) fully vaccinated (received two doses of a two-dose series and ≥14 days had elapsed since the second dose). In addition to routine facility follow-up, CDPH actively monitored facilities with breakthrough infections for 28 days to identify whether any new cases occurred in close contacts of the person with breakthrough infection.[††] Analyses were completed using SAS (version 9.4; SAS Institute). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[§§]

During the investigation period, an estimated 7,931 SNF residents and 6,834 staff members received two doses of COVID-19 vaccine. A total of 627 confirmed SARS-CoV-2 infections were identified across 75 of the 78 Chicago-based SNFs, including 353 (56%) among residents and 274 (44%) among staff members during the investigation period (Table 1). Three facilities had no confirmed SARS-CoV-2 infections after their first vaccination clinic. Approximately one half (47%) of resident cases occurred in men, 42% were in non-Hispanic Black persons, and the median age was 71 years. More than two thirds (72%) of staff member cases were in women, 38% were in non-Hispanic Black persons, and the median age was 42 years. Among the 627 cases, 447 (71%) occurred in unvaccinated persons, 145 (23%) in partially vaccinated persons, 13 (2%) in vaccinated but not immune persons, and 22 (4%) in fully vaccinated persons (Figure). These breakthrough infections occurred in 12 residents and 10 staff members and accounted for 16% (22 of 136) of SNF-associated cases occurring across all facilities ≥14 days after the second vaccination clinic at the respective facilities. No demographic or clinical differences were observed by vaccination status.

Among the 22 breakthrough infections, 18 (82%) were detected in persons who received testing as part of routine screening, and four (18%) occurred in residents who received testing before a hospital admission or procedure. Among the 18 breakthrough infections identified during routine screening, 14 were detected (across 10 facilities) while residents were receiving weekly testing from the facilities; staff members at all facilities were receiving testing at least weekly. The median interval from second dose to collection of a positive SARS-CoV-2 specimen was 29 days (interquartile range [IQR] = 23–42 days). The median interval between most recent positive NAAT result and last known negative test result was 7 days (IQR = 7–14 days).

[¶] First round vaccination clinics occurred during December 28, 2020–January 18, 2021. Persons were included in the study if infection occurred between the first clinic date at their respective facility and March 31, 2021. Moderna COVID-19 vaccination was exclusively administered at Chicago-based SNFs through the federal PPP. Six residents and two staff members received Pfizer-BioNTech COVID-19 vaccine through Chicago-based vaccine providers not participating in the federal PPP or facilities outside the city of Chicago.

[**] CDC breakthrough infection guidance: https://www.cdc.gov/vaccines/covid-19/health-departments/breakthrough-cases.html. Residents and staff members were excluded from the investigation if they had received 1) a positive SARS-CoV-2 test result from December 28 through the date of their facility's first vaccination clinic or 2) a known initial positive SARS-CoV-2 test result <90 days before their most recent SARS-CoV-2 test result.

[††] For residents, close contact was defined as being within 6 ft of a person for ≥15 minutes over a 24-hour period, regardless of personal protective equipment used. For staff members, close contact was defined as being within 6 ft of a person for ≥15 minutes over a 24-hour period when one or both persons were unmasked.

Abbreviations: I-NEDSS = Illinois' National Electronic Disease Surveillance System; IQR = interquartile range.

* Unvaccinated: received no COVID-19 vaccine doses; partially vaccinated: received one dose; vaccinated but not immune: received two doses but <14 days had elapsed since receipt of second dose; and fully vaccinated with breakthrough infection: received two doses and then received a positive SARS-CoV-2 test result ≥14 days after receipt of the second dose.

† Persons with the following races listed in I-NEDSS as American Indian or Alaska Native, Native Hawaiian or other Pacific Islander, other, or multiracial were categorized as non-Hispanic other.

§ Data on symptoms were extracted from I-NEDSS for unvaccinated, partially vaccinated, and vaccinated but not immune persons. Most COVID-19 case reports are entered into I-NEDSS through electronic laboratory reporting and provide minimal information (e.g., name, date of birth, and laboratory test and results) needed to meet reporting requirements. Data on symptoms in persons with breakthrough infections were supplemented with details from case investigations, which were not completed for nonbreakthrough cases. Symptom status for many persons with nonbreakthrough infection cases is unknown.

¶ Two residents were hospitalized for COVID-19–related reasons. Two additional residents were hospitalized for non-COVID-19–related reasons.

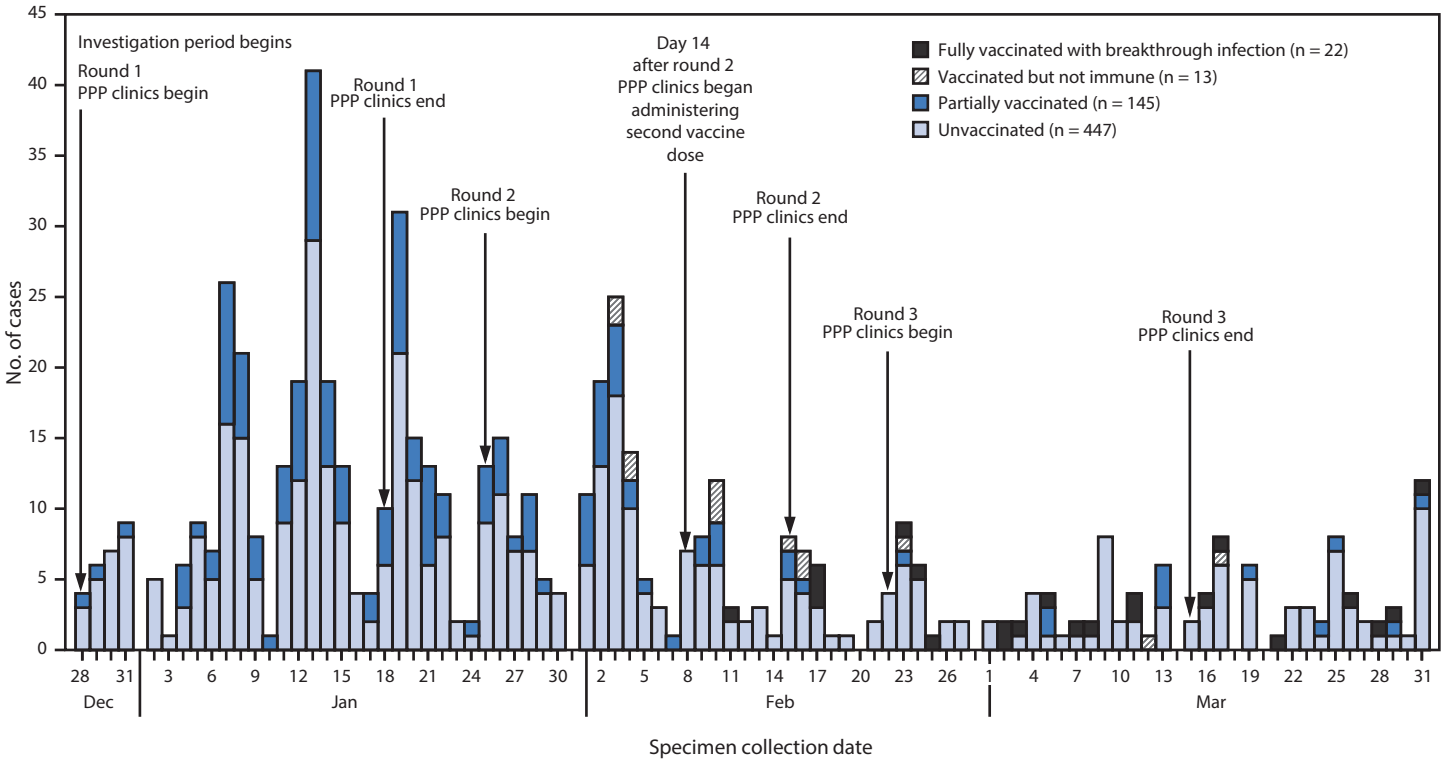
Two-dose vaccination coverage among residents and staff members at facilities with breakthrough infections ranged from 62% to 96% and 18% to 85%, respectively. Among the 15 facilities with breakthrough cases, attack rates[¶¶] for unvaccinated and vaccinated residents were 15% (89 of 604) and 0.8% (15 of 1,781), respectively. Among staff members, attack rates for unvaccinated and vaccinated persons were 6% (62 of 992) and 1% (12 of 1,135), respectively. Eleven facilities reported a total of 41 confirmed cases within 28 days after initial breakthrough infection at a facility (Table 2).[***] No facility-associated secondary transmission was determined to have occurred because the new cases that occurred after the initial breakthrough infection were not close contacts of the persons with breakthrough infections.

[¶¶] To calculate attack rates, residents and staff members who had never received COVID-19 vaccine (i.e., unvaccinated persons) and those who had received one COVID-19 vaccine dose of a two-dose series (i.e., partially vaccinated persons) were categorized as unvaccinated. Residents and staff members who had received two COVID-19 vaccine doses of a two-dose series and <14 days or ≥14 days had elapsed (i.e., vaccinated but not immune and fully vaccinated persons, respectively) were categorized as vaccinated. Aggregate vaccination data were only available for residents and staff members who received two doses of COVID-19 vaccine and did not have a SARS-CoV-2 infection. In the denominator, differentiation between persons who received two doses <14 days or ≥14 days was not possible.

[***] Cases identified within a 28-day monitoring window from the date of specimen collection for the breakthrough infection. For facilities with multiple breakthrough infections, 28-day monitoring windows might overlap, and new facility cases might be listed multiple times. As of April 12, 2021, nine of the 41 cases were breakthrough infections; seven of which are listed (see Table 2) and occurred during the investigation period.

MS-DOH-21-1816-A-001717

FIGURE. Confirmed SARS-CoV-2 infections (n = 627) among residents and staff members at 75* skilled nursing facilities, by specimen collection date and vaccination status† — Chicago, Illinois, December 2020–March 2021



Abbreviation: PPP = Federal Pharmacy Partnership for Long-Term Care Program.
* Among 78 Chicago-based facilities. Three facilities had no confirmed SARS-CoV-2 infections.
† Unvaccinated: received no COVID-19 vaccine doses; partially vaccinated: received one dose; vaccinated but not immune: received two doses but <14 days had elapsed since receipt of second dose; fully vaccinated with breakthrough infection: received two doses and then received a positive SARS-CoV-2 test result ≥14 days after receipt of the second dose.

Among the 22 persons with breakthrough infections, 14 (64%; eight residents and six staff members) were asymptomatic (Table 2). Three symptomatic persons (B3, E10, and G13) had mild, nonspecific symptoms; two (E8 and G12) had mild, specific symptoms; and three (A1, D6, and O22) had diagnosed pneumonia.††† Four residents were hospitalized: two (D6 and O22) for COVID-19–related reasons and two (A1 and D5) for reasons unrelated to COVID-19; one resident (O22) died.

Resident A1 received a diagnosis of pneumonia 9 days after receiving the second COVID-19 vaccine dose and 7 days before receiving a positive SARS-CoV-2 test result (Table 2). Although the timing of the patient's positive SARS-CoV-2 test result met the definition of a breakthrough infection, the clinical history indicated that the infection likely occurred <14 days after the second dose. Resident D6 was hospitalized for weakness and loss of appetite in association with pneumonia. Resident O22 experienced fatigue and respiratory symptoms and received a diagnosis of pneumonia. This patient had a positive SARS-CoV-2 test result on hospital admission and had concomitant group B β-hemolytic streptococcal bacteremia and a *Pseudomonas* urinary tract infection and died 7 days after hospital admission. The death certificate listed complications of COVID-19 infection as primary cause of death; underlying conditions were hypertension, diabetes mellitus, and chronic kidney disease.

Among 12 available specimens from seven patients with breakthrough infections, RT-PCR cycle threshold values were >28, indicating low levels of detectable virus. Six persons with breakthrough infections had a previous positive SARS-CoV-2 test result >90 days before the most recent test, including five persons who had negative test results (range = 1–43 tests) between the positive results (Supplementary Figure, https://stacks.cdc.gov/view/cdc/105130) and at least one negative NAAT result <14 days before the postvaccination positive test result. Five persons were asymptomatic during the second infection. Paired specimens for sequence comparison were unavailable.

††† Symptoms were categorized as nonspecific, mild, or moderate based on the National Notifiable Diseases Surveillance System and Council of State and Territorial Epidemiologists definition of symptomatic COVID-19. https://wwwn.cdc.gov/nndss/conditions/coronavirus-disease-2019-covid-19/case-definition/2020/08/05/

Discussion

Twelve SNF residents and 10 staff members had positive SARS-CoV-2 test results ≥14 days after receiving a second COVID-19 vaccine dose (breakthrough infections). Fourteen (64%) were asymptomatic, available RT-PCR cycle threshold values suggest low viral loads, and no facility-associated secondary transmission was detected. Two residents with breakthrough infections experienced COVID-related hospitalizations, one of whom died because of multiple concurrent infections. Although rare, postvaccination breakthrough infection can occur because COVID-19 vaccines do not offer 100% protection (*2*,*3*). Early studies suggest that COVID-19 vaccines protect against severe illness and might be effective at preventing infection (*1*); however, data on the impact of vaccination on transmission in congregate settings are limited. In addition, some persons whose infections met the case definition of a breakthrough infection might have had persistently positive

MS-DOH-21-1816-A-001719

TABLE 2. (*Continued*) Skilled nursing facility residents and staff members with SARS-CoV-2 breakthrough infections,* by facility and clinical characteristics — Chicago, Illinois, December 2020–March 2021

Abbreviations: Ct = cycle threshold; F = female; HA = headache; M = male; NA = not applicable; NAAT = nucleic acid amplification test; SOB = shortness of breath.

* Receipt of a positive SARS-CoV-2 NAAT (e.g., reverse transcription–polymerase chain reaction) or antigen test result from a respiratory specimen collected ≥14 days after completing the two-dose COVID-19 vaccination series.

† Missing Ct values are for specimens that were discarded by the laboratory and unavailable for sequencing.

§ Cases identified within a 28-day monitoring window from the date of specimen collection for the breakthrough infection. For facilities with multiple breakthrough infections, 28-day monitoring windows might overlap, and new facility cases might be listed multiple times.

¶ When a new case in a facility was identified, infection prevention specialists determined whether the person with the case met criteria to be considered a close contact of the person with the breakthrough infection. Data in this column represent the number of cases in persons that met the definition of a close contact and occurred after identification of the breakthrough infection as of April 12, 2021.

** Resident A1 had a positive SARS-CoV-2 test result 16 days after receiving the second dose of COVID-19 vaccine, which was an incidental finding when admitted to the hospital for new onset of seizures. The positive result might have been related to an episode of pneumonia diagnosed 9 days after the second dose. COVID-19 testing was not associated with compatible symptoms, and this resident was included because the resident's case met the laboratory-based breakthrough infection definition. This resident likely did not experience a breakthrough infection because previous pneumonia onset is suggestive of SARS-CoV-2 infection before full immunization.

†† Resident D5 had a positive preprocedural SARS-CoV-2 test result and was subsequently hospitalized for non-COVID-19–related reasons, including multiple falls and a bloodstream infection related to a midline catheter.

§§ Resident D6 was hospitalized for COVID-19-related reasons because of weakness and loss of appetite in association with pneumonia diagnosed at hospital admission.

¶¶ Based on the symptomatic disease case definition outlined by the Council of State and Territorial Epidemiologists, patient E10 had nonspecific COVID-19 symptoms. Previous testing history was examined using the Illinois' National Electronic Disease Surveillance System. No known previous positive SARS-CoV-2 were identified for this patient.

*** Resident O22 was hospitalized for COVID-19-related reasons because of fatigue, cough, SOB, and difficulty breathing. SARS-CoV-2 test result was positive, and resident received a diagnosis of pneumonia requiring hospital admission and intubation in the intensive care unit for hypoxic respiratory failure. Concomitant infections including group B streptococcal bacteremia and *Pseudomonas* urinary tract infection were also identified. The resident died 7 days after hospital admission.

NAAT results after initial infection; however, most had multiple confirmed negative interim test results. Additional data are needed to differentiate breakthrough infections from sequelae of previous infections and to determine whether persons with breakthrough infections can transmit virus.

The results in this report highlight the importance of COVID-19 vaccination in high-risk congregate settings such as SNFs; most fully vaccinated persons were not infected, did not have COVID-19–like symptoms, and did not have severe illness. Despite the identification of positive NAAT results during the investigation period, breakthrough infections did not lead to secondary transmission at these facilities.

Expanded testing of residents and staff members in these settings in response to clusters or outbreak investigations is also important, regardless of vaccination status, because these persons might have asymptomatic infections.§§§ A previous study found that vaccination has an estimated effectiveness of 63% against SARS-CoV-2 infection among SNF residents >14 days after the first dose through 7 days after the second dose (*8*). Additional studies are needed to assess the impact of full vaccination in SNFs and to understand how vaccination in settings that include older adults, immunocompromised persons, and persons with known history of SARS-CoV-2 infection compares with clinical trial efficacy data. Whether vaccinated asymptomatic persons can transmit SARS-CoV-2 is also unknown; therefore, facilities should continue to require residents to quarantine after close contact with an infected person.¶¶¶

Vaccine effectiveness estimates for prevention of SARS-CoV-2 infection and COVID-19 were not calculated because CDPH does not have access to SNF electronic medical records, limiting the ability to obtain individual-level data from facilities on all residents and staff members and to calculate person-time among vaccinated and unvaccinated persons who were not infected. Facilities did not have the capacity to provide line lists and vaccination information for noninfected residents and staff members.

The findings in this report are subject to at least four limitations. First, confirming whether patients with a breakthrough infection and a previous positive SARS-CoV-2 test result had a true reinfection or represented persons with prolonged shedding from previous infection was not possible. Intermittent prolonged SARS-CoV-2 shedding is well described (*9*). In addition to two SARS-CoV-2 tests ≥90 days apart, paired respiratory specimens are needed so that their genetic sequences can be compared.**** Data such as epidemiologic links to confirmed cases and clinical course can provide supporting evidence for reinfection but do not definitively identify reinfection events. Second, vaccination data in this report are limited to Chicago residents and persons vaccinated in Chicago; data were unavailable for staff members who were not Chicago residents and were vaccinated outside Chicago. Third, data entry errors or delayed surveillance reporting might prevent record matching, leading to an underestimate of breakthrough infections. Finally, although some specimens were submitted for genotyping to evaluate possible variant strains, results are pending and not yet available.

SNFs should continue to follow recommended infection prevention and control practices,†††† including work restrictions, isolation of persons with confirmed cases, quarantine of residents who have had close contact with persons with confirmed cases,

routine and outbreak testing of residents and staff members, and use of personal protective equipment, regardless of vaccination status. Maintaining high vaccination coverage among residents and staff members is also important to reduce opportunities for transmission within facilities and exposure among persons who might not have achieved protective immunity after vaccination.

April 21, 2021

CDC Resources

- **Self- testing guidance:** Community members have the option of either a self-collection kit or a self-test for COVID testing. Self-collection kits and self-tests can be performed at home or anywhere else. These self-collection kits and tests are available either by prescription or over the counter in a pharmacy or retail store without a prescription. Currently available self-collection kits and tests are used for the detection of current infection.
- **Guide for community partners:** CDC created a complementary resource specific to community-based organizations, the Guide for Community Partners. This guide can help organizations with community-level reach with racial and ethnic minority groups — or other under-resourced communities — get connected to COVID-19 vaccination confidence and access efforts and resources. The Guide includes practical ways to get involved, best practices, one-pagers, linked resources, data, and more to help guide organizations' efforts.
- **COVID-19 vaccine equity:** CDC released a short two-pager, COVID-19 Vaccine Equity: Best Practices for Community and Faith-Based Organizations. This resource provides an overview of strategies and interventions detailed in the Guide. Specifically, it provides best practices and examples for information and materials to disseminate, methods and platforms to use, useful and accessible venues and locations to conduct outreach and vaccination sites, trusted and influential messengers to engage, and vaccination appointment and site logistics to consider
- **New vaccine resources:**
  - Recommendation to Pause Use of Johnson & Johnson's Janssen COVID-19 Vaccine
  - How to Enroll as a COVID-19 Vaccination Provider
  - What Long-Term Care Facility Residents Need to Know About COVID-19 Vaccination
  - U.S. COVID-19 Vaccination Program: Vaccine Channel Portfolio by Jurisdiction
  - General Public User (Vaccine Recipient)
  - Resources for Jurisdictions, Clinics, and Organizations
- **CDC COVID-19 Home Page:** CDC's COVID-19 Home Page provides communities with COVID-19 related information and resources.

Morbidity and Mortality Weekly Report (MMWR)

- **April 21, 2021: Postvaccination SARS-CoV-2 Infections Among Skilled Nursing Facility Residents and Staff Members — Chicago, Illinois, December 2020–March 2021.** Early studies suggest that COVID-19 vaccines protect against severe illness; however, postvaccination SARS-CoV-2 infections can occur because COVID-19 vaccines do not offer 100% protection. Data evaluating the occurrence of breakthrough infections and impact of vaccination in decreasing transmission in congregate settings are limited. Skilled nursing facility (SNF) residents and staff members have been disproportionately affected by SARS-CoV-2 and were prioritized for COVID-19 vaccination through the federal Pharmacy Partnership for Long-Term Care Program. Routine health department screening has identified possible breakthrough SARS-CoV-2 infections occurring among fully vaccinated person 14 days or more after their second dose of COVID-19 vaccine.
- **April 21, 2021: COVID-19 Outbreak Associated with a SARS-CoV-2 R.1 Lineage Variant in a Skilled Nursing Facility After Vaccination Program — Kentucky, March 2021.** The Kentucky Department for Public Health (KDPH) and a local health department investigated a COVID-19 outbreak in a SNF that occurred after all residents and health care personnel (HCP) had been offered vaccination.

Upcoming Meetings

- **Emergency Advisory Committee on Immunization Practices (ACIP):** Friday, April 23, 11:00 AM- 5:00 PM EDT ACIP A virtual emergency meeting will be held to discuss Janssen (Johnson & Johnson) COVID-19 vaccine.
- **COVID-19 Partner Update April 26, 2021: Keeping up With Critical Diabetes Care and Prevention During COVID-19:** 3:00-4:00 PM EDT, Monday, April 26, 2021. Join CDC's weekly partner call for updates on the COVID-19 response, including new resources for the private sector and the general public. Register for the event here. For Q&A, please email eocevent337@cdc.gov with "Partner Call 4/26" in the subject line. This call will be recorded andposted with previous Partner Update webinars.
- **Global, Regional, and Local Approaches to COVID-19 Vaccine Equity: Sharing lessons for World Immunization Week:** 3:00 PM EDT, Tuesday, April 27, 2021. In celebration of World Immunization Week, the NACCHO Immunization and Global Health teams are hosting a webinar that will connect global, regional and local experiences related to COVID-19 immunization equity. Register for the event here.

Additional Resources

- **Diagnosis and Management of Suspected Vaccine-induced Immune Thrombotic Thrombocytopenia (VITT):** Tuesday, April 20, CDC and the American Society of Hematology hosted a webinar to address the rare cases of thrombosis with thrombocytopenia have been reported following vaccination with the Johnson & Johnson/Janssen COVID-19 vaccine. The recording of this webinar can be found here.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- MMWR Early Release: "Community Transmission of SARS-CoV-2 Associated with a Local Bar Opening Event – Illinois, February 2021" [Attachment, Link]
    - From the summary: *"Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred during February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students."*
- Partner Alert: Community of Practice webinar "School-based Screening Testing" [Link]
    - This week's CDC Community of Practice call is on **Thursday**, **April 8** at **2:00 pm ET**. The webinar will focus on the importance of the partnership between public health and education in establishing COVID-19 K-12 screening testing programs and provide information on assistance being offered to support these programs. You may join the call here or dial in using the call-in line below:
        - Zoom Dial-in: 1 646-828-7666
          Meeting ID: 161 148 9877
          Passcode: 66625007
- ELC webinar slides and recording of "Reopening Schools" held Thursday, April 1* [Attachment, Link]

On **Thursday**, **April 1**, ELC hosted a webinar regarding its newest supplemental funding package "ELC Reopening Schools" to review Reopening Schools guidance, subject matter expert perspectives, and a Q&A session. The slides from the webinar are attached, and a link to the recording is available here. ***Please note: the recording is a large file download.**

- COVID-19 Genomic Epidemiology Toolkit Follow Up & Focus Group [Link]
    - Thanks to all who have tried the **COVID-19 Genomic Epidemiology Toolkit**! The Toolkit modules, created by CDC with state and local partners, provide easy-to-use training materials for applying genomic epidemiology to SARS-CoV-2 surveillance and outbreak investigations. Please visit the COVID-19 Genomic Epidemiology Toolkit page as we continue to add new videos and resource links. In an effort to improve the Toolkit, we plan to host a **focus group** to gather feedback. We are looking for volunteers and would appreciate your participation. The focus group will entail an hour-long zoom call with other participants. The only requirements are that you have used the toolkit and are willing to discuss your feedback. To volunteer or to ask any questions, please email GenEpiToolkit@cdc.gov.
- CDC Partner Update Call: "Contact Tracing for COVID-19: Do we still need it? (You bet we do!) Ask an Expert – Q&A with a CDC Expert on Current COVID-19 Guidance" [Link]
    - CDC will host the next installment of its weekly partner call **Monday, April 12** at **3:00 pm ET**. Dr. Kyle Bernstein will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Then, Dr. Melanie Taylor will discuss contact tracing and why it is still important during the COVID-19 Response.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 4/12" in the subject line. The call will be recorded and posted to CDC's website here.
- CDC Media Statement: "CDC Issues Next Phase of the Conditional Sail Order for Cruise Ship Operators" [Link]
    - On **Friday**, **April 2**, CDC issued the next phase of technical guidance under the Framework for Conditional Sailing Order (CSO). From the statement: *[this phase requires]* "cruise lines to establish agreements at ports where they intend to operate, implement routine testing of crew, and develop plans incorporating vaccination strategies to reduce the risk of introduction and spread of COVID-19 by crew and passengers. Read the full statement here.

Standing Updates

- Webinar: White House COVID-19 Response Team w/ State & Local Health Officials [Link]
    - The White House COVID-19 Team will host a webinar **TODAY**, Tuesday, **April 6** at **6:00 pm EST**. Advance registration is required. After registering, you will receive a confirmation email with full call info.

    - Registration link: https://pitc.zoomgov.com/webinar/register/WN_IJV5E1zNRL2QmyyXrpki6Q
- CDC Partner Update – April 5 [Attachment]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – April 5 [Attachment]
    - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
    - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC 24/7
PROTECTING AMERICA'S SAFETY, HEALTH, AND SECURITY

April 5, 2021

CDC Resources

- **Science Brief: SARS-CoV-2 and surface (fomite) transmission for indoor community environments:** A new science brief describes the latest science of SARS-CoV-2 surface (fomite) transmission. The main way people are infected with COVID-19 is through close, person-to-person contact, typically between people who are near each other (within about 6 feet). People can be infected with the virus that causes COVID-19 through contact with contaminated surfaces and objects. However, the risk is considered to be low. In most situations, cleaning surfaces using soap or detergent is enough to reduce the chances of spread from surfaces.
- **Revised guidance on SARS-CoV-2 and surface transmission:** CDC released updated guidance on cleaning and disinfecting at home and on cleaning and disinfecting facilities in community settings. In most situations at home and in the community, cleaning with soap or detergent is enough to remove virus particles on surfaces well enough to keep spaces clean. This guidance is not intended for healthcare settings or for other facilities where specific regulations or practices for cleaning and disinfection may apply.
- **Technical instructions for mitigation of COVID-19 among cruise ship crew:** This guidance was updated to add routine COID-19 laboratory screening testing of all crew section, the procedures for embarking contractors and visitors overnight, and the procedures for embarking day contractors and visitors. Surveillance reporting requirements and the color-coding system were also updated. All CDC quarantine and isolation guidance for cruise ships can be found here.
- **COVID-19 Science Update**: Released on April 2, 2021, the Science Update provides summaries of prevention, mitigation, and intervention strategies; vaccination in health care workers; detection, burden, and impact of SARS-CoV-2; transmission of SARS-CoV-2; the B.1.1.7 variant; the natural history of SARS-CoV-2 infection; social, behavioral, and communication science.
- **COVID Data Tracker Weekly Review:** Released on April 2, 2021, the Weekly Review provides an interpretive summary of last week's key data from CDC's COVID Data Tracker.

Morbidity and Mortality Weekly Report (MMWR)

- **Early Release MMWR, April 5, 2021: Community Transmission of SARS-CoV-2 Associated with a Local Bar Opening Event – Illinois, February 2021.** Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred in February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students. Opening up settings such as bars, where mask wearing and physical distancing are challenging, can affect the community.

Upcoming Meetings

- **CDC COVID-19 Partner Update: When to clean, when to disinfect, and what science says about SARS-CoV-2 on surface:** Monday, April 19, 2021: 3:00-4:00 PM EDT. CDC invites partners to a presentation on a new science brief and

updated guidance documents regarding cleaning and disinfection. Register for the webinar in advance.

- **NACCHO webinar on the federal response to COVID-19:** Tuesday, April 6, 2021: 3:00-4:00 PM EDT. The National Association of County and City Health Officials invite local health department leadership and staff to participate in this webinar to hear from FEMA, HHS, and CDC on the role of each agency in the COVID-19 response. To join the call, please register here (only registered participants will be able to join).

COVID-19 Special Project:

ELC Reopening Schools

Support for screening testing to reopen schools and keep them operating safely

April 1, 2021

Welcome

Henry Walke, MPH, MD

Incident Manager, CDC COVID-19 Response

Director, Division of Preparedness and Emerging Infections

Agenda

- Overview
- ELC Reopening Schools
  - Activities
  - Workplans & budgets
  - Timeline and reporting dates
- CDC school SMEs
- Representatives from the field
- Questions

Overview

- The *American Rescue Plan Act of 2021*

  Provided approximately $12 billion to recipients for:

  - Testing in underserved populations ($2.25B)
  - **School-based COVID-19 screening testing for teachers, staff and students to assist schools in reopening safely for in-person instruction ($10B)**

ELC Reopening Schools

- Supports comprehensive screening testing for K-12 schools (public and private) in April 2021, extending through the end of the school year and into summer/subsequent school year, as funds allow.
- Maintains integral role of public health in the testing ecosystem.
- Ensures a holistic assessment and monitoring of disease burden within any given community.

ELC Reopening Schools

- $10B awarded to all 64 recipients according to a population-based formula.
- 85% of the recipient award must be allocated to support school districts to conduct screening testing.
- 16-month funding period (April 1, 2021 – July 31, 2022)

Budgets

- Spending is permitted as soon as funds are available. Costs must align with guidance.
- Funds cannot be used to cover costs incurred before the date of award.
- Revised budget due sixty (60) days after the award is issued
  - Submit as a 'budget revision amendment' in GrantSolutions.
  - Courtesy copy in REDCap REDCap ‘ELC Reopening Schools: COVID Award’ portal under the ‘ELC Reopening Schools Financial Reporting’ page.
- For contractual agreements for school district support, submit contract details via Grant Note until revised budget finalized.

Financial Reporting

Starting thirty (30) days from award issuance, monthly financial reporting.

- Due on the 5th day of the month for the prior month financials
- Expenditures and unliquidated obligations (ULOs)
- Reported in the REDCap
  - In 'ELC Reopening Schools: COVID Award' portal
  - Under the 'ELC Reopening Schools Financial Reporting' page

Workplans

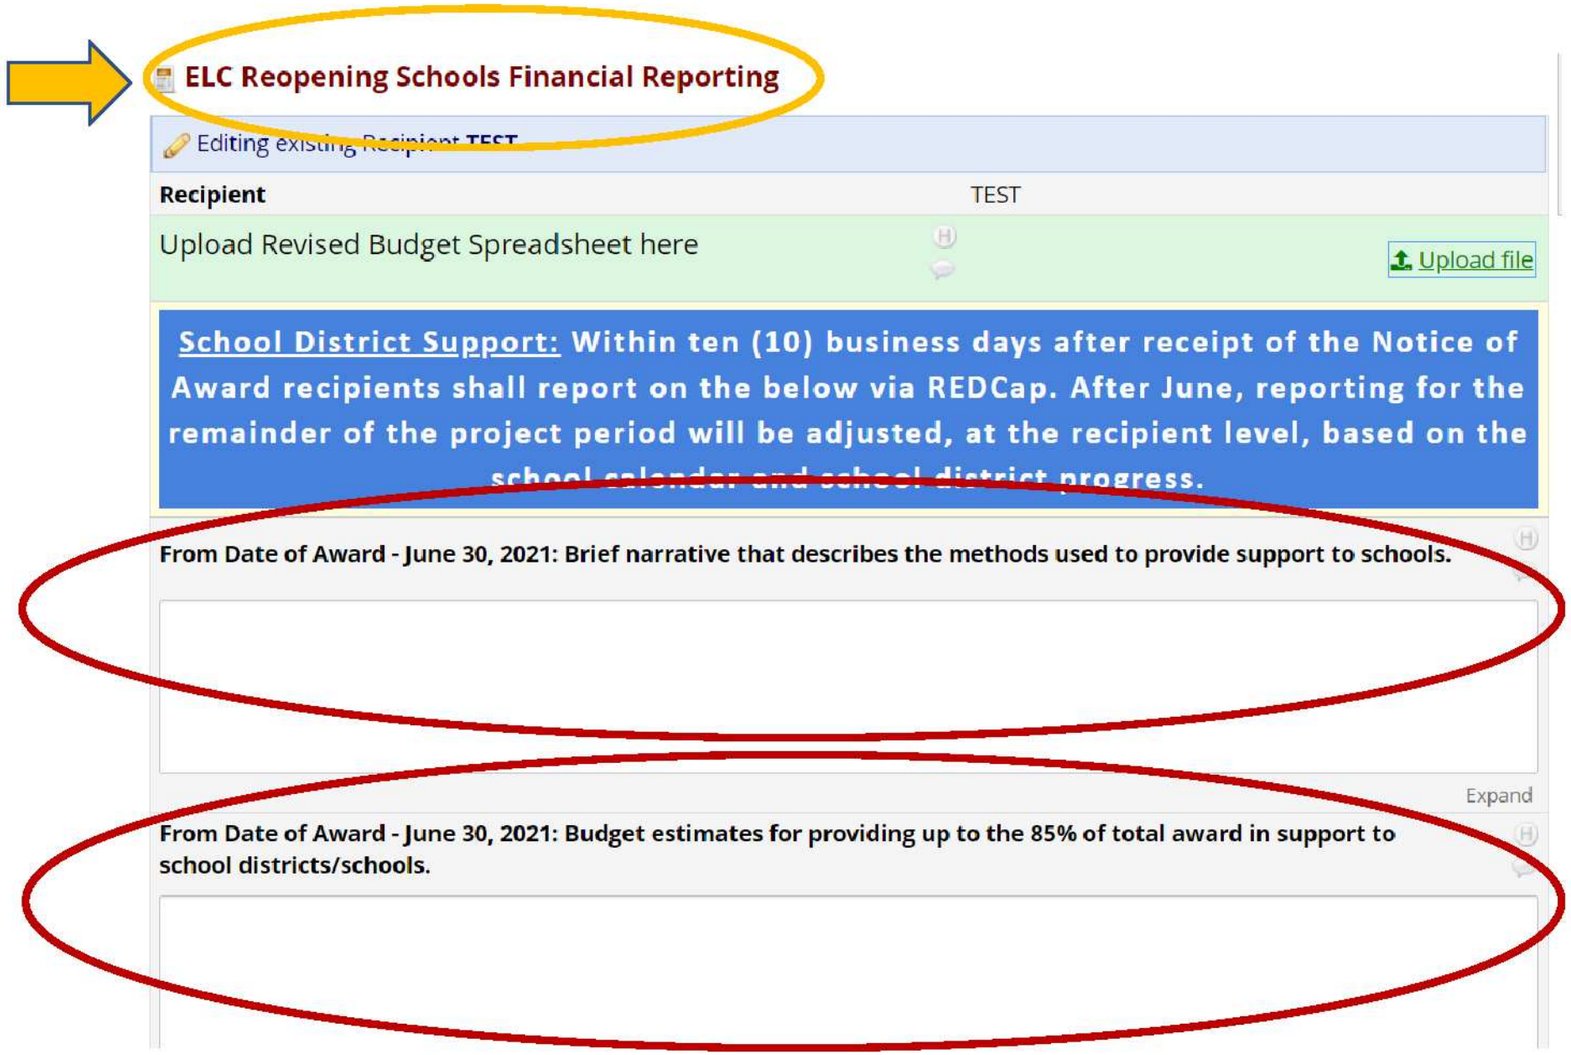
- Workplans are streamlined for this award
- Three required activities:

1. Rapid deployment of screening testing resources for the current school year.
   Estimated timeframe: April through June
2. Development of K-12 screening testing implementation plan.
   Estimated timeframe: June and July
3. Implementation of screening testing action plan for the following school year.

Required Activity 1

Rapid deployment of screening testing resources for the current school year

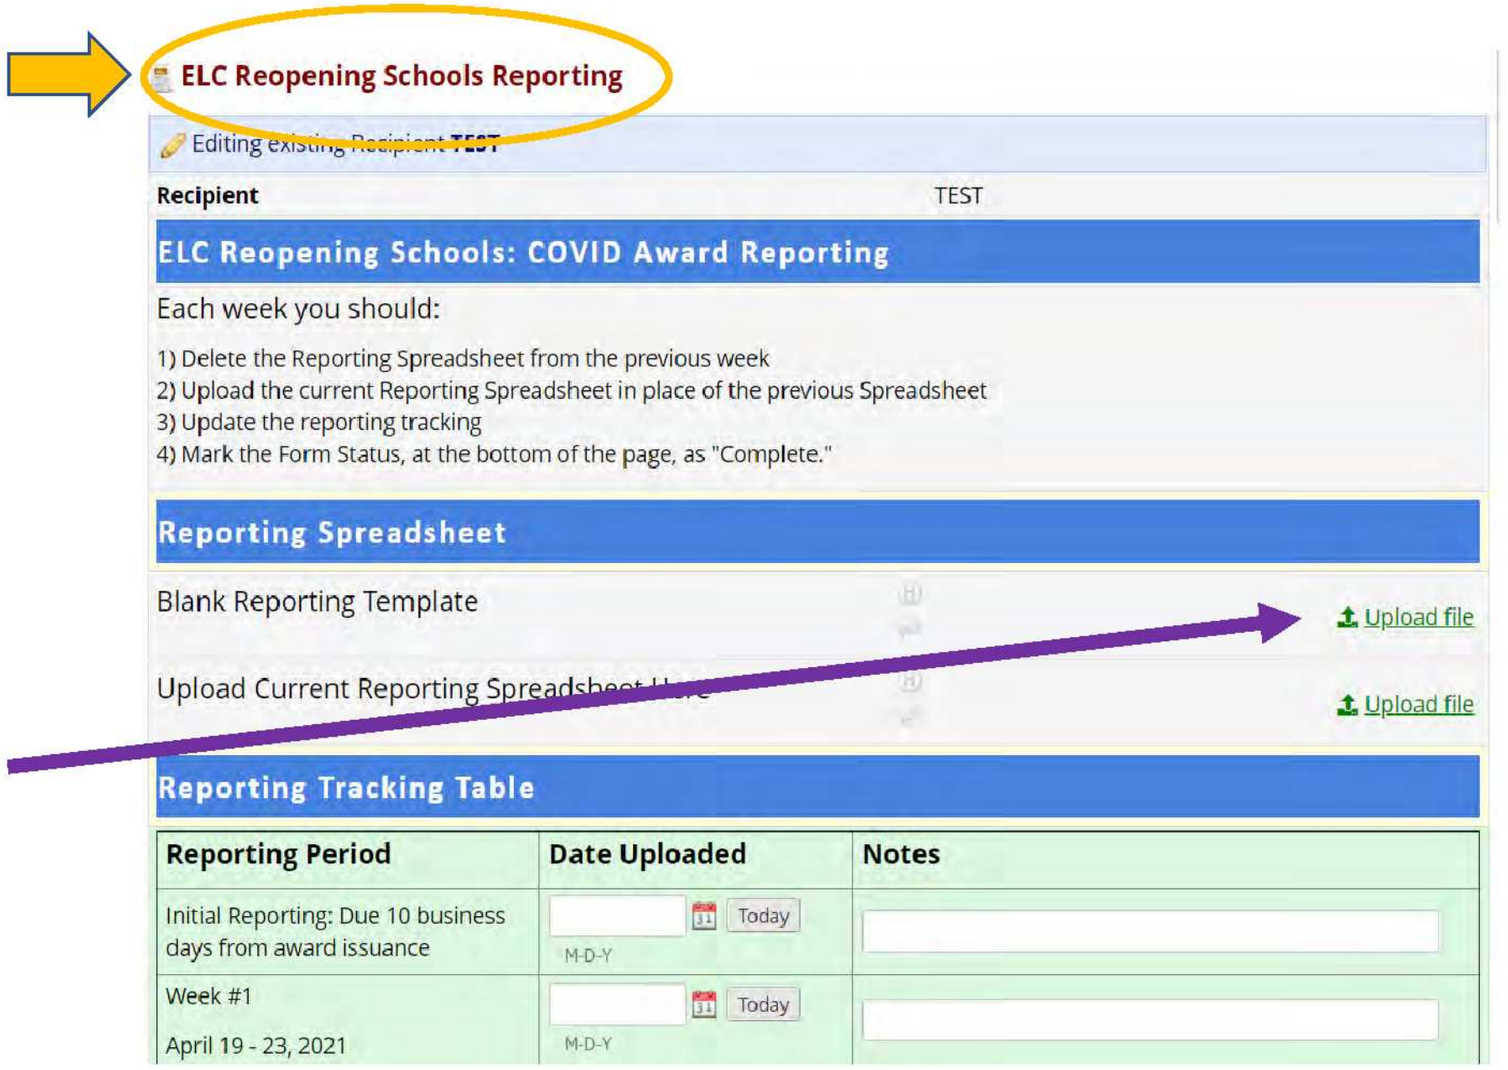
- Complete the narrative and estimates for School District Support
- Update weekly, as needed, through end of June 2021



Required Activity 1

Rapid deployment of screening testing resources for the current school year

You can find the 'Blank Reporting Template' here



- To reduce burden on recipients, ELC is creating individualized reporting templates that list school districts
- Plan is to make available through REDCap early next week (April 5 or 6)
- Review 'Blank Reporting Template' to ensure school districts are all listed

CK19-1904: ELC Reopening Schools COVID Award - Alabama - April 12 - April 16

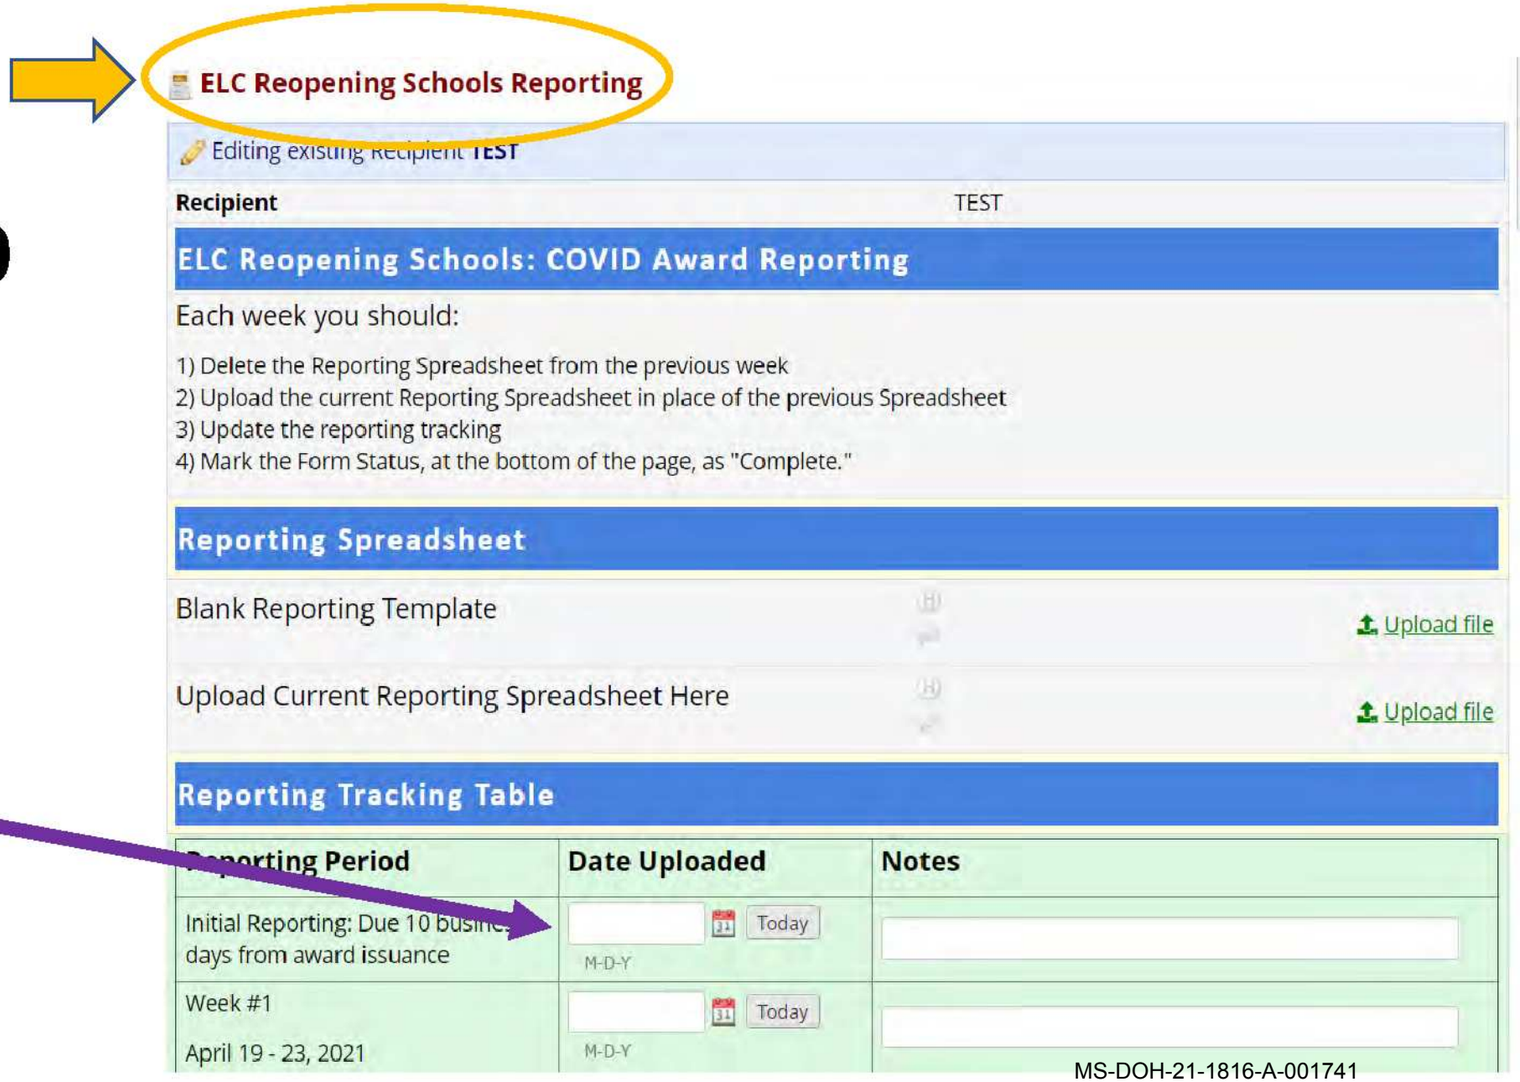
Place Holder

County	School District Name	Week	Total Enrollment	Tests Conducted: PCR	Tests Conducted: Antigen	Positive Cases (All test types)	Notes
Autauga County	Autauga County	April 12 - April 16					
Baldwin County	Baldwin County	April 12 - April 16					
Barbour County	Barbour County	April 12 - April 16					
Barbour County	Eufaula City	April 12 - April 16					
Bibb County	Bibb County	April 12 - April 16					
Blount County	Blount County	April 12 - April 16					
Blount County	Oneonta City	April 12 - April 16					
Bullock County	Bullock County	April 12 - April 16					
Butler County	Butler County	April 12 - April 16					
Calhoun County	Anniston City	April 12 - April 16					

April 12 - April 16 | April 19 - April 23 | April 26 - April 30 | May 3 - May 7 | May 10 - May 14 | ...

Weekly Reporting Requirement

- Submit in 'Initial Reporting' slot within **10 business days from award issuance**
- Mark date file is uploaded



Weekly Reporting Requirement

- Starts fifteen (15) days after the award issuance
- Report:
    1. The number of tests conducted by school districts and private/charter schools
    2. Test type
    3. Cases identified

CK19-1904: ELC Reopening Schools COVID Award - Alabama - April 12 - April 16

Place Holder

County	School District Name	Week	Total Enrollment	Tests Conducted: PCR	Tests Conducted: Antigen	Positive Cases (All test types)	Notes

April 12 - April 16 | April 19 - April 23 | April 26 - April 30 | May 3 - May 7 | May 10 - May 14 | ...

Weekly Reporting Requirement

Reporting Tracking Table

Reporting Period	Date Uploaded	Notes
Initial Reporting: Due 10 business days from award issuance	M-D-Y Today	test
Week #1 April 19 - 23, 2021	M-D-Y Today	
Week #2 April 26 - 30, 2021	M-D-Y Today	
Week #3 May 3 - 7, 2021	M-D-Y Today	
Week #4 May 10 - 14, 2021	M-D-Y Today	
Week #5 May 17 - 21, 2021	M-D-Y Today	
Week #6 May 24 - 28, 2021	M-D-Y Today	
Week #7 May 31 - June 4, 2021	M-D-Y Today	
Week #8 June 7 - 11, 2021	M-D-Y Today	
Week #9	M-D-Y Today	

- Reporting continues weekly until the end of June
- Mark date file is uploaded

Performance Measures

- Submitted through REDCap
- [Weekly/monthly] reporting schedule
- Number of screening tests performed
- Types of screening tests performed
- [Count/percent positive]

Timeline

Within 5 days after NOA	Authorized Official acknowledges receipt of this guidance by submitting a Grant Note in GrantSolutions *Letter template provided in guidance*.
10 days after NOA	Brief narrative on school support; budget estimates for up to 85% of award for school support; school list; estimated number enrolled for your support; & frequency of testing
15 days after NOA, weekly until 6/30/21	Performance measures: number of tests conducted by school district, test type, and cases identified
Beginning 5/1/21	Monthly financial reports in REDCap & GrantSolutions
6/1/21	Revised budget due in REDCap
After June	Performance reporting schedules will be adjusted individually for recipients

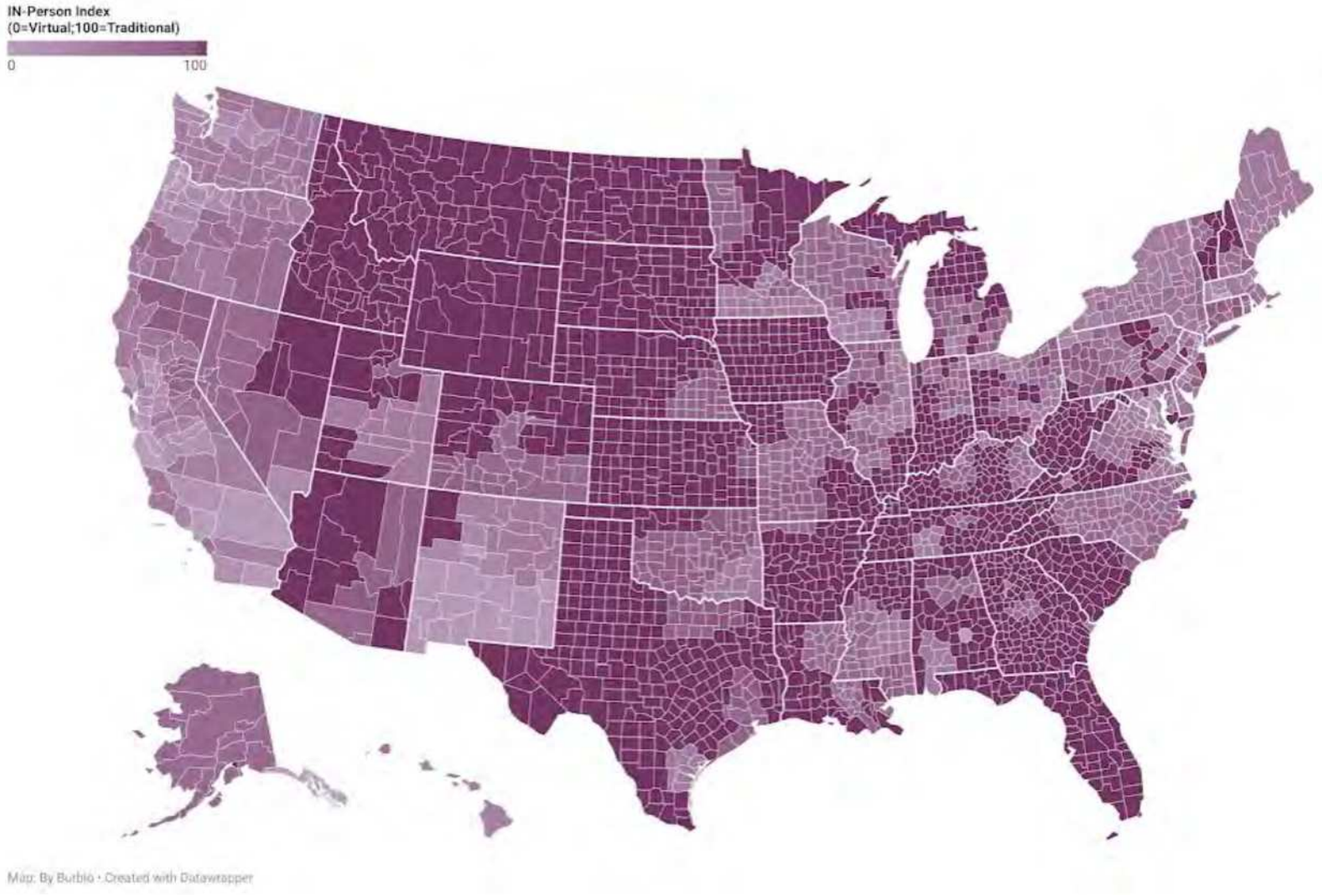
What's the *purpose* of testing in K-12 schools?

- **Reopening Schools**
  - virtual → hybrid
  - hybrid → in-person

- **Building Confidence**
  - teachers, staff and parents
  - schools are safe
  - transparent



Source: CNN according to data compiled by Education Week:
https://www.cnn.com/interactive/2020/health/coronavirus-schools-reopening/

Source: Burbio K-12 School Opening Tracker, estimates as of March 31, 2021

What's the *purpose* of testing in K-12 schools?

- **Layering Prevention**
  - testing (additional layer of prevention)
  - identify cases
- **Improving Mitigation**
  - identify in-school transmission
  - address root causes
- **Evolving Purpose**
  - diagnostic, screening, surveillance

Photo Credit (top): The COVID-19 Educational Testing Toolkit, Shah Family Foundation: https://covidedtesting.com/

Funding Landscape: K-12 School Testing

$550M HHS: Increased Community Access to Testing (ICATT)

HHS Continues Community Based Testing Sites for COVID-19

Today, the Department of Health and Human Services (HHS) announced the extension of the Community Based Testing Site program for COVID-19 testing, through partnership with national pharmacy and retail chains CVS, Rite-Aid, Walgreens, Quest (through services at Walmart) and service provider eTrueNorth (through services at Health Mart and Topco locations). The partnership has resulted in establishing more than 3,300 COVID-19 testing locations in all 50 states, the District of Columbia, and Puerto Rico. To date, more than 5.6 million tests have been conducted as a result of this partnership.

The Community Based Testing Site program began in the spring of 2020 and includes a large percentage - over 70% - of testing sites located in communities with moderate-to-high social vulnerability, as evidenced by their racial and ethnic composition, their household composition, their socioeconomic status, and similar considerations.

$10B CDC to 64 Jurisdictions (State Departments of Health)

Support COVID-19 screening testing to help schools reopen: Consistent with the American Rescue Plan (P.L. 117-2), the Centers for Disease Control and Prevention (CDC) will provide $10 billion to states to support COVID-19 screening testing for teachers, staff and students to assist schools in reopening safely for in-person instruction. CDC's *Operational Strategy for K-12 Schools through Phased Mitigation*, released in February 2021, makes clear that screening testing is a tool schools can utilize to help reopen safely as part of a comprehensive COVID-19 mitigation approach. Using existing funding mechanisms, this funding will be able to be deployed quickly as part of a strategy to help get schools open in the remaining months of this school year. In addition to ensuring diagnostic testing of symptomatic and exposed individuals, serial screening testing will help schools identify infected individuals without symptoms who may be contagious so that prompt action can be taken to prevent further transmission. With this ARP funding, states can support the critical testing and testing supports

$50M NIH for RADx-UP for Implementation Science

Research Opportunity Title: RADx-UP Return to School Diagnostic Testing Approaches (OT2 Clinical Trial Optional)

OTA-21-004

Participating Organization(s): National Institutes of Health

Components: This Other Transaction Research Opportunity Announcement (OT ROA) is part of the Rapid Acceleration of Diagnostics℠ for Underserved Populations (RADx-UP℠) Program. The research opportunity will be administered by the Office of the Director on behalf of RADx-UP.

Funding Instrument: The funding instrument is the Other Transaction (OT) Award mechanism.

OT awards are not grants, cooperative agreements, or contracts, and uses Other Transaction Authority, provided by Congress. Policies and terms for individual OT awards may vary between awards. Each award is therefore issued with a specific Agreement, which is negotiated with the recipient and details specific terms and conditions for that award.

$650M HHS/DOD for Operation ET (Expanding Testing)

Launching a pilot program to expand COVID-19 testing for schools and underserved populations through coordinating centers. HHS, in partnership with the Department of Defense (DOD), is investing $650 million to expand testing opportunities for K-8 schools and underserved congregate settings, such as homeless shelters, directly through new regional coordinating centers. These coordinating centers will organize the distribution of COVID-19 testing supplies and partner with laboratories across the country, including universities and commercial labs, to collect specimens, perform tests, and report results to the relevant public health agencies. These coordinating centers will identify existing testing capacity, match it up to an area of need, and fund that testing.

CDC Guidance

Photo Credit: COVID-19 Testing in K-12 Schools: Insights from Early Adopters, RAND Corporation, 2021: https://www.rand.org/pubs/research_reports/RRA1103-1.html

Essential Elements of Safe In-person Learning

1. **Consistent** implementation of **layered prevention strategies** to reduce transmission of SARS-CoV-2 in schools
2. **Indicators of community transmission** to reflect level of risk
3. **Phased prevention**

Additional layers of COVID-19 prevention

- **Testing** to identify individuals with SARS-CoV-2 infection
- **Vaccination** for teachers and school staff

Levels of Community Transmission

Indicator[1]	Low Transmission Blue	Moderate Transmission Yellow	Substantial Transmission Orange	High Transmission Red
Total new cases per 100,000 persons in the past 7 days[2]	0-9	10-49	50-99	≥100
Percentage of NAATs that are positive during the past 7 days[3]	<5.0%	5.0%-7.9%	8.0%-9.9%	≥10.0%

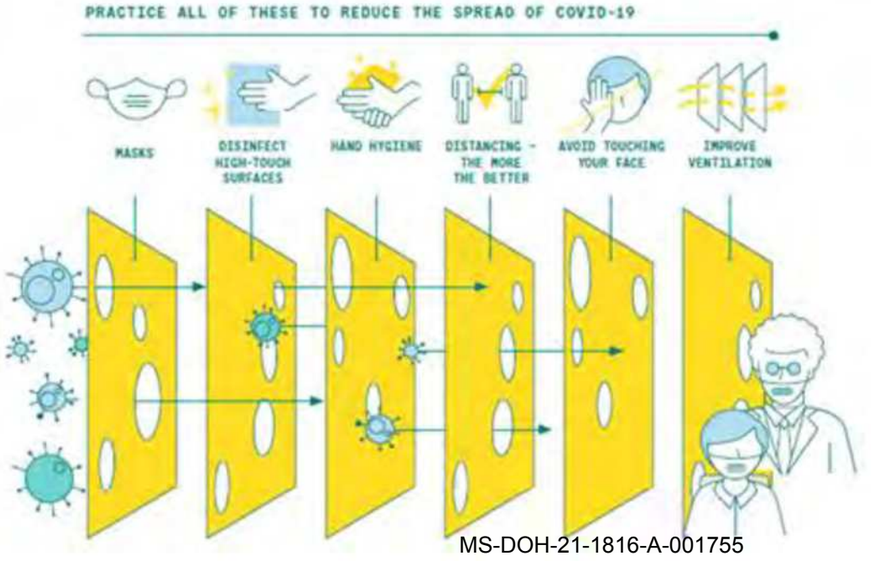
[1]If the two indicators suggest different levels, the actions corresponding to the higher threshold should be chosen. County-level data on total new cases in the past 7 days and test percent positivity are available on the County View tab in CDC's COVID Data Tracker.

[2]Total number of new cases per 100,000 persons within the last 7 days is calculated by adding the number of new cases in the county/community in the last 7 days divided by the population in the county and multiplying by 100,000.

[3]Percentage of positive diagnostic and screening nucleic acid amplification tests (NAATs) during the last 7 days is calculated by dividing the number of positive tests in the county during the last 7 days by the total number of tests resulted over the last 7 days. Additional information can be found on the Calculating Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) Laboratory Test Percent Positivity: CDC Methods and Considerations for Comparisons and Interpretation webpage.

Testing Identifies Individuals with SAR-COV-2 Infection and Limits Outbreaks

- In the K-12 Operational Strategy, testing is framed as additional COVID-19 prevention in schools, along with vaccination.
- Diagnostic testing: **all schools** should offer referrals to any student, teacher, staff member who has symptoms at school and those who were exposed.
- Screening testing: **some schools** may elect to use screening testing as a strategy to identify cases and prevent secondary transmission.
  - Added layer of mitigation—it doesn't replace other mitigation strategies
  - At schools that offer screening testing: weekly testing recommended for teachers (all levels), students (moderate, substantial, high levels)



MS-DOH-21-1816-A-001755

Figure Credit: COVID-19 Testing in K-12 Settings: A Playbook for Educators and Leaders, Rockefeller Foundation: https://www.rockefellerfoundation.org/wp-content/uploads/2021/02/The-RockefellerFoundation-Covid-19-K-12-Testing-Playbook-for-Educators-and-Leaders.pdf

Testing Recommendations: K-12 Schools Operational Strategy

Low Transmission Blue	Moderate Transmission Yellow	Substantial Transmission Orange	High Transmission Red
All schools implement 5 key prevention strategies: masks required; physical distancing; handwashing and respiratory etiquette; cleaning and maintaining healthy facilities; contact tracing in combination with quarantine and isolation **Diagnostic testing:**[1] symptomatic students, teachers, and staff and close contacts referred for diagnostic testing			
Screening testing[2]			
Screening testing of teachers and staff offered at least once per week			
No screening testing for students	**Screening testing for students** offered at least once per week[3]		
Testing for high-risk sports: testing recommended at least once per week[4] **Testing for low and intermediate-risk sports:** testing recommended at least once per week		**Testing for high-risk sports:** testing recommended twice per week **Testing for low and intermediate-risk sports:** testing recommended at least once per week	

[1]Diagnostic testing for SARS-CoV-2 is intended to identify occurrence of SARS-CoV-2 infection at the individual level and is performed when there is a reason to suspect that an individual may be infected, such as having symptoms or suspected recent exposure.

[2]Screening testing is intended to identify infected asymptomatic individuals who may be contagious so that measures can be taken to prevent further transmission.

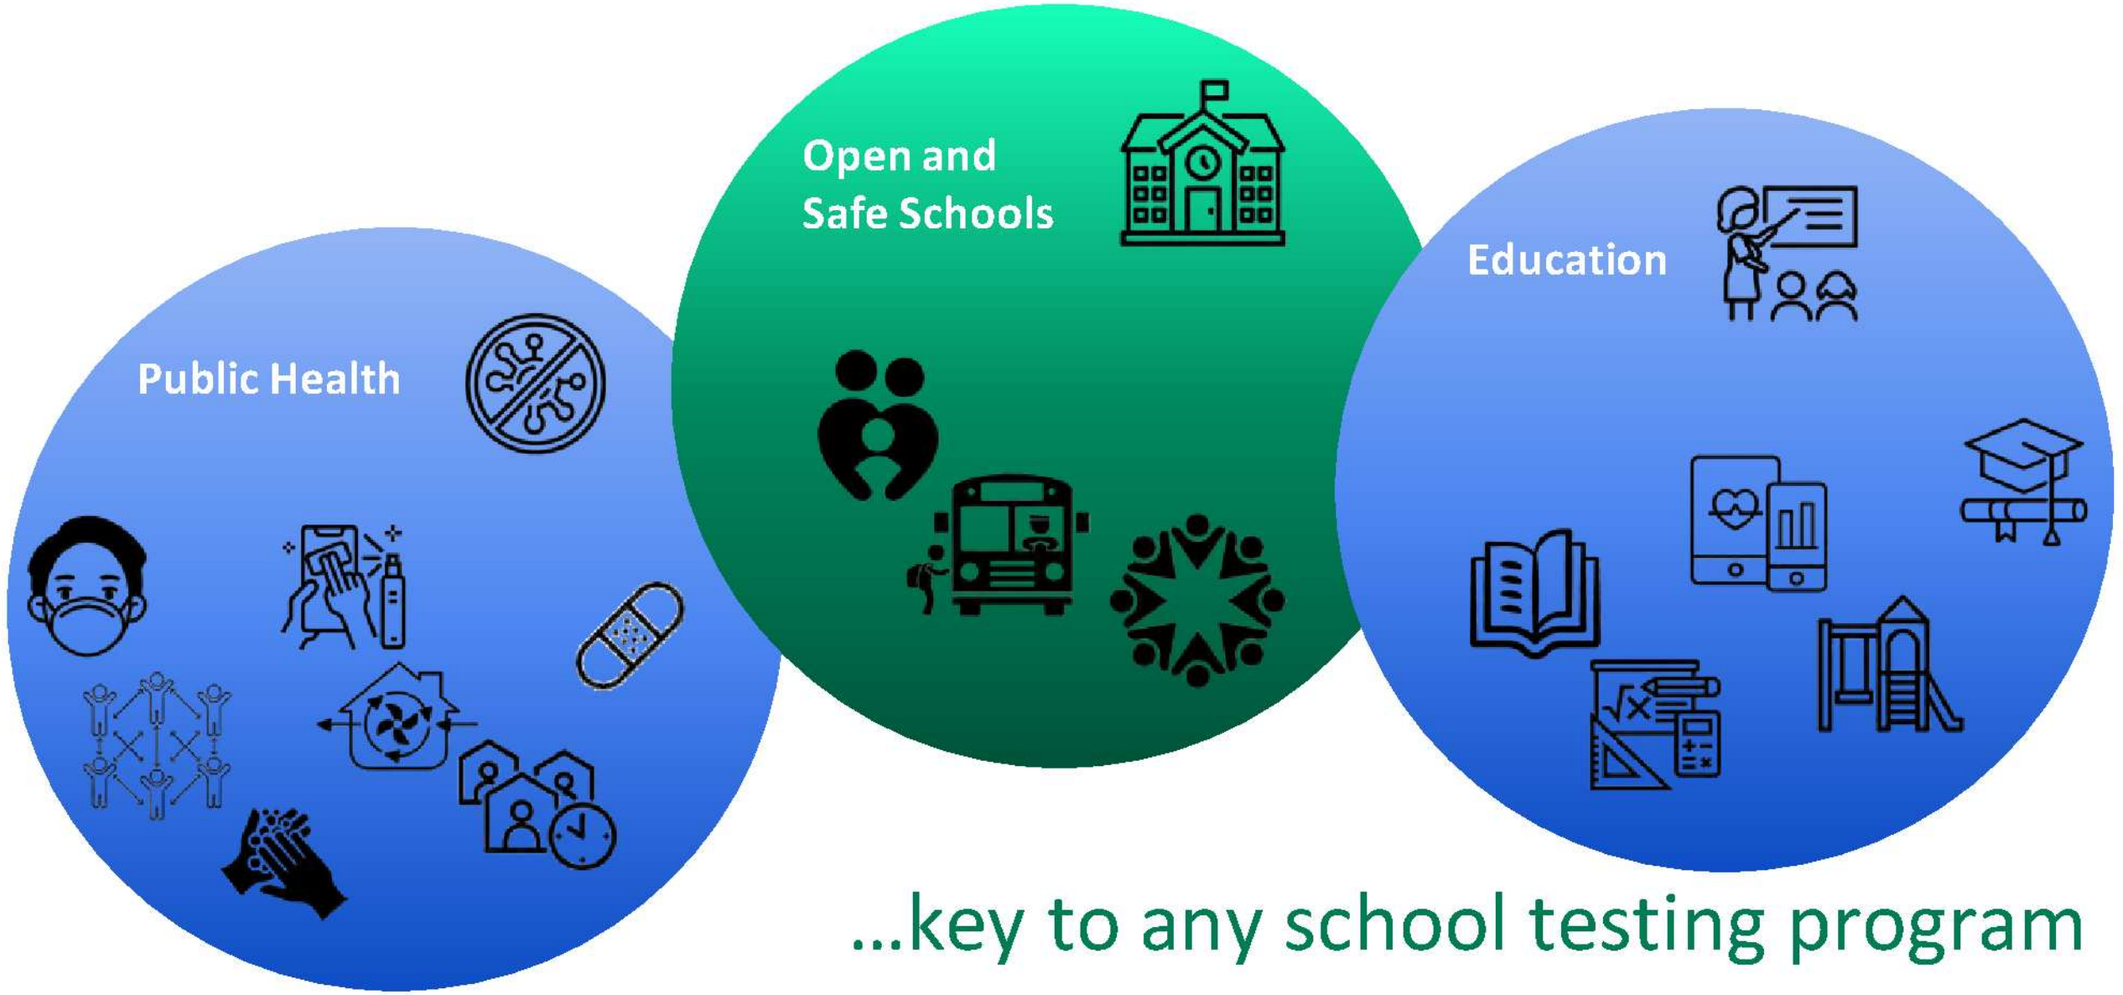
[3]Schools may ***consider testing a random sample of at least 10% of students or may conduct pooled testing of cohorts/pods for screening testing in areas of moderate and substantial community transmission***.

[4]Schools may consider using screening testing for student athletes and adults (e.g., coaches, teacher advisors) who support these activities to facilitate safe participation and reduce risk of transmission. For an example risk stratification for sports, see NCAA Transmission Risk Summary.

Working with Schools

Photo Credit: COVID-19 Testing in K-12 Schools: Insights from Early Adopters, RAND Corporation, 2021: https://www.rand.org/pubs/research_reports/RRA1103-1.html

Common ground and shared priorities…

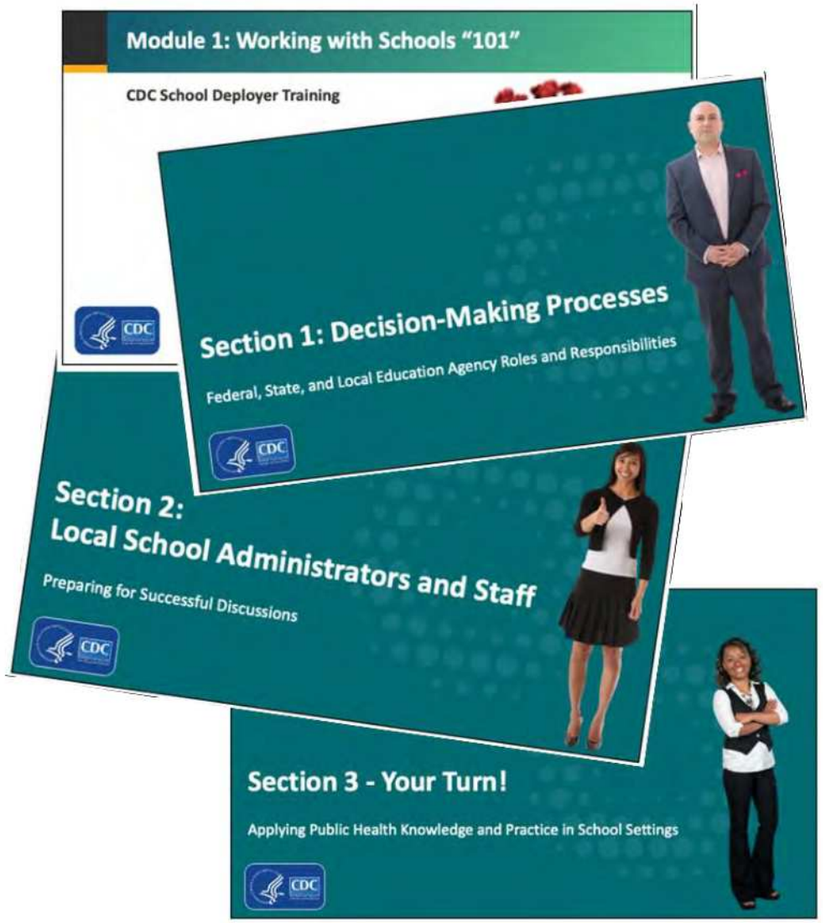


…key to any school testing program

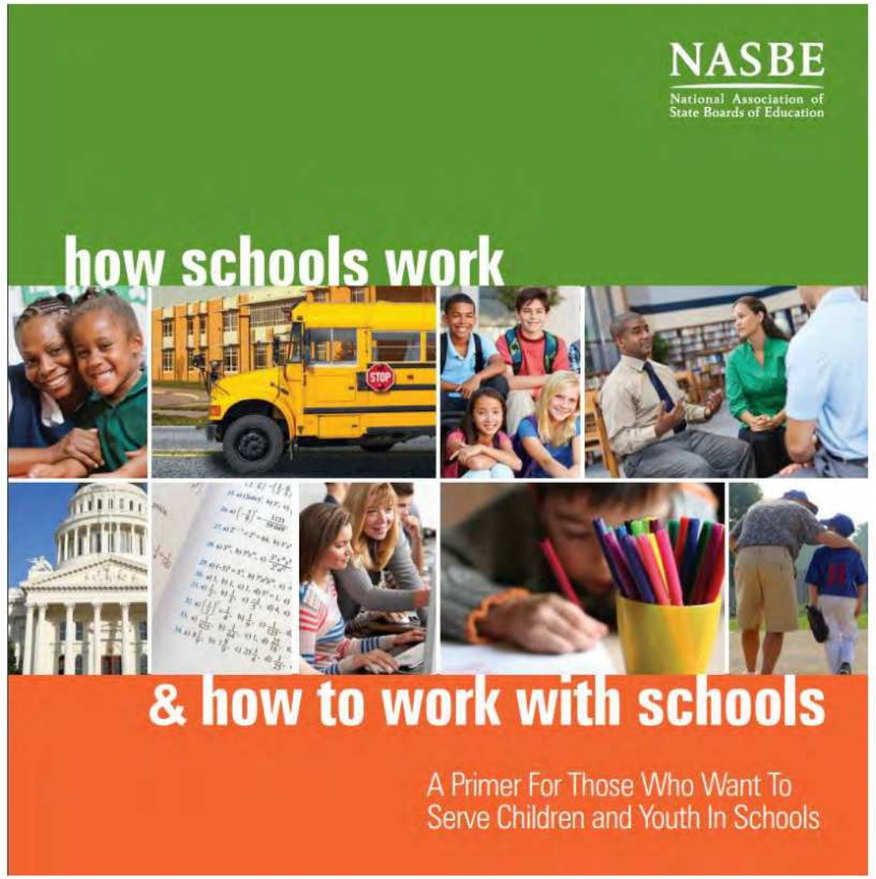
MS-DOH-21-1816-A-001758

Photo Credit: COVID-19 Testing in K-12 Settings: A Playbook for Educators and Leaders, Rockefeller Foundation:

How to work with Schools



https://www.train.org/main/course/1096902/



https://nasbe.nyc3.digitaloceanspaces.com/2020/01/How-Schools-Work-2014.pdf

Guiding Principles

- Education's **primary goal** is to educate students
- Health, safety, development and well-being may be **secondary priorities**
- Concerns about **safety**, in particular, can affect access to some schools
- Schools are **busy** places; plan your involvement carefully
- School leaders and personnel have **multiple responsibilities and priorities**
- The **needs of schools** differ from district to district
- Education **decision-making is diffused** and variable
- **Multiple people or groups** are usually involved in the decision-making program
- **Several levels of review** before decisions are made
- Education leaders cannot address all of their **needs** alone
- Education has its own **acronyms** and **terminology**

Program Design

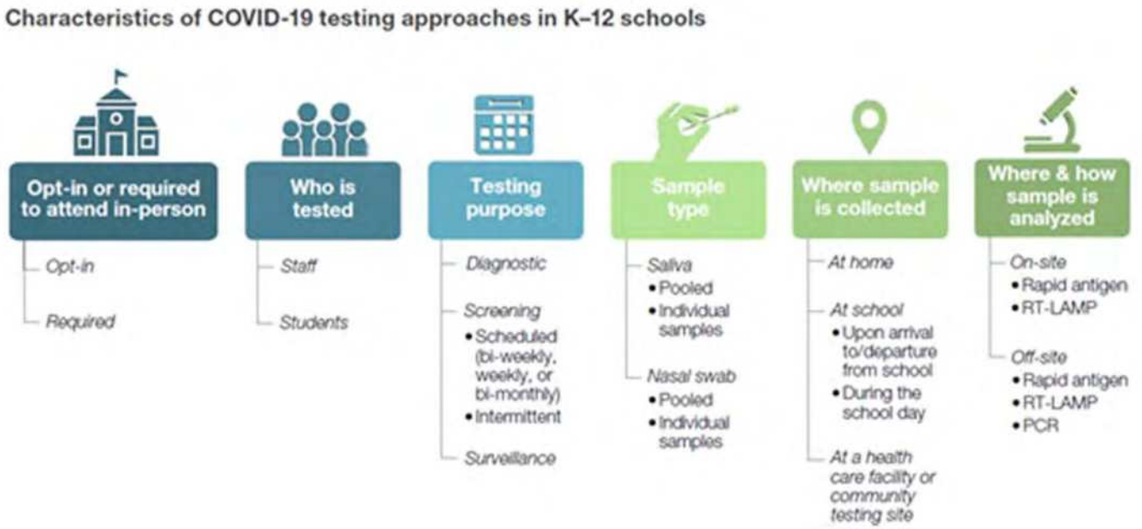

Figure Credit: COVID-19 Testing in K-12 Schools: Insights from Early Adopters, RAND Corporation, 2021:

Program Design

- **Purpose** (screening, diagnostic, surveillance)
- **Policy Approach** (opt-in, opt-out, mandatory)
- **Consent** (streamline, program)
- **Population** (students and staff; risk)
- **Participation** (demand creation, athletic programs, extracurricular activities)
- **Modality** (individual-pooled, pooled, point of care)
- **Test Type** (PCR, antigen, etc.)
- **Vendors** (service model, tiered)
- **Labs** (capacity, funding)

Considerations in Implementing Screening Testing in K-12 Schools

- Priorities for testing:
  - Teachers and staff
  - High school students, then middle school students
  - Elementary school students

- Prioritize access to testing in **schools that serve populations experiencing a disproportionate burden of COVID-19 cases or severe disease**.
  - Communities with moderate or large proportions of groups that experienced disproportionately high rates of COVID-19
  - Geographic areas with limited access to testing

Elements Needed for Screening Testing in K-12 Schools

- Dedicated infrastructure, staffing, and resources to support school-based testing
- CLIA certificate of waiver
- Mechanism to report all testing results
- Timely reporting of results (<24 hours) is key
- Ways to obtain parental consent for minors and informed consent for adults
- Physical space to conduct testing safely and privately, protocols to maintain confidentiality of results
- Plans to confirm result of antigen testing need to be established

Level of Readiness: Starting, Scaling or Sustaining K-12 Testing

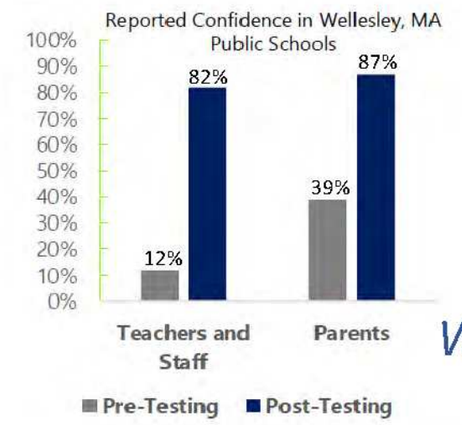
Program Benefits: K-12 School Testing

Intangible

- Reassurance, confidence, trust
- Feel safer
- Increased comfort with in-person learning



Tangible

- Identify and isolate individuals with COVID-19
- Prevent ongoing transmission
- Identify and improve prevention measures
- School COVID-19 prevalence; transparency

*While half of families reported no perceived detriments, it is important address community concerns.**

*Doron et al. (2021) Weekly SARS-CoV-2 screening of asymptomatic students and staff to guide and evaluate strategies for safer in-person learning. BMJ Yale, medRxiv preprint: https://www.medrxiv.org/content/10.1101/2021.04.21.21255864v1

Building Stakeholder Confidence

Wide-spread adoption and participation relies on building confidence for participants by understanding their priorities and concerns. State and local leadership must proactively reassure and address the concerns of stakeholders.

	Superintendents	Teachers and Staff	Parents	Students
Priorities and Concerns	• All willing individuals are getting tested • Results are obtained quickly • Payments and funding vehicles are in place	• Keeping themselves and students safe • Preparing for when someone gets sick in school • Missing work when they test positive • Data privacy • Test collection safety	• Safety of children • Testing without parent/guardian present • Perceived Cost / Time of confirmatory test if applicable • Data privacy • Test collection safety	• Fear of getting the swab • Test collection safety • Stigma / lost school time linked to positive results
Actions to Build Confidence	• Set frequency and sensitivity standards • Provide easy to use consent forms • Provide central POC to ask questions	• Provide guidance on isolation and other mitigation strategies • Bring in trained people to administer tests • Be transparent about data privacy and use	• Provide information on getting confirmatory tests • Make consent easy to understand • Provide results quickly • Be transparent about data privacy and use	• Make the testing process as easy as possible to reduce stress and anxiety • Provide guidance on what do you if you're feeling sick

***Note: The Rockefeller K-12 Playbook provides a tactical communications plan to engage stakeholders including who is responsible for the communication.**

Lessons Learned from K-12 Screening Testing Programs

Three Testing Models:

1. New York City Public Schools
2. Children's Hospital of Philadelphia - Regional Testing Program
3. Utah's Statewide Test to Play/Test to Stay

New York City Public Schools

- Continuously monitor school safety by testing 20% of asymptomatic students and staff physically present in school each day.
- Establish a joint coordination center of agencies working in school health to manage the complex process of continuously receiving, investigating, and acting upon COVID-19 cases.
- Voluntary testing creates challenges – need to actively encourage testing at school rather than in the community to reduce turnaround time, cost, and variability in quality of results.

Children's Hospital of Philadelphia

- Use point of care testing through a health order permitting schools to test under existing laboratory licenses
  - Simplified testing and analysis processes
  - Allowed for standardized training of staff conducting testing
- To meet resources needed for a large-scale testing program:
  - Worked with HHS and CDC to get rapid POC tests (BinaxNow; Que)
  - Used an app (STRAC) and data dashboard that allowed for timely, high volume reporting

Utah - Test to Play/Test to Stay

- Testing preserves in-person school days and extracurricular activities
  - **Test to Play:** rapid antigen testing every 14 days; required for participation in extracurricular activities
  - **Test to Stay:** school-wide testing when outbreak threshold is crossed; required for in-person learning
- Use consistent communication to gain family/community support
- Allow for time and resources needed to train staff and obtain large numbers of rapid antigen test kits
- Work with local health departments and school health partners to increase capacity to conduct testing and respond to positive test results

Summary of Lessons Learned

- School-based COVID-19 screening testing helps to:
  - Preserve in-person instruction and extracurricular activities
  - Reduce in-school transmission
- Recommendations:
  - Combine testing with prevention measures
  - Decide whether testing will be mandatory or voluntary
  - Assess inventory and training needs
  - Determine how test results will be reported and processed
  - Promote collaboration between agencies working on school health

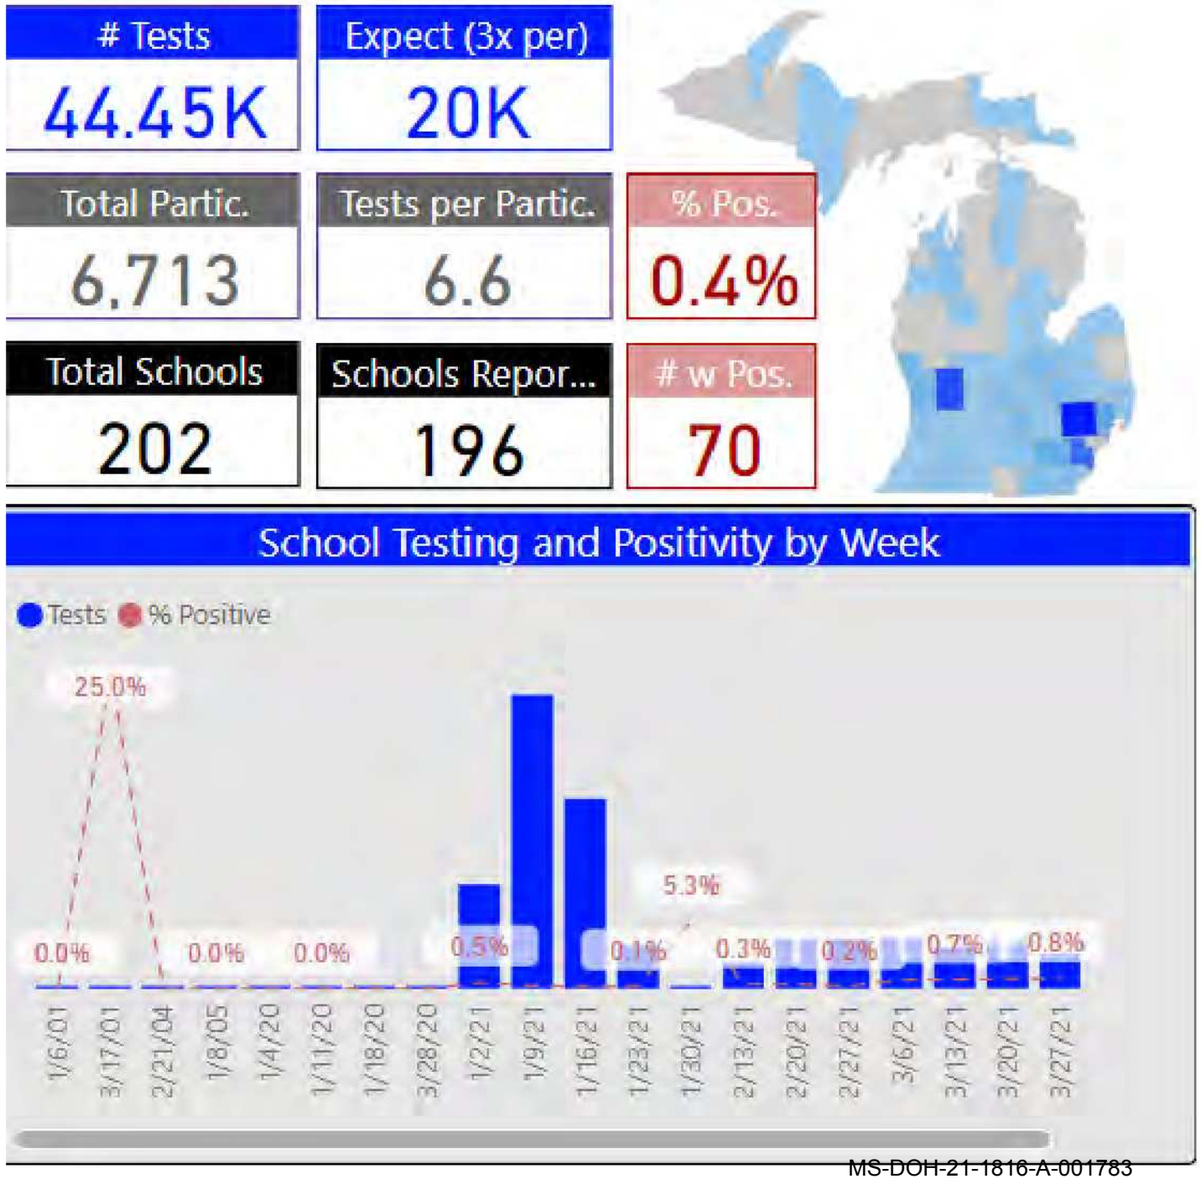
Fall Sports Testing Pilot –
Assessed feasibility of antigen testing in K-12

Barriers we worked through

- Supply chain
- CLIA Waivers
- Order for tests
- Biohazard
- Teaching non-medical staff to perform tests
- Reporting of tests



Winter Schools Testing Program

- Mandated for “mask-less” sports
- Available for other students/athletes/educators

Barriers

- Lack of participation where not mandatory
- Lack of cooperation with case investigation, quarantine etc.

K-12 NATIONAL TESTING ACTION PROGRAM (NTAP)

Connecting schools with the nation's leading testing companies to safely reopen

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Table of contents

Introduction and current K-12 landscape	7
Successful programs: testing works to keep schools safer	12
K-12 National Testing Action Program: overview	24
K-12 National Testing Action Program: logistics	39
Appendix and references	53

Context

- The K-12 National Testing Action Program (NTAP) is a plan to provide free Covid-19 testing for K-12 public schools to enable safe in-person learning

Situation

- Due to Covid-19, a majority of US K-12 public schools are operating remotely or in hybrid learning
- Online learning is not an adequate replacement for in-person school and is creating large education and socialization gaps

Complication

- Teachers, students and communities may fear the spread of Covid-19 in schools
- Schools are not fully equipped to provide necessary mitigation measures including testing
- While testing capacity exists, labs do not have a clear signal on how to make capacity readily available to schools
- The value of testing is getting lost amid the focus on vaccination

Question

- How do we safely and sustainably re-open the nation's K-12 public schools as quickly as possible?
- How do we make testing free, easy and widely available for schools?

Answer

1. ***Implementation of full safety and mitigation activities***
2. ***Prioritized vaccination for teachers and staff***
3. ***Weekly testing for students, teachers and staff***

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

K-12 National Testing Action Program (NTAP) Summary (1 of 2)

The school changes stemming from the Covid-19 pandemic have significant impacts:

- Student learning, as well as mental and physical health, particularly for underserved populations
- Parent economic security, particularly for women
- Teacher well-being, including where they focus their money, time, and mental health
- The national economy, including billions of dollars of projected losses

K-12 testing programs can help reopen schools:

- Testing programs work to quickly identify positive cases for isolation, keeping school infection rates well below their local community. Schools are the safest place for kids and adults and are safer than the grocery store
- Logistics are feasible for public schools, both large and small. Testing protocols become second nature within weeks
- Testing dramatically increases confidence in re-opening for teachers and parents. We have seen confidence grow from about 20% to over 80%
- Federal actions provide funding & demonstrate the importance of testing as the "missing link" to re-open schools and get all students back for in-person learning

Re-opening schools safely this spring requires:

1. Safety and mitigation measures (masking, distancing, cohorting, etc.)
2. Teacher and staff vaccination
3. Regular and reliable testing of students and adults

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

K-12 National Testing Action Program (NTAP) Summary (2 of 2)

Testing protocols are critical to program success:

- Step 1 - PCR 'pooling' or antigen tests with either anterior nasal swabs or saliva
  - Screening testing frequency is often once per week for students and up to twice per week for teachers and staff
- Step 2 - Follow-up diagnostic PCR or rapid antigen testing for individuals in positive pools
- Optional but recommended Step 0 - Test all participants as program begins

NTAP implementation and logistics requires diligent planning and partnership:

- Labs provide lab testing and logistics (including information systems) to schools and parents
  - Capacity for schools must be guaranteed and must not be reduced
  - School testing capacity must not reduce testing capacity or increase Turn Around Time for the general public
- All results must be returned to schools and test takers in 24 hours or fewer
- Costs for tests and additional test-related costs at each school are reimbursed by the state from their allocation of the $10 billion federal allocation of the American Rescue Plan Act for school testing

K-12 NTAP compilation team includes:

- Representatives from the nation's largest labs and test manufacturers with deep experience in Covid-19 testing for schools
- Representatives from the world's largest lab supply manufacturers with deep experience in manufacturing and distribution
- Representatives from information service providers
- In addition, the team met with school superintendents, principals, teachers and parents to inform the plan

HEALTH CATALYSTS GROUP

Introduction and current K-12 landscape

Impact of school changes on students

- Impact on learning:
  - **25% decrease** in **post-educational learning potential** among ninth graders in poorest communities
  - Returning students expected to have only **63-68% and 37-50% annual learning gains** in reading and math respectively

Food insecurity and mental health:

- **169.6M** school meals missed weekly impacting **student nutrition** & **food security**
- **24%** increase in **emergency department visits related to mental health** for **children aged 5-11** and **31%** increase among **adolescents aged 12-17**

Minority Populations

In Washington D.C., the number of **Black and Latino children who met literacy benchmarks dropped by 12-14%** compared to white students, whose numbers dropped by 6%

Black and Latino students could experience **learning losses equivalent to 9-10 months** as a result of the pandemic

The ROCKEFELLER FOUNDATION

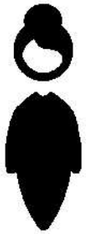
HEALTH CATALYSTS GROUP

Sources: Washington Post , New York Times ,Yale, AERA, AJPH, CDC, The Atlantic, USDA, CDC, NYT

Impact of school changes on parents

70% of working parents
do not have access to regular caregivers, and their return to work is dependent on in-person schooling for their children

4 in 10 parents
say they have less job security due to the pandemic and fear being penalized because they have childcare responsibilities



4x more women
compared to men left the workforce as the new school year began due to students at home

Sources: Brookings, Catalyst, NPR

MS-DOH-21-1816-A-001796

Impact of school changes on teachers

3 in 4 teachers

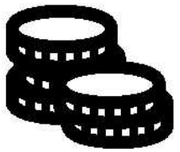
are working more hours during Covid-19 than before; of these, nearly **one in 5** were working more than 15 hours more per week during Covid-19

3 in 4 teachers

report their school or district does not provide adequate access to counselors and mental health support for both students and teachers

9 in 10 teachers

felt their expertise was not appropriately tapped by decision-makers in the transition to distance and hybrid learning; nearly half of these expert teachers said their expertise was not tapped at all



1 in 3 teachers

report spending more out-of-pocket money teaching under Covid-19 than before; one-quarter are spending more than $500 more than before

The ROCKEFELLER FOUNDATION

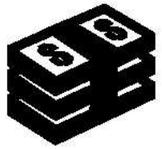
HEALTH CATALYSTS GROUP

Source: National Board for Professional Teaching Standards

Impact of school changes on economy

$2.5 trillion

estimated cost to the U.S. in future earnings of four months of lost education – equivalent to 12.7% annual GDP



$350 billion

of lost revenue and growth could be reversed with the opening of schools, according to some estimates

13.8 million

Years of Life Lost (YLL) may be associated with the school closures during the Covid-19 pandemic

$64.5 billion per year

in lost wages and economic activity from women leaving the labor force and/or reducing working hours to assume caretaking responsibilities

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

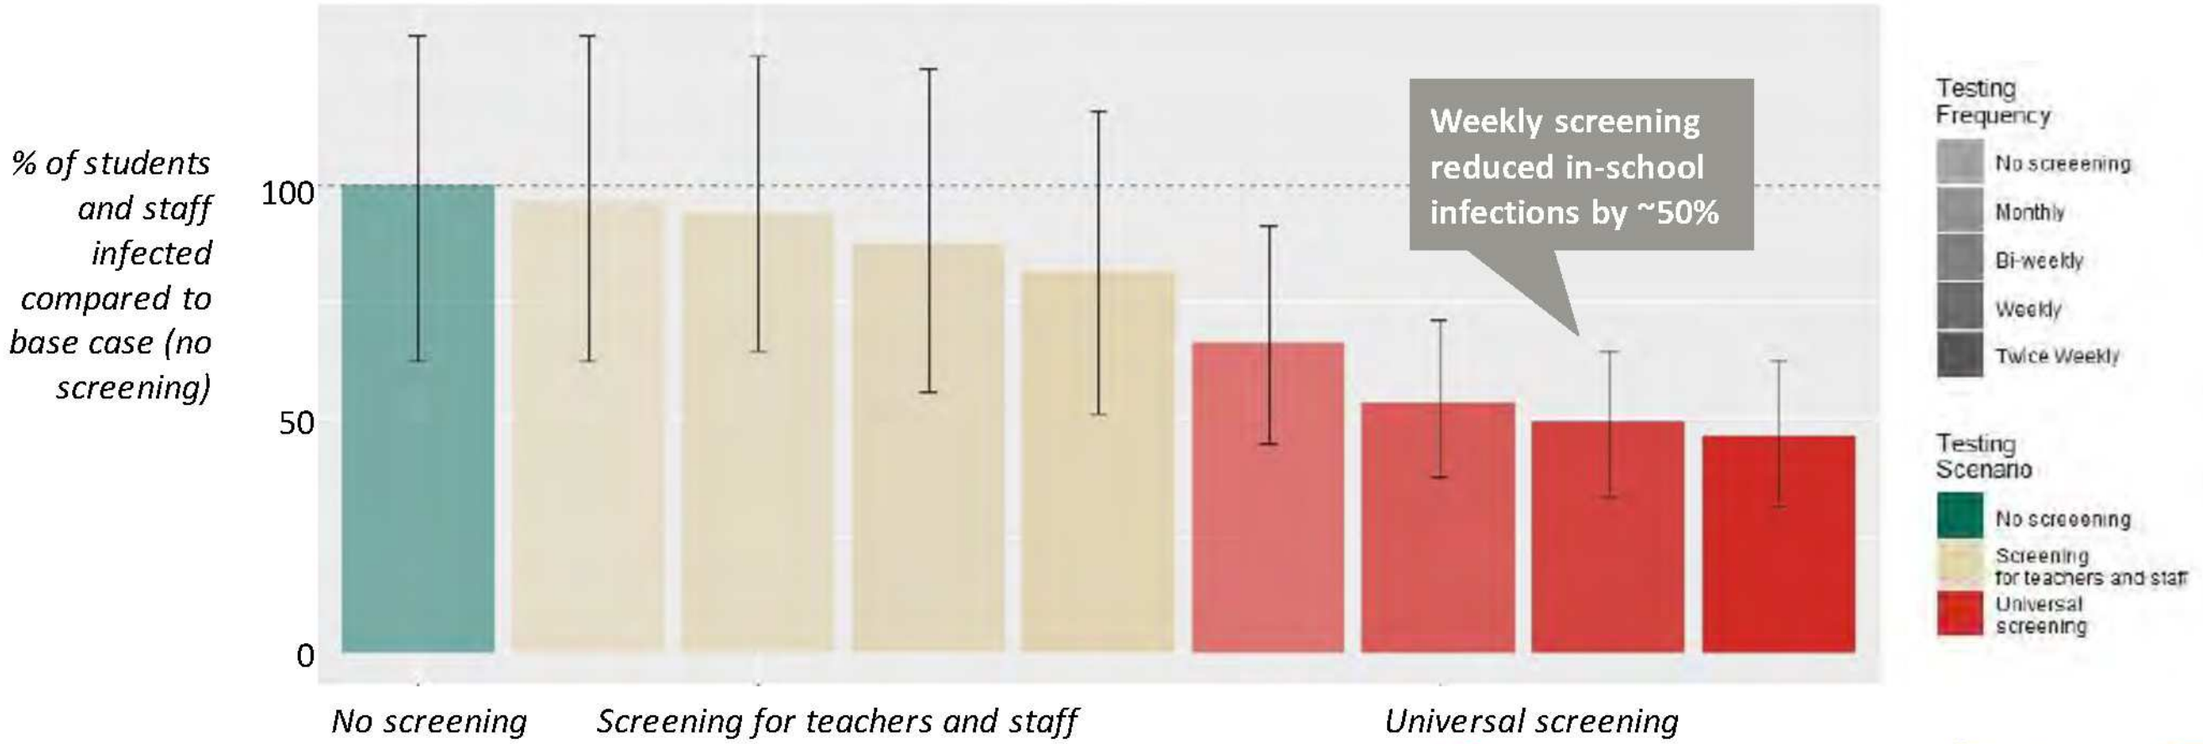
Sources: Brookings, USA Today, JAMA, Center for American Progress

Successful programs: testing works to keep schools safer

Regular testing in schools can reduce infection

Evidence from Mathematica and RAND Corporation, supported by The Rockefeller Foundation, found that **weekly testing** of all students, teachers and staff can **reduce in-school infections by an estimated 50%**

Cumulative COVID-19 infections among students and staff in high schools



The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Source: Mathematica

School prevalence rates are 10x lower than community rates

Aggregate data across multiple schools and their contiguous communities shows **average school positivity is 0.25% to 0.5%** while surrounding **community positivity is ~ 7.23%***

NYC

0.53% positivity rate in K-12 schools

5.60% positivity rate in community

COLORADO

0.5% positivity rate among teachers

4% positivity rate across the state

CDC and others support a return to in-person schooling, citing low prevalence rate in schools as a key part of the justification

Disclaimer: It is important to note that community testing is an opt-in process, and the actual community positivity may be different

*Calculated by aggregating data collected by Ginkgo, CiC Health and JCM Analytics

Successful K-12 testing: Massachusetts Schools (1 of 2)

Program overview:

- **Weekly testing** for every classroom across the state **(900K+ students)**
- Students and staff **self-swab** with a lower nasal swab
- **10+ swabs pooled together** and run using an accurate molecular test
- Samples processes at **local and regional labs**
- **Follow-up testing** for individuals in positive pools using Abbot BinaxNOW

Initial data:

154
school districts have rolled out testing

940 or 50%
of public schools participating

~13,000 tests
in first week of testing

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Sources: Boston Globe, Boston Herald, WPS Viral Testing Information, Mass. DoE

Successful K-12 testing: Massachusetts Schools (2 of 2)

Pooled testing in Massachusetts, a collaborative effort between the Massachusetts Department of Public Health and the Department of Elementary and Secondary Education with implementation support from the Shah Family Foundation, is the **first statewide pooled testing effort to offer weekly testing to *all* students, teachers and staff in public schools**. The program launched in January and schools are already testing students

Pooled testing offering:

- The tests are front-end or on-site pooling of swabs where roughly 10 swabs are put into one tube and sent to the lab for **less than $5/swab**
- **Rapid antigen tests are provided free to schools** to do follow-up tests of positive pools
- Vendors also provide individual PCR tests for **follow-up testing for $26.50-$85**
- The **state is paying for the first phase of the program through March 28** for any interested district. To continue programs, districts may use other federal funds

Operationalizing school testing:

- Most schools are **administering the program themselves** using nurses and other school staff to administer program and observe tests
- Some **larger school districts are contracting** with ambulance companies or bringing in nursing students to help with program administration

Key partners:

Massachusetts Department of Elementary and Secondary Education — Program design and outreach

Shah Family Foundation — Implementation support

Commonwealth of Massachusetts Department of Public Health — Public health guidance

Key learnings

- More districts, including more urban districts, are **returning to in-person learning with testing**
- Early data indicate that **positivity rates in schools are lower than community rates**
- Pooled testing is more **doable & manageable** than some might realize – it is very possible to implement the initiative within all kinds of districts
- It's essential for the state to establish critical components of this initiative – including **funding, a state contract list, and regulatory** enablement – but **districts need to have the ability to adapt** the model to reflect the strengths & challenges of local contexts
- It's very important to **aggregate resources**, examples and tools to streamline the process for everyone (e.g., common consent form in multiple languages, Covid Ed Testing website)
- High quality **parent engagement** is crucial
- It is vital to have **good vendor and inter-governmental partners**

The Rockefeller Foundation | Health Catalysts Group | CDC

Sources: Boston Globe, Mass. DoE, Mass DoE memo, Covid Ed Testing

Successful K-12 testing: NYC public schools

In September, BioReference embarked on a journey in collaboration with **New York City Health and Hospitals** to **bring school back** and help keep teachers and students safe **throughout the school year**

64 BioReference teams in the field
200 Schools per day
1200 Total schools

TAT **<38 hours**
209,790 students and staff tested to date
.47% positivity

1 Order → 2 Collect → 3 Transport → 4 Accession → 5 Test → 6 Report

-Turn-key operation that includes a pre-accessioning process, onboarding, training, scheduling, consent, collection and timely TAT
-PCR lab-based testing
-Multiple daily communications with city and school command center
-Minimal disruptions in schools including normalizing testing for younger students
-Daily analytics of results

The ROCKEFELLER FOUNDATION | HEALTH CATALYSTS GROUP | CDC

Sources: BioReference

Successful K-12 testing: District of Columbia schools

Current status:

All students and staff tested weekly

Over 605 samples from students and staff tested each event

7.3 people in the average pool

2 positive pools (1 faculty, 1 kindergarten) to date

WASHINGTON INTERNATIONAL SCHOOL

UNITEDHEALTH GROUP

Key learnings

- **Pooling in a pod is the most cost-effective** and sustainable method for testing
- Staff and older students can **self-swab**
- **Transparent communication** to parents, staff and students about importance of testing (in multiple languages) is critical
- Pooling-specific, cloud-based **information management** system should be used to effectively **track data**
- Clear **standard operating procedures** and setting up a governance structure is critical for success
- A **list of FAQs** should be created and updated as necessary to address staff and family concerns

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Source: UnitedHealth Group

Successful K-12 testing: Baltimore city schools

Baltimore city schools have been utilizing weekly testing with different systems for elementary, middle and high schools

CBS Baltimore

Baltimore City Schools To Offer Weekly COVID-19 Testing For Students, Staff

FOX 5 NEWS

Baltimore City Schools re-open with voluntary in-person learning

by Rachel Aragon | Monday, March 1st 2021

Current status:

- **~10K** students and staff tested
- **750+** pools
- **78** schools (soon to be 110)

Common characteristics:

- Weekly testing
- Parent consent is required for in-person learning, which includes Covid-19 screening/testing

Elementary and middle schools:

- Students and staff self-collect with lower nasal swabs
- 5-25 individuals pooled together
- Samples processed at local/regional lab
- Results ~24 hours from when samples arrive at the lab
- If a positive result, classrooms will quarantine for 2 weeks and follow up with individual PCR tests

High schools:

- Students and staff self-collect individual saliva samples
- Samples processed at a mobile lab in DC
- Results ~8 hrs from when samples arrive at the lab
- Individuals and close contacts will quarantine for 2 weeks if a positive result

The ROCKEFELLER FOUNDATION | HEALTH CATALYSTS GROUP | CDC

Sources: Concentric by Ginkgo, CBS Baltimore, Fox 5 News

Successful K-12 testing: Delaware public schools

- School testing in Delaware, a collaborative effort between the Delaware Health and Social Services and Department of Education, has successfully demonstrated a scalable, in-person, low-resource program utilizing BD antigen tests. This program started in a handful of public charter schools and has quickly expanded across the state with buy-in from parents, staff and administrators

Current status:

75+ public schools participating

33% of schools in Delaware

5,000+ students and staff tested

Easy to implement:

- Flexible program implemented by school staff. Estimated need for 2-3 FTE / 1,000 people
- Automated results reporting expected to simplify workflow further

Return to school:

- Positive cases have been identified without impacting school opening
- Schools see parents switching back from virtual to in-person education

Key learnings

- Prioritizing **communication** to all stakeholders throughout the process is key
- Students can be introduced to swabbing in a **drive-through environment** with parents nearby
- Focusing on **logistics** is crucial. **Walk-up service** may work well for older students, while **classroom service** may fit for cohorted and youngest students
- **Self-swabbing** under observation with oldest students improves throughput and logistics
- Clear guidance on obtaining **consent** and addressing **legal requirements** early is critical
- Continuous **feedback** from all stakeholders can make the program sustainable
- Objective **assessment of test results** minimizes staff confusion and improve logistics
- **Reporting and documentation** is a significant resource challenge. **Automating reporting** may save 2 FTE time

The ROCKEFELLER FOUNDATION

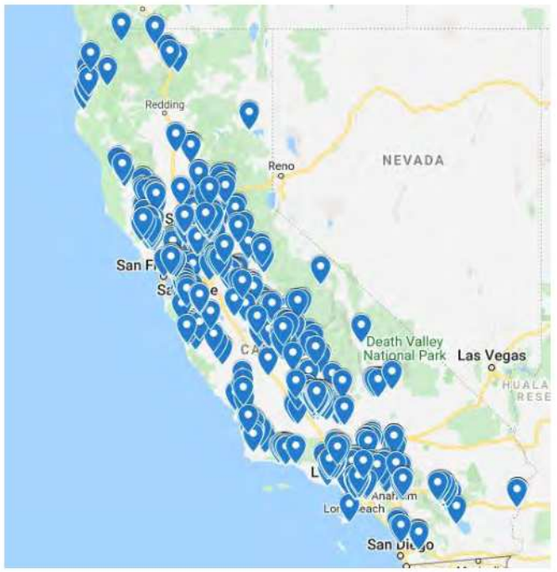
HEALTH CATALYSTS GROUP

CDC

Sources: NCES, Delaware Health and Social Services

Successful K-12 testing: California schools

- A collaboration between Color and Perkin Elmer to provide access to high-quality, fast PCR testing for public and private schools throughout California started with a focus on testing staff and has expanded to include students and student athletes. The program led by the California Department of Public Health has supported statewide onboarding for all school districts and standardized a scalable model across diverse populations



Map of CA K-12 schools testing

10,000+

Schools eligible for program

1,600+

School staff trained

50,000+

K12 tests in less than 6 weeks

Key learnings

- Standardized, state-level onboarding of over **1,000 districts** helps provide **clean, school-level data to the state** for public health planning and interventions
- Creating plug-and-play processes such as **pre-assembled testing kits significantly reduces errors** during sample collection and increases scalability
- **One-time consent and HIPAA authorization** early is critical to streamline testing processes
- **In-house staff can be trained at scale** to support sample collection and program administration when coupled with easy-to-use software and centralized support infrastructure
- **Clear funding models help improve access** for underserved populations
- In addition to capacity requirements, key pieces of successful implementation also include **coordinated onboarding, shipping and information management** between testing partners
- **Simplified logistics** and consistent, easy-to-understand processes has supported **effective use of time and resources** and increased time spent in the classroom in K-12 California schools

Source: Color, California Dept. of Education

Successful K-12 testing: nationwide pilot with PCR pooling

Current status of Concentric by Gingko's pilot of **pooled testing** in over 130 schools across 11 states:

- **<15 minutes** to run a full-classroom collection
- **1000+** classrooms tested
- **10,000+** students and educators tested
- **32** positive individuals identified and isolated to reduce transmission

Kids feel empowered to self-swab, help their community, and teach others

> Swabs go "**Boogers down**".
>
> YORK ACADEMY

> You only have to go up to **the squishy part of your nose**.
>
> PARK STREET SCHOOL

> We have a jingle - "**1, 2, 3, 4 - switch it over, do 4 more**"
>
> SHARON PUBLIC SCHOOLS

> It's a **free chance to pick your nose**, and no one is going to yell at you.
>
> SHARON PUBLIC SCHOOLS

Key learnings

- Clear communication increases confidence among students, parents, teachers and administrators
- Streamlined and human-readable consent forms are vital for ensuring parent buy-in
- Build infrastructure (including registration portals) that can scale
- Streamlining school onboarding virtually (via a website and videos) enables rapid scale
- Minimized disruption to classroom is needed for adoption (<15 minutes and self-collection)
- Pod-pooling approach can work in a wide range of schools (multiple states, low-income areas, minority communities, etc.)

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Source: Concentric by Gingko

Successful K-12 testing: Cross-City Learning Group pilot sites

The Cross-City Learning Group was formed through The Rockefeller Foundation's partnerships with HHS, Duke-Margolis Center for Health Policy, Johns Hopkins University, Mathematica and **six cities/states willing to pilot testing programs**

Washington D.C.

8
learning hubs

Rhode Island

78
schools and learning education agencies

New Orleans

45
schools

Tulsa

70
schools

Louisville

12
regional testing sites

Los Angeles

60
Parks and Recreation centers

Key learnings

- Engaging early with district administrators and local partners can help gain their buy-in and support for identifying resources
- Clear communications, delivered by trusted leaders in the community, are needed to build community members' understanding of the program and encourage participation
- The testing approach should be designed using both evidence-based guidance and on-the-ground knowledge of what will be acceptable to students, parents, teachers and staff

HEALTH CATALYSTS GROUP

Sources: The Rockefeller Foundation, Mathematica

K-12 National Testing Action Program: Overview

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

CDC

MS-DOH-21-1816-A-001812

What is the vision: K-12 National Testing Action Program

Testing is the missing link to K-12 schools reopening safely in-person this spring

Thus, the K-12 National Testing Action Program focuses on:

A. **Free and easy testing** for schools, kids and parents

B. Reliable and predictable testing availability for schools

C. **No reduction** of testing availability elsewhere in the country

D. Public and private **resources mobilized** and coordinated for sustainable capacity

E. A maximum **24-hour turnaround time** – from swab to results

F. **Simple procurement, funding and implementation** processes, including results reporting

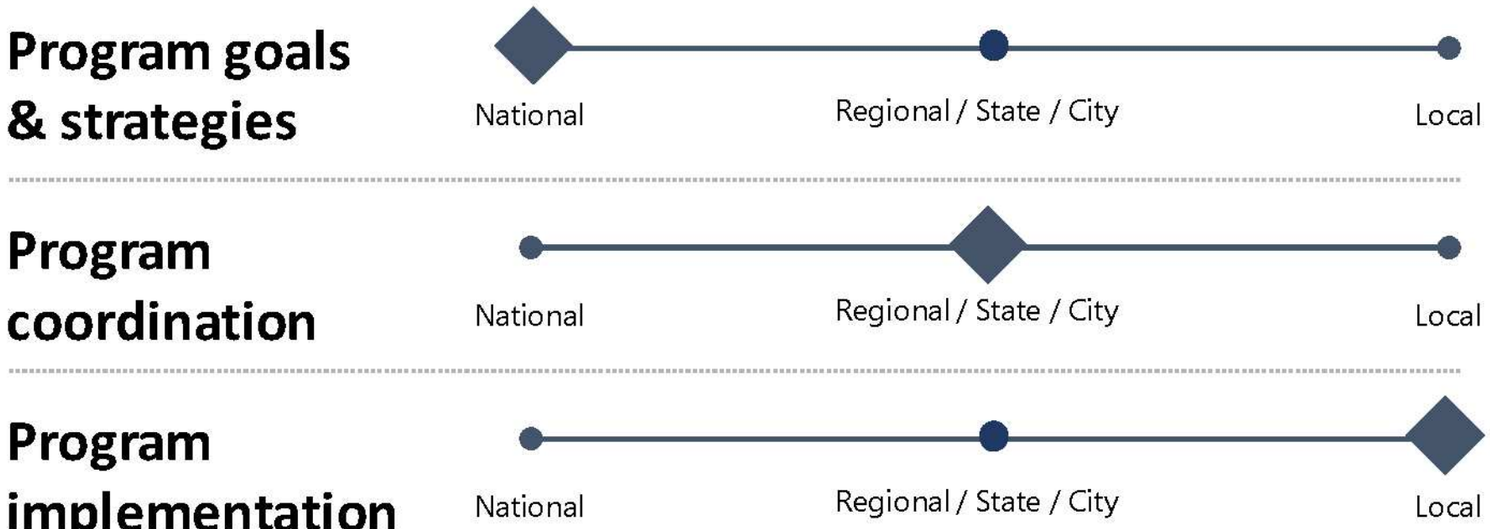
G. Ability to **adapt and improve**, keeping pace with scientific advances

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

How does it work: national, regional and local collaboration

The K-12 National Testing Action Program is designed to be **federally guided, state/regionally coordinated, and locally implemented**, all with the aim to **support the safe reopening of 100% of K-12 schools**



K-12 NTAP will provide enough support to test:

- 100% of willing students weekly (per appropriate consent/assent)
- 100% of willing teachers and all staff up to twice weekly

"Everything should be made as simple as possible but no simpler" – Albert Einstein

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Key requirements for successful K-12 testing programs

Easy

Testing an entire classroom should take minimal time (e.g., ~12 minutes). Testing must be easy for students as young as kindergarten to do. Logistics should be streamlined and should not burden school staff

Effective

Testing should be accurate and give school communities data that provides them with confidence to maintain in-person learning

Accessible

Testing should be easy to access for every school and should be easily scalable to cover entire school districts

Affordable

The cost of testing should allow for every student to be tested every week. Federal funding may be leveraged to cover costs

How to choose a test: steps in the testing protocol

A strong testing protocol consists of three steps:

Step 0

Initiation testing *(if possible)*

When program begins – especially for schools in high prevalence areas – all students, teachers and staff should be tested individually or in small pods before regular weekly testing begins*

Step 1

Asymptomatic screening

High-quality 'pooled' PCR tests or antigen tests administered weekly to students and twice-weekly to teachers and staff

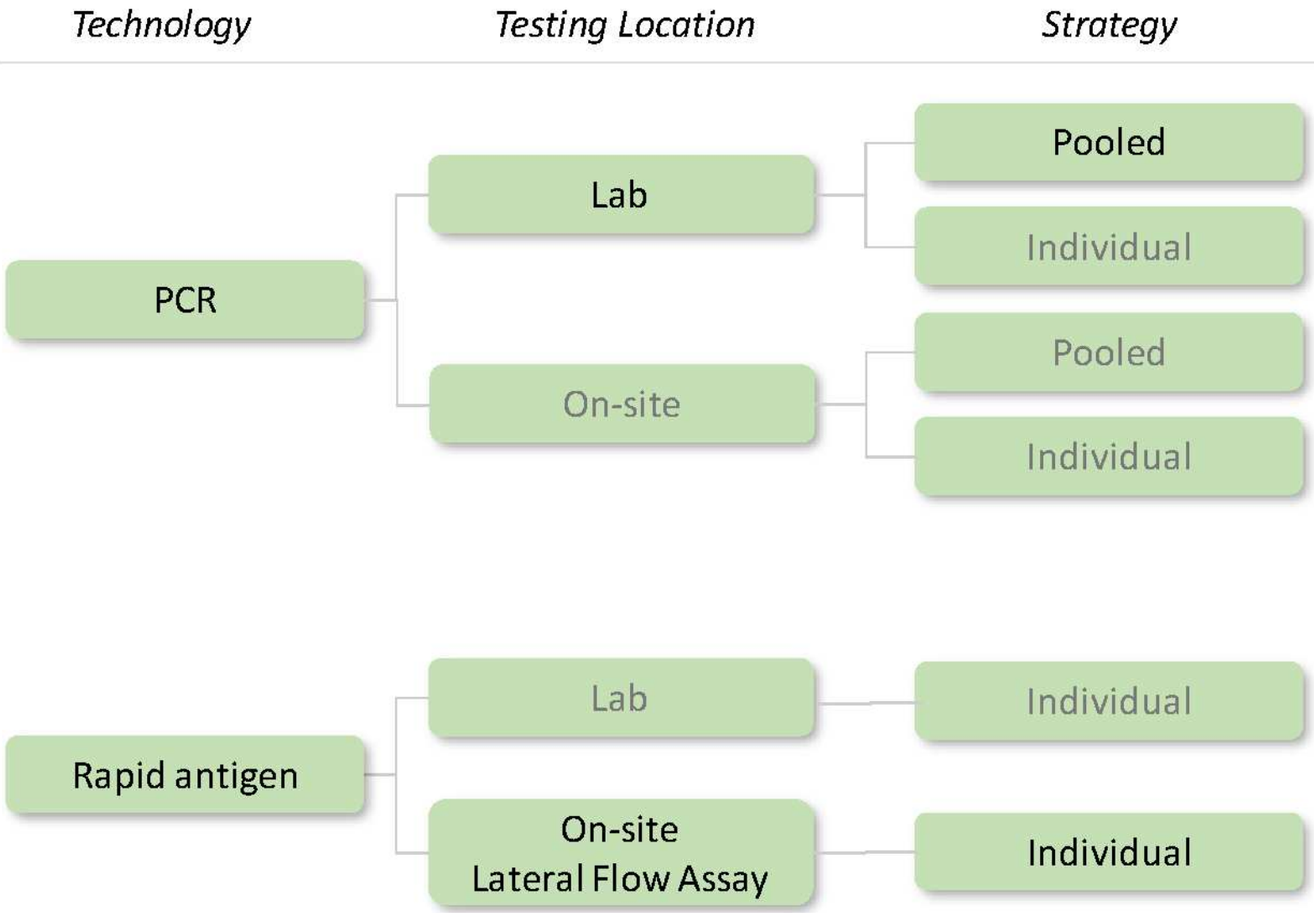
Step 2

Positive pool follow-up testing as required

For individuals in positive pools, provide individual PCR or antigen diagnostic tests: via at-home, on-site, clinic, lab or pharmacy testing

*While Step 0 is not discussed in further detail here, it is possible to leverage similar testing strategies to those described for steps 1 and 2. The purpose of Step 0 is to identify infected individuals before regular testing begins, which will make it easier to identify new cases moving forward.

How to choose a test: asymptomatic screening options (step 1)



Multiple testing technologies and systems will be needed to collectively meet school demand and diversify the supply chain. Common types of testing include:

Pooled PCR testing is recommended as the preferred option for routine screening testing. Samples are collected at the school and sent to a lab for processing. Data management handled by test provider.

Rapid antigen testing is recommended for routine asymptomatic testing of parts of a population or for diagnostic testing. Samples are collected at the school and tested on-site for fastest results. Data management is handled by provider, in-state or vendor-provided portals. Individual testing for screening can be advantageous if the number of cases is high in a school.

How to choose a test: follow-up testing options (step 2)

Step 2 testing options:

Follow-up test:

- Same Sample Reflex: Test provider can deconvolute a positive PCR pool directly with the initial saliva or nasal swab, most common with lab-pooling where part of each sample may be available for retest.
- New Sample Reflex: A new sample from those in the positive pool is collected and then retested.
- Rapid antigen test

Pre-paid coupon: Can be redeemed at a local retail pharmacy, clinic, testing lab or hospital to obtain proof of negative result to return to school

At-home kit: Can be used to self-collect a nasal swab or saliva sample and ship it back to a lab for testing. A pre-paid shipping label will be provided

Other sources: Collaboration with local Public Health Lab or university or other community labs may be used to get a confirmatory test using a pre-paid coupon

Benefits of the K-12 NTAP program

- ✓ Provides schools and families the **flexibility** to choose the right test option and location for them
- ✓ Improves **equity and access to confirmatory testing**
- ✓ Quickly allows students to get the confirmatory results required to return to school
- ✓ Optimizes use of **local testing resources** based on availability and preference
- ✓ **No cost to families or schools**

The ROCKEFELLER FOUNDATION HEALTH CATALYSTS GROUP

PCR pooling: the evolution of PCR testing

The path from individual to pooled testing: what we've learned

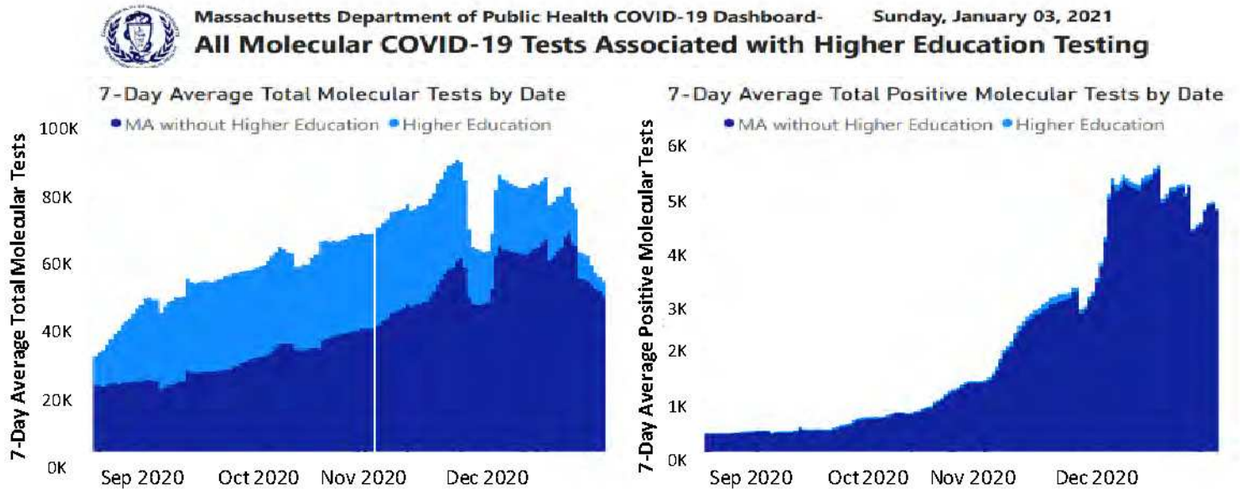
Colleges and universities demonstrate effectiveness of testing, infection control, and isolation measures by creating sub-communities with lower Covid-19 prevalence and test positivity rates than the surrounding communities

Tufts University implemented a **regimented individual PCR testing strategy** in partnership with the Broad Institute to obtain community prevalence data across campus sites

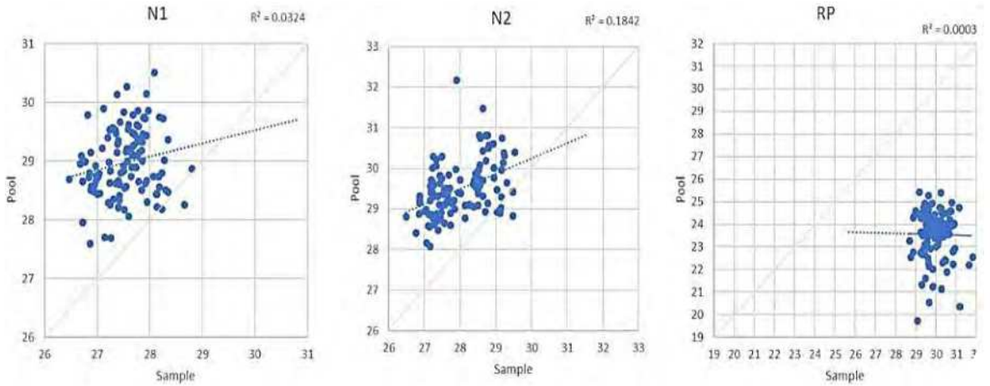
High costs limit the accessibility of repeated individual PCR testing for K-12 communities

Tufts University designed a **study of pooled testing to evaluate the specificity and sensitivity** of a pooled assay, which provides great confidence in identifying all positive individuals using pooling. Pooling becomes more popular in K-12 schools

While sample dilution was an upfront concern for pooling, as it could result in false negatives, pilot results from 1576 individuals (students, staff, faculty, etc.) **showed 100% congruence between pooled and individual results, no false negative results, and slightly elevated CT-values**



Data Sources: COVID-19 Data provided by the Bureau of Infectious Disease and Laboratory Sciences; Tables & Figures created by the Office of Population Health. Note: All data are current as of 11:59 PM on 1/2/21. Due to lag in reporting by labs, counts for most recent dates are likely to be incomplete. This includes individuals who have had more than one molecular test



Ct results comparing pool Cts (y-axis) with the Ct value of the corresponding single positive sample (x-axis). Each graph represents a different probe; N1 and N2 detect regions of SARS-CoV-2 virus RNA while RP represents host genetic material abundance. Blue line: trendline of data; grey line: y=x bisector.

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

PCR pod pooling: how it works

Classroom pooling

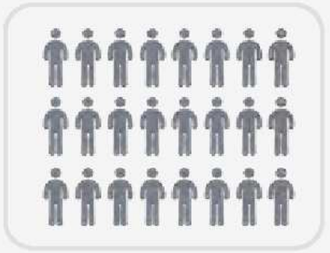
All students and teachers in a pod **swab their noses** with short swabs (think: cotton swabs). Swabs are placed in one tube (this is the "pooling" step). This pool is then run as a single test at a local lab.

Key benefit: **groups of 25 people can be tested using one test**. For a school of 500, only 20 tubes must be collected and managed, instead of 500 when testing individually.

Only positive pools result in further action. Next steps are decided by the school.

STEP 1 - **Pods self-swab**

Individuals in a pod (e.g., classroom) self-swab and place swabs into a single tube. Takes minutes to complete for an entire pod



STEP 2 - **Test the pools**

Each tube is then run using one test at a local lab, and the classroom is provided with one result

STEP 3 - **Get results**

Results can be used by schools to make more informed decisions, detect the virus earlier, and mitigate spread

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

PCR pod pooling: testing options following a positive pool

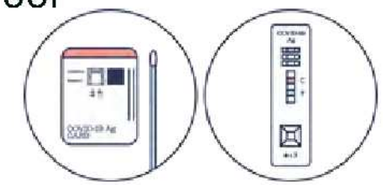
What happens if there's a positive pool?

The solution will look a little different for each school based on unique circumstances. **However, K-12 NTAP recommends all follow-up testing be fully government funded to ensure equitable access and fast results, with no additional administrative or billing burden.**

Approaches for follow-up testing:

School-based testing (preferred option)
Rapid antigen tests or on-site collection for lab-based nasal or saliva tests administered at school

At-home testing
Self-collected nasal or saliva sample sent to labs for testing using pre-paid shipping



Pre-paid coupon
Coupon redeemable at local pharmacies, clinics, testing labs or hospitals to obtain proof of negative result to return to school

Community-based testing
Tests administered at pharmacies, clinics, doctor's offices, community centers or other publicly accessible sites

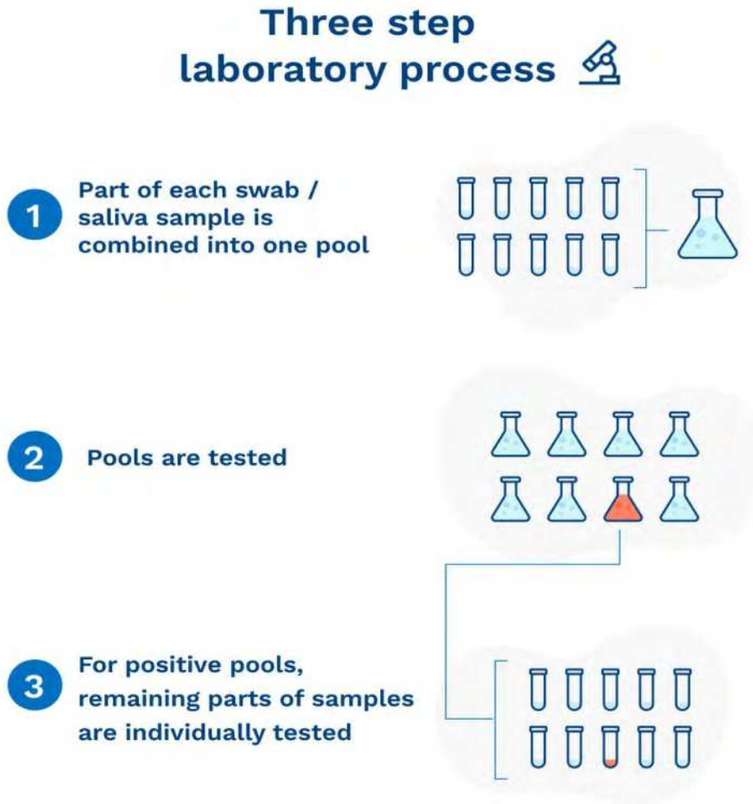
The ROCKEFELLER FOUNDATION HEALTH CATALYSTS GROUP CDC

PCR in-lab pooling: how it works

In-Lab Pooling

All students and teachers **swab their noses** with short swabs (think: cotton swabs) or **produce saliva samples** samples in individual tubes. Tubes are sent to the lab where part of each sample is combined with other samples to form a pool. This pool is then run as a single test at a local lab.

Key benefits: school can benefit from the efficiency of pooled testing **without the need for separate follow-up sample collection**. It also allows for the use of tests with **at-home sample collection options**, which can minimize the operational burden on schools



SHAH FAMILY FOUNDATION

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

PCR pooling: sensitivity

Studies comparing the sensitivity of pooled versus individual tests confirm that **PCR pooling is more than sufficient** for asymptomatic screening tests and has **similar sensitivity to individual**

BROAD INSTITUTE

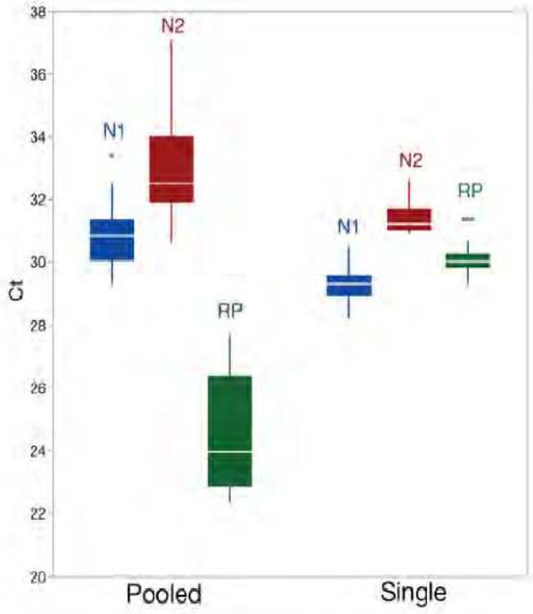
A study conducted by *The Broad Institute* found comparable levels of detection when samples are pooled or individually tested

Results show that the sensitivity was comparable for pooled and individual/single samples

Notes on the graph:

- *10 samples* were pooled together to compare sensitivity ***N1 and N2*** samples look for Covid-19 virus genome and ***RP*** samples look for human genome (control)
- A lower Ct value means a higher amount of virus genome is present
- The RP Ct is significantly lower in the pool as expected since human genomic material is present on both positive and negative swabs

Pooled vs individual testing sensitivity



UNITEDHEALTH GROUP

A study by the *UnitedHealth Group* showed pooled testing had comparable performance to individual PCR testing

Results show that up to 15 samples could be pooled together to reduce costs and supplies while maintaining accuracy of results

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Sources: Pooling for SARS-CoV2 Surveillance: Validation and Strategy for Implementation in K-12 Schools, Bethany L Hyde, Ethan Berke, Prat Verma

Rapid antigen: how it works

Rapid antigen testing

Students and teachers have their noses swabbed with short swabs. Each swab is applied to a test card or cassette and allowed to run for the appropriate amount of time.

Each person tested has their own test. For a school of 500, a total of 500 tests are needed to test everyone.

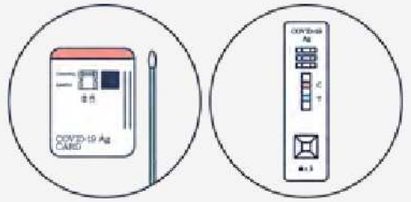
Once the necessary time has elapsed, **trained staff interpret and record each result**. Positive results are communicated to the individuals and families.

STEP 1 - **Individuals swabbed**

Individuals are swabbed either by a trained staff member or a healthcare professional

STEP 2 - **Test each swab**

Each swab is applied to a test card or cassette by a trained staff member or healthcare professional



STEP 3 - **Get results**

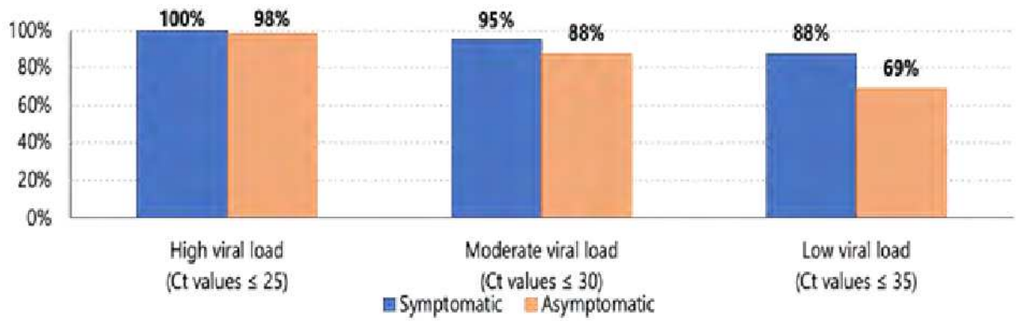
Results are interpreted and recorded by a trained staff member or healthcare professional. They can be used to make more informed decisions, detect the virus, and mitigate spread

Test Result:
Negative

Rapid antigen: use for pool deconvolution

Given the speed, accuracy, price and widespread availability, some schools are using **rapid antigen testing as a way for recommended follow-up testing** to support the pooled test program

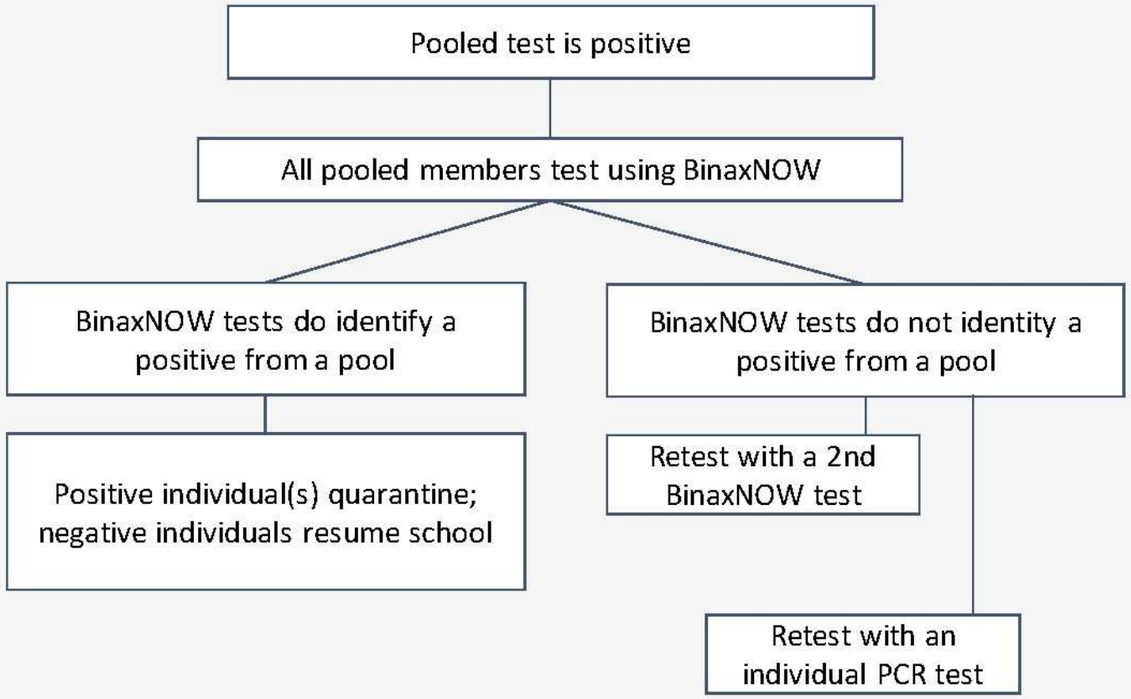
Percentage of positive PCR tests accompanied by a positive BinaxNOW test, by viral load
All other results were false negatives (PCR positive & BinaxNOW negative)



When compared to PCR tests, BinaxNOW is **accurate in detecting COVID-19 in children with moderate to high viral loads,** even if they are asymptomatic.

These children are the most likely to be highly contagious and transmit the disease.

One potential follow-up testing approach
Example: BinaxNow in Massachusetts

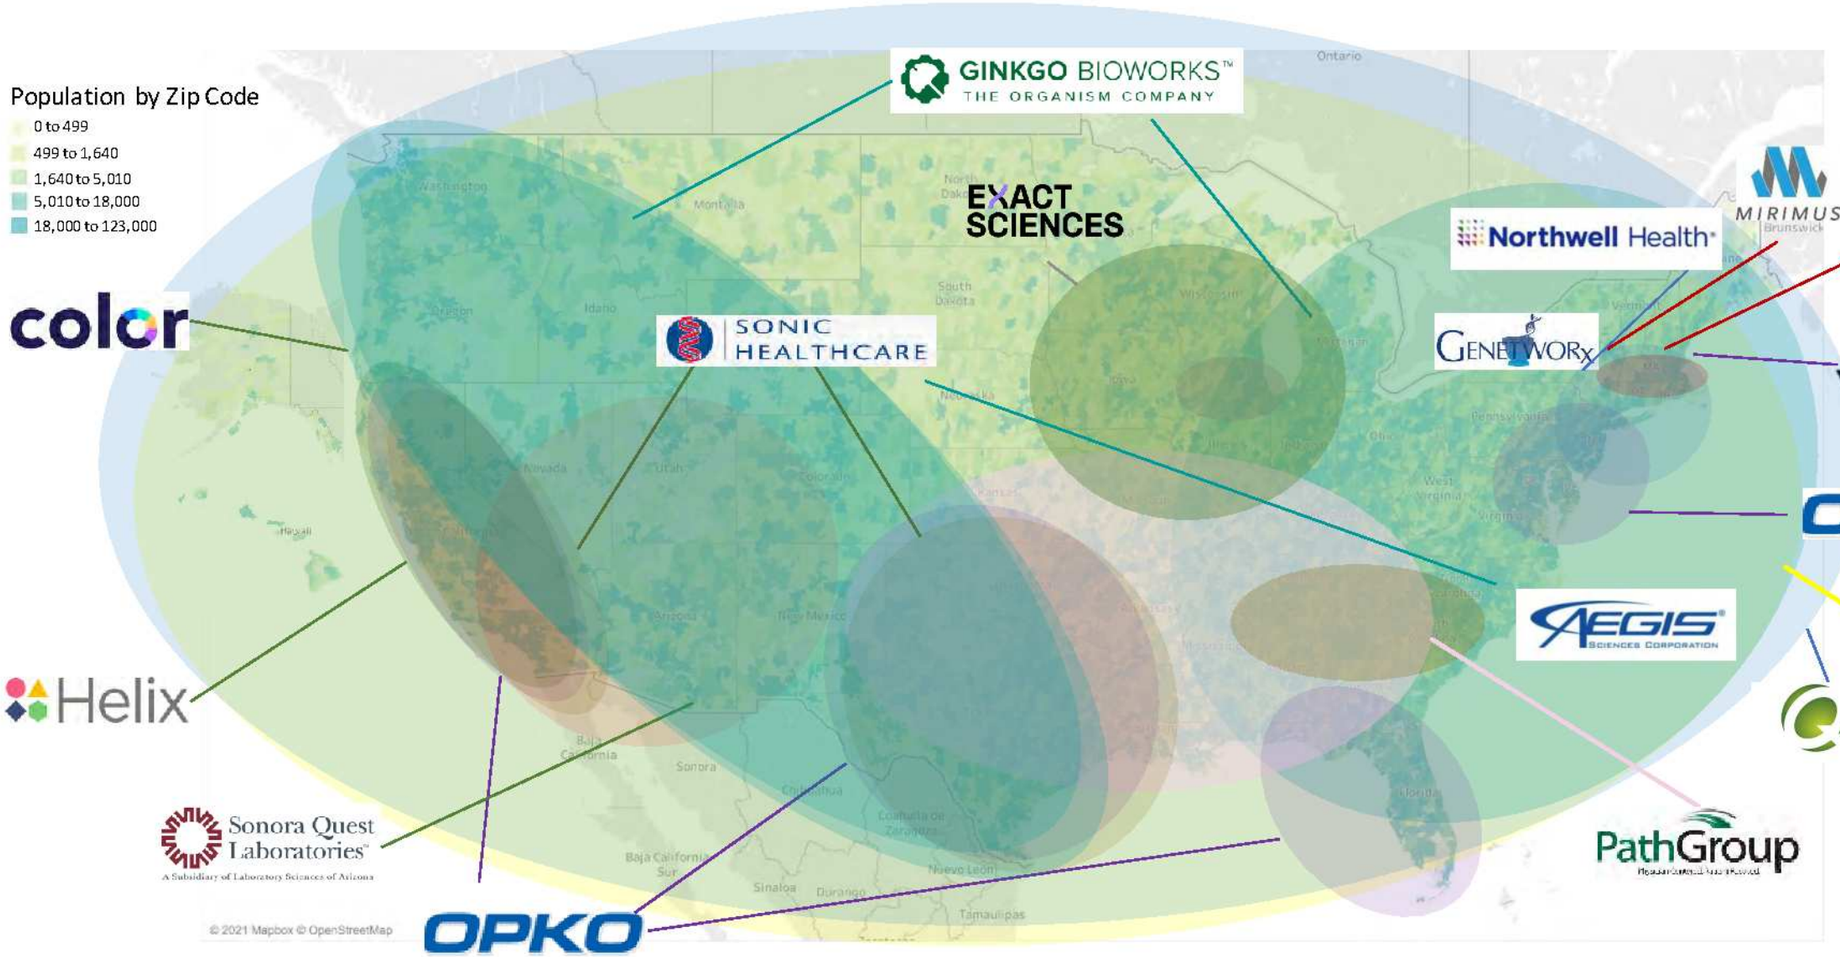


The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Sources: Massachusetts Department of Elementary and Secondary Education, BinaxNow Study, Covid Response Advisors

Who provides testing: testing footprint for scaling K-12 testing



Antigen Test Suppliers

- QUIDEL
- BD
- Abbott

Note: Lab coverage areas are approximate within national map. Additional coverage possible through public health and university labs

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

What will it cost: all-in cost estimates and assumptions

ALL-IN COST PARAMETERS

$30 per person for Step 1: asymptomatic testing

$10-15 per person: pooled PCR or antigen tests
$15-20 per person: school administrative costs

$60 per person for Step 2: positive pool follow up

$40-50 per person: individual PCR or antigen
$5-10 per person: school administrative costs

ASSUMPTIONS

Per person testing costs, including school administrative costs, are estimated from current operations in school testing programs

Assumption that ~1% of pools are positive and require deconvolution / Step 2 testing

Note: These numbers are included as an illustration of current market conditions. As more testing vendors enter this market, we expect the resulting competition will drive prices down.

CDC

MS-DOH-21-1816-A-001828

Minimum standards for program success

STANDARDS FOR SUCCESS

A. School and community alignment and engagement

B. 'Right test, right place, right time'

C. Necessary supply of tests, supplies and other resources

D. Resources to administer and process tests efficiently and effectively

E. Clear public health guidance and resources for every stage of the process

F. Reporting and data systems

G. Regulatory support

H. Ensuring equity and broad access

Minimum standards help ensure quality testing programs are available to all students, teachers and all staff, while still allowing the schools flexibility to design and customize their programs based on their unique context and needs

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Program minimum standards (1 of 2)

A. School and community alignment, engagement and education

- School committees, superintendents, teachers, unions and families should understand the goals of the testing program and how it helps to safely and sustainably reopen

B. ''Right test, right place, right time" (pooling or individual testing strategy)

- A standardized menu of testing protocols and workflows should be designed for schools that offer 24-hour results to test takers
- Testing programs should screen students and staff at a frequency that prevents outbreaks and enables the quarantining of individuals who test positive

C. Necessary supply of tests, supplies and other resources

- A stable and reliable supply of tests with a consistent process and result reporting should be available
- Fulfilling school demand nationally requires multiple types and sources of tests

D. Resources to administer testing programs efficiently and effectively

- Testing service providers should manage procurement, contracting and onboarding with individual districts and schools
- Testing playbooks and toolkits can explain how to roll out and manage a testing program at the district or school level
- Testing lead or coordinator should be appointed for each school; potentially a school nurse, school administrator, district administrator, or USPHS Commissioned Corps

E. Clear public health guidance and educational resources for every stage of the process

- Easy-to-understand rationale for and explanation of testing protocol is critical
- There should be an explanation of how schools and families should react to a positive case in school or in household
- Situations that necessitate confirmatory tests require some guidance
- Protocol for quarantine and return-to-school should be published

The ROCKEFELLER FOUNDATION HEALTH CATALYSTS GROUP

Program minimum standards (2 of 2)

F. Reporting and data systems

- Aggregate pool results should be reported to school, parents and students; tracking should be facilitated by online secure software products
- Any positive individual diagnostic results – whether antigen or molecular -- should be reported to local public health authorities per existing public health laws and facilitated by HIPPA-compliant software products
- Test results are intended to keep school open and are not aimed at individual diagnostics

G. Regulatory support

- Standard consent for adults and students is necessary, including release of personal health data as appropriate
- A quick and easy option is to have schools designated as CLIA sites for POC testing when relevant
- It can be useful to have a standing physician order to authorize individual diagnostic tests under school testing protocol

H. Ensuring equity and broad access

- All public schools and districts are encouraged to participate in program
- Testing programs should be offered at no cost to schools or participants or families
- State and local customization can provide varying levels of support for school districts with differing needs
- Test demand forecast can be created on objective factors (# students, ages, geographic densities et. al.)

What do schools do: rubber hits the road – operation overview

There are 4 key steps to executing K-12 NTAP, but each component within the key steps must be designed and executed based on individual needs of the school

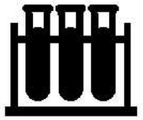
Key steps

1) Coordination & administration	2) Testing modality selection	3) Facility set-up	4) Results reporting
• Establish key positions & roles • Hire, train and build partnerships • Receive authorization and registration for testing	• Choose testing partner(s) • Finalize protocols for Step 1 Asymptomatic Screening and Step 2 Follow-up Testing for positive pools • Decide on Initiation Testing	• Set-up on-site, centralized, decentralized or other physical models	• Decide reporting strategy • Establish procedures for reporting positive results and confirmatory testing

Considerations for tailoring design and execution

Local epidemiology

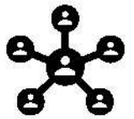
Student population needs (age, special needs, etc.)



Access to approved contracts and vendors

Proximity to labs

Human and financial resources



Number of students, teachers and staff

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

For additional resources to support school operations and planning, see: Testing for America

What do schools do: coordination and administration

Successful implementation, coordination and administration requires that schools fill staff positions prior to launching K-12 NTAP; schools can choose to hire additional employees, partner with external stakeholders, and/or train existing staff for these roles

Positions necessary to implement K-12 NTAP

Coordinator(s)
Oversee the daily operations and verify authorization/consent and registration

- **Ushers** — *Direct students, teachers and staff to testing locations*
- **Test Administrators** — *Collect or oversee sample collection*
- **Logistics Leads** — *Ship collected samples to labs and maintain shipping records*
- **Quality Controllers** — *Manage safe testing environment and disposal of biohazards*
- **Results Manager** — *Ensure all results are promptly shared with key stakeholders*

Depending on the position being filled and experience of the individual, specific trainings and certifications may be needed

A combination of hiring, training and partnerships can be used for these positions. Options include:

- **Hire temporary employees**
- **Partner with external stakeholders** (e.g., Commissioned Corps or health professionals)
- **Train existing staff**

Example: Watertown Public Schools, Broad Institute and CIC Health collaborated to administer individual testing for high need students

✓

✓

»» Cost savings from leveraging in-house resources

Source: Watertown Public Schools

What do schools do: setting up collection facilities

To maintain quality and consistency, on-site collection (e.g., at schools, local pop-up labs, etc.) is preferred to at-home collection. School's can tailor their on-site collection set up based on size, resource availability and testing modality

Set-up options

Centralized (walk-up)

Examples: Gym, cafeteria

When it works well:

- ✓ High-volume testing
- ✓ Limited testers available
- ✓ Test technologies that require more equipment or storage

Challenges:

- ✓ Space may already be in use for other school activities and social distancing needs

Decentralized

Examples: Individual classrooms

When it works well:

- ✓ Homeroom or pod model
- ✓ Minimizes day-to-day disruptions for younger students (more familiar to them)

Challenges

- ✓ Staff capacity
- ✓ Transporting PPE and supplies to each location (e.g., hazard waste removal)

Centralized (drive-thru)

Examples: Parking lot, drop-off zones

When it works well:

- ✓ Areas with high community prevalence (limits potentially infected individuals from entering common areas)
- ✓ For testing one-time visitors, substitute teachers, etc.

Challenges:

- ✓ Sufficient physical space may not be available

Photo Credit: Natasha Bhalla

Example: Washington International School and UnitedHealth Group collaborated to perform weekly pooled rapid testing

- 👍 Centralizing sample collection to make it easy was the key to success
- 👍 Using a phased approach allowed continuous improvement in sample collection methods

Alternative collection approaches

At-home collection may be used for several reasons including when individuals are showing Covid-19 symptoms or when a school lacks the staff needed to test the volume of students necessary

Off-premise testing at pharmacy or other third-party location may be used when individuals prefer their primary care provider to testing in school

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

Source: UnitedHealth Group

What do schools do: results reporting

Regular and prompt reporting of results to testing participants and their families, schools and school districts and the state and federal government is critical to maintaining safe school environment and overall public health

What to report on

Results to students, teachers and staff

PCR pool test results / antigen test results
Clearly and promptly provide test results as soon as they are available

Quarantine and isolation guidance
Reshare quarantining and isolation guidelines when positive pools/individual tests are identified

School positivity rates and trends
Regularly share updates to the school community on the total number of cases and positivity trends to maintain trust

Results to local, state and federal government

Positive cases
Provide regular updates on the total number cases and positivity trends at school or school district level (according to state and federal guidelines)

Tools and technologies to facilitate reporting

- **Centralized information platform** to store data with the ability to remove PII and aggregate at school district level as needed per FERPA and HIPAA guidelines
- **Website and/or text messaging** options to share results as soon as they are available
- **Inquiry form** to get status updates if the test results are not available in the expected timeframe

Example: Washington International School and UnitedHealth Group collaborated to perform weekly pooled rapid testing

- Use cloud-based information management system to track results and communication
- Report results to parents, staff and students within 40 minutes
- Created list of easily accessible FAQs about testing, operations, data security and safety

School operations in action: school nurse perspective

Nurse Jamie is the head nurse at a high school in a city supporting the school principal and the district superintendent as they adopt the K-12 NTAP. She firmly believes that both students and teachers should be tested regularly if the school is to reopen for in-person learning

Coordination and test modality

Over the last few weeks, the Nurse Jamie (testing coordinator), the district superintendent, principal and school nurses have coordinated to obtain consent to test and completed registration to begin testing. They have determined that groups of 10 students will be pooled and teachers tested individually, all via PCR testing. Pre-paid vouchers for confirmatory testing will be provided to parents in positive pools

Set-up

Nurse Jamie, in close collaboration with the school nurses, helped by hiring additional temporary staff to help with ushering, testing and shipping tasks. She also helped coordinate the set-up of testing booths in the gym for students and a separate area to test teachers. The testing team conducted a dry run of all operation on Sunday before school reopened

Sample collection

It's Monday and students and teachers begin to arrive to school. Nurse Jamie is in the command center of the school making sure that all individuals are getting tested. Once all the test samples are collected, Nurse Jamie checks in with the logistics staff to ensure all samples get shipped promptly to the nearby labs

Results reporting

Nurse Jamie gets to school early on Tuesday and sees she has an email from the lab saying that 2 pools in grade 8 tested positive. She immediately sends an email voucher to the parents of the students in the pool to get an individual test

When she comes back on Wednesday, she sees emails from all the parents who needed to get individual tests and 3 out of the 30 students were positive while the others negative for Covid-19. She authorized the remaining 27 to come back to school the following Monday and shared the update with school Principal and Superintendent

The ROCKEFELLER FOUNDATION

HEALTH CATALYSTS GROUP

School operations in action: student perspective

Molly's school has worked hard to implement the K-12 NTAP program, which is a national testing strategy that allows teachers and students to safely come back to school in-person. She can hardly contain her excitement to start school this coming week because she will finally be able to see her friends and teachers in-person

Engagement | **Testing** | **Results**

Over the last few weeks, Molly's parents have been talking with the school about the new testing program to understand all the steps they are taking to safely test Molly and keep her safe when she is in school. They have filled out required consent forms and registered for regular testing

It's Monday and when Molly arrives at school with her new rainbow mask, one of the school staff checks her in and directs her to head to the gym with the rest of her homeroom classmates. There are arrows on the ground directing her to one of the several tables that are set up in the gym. She only waits in line for 5 minutes (standing 6 feet apart from her classmates of course)

When it is her turn, the school nurse watches Molly swab her nose. That took only a minute and wasn't as scary as she thought it would be! Then Molly follows the arrows out of the gym and back to her class for the rest of the day

Molly comes back to school on Tuesday. While her whole class is there, the class next to them is empty because someone in that pod had a positive test. The teacher explains that the students in that pod will be tested again to confirm the positive individual

Molly's parents are made aware the positive pod pool but reminded of schools' general low overall prevalence rate. They are also reminded of the voucher program which will enable those students to get confirmatory antigen tests to confirm the positive individual, who will then remain at home for the necessary time

Molly's parents receive another email from the school on Wednesday confirming the Covid-19 positive individuals were successfully identified and asked to continue in-home learning for at least 2 weeks and provide a Covid-19 negative result. For contact tracing purposes, they were also told that Molly was not in contact with the Covid-19 positive individuals and should attend school normally

The ROCKEFELLER FOUNDATION | HEALTH CATALYSTS GROUP | CDC

Who is needed: building confidence for participants

Wide-spread adoption and participation relies on building confidence for participants by understanding their priorities and concerns. State and local leadership must proactively reassure and address the concerns of stakeholders

	Superintendents	Teachers and staff	Parents	Students
Priorities and Concerns	• All willing individuals are getting tested • Results are obtained quickly • Payments and funding vehicles are in place	• Keeping themselves and students safe • Preparing for when someone gets sick in school • Missing work when they test positive • Data privacy • Test collection safety	• Safety of children • Testing without parent/guardian present • Perceived cost and time of confirmatory test if applicable • Data privacy • Test collection safety	• Fear of getting the swab • Test collection safety • Stigma or lost school time linked to positive results
Actions to Build Confidence	• Set frequency and sensitivity standards • Provide easy-to-use consent forms • Provide central POC to ask questions	• Provide guidance on isolation and other mitigation strategies • Bring in trained people to administer tests • Be transparent about data privacy and use	• Provide information on getting confirmatory tests • Make consent forms easy to understand • Provide results quickly • Be transparent about data privacy and use	• Make the testing process as easy as possible to reduce stress and anxiety • Provide guidance on what do you if you're feeling sick

*Note: The Testing for America K-12 Playbook provides a tactical communications plan to engage stakeholders including who is responsible for the communication

CDC RECOMMENDS SCREENING TESTING TO REDUCE TRANSMISSION

"Viral testing strategies in partnership with schools should be part of a comprehensive prevention approach. Screening testing is intended to identify infected people without symptoms…to prevent further transmission." – CDC Guidelines

	CDC Recommendations for Screening Testing		
Community transmission	**Students**	**Teachers**	**Athletics**
Low (~30% of states) *In last 7 days, 0-9 new cases per 100K, <5% positive tests*	• **No screening** testing	• At least **once per week**	• At least **once per week**
Moderate (~70% of states) *In last 7 days, 10-49 new cases per 100K, 5-7.9% positive tests*	• At least **once per week**	• At least **once per week**	• At least **once per week**
Substantial or High (~0% of states) *In last 7 days, 50+ new cases per 100K, 8%+ positive tests*	• At least **once per week**	• At least **once per week**	• **Twice per week** for high-risk sports, at least once per week for all others

Given the **CDC recommends screening testing in schools in most instances**, it is critical to establish a program that is **easy to administer** and **requires minimal additional resources** from schools

HEALTH CATALYSTS GROUP

GUIDING PRINCIPLES FOR K-12 NTAP DEVELOPMENT

The K-12 NTAP team operates by a set of core principles which have guided the design and implementation of the program:

Think Big but Design Small – Standardize guidance to be widely applicable and scalable yet also tailorable for state-level coordination and school or district-level implementation

Provide Clear, Simple and Realistic Guidelines – Encourage use and adoption by making the guidelines easy to follow and proactively identifying ways to reduce barriers

Be Reasonably Comprehensive – Provide a common platform to understand the minimum requirements for K-12 testing at a broad level to enable the return of in-person learning

Be Focused – Prioritize testing solutions and strategies. Other mitigation strategies are assumed but secondary to this program (e.g., vaccine distribution, masking, physical distancing)

Enable Agility – Develop a plan that is practical and sustainable, while acknowledging the dynamic environment and likely necessity of real-time adaptation

Build Capacity – Identify ways meet demand for K-12 testing without diminishing existing testing capacity

Minimize Burden – Minimize burden on schools and families throughout the process to increase adoption

Subject: HHS COVID-19 Update - 4/5

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 5, 2021:

Highlights from Friday and Monday's White House COVID-19 Response Team briefing:

Jeff Zients

- **Vaccine Supply:** Last week, a total of more than 33 million doses went out to states, Tribes, and territories, and through the federal channels, including pharmacies and community health centers. This is a record level of weekly vaccine supply.
- **Mask Mandates:** We are working to put this pandemic behind us as fast as we can, but we're not there yet. We need everyone to do their part. That's why the President called on every governor, mayor, and local leader to maintain or reinstate mask mandates.

Andy Slavitt

- **Increasing the Number of Vaccination Sites:** Last week, we announced five new sites — in Maryland, Wisconsin, Tennessee, Missouri, and Indiana. And today, we're announcing three additional sites: The first is at the Columbia Place Mall in Columbia, South Carolina. The second is at the Colorado State Fairgrounds in Pueblo, Colorado. And the third is at the Minnesota State Fairgrounds in St. Paul, Minnesota, home of the Minnesota State Fair. Across the country, there's already 25 existing mass vaccination sites that have a combined capability to administer over 95,000 shots per day. Importantly, these new sites will advance our work to equitably distribute vaccines and reach communities that have been hurt the most by the pandemic.
- **Number of People Vaccinated:** We're now averaging 3.1 million shots per day over the most recent seven-day period. Over the weekend, there were more than 4 million recorded vaccinations in a single day for the first time. As of today, nearly one in three Americans and over 40 percent of adults have at least one shot, and nearly one in four adults are fully vaccinated. Seventy-five percent of seniors have now been vaccinated, and more than 55 percent of seniors are fully vaccinated.
- **Johnson & Johnson, AstraZeneca:** It's important to mention that all the Johnson & Johnson vaccine that's available in the U.S. has been authorized by the FDA. None of it came out of this plant in question, and Johnson & Johnson will have the 100 million doses by the end of May as they promised. With assistance from the Health and Human Services Department, Johnson & Johnson has taken complete control of the plant in question, in order to eliminate the potential for any cross-contamination. AstraZeneca is still scheduled to go through the FDA's authorization process as soon as an application is submitted.

Dr. Walensky

- **Case Update:** CDC's most recent data show the seven-day average of new cases is about 64,000 cases per day. This is up approximately 7 percent compared to the prior seven-day period. Hospital admissions have also increased. The most recent seven-day trend average is about 4,970 admissions per day, up about 3 percent from the previous seven-day period. Deaths have decreased to an average of approximately 800 per day. Importantly, we are now entering our fourth week of increased trends and cases.
- **Avoiding a Surge:** As the trends and data have been indicating, cases are increasing nationally, and we are seeing this occur predominantly in younger adults. As more schools are reopening, it's even more important to make sure they do so safely, with strict adherence to CDC guidance, and for all of us to roll up our sleeves for a vaccine as soon as we can. We are learning that many outbreaks in young people are related to youth sports and extracurricular activities. According to CDC guidance, these activities should be limited, but if they are not, the risks of clusters can be prevented with cadence testing strategies, as are being rolled out in so many different places.
- **MMWR:** The Illinois Department of Public Health and staff from a local public health department evaluated a COVID-19 outbreak associated with a bar in a rural area of Illinois. While table spacing and signs encouraged physical distancing and masking, people who attended the event reported that mask use was inconsistent and that six feet of distance was not maintained. The evaluation found 46 COVID-19 cases linked to this event. Of those, 26 were patrons, 3 were bar staff. Seventeen secondary cases occurred among contacts of people who attended the opening and got COVID-19; 12 were household contacts, 3 were long-term care facility contacts, and 2 were school-related contacts. Transmission associated with this opening event also resulted in eight households with infections, a school closure affecting 650 children, and the hospitalization of a long-term care facility resident.
- **Updated CDC Cleaning and Disinfecting Guidance:** CDC has updated its guidance for cleaning and disinfecting facilities and homes to reflect the science on transmission. People can be affected with the virus that causes COVID-19 through contact with contaminated surfaces and objects. However, evidence has demonstrated that the risk by this route of transmission is low. In most situations, regular cleaning of surfaces with soap and detergent, not necessarily disinfecting those surfaces, is enough to reduce the risk of COVID-19 spread.
- **Updated Guidance for Fully Vaccinated People:** We state that fully vaccinated people can resume travel at low risk to themselves. For domestic travel, fully vaccinated people do not need to get a COVID-19 test before or after travel and do not need to self-quarantine after travel. For international travel, fully vaccinated people do not need to get a COVID-19 test before they leave the United States unless it is required by their international destination. However, fully vaccinated people should get tested and have a negative test result before they board an international flight back into the United States and have a negative test three to five days after arrival, but they do not need to quarantine when they arrive here. Our guidance reiterates that all travelers, regardless of vaccination status, should continue to wear masks on planes, buses, trains, and other forms of public transportation while traveling. While we believe that fully vaccinated people can travel at low risk to themselves, CDC is not recommending travel at this time due to the rising number of cases.

Dr. Fauci

- **COVID-19 and Pregnancy:** In November 2020, the CDC did an analysis of about 400,000 women with symptomatic COVID-19. Though the numbers were small, it became clear then that there was very likely an increased risk among pregnant women versus non-pregnant women for adverse outcomes of the pregnancy itself and for them as pregnant women if they contracted the disease, COVID-19.
- **Vaccinations and Pregnancy:** Observational data from vaccinated pregnant individuals are currently being collected both by the CDC and no specific safety signals have been observed thus far among pregnant vaccine recipients. As I mentioned, as of a few days ago, there have been close to 70,000 V-Safe participants that were pregnant at the time they received the vaccination. The CDC is currently

enrolling participants to analyze the data and better understand how vaccination affects pregnant women. In a study recently published in the American Journal of Obstetrics and Gynecology, in 131 reproductive-age vaccine recipients, it became very clear that vaccine-induced, robust immune responses in pregnant women — similar to that in non-pregnant woman — not only was the immunogenicity but the reactogenicity was similar. And importantly, and very favorably, there was immune transfer to the neonates, which occurred both via the placenta in utero as well as through breast milk. In other words, things look very good for the association between vaccination and protecting pregnant women from adverse outcomes from themselves and their fetus.

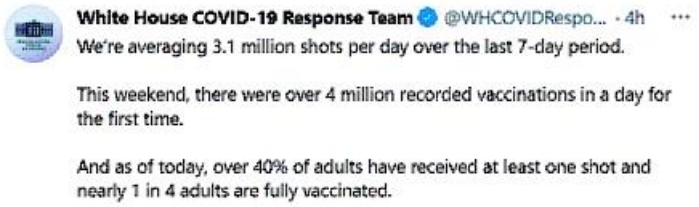
- **Vaccine Rollout Strategy:** We have been concerned, and still are, that when you look at the level of protection after one dose, you can say it's 80 percent, but it is somewhat of a tenuous 80 percent because the level of neutralizing antibodies against the coronavirus. When you just leave it at one dose, the question is: How long does it last? When you're dealing with variants that clearly might be diminished somewhat in their capability through the vaccine-induced antibodies, you're in a tenuous zone if you don't have the full impact. For that reason, although we always continue to keep an open mind, we consider the route that we're on now is the best route.
- **Vaccine Effectiveness:** Vaccines work very well in the real-world setting. They work against variants, although we need further data to confirm that. They are durable for at least six months. And they work in adolescence. These are very good reasons for everyone to get vaccinated as soon as it becomes available to you.

Dr. Murthy, U.S. Surgeon General

- **COVID-19 Public Education Campaign:** Our COVID-19 public education campaign has three goals: One, provide information. We want to give the American people facts to slow the spread of COVID-19 and to protect themselves. Two, build trust. We need to help build confidence in the vaccines by making sure people get accurate, scientific information from trusted sources. And three, connect people to vaccines. We need to mobilize our communities across our country to increase awareness of how you can get the vaccine when it's your turn. This is why we launched the COVID-19 Community Corps, a nationwide grassroots network of health professionals, community organizations, faith leaders, businesses, and Americans from all walks of life who are collectively stepping up to be leaders for their communities in this national vaccination effort. Our plan is to equip them with CDC-approved materials to help them deliver science-based information to their network. We launched with about 275 founding members, and in less than 24 hours, 2,500 more members have signed up.

Vaccine Updates

Vaccination Update: CDC released their COVID data tracker weekly review last Friday, providing an update on the status of vaccinations and the number of reported cases. The United States has administered over 167 million doses **of COVID-19 vaccine**, **with over** 62 **million people having been fully vaccinated.**



Percent of Vaccine Administered: The majority of U.S. states and territories have administered at or above 89% of their first vaccine doses delivered. Because the supply of vaccine is currently limited, CDC made vaccine rollout recommendations. Each state then makes its own plan for who will be vaccinated first and how people can get a vaccine once it is available to them.

Vaccination Demographic Data: CDC updated their vaccination demographic data and information regarding the reported numbers.

Different Vaccines: CDC updated their fact sheet on the different COVID-19 vaccines, which include Pfizer-BioNTech, Moderna, and Johnson & Johnson/ Janssen. The best COVID-19 vaccine is the first one that is available to you. Do not wait for a specific brand. The CDC does not recommend one vaccine over another.

Mobile Vaccination Units: On Friday, the first FEMA mobile vaccination unit is operating in Bridgeport, Connecticut through early next week, bringing vaccinations to hard-to-reach and high-risk populations who cannot access services from larger, fixed centers. Currently, the unit is focusing its efforts on eastern and southwestern areas in the state. A second mobile vaccination unit began administering vaccinations in the Eastern Shore area of Maryland on Saturday.

FDA Approved Moderna's Plan to Increase Doses: On Friday, the FDA announced two revisions regarding the number of doses per vial available for the Moderna COVID-19 Vaccine. The first revision clarifies the number of doses per vial for the vials that are currently available, in that the maximum number of extractable doses is 11, with a range of 10-11 doses. The second revision authorizes the availability of an additional multi-dose vial in which each vial contains a maximum of 15 doses, with a range of 13-15 doses that can potentially be extracted. The Fact Sheet for Healthcare Providers Administering Vaccine (Vaccination Providers) and Prescribing Information have been revised to reflect the new information and are intended to help frontline workers administering COVID-19 vaccines understand the number of doses that can potentially be extracted per vial.

FDA Provides PREPP Update: The FDA updated their COVID-19 Pandemic Recovery and Preparedness Plan (PREPP) initiative, identifying five key activities for further development and implementation. These include: reviewing aspects of the EUA processes for medical products and identifying areas for potential improvement in order to ensure transparency and facilitate appropriate integration of these products including diagnostics, therapeutics and vaccines into medical care; reviewing science-based communications to ensure the agency continues to provide timely and accurate communications to the public; evaluating inspectional approaches using next-generation assessment technologies, such as virtual and video-enabled platforms, to further our inspectional reach; evaluating the current supply chain tracking, monitoring and assessment systems to identify gaps and challenges to help stakeholders improve supply chain resilience. View the January 2021 release and summary report here.

BARDA and Johnson & Johnson Expands Trial to Include Adolescents: BARDA and Janssen Pharmaceutical Companies of Johnson & Johnson (Janssen), are increasing ongoing efforts to develop an expanded indication for a vaccine to prevent COVID-19 in adolescents ages 12-17. BARDA is supporting additional development of Janssen's COVID-19 investigational vaccine, Ad26.COV2.S, with expansion of a Phase 2a clinical trial for adolescents participating with their parents' consent. The clinical trial is the next step in assessing the safety and efficacy of Ad26.COV2.S in volunteers 12-17 years of age. The trial is currently ongoing in the UK and Spain. Preparations for the clinical trial in the US and other countries are ongoing.

Testing and Treatment

COVID-19 Variants: CDC updated their fact sheet on the variants of the virus, as well as their information on variant cases and variants proportions in the U.S. Multiple variants of the virus that causes COVID-19 are circulating globally and within the United States. There are currently five variants of concern in the United States: B.1.1.7 (U.K.), B.1.351 (South Africa), P.1 (Brazil), B.1.427 (California), and B.1.429 (California). It is important to protect yourself and others against COVID-19 by wearing a mask, staying at least 6 feet apart, avoiding crowds, washing your hands, and getting vaccinated when it's available to you.

FDA COVID-19 Update: On Friday, the FDA released an update on their ongoing response efforts to the COVID-19 pandemic. Following recent FDA actions to support test development, the FDA took swift action this week to get more tests for screening asymptomatic individuals on the market. The FDA also posted a new web page SARS-CoV-2 Viral Mutations: Impact on COVID-19 Tests for clinical laboratory staff and health care providers about the impact of viral mutations on COVID-19 molecular, antigen, and serology tests. Furthermore, the FDA posted translations of the Consumer Update: Learn More about COVID-19 Vaccines From the FDA in five additional languages: Chinese, Korean, Spanish, Tagalog, and Vietnamese. As part of the FDA's effort to protect consumers, the agency issued a warning letter jointly with the Federal Trade Commission to Natural Adventure, LLC for selling unapproved products with fraudulent COVID-19 claims. Moreover, the FDA provided COVID-19 testing updates.

Guidance for Cleaning and Disinfecting: CDC updated their information on both cleaning your home and cleaning your facility every day and when someone is sick. The virus that causes COVID-19 can land on surfaces. It's possible for people to become infected if they touch those surfaces and then touch their nose, mouth, or eyes. In most situations, the risk of infection from touching a surface is low. The most reliable way to prevent infection from surfaces is to regularly wash hands or use hand sanitizer.

Reopening Guidance

CDC General Updates on Travel: CDC updated their guidelines on travel, their fact sheet on when not to travel, and information on travel-associated exposures. They also updated their fact sheet on safer travel Ideas, their traveling and COVID page, and their travel FAQs. Furthermore, CDC updated their travel health notices regarding the risk assessment for COVID-19 in other countries.

CDC Guidelines on Domestic Travel: provided updated information for domestic travel during COVID-19, including the following: Fully vaccinated travelers are less likely to get and spread COVID-19. People who are fully vaccinated with an FDA-authorized vaccine can travel safely within the United States; fully vaccinated travelers do not need to get tested before or after travel unless their destination requires it and they do not need to self-quarantine Fully vaccinated travelers should still follow CDC's recommendations for traveling safely including: wear a mask over your nose and mouth, stay 6 feet from others and avoid crowds, and wash your hands often or use hand sanitizer.

CDC Guidelines on International Travel: CDC also updated their guidance surrounding international travel during COVID-19 stating that while fully vaccinated travelers are less likely to get and spread COVID-19, international travel poses additional risks and even fully vaccinated travelers are at increased risk for getting and possibly spreading new COVID-19 variants. CDC recommends delaying international travel until you are fully vaccinated. If you are fully vaccinated with an FDA-authorized vaccine: you should continue to follow CDC's recommendations for traveling safely and get tested 3-5 days after travel; you do not need to get tested before leaving United States unless your destination requires it; and you do not need to self-quarantine after arriving in the United States. Review the updated fact sheet more information on protocols once returning from international travel.

Cruise Ship Guidance: CDC released a new phase of the Framework for Conditional Sailing Order for cruise ships operating or seeking to operate in U.S. waters. CDC published Technical Instructions for cruise ship operators and for local health authorities outlining this phase of the Conditional Sailing Order. CDC recommends that all people avoid travel on cruise ships, including river cruises, worldwide. That's because the chance of getting COVID-19 on cruise ships is high since the virus appears to spread more easily between people in close quarters aboard ships. It is especially important that people with an increased risk of severe illness defer travel on cruise ships, including river cruises. CDC has issued a Level 4 Travel Health Notice for cruise ship travel. CDC also updated their guidance for ship crew members on how to protect themselves and others, as well as criteria for the commercial transport of crew that ships must meet.

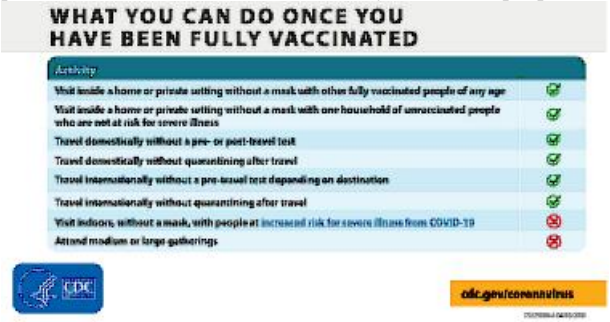
Information for Specific Populations

Schools and Childcare Programs: CDC updated their guidance on COVID-19 safety protocol for schools and childcare. There is specific information for teaching staff, administrators, and the general public. CDC also updated their information for school staff and childcare workers regarding their edibility for their COVID-19 vaccination. U.S. teachers, school staff, and childcare workers in pre-K-12 schools and childcare programs are eligible for COVID-19 vaccination. CDC outlines who can get vaccinated and how to schedule your appointment here.

Staffing Resources: CDC updated their resources and guidance for strengthening the public health workforce. Enhancing frontline public health capacity in state, local, tribal, and territorial health departments to intensify the coordinated response to COVID-19 is critical.

Guidance for Fully Vaccinated People: In a press release, CDC updated their guidance for people who have been fully vaccinated. Based on what we know about COVID-19 vaccines, people who have been fully vaccinated can start to do some things that they had stopped doing because of the pandemic. We're still learning how vaccines will affect the spread of COVID-19. After you've been fully vaccinated against COVID-19, you should keep taking precautions – like wearing a mask, staying 6 feet apart from others, and avoiding crowds and poorly ventilated spaces – in public places until we know more. These recommendations can help you make decisions about daily activities after you are fully vaccinated.

They are *not* intended for healthcare settings. For more information, visit the CDC science brief on the background rationale and evidence for public health recommendations for fully vaccinated people.



Guidance for Older Adults: CDC updated their information for older adults. Risk for severe illness with COVID-19 increases with age, with older adults at highest risk. Certain medical conditions can also increase risk for severe illness. People at increased risk, and those who live or visit with them, need to take precautions to protect themselves from getting COVID-19.

Tribal Communities: CDC updated their information for tribal community members, tribal leaders, and tribal partners on COVID-19 prevention and support.

Temporary Halt in Residential Evictions: CDC updated their information on the temporary halt in residential evictions to prevent the further spread of COVID-19. Director Dr. Rochelle Walensky signed a declaration determining that the evictions of tenants could be detrimental to public health control measures to slow the spread of SARS-Cov-2, the virus that causes COVID-19.

Marketplace Webinar Invitation: Information to Help Tribal Communities: In partnership with the Center for Consumer Information and Insurance Oversight (CCIIO), the CMS Division of Tribal Affairs is co-hosting a webinar providing Marketplace updates on Thursday, April 8, at 1:00 PM ET. This presentation will highlight recent policy changes that may impact American Indian and Alaska Natives (AI/AN), including the special enrollment period (SEP) from February 15 to May 15, 2021, CMS outreach efforts, and the American Rescue Plan Act of 2021 (ARP). Additional information on enrollment of tribal citizens and other Indian Health Service (IHS) eligible individuals in health insurance coverage through a Marketplace, including use of Tribal Sponsorship, will also be presented. You can register here.

CDC's COVID-19 Weekly Partner Calls: CDC released information regarding upcoming partner calls, including with representatives from community-based organizations, local government, the private sector, academia, and the general public to learn more about how they can help slow the spread of COVID-19 in their communities. Each week we feature experts from different parts of CDC's COVID-19 response to deep dive into specific topics, helping you learn more about the latest scientific findings, guidance for operations, information resources, and answering your COVID-19 questions. Sign up to join a call here.

Community Spotlights: CDC updated their community features page to include more information about grassroots efforts in Southwest Kansas to educate refugee communities about COVID-19.

CMS Updates

Acute Hospital Care at Home Program: CMS updated the approved list of hospitals for the Acute Hospital Care at Home Program. The Acute Hospital Care at Home program is an expansion of the CMS Hospital Without Walls initiative launched in March 2020 as a part of a comprehensive effort to increase hospital capacity, maximize resources, and combat COVID-19 to keep Americans safe. This program creates additional flexibility that allows for certain health care services to be provided outside of a traditional hospital setting and within a patient's home. The approved list of hospitals will be moving to the CMS Hospital at Home webpage beginning April 9, 2021.

Research

Community Transmission of SARS-CoV-2: CDC released an *MMWR* on the community transmission of SARS-CoV-2 associated with a local bar opening event in Illinois. Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred during February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students. Opening up settings such as bars, where mask wearing and physical distancing are challenging, can affect the community. As community businesses reopen, prevention measures should be emphasized, including limiting building occupancy, improving ventilation, prioritizing outdoor seating, enforcing correct mask wearing and physical distancing, staying home when ill, and encouraging COVID-19 vaccination to reduce transmission on site and within the community.

Surface Transmission: CDC released a new science brief on SARS-CoV-2 and surface (fomite) transmission for indoor community environments. The principal mode by which people are infected with SARS-CoV-2 (the virus that causes COVID-19) is through exposure to respiratory droplets carrying infectious virus. It is possible for people to be infected through contact with contaminated surfaces or objects (fomites), but the risk is generally considered to be low.

Vaccines by Jurisdiction: CDC released a report providing an overview of the multiple channels being used to ensure all Americans have access to COVID-19 vaccine. Jurisdictional delivery and administration portfolios vary across the United States because of population variability.

COVID-19 Outbreak in a State Prison: CDC updated an *MMWR* on the rapid spread of SARS-CoV-2 in a State Prison after introduction by newly transferred incarcerated persons in Wisconsin.

COVID-19 Vaccine Response in Pregnant and Lactating Women: As mentioned above by Dr. Fauci, a study by the American Journal of Obstetrics and Gynecology found that COVID-19 mRNA vaccines generated robust humoral immunity in pregnant and lactating women, with

immunogenicity and reactogenicity similar to that observed in non-pregnant women. Vaccine-induced immune responses were significantly greater than the response to natural infection. Immune transfer to neonates occurred via placenta and breastmilk.

Community Transmission of SARS-CoV-2 Associated with a Local Bar Opening Event — Illinois, February 2021

Samira Sami, DrPH[1]; Caitlin R. Turbyfill, MPH[1]; Shelby Daniel-Wayman, MPH[2]; Stacy Shonkwiler, MSN[3]; Kiva A. Fisher, PhD[1]; Macey Kuhring[3]; Aaron M. Patrick[3]; Stephanie Hinton, MHS, MA[1]; Amanda S. Minor, MPH[3]; Jessica N. Ricaldi, MD, PhD[1]; Ngozi Ezike, MD[2]; Judy Kauerauf, MPH[2]; Wayne A. Duffus, MD, PhD[2]

During February 2021, an opening event was held indoors at a rural Illinois bar that accommodates approximately 100 persons. The Illinois Department of Public Health (IDPH) and local health department staff members investigated a COVID-19 outbreak associated with this opening event. Overall, 46 COVID-19 cases were linked to the event, including cases in 26 patrons and three staff members who attended the opening event and 17 secondary cases. Four persons with cases had COVID-19–like symptoms on the same day they attended the event. Secondary cases included 12 cases in eight households with children, two on a school sports team, and three in a long-term care facility (LTCF). Transmission associated with the opening event resulted in one school closure affecting 650 children (9,100 lost person-days of school) and hospitalization of one LTCF resident with COVID-19. These findings demonstrate that opening up settings such as bars, where mask wearing and physical distancing are challenging, can increase the risk for community transmission of SARS-CoV-2, the virus that causes COVID-19. As community businesses begin to reopen, a multicomponent approach should be emphasized in settings such as bars to prevent transmission* (*1*). This includes enforcing consistent and correct mask use, maintaining ≥6 ft of physical distance between persons, reducing indoor bar occupancy, prioritizing outdoor seating, improving building ventilation, and promoting behaviors such as staying at home when ill, as well as implementing contact tracing in combination with isolation and quarantine when COVID-19 cases are diagnosed.

Investigation and Findings

On February 17, 2021, IDPH was notified through the state's outbreak reporting system of a possible COVID-19 outbreak (i.e., five or more cases linked to a common location) in persons who attended an opening event at a bar in a rural Illinois county. The event had occurred indoors, with no outside air flow, approximately 2 weeks earlier in a 2,800-sq-ft bar during normal operating hours (4:00 p.m. to 1:00 a.m.). Six employees staffed the bar. Although the total number of bar patrons who attended the event is unknown, the bar accommodates approximately 100 persons. Before the event, IDPH reported a 7-day average daily COVID-19 incidence of 41–42 cases per 100,000 persons in the county; 14 days after the event, the 7-day average daily incidence had more than doubled, to 86–87 cases per 100,000 persons (*2*). On February 12, through routine testing and contact tracing, local health department staff members identified a cluster of cases linked to the bar event, including a case in an asymptomatic attendee who received a confirmed COVID-19 diagnosis the day before the event.

A bar attendee case was defined as the onset of COVID-19–like symptoms or receipt of a positive SARS-CoV-2 test result within 14 days of the bar opening event in a bar patron or employee who reported attending the event and who had no previous identified epidemiologic link to a COVID-19 case outside that setting. A confirmed case was defined as receipt of a positive SARS-CoV-2 nucleic acid amplification test (NAAT) or antigen test result by a person who attended the event, and a probable case was defined as COVID-19–like symptoms in a person who attended the event but had no laboratory confirmation of infection.† A secondary case was defined as receipt

of a positive SARS-CoV-2 NAAT or antigen test result by a close contact of a person with event-associated COVID-19.[§]

Local health department staff members, per standard practice, conducted case investigations within 48 hours of receipt of a positive SARS-CoV-2 test result in the county using a standardized questionnaire; demographic data, symptoms, and symptom onset date were entered into an electronic contact tracing platform. Through routine case investigation, local health department investigators identified a cluster of cases linked to the bar opening event through case reports indicating that persons attended the event or were close contacts of a person with an event-associated case during the 14 days before symptom onset or the testing date. All persons with a bar attendee case or secondary case of COVID-19 were interviewed by local health department staff members. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[¶]

Bar patrons and employees. By February 16, 2021, 29 bar attendee cases had been identified among persons who reported attending the opening event (Figure), including 26 (89.7%) in bar patrons and three (10.3%) in employees; all identified cases were confirmed by NAAT or antigen testing, except one probable case in a person who had COVID-19–like symptoms but did not receive testing (Table). Three additional employees worked during the event, all of whom had received a positive test result during the preceding 90 days and had completed 10 days of isolation from symptom onset or test date. Among persons with bar attendee cases, 25 (86.2%) had symptomatic illnesses. Among persons with symptom onset after the start of the event, onset dates ranged from 1 to 7 days after the event. Four (13.8%) persons with bar attendee cases reported having symptoms on the day of the event and were not reported to be contacts of one another before the event. Event attendees reported inconsistent mask use and not maintaining ≥6 ft of physical distance, despite table spacing and signs encouraging physical distancing and mask use. Most persons with bar attendee cases were adults aged 18–44 years (75.9%), male (65.5%), and non-Hispanic White persons (79.3%). One of the 29 persons with a bar attendee case, a bar patron, had received a COVID-19 vaccination before the event (the first dose, 5 days before receipt of the positive SARS-CoV-2 test result). No other persons with bar attendee cases had received a COVID-19 vaccination.

Secondary community cases. After the bar opening event, at least 71 close contacts of persons with bar attendee COVID-19 were reported; among these, 37 (52.1%) received testing, 17 (45.9%) of whom received a positive test result within 14 days of the contact. Two persons with secondary COVID-19 cases were school-related contacts of persons with bar attendee COVID-19, three were LTCF contacts, and 12 were household contacts. Among the 17 persons with secondary cases of confirmed COVID-19, 13 were symptomatic, with symptom onset dates ranging from 3 to 11 days after the event. Median age was 28 years (range = 10–71 years), and nine persons were female.

One bar attendee with COVID-19 reported the onset of a runny nose 2 days after the event and reported 26 close contacts at school during indoor sports practice and in-person school instruction. Two student athletes who were close contacts of this person subsequently received COVID-19 diagnoses 8 and 13 days after the event. Local health department officials were notified by a school official that the school district would close for 2 weeks beginning February 18 because 13 staff members were in isolation, in quarantine, or absent because their own child was quarantined.

One bar attendee who worked at an LTCF as a certified nursing assistant was asymptomatic and received a positive test result during routine COVID-19 testing at the facility 4 days after the event. After receipt of the positive test result, all LTCF residents and staff members in the facility were tested; three secondary cases (one in a staff member and two in residents) in persons who were close contacts of the bar attendee with COVID-19 were identified in the facility 5–9 days after the event. One resident with a secondary case was hospitalized on February 20, within 14 days of the positive test result, and was discharged the same day. None of the four persons in the LTCF with bar attendee or secondary COVID-19 had received a COVID-19 vaccination; all LTCF staff members and residents had been previously offered the vaccine.

By February 26, 12 household contacts in eight different households had received positive SARS-CoV-2 test results, including five school-aged children. Local health department staff members interviewed household contacts to assess exposures. Secondary household cases were linked to nine (31.0%) of 29 bar attendee cases. Eleven persons were symptomatic, and cases were confirmed by NAAT or antigen testing. No household contacts with COVID-19 were hospitalized.

Discussion

An event held to celebrate a bar opening led to an outbreak among bar patrons and employees and was the likely source of subsequent COVID-19 transmission among household members, LTCF residents and staff members, and school athletes, leading to 46 cases, hospitalization of an LTCF resident, and a school closure affecting 650 children. Attendees included one person with an asymptomatic infection who received

[§] Close contact is defined as being within 6 ft of a person with laboratory-confirmed or probable SARS-CoV-2 infection for a cumulative total of ≥15 minutes in a 24-hour period. https://www.cdc.gov/coronavirus/2019-ncov/php/contact-tracing/contact-tracing-plan/appendix.html#contact

¶ COVID-19–like symptoms in a person with an epidemiologic link to the bar opening event but no laboratory confirmation of infection.

a COVID-19 diagnosis the day before the event and four symptomatic persons who subsequently received a COVID-19 diagnosis after the event. Asymptomatic persons are estimated to account for approximately 40%–45% of infections (*3*); the high percentage (82.6%) of symptomatic persons who were linked to the bar opening event suggests that the total number of cases in this outbreak was higher than reported and highlights the need for increased testing and reporting through contact tracing, in combination with isolation and quarantine, to promptly reduce transmission. As community businesses begin to reopen, these findings underscore the importance of businesses and individuals adhering to public health prevention and mitigation guidelines to reduce additional community transmission, including isolation after receipt of a COVID-19 diagnosis and while experiencing COVID-19–like symptoms, even as vaccination efforts expand.

Similar gatherings that involve eating or drinking, such as on-premises dining at restaurants, weddings, and night clubs, have been associated with increased risk for acquiring COVID-19 and have the potential to become super-spreading

MS-DOH-21-1816-A-001861

events for SARS-CoV-2 infection (*4*–*8*). This investigation further demonstrates that inconsistent mask use and inadequate physical distancing in an indoor environment can increase transmission risk** (*9*,*10*). According to CDC's COVID-19 guidelines for restaurants and bars, reducing patron capacity, ensuring adequate room air ventilation, prioritizing outdoor seating, and promoting behaviors such as staying at home when ill, washing hands often, wearing masks, and maintaining physical distance are important strategies to reduce the spread of SARS-CoV-2 infection (*1*).

The findings in this report are subject to at least four limitations. First, interviews were voluntary, and many community members were reluctant to disclose contacts or additional details about themselves, including their occupation. Therefore, the number of cases described in this report is likely lower than the actual number of bar attendee and secondary cases associated with the event. Second, it is unlikely that all asymptomatic cases were counted, and not all contacts were tested; therefore, some infected contacts might have been missed. Third, information on individual-level behaviors such as wearing masks and physical distancing was not collected from persons with cases. Finally, specimens were not available for whole genome sequencing; thus, the relationship among strains was not documented, and whether the increase in county-level incidence might be attributed to variants that spread more easily than the original SARS-CoV-2 strain cannot be determined.

Bars can play a role in community spread of COVID-19 because of limited mask use while eating or drinking and lack of consistent physical distancing. These findings show that SARS-CoV-2 transmission originating in a business such as a bar not only affects the patrons and employees of the bar but

MS-DOH-21-1816-A-001862

Summary

What is already known about this topic?

Gatherings in settings where mask wearing and physical distancing do not occur are known to increase the spread of COVID-19.

What is added by this report?

Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred during February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students.

What are the implications for public health practice?

Opening up settings such as bars, where mask wearing and physical distancing are challenging, can affect the community. As community businesses reopen, prevention measures should be emphasized, including limiting building occupancy, improving ventilation, prioritizing outdoor seating, enforcing correct mask wearing and physical distancing, staying home when ill, and encouraging COVID-19 vaccination to reduce transmission on site and within the community.

can also affect an entire community. As community businesses begin to reopen, considering additional prevention measures is important, such as limiting building occupancy levels and improving ventilation, especially in locations where consistent and correct mask wearing and physical distancing are difficult to enforce. Businesses can work with local health officials to promote behaviors and maintain environments that reduce the risk for SARS-CoV-2 transmission and develop strategies for reopening safely to prevent outbreaks in the community, such as modifying layouts and operating procedures (*1*).

Acknowledgments

COVID-19 case investigators and contact tracers in the local health department.

- Extension: CDC Public Health Worker Mental Health Survey [Link]
    - CDC is conducting a survey intended for people who worked in STLT public health departments in 2020, in an effort to understand and address the mental health impacts and support needs of our crucial public health workforce on the frontlines of the COVID-19 response. All full-time and part-time employees, contractors, fellows and others who work at the health department are eligible to participate, and we encourage you to broadly disseminate the survey to relevant staff.
    - **The survey deadline has been extended to Friday, April 16.** The 10-15 minute anonymous survey is available here.
- Webinar: "COVID-19 Case Surveillance Public Use Data with Geography – Overview of Privacy Protections" [Attachment, Link]
    - CDC will host a webinar **Friday, April 16** at **2:00 pm EDT** to discuss privacy protections for the new COVID-19 Case Surveillance Public Use Data with Geography. Please email questions in advance to eocevent394@cdc.gov with "Question for 4/16 CDC webinar on new public use dataset" in the subject line. Call information is available below:
        - Weblink: https://cdc.zoomgov.com/j/1618567396?pwd=WE9RWitrS09pdk1KSnA5TnhNdEVjQT09
          Meeting ID: 161 856 7396
          Telephone: (669) 254-5252 or (646) 828-7666 or (551) 285-1373 or (669) 216-1590
          Passcode: 44193919
    - An .ICS calendar file is also attached for your convenience.
- MMWR Early Release: "Factors Associated with Participation in Elementary School–Based SARS-CoV-2 Testing — Salt Lake County, Utah, December 2020–January 2021" [Attachment, Link]
    - From the report: *"As schools consider reopening, in-school specimen collection for SARS-CoV-2 testing could help reach potentially underserved populations to reduce community transmission. Explaining testing procedures in a parent's or guardian's preferred language, as was done in this situation, might also be important for promoting participation."*

Standing Updates

- CDC Partner Updates – April 7 & 9 [Attachments]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Updates – April 6, 7, & 8 [Attachments]
    - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the

week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.

- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC Resources

- **COVID-19 Vaccine Clinician Resources Update:** CDC's Prevaccination Checklist is now available in English and **six** additional languages: Arabic, Spanish, French, Korean, Simplified Chinese, Vietnamese. Translations are available on the *Product Info by Vaccine* webpages under the Administration Resources section (Pfizer-BioNTech, Moderna, and Janssen/J&J).
- **Grassroots Efforts in Southwest Kansas Educate Refugee Communities about COVID-19:**When COVID-19 hit Southwest Kansas in spring of 2020, there was little information on COVID-19 available in languages apart from English. Essential workers from refugee communities turned to their neighbors, who are also healthcare providers, for answers in their own languages. More about Kansas Refugee Communities
- **Baltimore African American Faith Community is Key in Promoting Vaccine Confidence:**The African American faith community in Baltimore has been integral to educating the public about the risks posed by flu and the importance of vaccination. This work now provides immunization partners with lessons learned for the COVID-19 vaccination program. More about Baltimore's Faith Community
- **Connecticut Uses Social Media to Engage Long-term Care Residents:**To connect with residents of long-term care facilities and their families, the Connecticut Long Term Care Ombudsman Program (LTCOP) partnered with colleagues from other state government agencies to hold weekly Facebook Live events. More about Connecticut LTCOP
- **FluView:** The Weekly U.S. Influenza Surveillance Report (FluView), lists key updates for influenza each week. These updates include viruses detected, illnesses reported in clinics, rates of severe disease, reports on U.S. Virologic Surveillance, and Influenza Virus Characterization.
- **Emergency Preparedness Tips for Parents of Children with Special Healthcare Needs** April is National Autism Awareness Month and a month to start preparing for severe weather. This CDC Public Health Matters blogpost provides tips on proper planning for emergencies, peace of mind exercises, and links to additional guides for families who have children with special needs.

Morbidity and Mortality Weekly Report (MMWR)

- **Early Release MMWR, April 7, 2021: Factors Associated with Participation in Elementary School-Based SARS-CoV-2 Testing — Salt Lake County, Utah, December 2020–January 2021.** Link to article here. CDC partnered with the University of Utah and Utah state and local health departments to offer free, in-school testing as part of elementary school COVID-19 transmission investigations in one Utah school district. An analysis found that compared with Non-Hispanic White students, participation in the testing offered was higher among students identifying as Hispanic/Latino white or as members of a racial minority group. As schools consider reopening, in-school testing could help reach potentially underserved populations to reduce COVID-19 spread in the community.

Upcoming Meetings

- **COVID-19 Partner Update April 12, 2021: Contact Tracing for COVID-19: Do we still need it? (You bet we do!):** 3:00-4:00 PM EDT, Monday, April 12, 2021. Join CDC's weekly partner call for updates on the COVID-19 response, including new resources for the private sector and the general public. Register for the event here. For Q&A, please email eocevent337@cdc.gov with "Partner Call 4/12" in the subject line.
- **Community of Practice Call: School-based Screening Testing:** 2:00-3:00 PM EDT, Thursday, April 8, 2021. This week's Community of Practice call will focus on the importance of the partnership between public health and education in establishing COVID-19 K-12 school screening testing programs and provide information on assistance being offered to support these programs.
- **AUCD, ASTHO, and NACCHO Webinar Series: COVID-19 Vaccination and Reaching People with Disabilities:** 1:00-2:00 PM EDT, April 7, April 8, 2021. AUCD, ASTHO, and NACCHO are hosting webinars: COVID-19 Vaccination and Reaching People with Disabilities. Join to hear about promising practices on how states are reaching people with disabilities. Register here.

Additional Resources

- **Federal Emergency Management Agency (FEMA) to Help Pay Funeral Costs for COVID-19-Related Deaths:** In early April, FEMA will begin providing financial assistance financial assistance for funeral expenses incurred after Jan. 20, 2020 for deaths related to coronavirus (COVID-19) to help ease some of the financial stress and burden caused by the pandemic. FEMA is now moving rapidly to implement this funeral assistance program nationwide.
- **VaccineFinder:** VaccineFinder helps individuals find clinics, pharmacies, and other locations that offer COVID-19 vaccines.
- **Characteristics of Multisystem Inflammatory Syndrome in Children During COVID-19:** Authored by Ermias D. Belay, M.D., of the Centers for Disease Control and Prevention, this study examined the clinical and other characteristics of multisystem inflammatory syndrome in children in the United States, a condition that occurs in association with the COVID-19 pandemic.

PROTECTING AMERICA'S SAFETY, HEALTH, AND SECURITY

April 9, 2021

CDC STLT Support Task Force Friday Feature: STLT Task Force/Section Deployment to assist the Shoshone-Bannock Tribes

Tribal leaders invited CDC's Tribal Support Section (TSS) to provideCOVID-19 technical assistance in the areas of vaccine rollout, strategic community outreach, and interdepartmental process development. Two vaccine coordinators and three public health advisors were deployed from March 5 to March 31 and focused on vaccine coordination, contact tracing, and data management support. The five deployers helped develop tribal guidance related to community safe reopening planning, assessment of COVID-19 vaccine hesitancy and barriers, sources for COVID-19 related information, analysis of Indian Health Service (IHS) and Tribal Health vaccination data, operationalization of mass vaccination clinics/events, and the establishment of a mobile vaccine unit. Communication to promote vaccine demand including the development of written communications products, presentations on the tribe's weekly Facebook Live, and discussion sessions to engage key audiences (e.g., casino executives, COVID screening/testing staff, contact tracers, business council, etc.) helped ensure nearly 50% of the estimated 5,500 eligible tribal members received their first vaccine dose. TSS is appreciative of the invitation extended by the Shoshone-Bannock Tribes and for the opportunity to collaborate with our tribal partners, including Tribal Health and Human Services, IHS, and Health Resources and Services Administration (HRSA). The collaborative environment and continued efforts by the tribes and their partners led to the success of this work. To connect with CDC's Tribal Support Section, please email: eocevent362@cdc.gov.

CDC Resources

- **Mental health survey:** CDC's STLT Task Force/Health Department Section is collecting data on the mental health of those who worked in state, tribal, local, and territorial public health departments in 2020 and will look at demographics, job categories and questions to assess symptoms of anxiety, depression, and post-traumatic stress disorder (PTSD). We also hope to hear about your organizational support and the ways you've coped throughout the pandemic. As of April 8, approximately 15,000 individuals have completed the survey! Thank you for your continued support and efforts. Due to requests for more time from multiple health departments, the project team has extended the survey to Friday, April 16, 2021. Please let your members know about this extension. For more information on CDC's mental health study, please contact the survey team at eocevent442@cdc.gov.
- **Tribal Communities: Plan, Prepare, and Respond:** The CDC maintains a comprehensive website that contains resources for both tribal community members as well as tribal partners. The site was recently updated with additional information on the CDC funding agreement, which adds to the information on prevention, strategies, mental health guidance, and considerations for tribal ceremonies, in addition to many other resources.
- **Post-COVID Conditions: Information for Healthcare Providers:** On April 8, the CDC updated the guidance found on here for healthcare providers. Some patients who have been infected with SARS-COV-2 have symptoms and clinical findings that persist beyond four weeks or can recur following initial recovery. Persistent symptoms and clinical findings can occur regardless of the severity of acute COVID-19. Medical and research communities are still learning about these post-acute symptoms and clinical findings.

- **Post-COVID Conditions:** On April 8, the CDC updated the guidance found on here for post-COVID conditions. Although most people with COVID-19 get better within weeks to months of illness, some do not. CDC and experts around the world are working to learn more about short- and long-term health effects associated with COVID-19, who gets them, and why.

Morbidity and Mortality Weekly Report (MMWR)

- **April 9, 2021, COVID-19 Incidence and Mortality Among American Indian/Alaska Native and White Persons — Montana, March 13–November 30, 2021:** Link to article here. COVID-19 incidence and mortality rates among AI/AN persons in Montana were 2.2 and 3.8 times, respectively, those among white persons. The case-fatality rate among AI/AN persons was 1.7 times that among White persons. These findings reinforce importance of using state-level surveillance to develop state and tribal COVID-19 vaccine allocation strategies and to inform local implementation of culturally appropriate public health measures that might help reduce COVID-19 incidence and mortality in AI/AN communities.
- **April 9, 2021, Use of Stay-at-Home Orders and Mask Mandates to Control COVID-19 Transmission — Blackfeet Tribal Reservation, Montana, June–December 2020:** Link to article here. In the Blackfeet Tribal Reservation, enforcement of stay-at-home orders and mandated use of face coverings in public, with potential fines and jail for noncompliance, were associated with a thirty-three-fold reduction in COVID-19 incidence from its peak of 6.40 cases per 1,000 residents per day on October 5 to 0.19 on November 7, 2020. Enforcement of stay-at-home orders and mask use mandates, coupled with robust public health investigations, have been shown to reduce COVID-19 incidence.
- **April 9, 2021, Notes from the Field: COVID-19 Case Investigation and Contact Tracing Program — Spirit Lake Tribe, North Dakota, September–November 2020:** Link to the article here. In the Fall of 2020, in response to increasing incidence of COVID-19 on the Spirit Lake Reservation, CDC assisted the Spirit Lake Tribe in building a tribally managed program for comprehensive COVID-19 case investigations, case notification, contact tracing, contact testing, and contact management to ensure timely implementation of these critical epidemic control measures.
- **April 9, 2021, COVID-19 Stats: College and University* COVID-19 Student Testing Protocols, by Mode of Instruction (N = 1,849) — United States, Spring 2021:** Link to article here. Study that exams the number of public and private, nonprofit 4-year U.S. colleges and universities that provide some type of COVID-19 testing for asymptomatic students. The study also looks at how testing is offered in schools that are conducting classes in-person, online, or in a hybrid setting.

Upcoming Meetings

- **COVID-19 Partner Update April 12, 2021: Contact Tracing for COVID-19: Do we still need it? (You bet we do!):** 3:00-4:00 PM EDT, Monday, April 12, 2021. Join CDC's weekly partner call for updates on the COVID-19 response, including new resources for the private sector and the general public. Register for the event here. For Q&A, please email eocevent337@cdc.gov with "Partner Call 4/12" in the subject line.

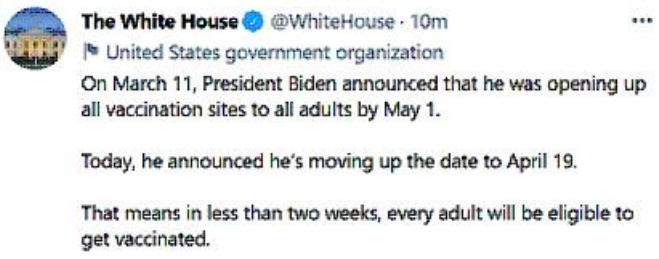
From: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Sent: Tuesday, April 06, 2021 7:49 PM EDT
To: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Subject: HHS COVID-19 Update - 4/6

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 6, 2021:

President Biden's Remarks on the State of Vaccinations:

- **New Vaccination Goal:** On March the 11th, I announced that I was opening up all vaccination sites to all adults by May 1st. Many governors — Democrats and Republicans — responded and decided to beat that day, which was good. Thanks to their hard work and the hard work of the American people, and the hard work of my team, I'm announcing today that we're moving that date up from May 1st to April 19th, nationwide. That means, by no later than April 19th, in every part of this country, every adult over the age of 18 — 18 or older — will be eligible to be vaccinated. Many states have already opened up to all adults. But beginning April 19th, every adult in every state, every adult in this country is eligible to get in line to get a COVID vaccination.
- **Vaccination Update:** Yesterday, we crossed 150 million shots in 75 days — the first 75 days my administration, on our way to hitting our goal of 200 million shots by the 100th day in office. That, of course, is the new goal I set after passing the original mark of 100 million shots in my first 100 days, doing it in just 58 days. We're now administering an average of 3 million shots per day — over 20 million shots a week. On Saturday alone, we reported more than 4 million shots were administered. We're the first country to administer 150 million shots and the first country to fully vaccinate over 62 million people. The good news is we're on track to beat our goal of 200 million shots in the first 100 days. More than 75 percent of the people over the age of 65 have gotten shots, up from 8 percent when we took office. That's a dramatic turnaround and critical because seniors account for 80 percent of all COVID deaths. To help support my goal of safely reopening a majority of K-through-8 schools by my 100th day in office, I directed states in early March to make educators and childcare workers eligible for vaccines, and to set a goal of getting all who wanted the vaccination to be able to have one and to do it in the month of March. I'm pleased to report, according to CDC estimates, over 80 percent of teachers, school staff, and childcare workers received at least one shot by the end of March. And because our vaccine program is in overdrive, we're making it easier to get a vaccination shot. Last week, I announced that by April 19th of this month, 90 percent of all Americans will be within five miles of a vaccination site.
- **Vaccine Effectiveness:** We're getting more and more data on just how effective the vaccines are. Dr. Fauci recently cited two studies from the New England Journal of Medicine that found fully vaccinated care workers — healthcare workers on the frontlines had an extremely low infections rate, less than two-tenths of one percent, compared to unvaccinated healthcare workers who had considerably higher infection rates.
- **COVID-19 Cases and Variants:** New variants of the virus are spreading and they're moving quickly. Cases are going back up. Hospitalizations are no longer declining. While deaths are still down — way down from January — they're going up in some places. I understand that people may find it confusing that the vaccination program is saving tens of thousands of lives, but the pandemic remains dangerous. Let me explain it in a single word: Time. Time. Even moving at the record speed we're moving at, we're not even halfway through vaccinating over 300 million Americans. This is going to take time. Remember: For a two-dose vaccine, it takes weeks from the time you get your first one until you are able to get your second shot, which makes you fully protected.
- **Importance of Following CDC Guidelines:** We aren't at the finish line. We still have a lot of work to do. We're still in a life-and-death race against this virus. Until we get more people vaccinated, we need everyone to wash their hands, socially distance, and mask up in a recommended mask from the CDC.
- **Getting Vaccinated:** I want to make a direct appeal to our seniors and everyone who cares about them. While we have made incredible progress vaccinating three quarters of our seniors and putting vaccination sites within five miles of 90 percent of the public, it still isn't enough. It's simple: Seniors, it's time for you to get vaccinated now. Get vaccinated now. To make it easier, my administration is sending aid to community groups to drive seniors to vaccination sites. We're incredibly grateful to all the volunteers, houses of worship, and the civic groups that are helping us in this effort. As I ask seniors to sign up for their shots now, I also have a message for people under 65. If you know someone over 65 who has not gotten this life-saving vaccine, call them now. Work with them to get their shots this week or next. Pick them up, drive them. It can be your parents, your grandparents, your aunt, uncle, your neighbors.
- **Access to Vaccines:** We know that there are a number of seniors and people with disabilities and people in many communities of color who may be isolated and lack access to transportation. That's why we're ramping up transportation to vaccination centers and deploying more mobile units and pop-up clinics in the places close to where people live. That's why we're working with faith-based organizations and other community groups to host vaccination clinics, sign people up for appointments, get help — help them get those appointments. That's why we're sending even more vaccines to community health centers, like the one I was in today, that all together serve nearly 30 million Americans, like the ones I visited today. Two thirds of the patients at community health centers live at or below the poverty level. Sixty percent are racial and ethnic minorities. To reach them, we're investing nearly $10 billion to expand testing, treatment, and vaccinations for the hardest hit yet most underserved communities.



Case Update

New Cases (based on 7-day rolling average)

- **30,532,965** US cases
- **3.0% increase** in new cases (7-day average), as of April 4th; (was 13.2% increase last week)

Testing

- **381,757,068** tests completed (4/6)
- **5.7%** positive test rate as of the week of 3/27 – 4/2 (was 5.0% last week)

Hospitalizations

- **1,971,219** total COVID hospital admissions
- The 7-day average (3/28-4/3) number of new confirmed COVID-19 admissions **increased** to **4,843** admissions per day from last week's 7-day average (3/21-3/27) of **4,693** admissions per day

Deaths

- **554,064** total US deaths
- The 7-day average (3/29-4/4) number of reported deaths **decreased by 20.4%** week on week (from 985 to 781 deaths per day)

Vaccines

- **168,592,075** vaccine doses **administered** (4/6)
- **32.6%** (108.3 million people) of the population has received **1 or more doses** and **19%** (63 million people) of the population have been **fully vaccinated**
- **75.9%** of adults 65 and older have received **at least 1 dose** and **56.6%** have been **fully vaccinated**

Vaccine Updates

FEMA Vaccination Sites: This week, federal pilot community vaccination centers are scheduled to open in Gary, Indiana; Greenbelt, Maryland; St. Louis; Memphis, Tennessee and Milwaukee, while FEMA mobile vaccination units have begun operations, bringing vaccinations to hard-to-reach and high-risk populations who cannot access services from fixed sites. Four units are operational: one in Connecticut, two in Maryland and one in Oregon. FEMA has now provided more than $4.5 billion to 42 states, Washington D.C., four tribes and five territories for expenses related to COVID-19 vaccination at 100% federal cost share. These funds cover critical supplies, staffing, training and transportation needs that support increased vaccination efforts.

County-Level Vaccination Data: CDC updated their tracker on county-level vaccination data. This site allows users to explore standardized data across the country, including vaccine data.

V-Safe Pregnancy Registry: CDC updated their information on the V-Safe COVID-19 Vaccine Pregnancy Registry. As of April 5, 2021, more than 77,000 v-safe participants have indicated they were pregnant at the time they received COVID-19 vaccination. CDC is currently enrolling eligible participants and analyzing data to better understand how COVID-19 vaccination affects pregnant people. As CDC learns more about the effects of vaccination during pregnancy, data will be presented at the Advisory Committee on Immunization Practices (ACIP) meetings, which are open to the public, and in published reports.

Reported Adverse Events After COVID-19 Vaccinations: Over 167 million doses of COVID-19 vaccines were administered in the United States from December 14, 2020, through April 5, 2021. During this time, the Vaccine Adverse Event Reporting System (VAERS) received 2,794 reports of death (0.00167%) among people who received a COVID-19 vaccine. CDC and FDA physicians review each case report of death as soon as notified and CDC requests medical records to further assess reports. A review of available clinical information including death certificates, autopsy, and medical records revealed no evidence that vaccination contributed to patient deaths. CDC and FDA will continue to investigate reports of adverse events, including deaths, reported to VAERS.

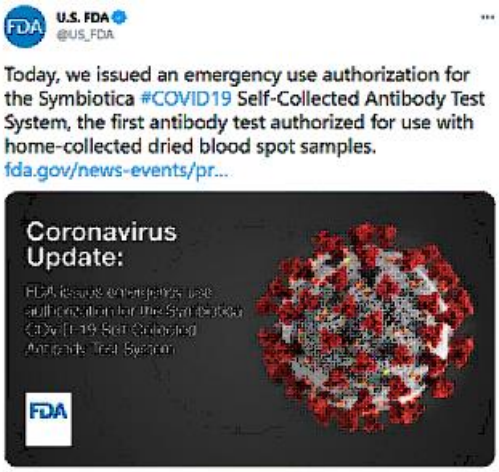
COVID-19 Vaccination Toolkit: CDC updated their COVID-19 vaccination toolkit for health departments and other public health partners. This toolkit provides information for public health partners to help educate communities and promote COVID-19 vaccination. The CDC also updated their information on promoting vaccine confidence.

Resources for Sharing Real-Time Vaccine Information: CDC updated their resources for sharing real-time vaccine information. Virtual communication tools, like virtual town halls, livestreams, and social media, offer public health professionals the ability to engage and disseminate vital information to the public while maintaining social distancing. This page also includes non-CDC resources for virtual meetings.

Customizable COVID-19 Vaccination Content: CDC updated their information on customizable COVID-19 vaccination content for health departments and other public health partners. Health departments and other public health partners can use the content in a variety of formats. It can be customized for newsletters, emails, blogs, matte articles, or other forms of communication. Health departments and public health partners can add their own logos and customize the text to make it appropriate for their community.

Testing and Treatment

FDA Issues EUA for the Symbiotica COVID-19 Self-Collected Antibody Test System: The FDA today announced it has issued an emergency use authorization (EUA) for the Symbiotica COVID-19 Self-Collected Antibody Test System, the first antibody test authorized for use with home collected dried blood spot samples. Samples collected at home are then sent to a Symbiotica, Inc. laboratory for analysis. The COVID-19 Self-Collected Antibody Test System is authorized for prescription use with a fingerstick dried blood sample that is self-collected by an individual age 18 years or older or collected by an adult from an individual 5 years of age and older. The test is intended to aid in identifying individuals with an adaptive immune response to SARS-CoV-2, indicating recent or prior infection. The COVID-19 Self-Collected Antibody Test System should not be used to diagnose or exclude acute SARS-CoV-2 infection. Currently, it is unknown how long antibodies persist following infection and if the presence of antibodies confers protective immunity.



Drug Applications During the COVID-19 Pandemic: The FDA issued and immediately implemented a new guidance: Development of Abbreviated New Drug Applications During the COVID-19 Pandemic – Questions and Answers. The guidance provides general recommendations to prospective generic drug applicants related to generic drug product development and regulatory submissions in the form of questions and answers that have been received and addressed by the FDA during the COVID-19 public health emergency. The FDA is issuing this guidance so that the development of generic drugs and submission of applications can continue during the COVID-19 public health emergency, ultimately helping to ensure that Americans continue to have access to safe, effective generic drugs.

New Initiative for At-Home Testing: NIH Director, Dr. Francis Collins, comments on the launch of the new innovative community health initiative called "Say Yes! COVID Test," led by the CDC, in close collaboration with state and local public health departments and the NIH. The initiative, the first large-scale evaluation of community-wide, self-administered COVID-19 testing, was launched last week in Pitt County, NC, and will start soon in Chattanooga/Hamilton County, TN.

Mask Guidance: CDC updated their guidance for wearing masks, in order to help slow the spread of COVID-19. CDC recommends that people wear masks in public settings, at events and gatherings, and anywhere they will be around other people. Effective February 2, 2021, masks are required on planes, buses, trains, and other forms of public transportation traveling into, within, or out of the United States and in U.S. transportation hubs such as airports and stations. CDC updated their guidance on how to select, wear, and clean your mask. Furthermore, CDC updated their information on how masks can better protect you, and how to improve the fit and filtration of your mask.

Reopening Guidance

Crew Disembarkations through Commercial Travel: CDC updated their information regarding crew disembarkations through commercial travel**.** CDC is committed to helping cruise lines provide for the safety and well-being of their crew members while onboard cruise ships and as they disembark. CDC is allowing crew members to disembark from all cruise ships in U.S. waters with certain precautions. Cruise lines with complete and accurate response plans are able to use commercial travel to disembark crew members from certain ships if the ships meet certain criteria set by CDC. Criteria include no confirmed cases of coronavirus disease 2019 (COVID-19) or COVID-19-like illness onboard the ship within the last 14 days. These ships are also able to lessen certain social distancing restrictions onboard. Cruise lines with complete and accurate COVID-19 response plans but not meeting the above criteria will still be able to disembark their crew members using noncommercial travel. Cruise lines must have measures in place to ensure those involved in transport are not exposed to the virus that causes COVID-19 and follow all CDC requirements to prevent interaction of disembarking crew with the public. Additionally, CDC recommends that all eligible port personnel and travelers (passengers and crew) get a COVID-19 vaccine when one is available to them.

Information for Specific Populations

Staffing Resources: CDC updated their resources and guidance for strengthening the public health workforce. Enhancing frontline public health capacity in state, local, tribal, and territorial health departments to intensify the coordinated response to COVID-19 is critical.

Requirement for Air Passengers Arriving in the U.S: CDC updated their information regarding the requirement for proof of negative COVID-19 test or recovery from COVID-19 for all air passengers arriving in the United States. If you plan to travel internationally, you will need to get tested no more than 3 days before you travel by air into the United States and show your negative result to the airline before you board your flight, or be prepared to show documentation of recovery (proof of a recent positive viral test and a letter from your healthcare provider or a public health official stating that you were cleared to travel).

Essential Services and Critical Infrastructure: CDC updated their fact sheet on how essential services can plan, prepare, and respond to COVID-19 in order to prevent spread of the virus and ensure essential functions continue.

CDC Podcast: CDC Director Dr. Rochelle P. Walensky joins CDC Foundation President and CEO Dr. Judy Moore to discuss the agency's latest work to combat COVID-19 and how public health professionals can help prepare communities for a new normal.

Research

SARS-CoV-2 May Infect Mouth Cells: In an NIH study, researchers find that SARS-CoV-2, the virus that causes COVID-19, can infect cells in the mouth. The findings suggest that the mouth, via infected oral cells, may play a bigger role in SARS-CoV-2 infection than previously thought. Saliva infected by these cells might help infect the lungs when it is breathed in and the gut when it is swallowed. A better understanding of the mouth's role in SARS-CoV-2 infection could help to develop interventions and treat oral symptoms of COVID-19.

COVID-19 Kidney Care Challenge: HHS announced the seven winners in Round 2 of the COVID-19 Kidney Care Challenge. Ranging from digital health to genetic sequencing approaches, their resourceful solutions aim to reduce risk during the pandemic.

Marvin Figueroa, Director
Office of Intergovernmental and External Affairs

Subject: HHS COVID-19 Update - 4/7

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 7, 2021:

Highlights from the White House COVID-19 Response Team Briefing

Andy Slavitt

- **New Vaccination Goal:** The President announced yesterday that all adult Americans will be eligible to be vaccinated by April 19. This is ahead of the original May 1st timeline that he set last month. This means that there is no better time for seniors who haven't been vaccinated to get their shot now. At this point, over 76 percent of seniors have had at least their first shot. If you know a senior who has not yet had the opportunity to get a shot, consider helping them arrange that opportunity and see what help they need. A number of seniors live alone and may need transportation or other help. The good news is there are more and more locations in more places available for them. President Biden also announced that we crossed 150 million shots in just 75 days of his administration.
- **School Reopening**: At the beginning of March, the President directed states and the Federal Retail Pharmacy Program to prioritize the vaccination of teachers, school staff, and childcare workers during the month of March. As the President announced yesterday, as of the end of March, the latest CDC estimates show that almost 80 percent of pre-K through 12th grade teachers, school staff, and childcare workers received at least one shot. The Department of Education released the latest round of data from its own ongoing survey on the impact of COVID-19 on K through 8th grade students and the state of school reopening in the nation. This is encouraging early data — covering the month of February — and shows progress toward the President's goal to have K through 8th grade schools open five days a week.
- **Expanding Vaccination Sites:** We're announcing today that we are expanding our community health center vaccine program so that all of the nearly 1,400 community health centers can sign up to receive and administer doses to their patients. Many community health centers are located in underserved communities and serve patients that are predominantly either uninsured or underinsured.

Dr. Walensky

- **Case Update:** CDC's most recent data show that the seven-day average of new cases is a little more than 63,000 cases per day. This is up approximately 2.3 percent compared to the prior seven-day average. Hospital admissions also continue to increase. The most recent seven-day average — about 5,000 admissions per day — is up about 2.7 percent from the prior seven-day average. And deaths decreased 19.7 percent to a seven-day average of 745 per day.
- **Case Data and Variants:** Across the country, we are hearing reports of clusters of cases associated with daycare centers and youth sports. Hospitals are seeing more and more younger adults — those in their 30s and 40s — admitted with severe disease. Data suggests this is all happening as we are seeing increasing prevalence of SARS-CoV-2 variants, with 52 jurisdictions now reporting cases of variants of concern. Based on our most recent estimates from CDC surveillance, the B.1.1.7 variant is now the most common lineage circulating in the United States.
- **Avoiding a Surge:** We have to recognize the high risk of infection in areas of high community transmission. I encourage communities to consider adjustments to meet their unique needs and circumstances. We have guidance on CDC's website on how to host small events safely, recognizing that our goals are to decrease transmission of COVID-19 and, importantly, to keep schools open and students engaged in in-person learning. We are vaccinating, on average, 3 million Americans every single day — getting shots into arms, providing protection. I urge everyone who has not received a COVID-19 vaccine to roll up their sleeves and join the nearly 108 million people who have already received at least one dose.

Dr. Fauci

- **Duration of Immunity to Natural Infection:** Regarding natural infection, we now have a considerable amount of information related to the duration of what we hope we'll be able to delineate more confidently — namely, what's called the "correlate of immunity." A paper from Science from a couple of months ago looked at the multiple immune memory responses, including both antibodies CD4 and CD8 T cells following natural infection. About 95 percent of the subjects in this study maintained antibodies six months after infection. I want people to realize that that's at least six months. They did not look further than this, so it might be much longer.
- **Duration Following Vaccination:** One representative study, which came out yesterday in the *New England Journal of Medicine* , looked at the persistence of responses through six months following the Moderna vaccine. But there's every reason to believe that similar results will be seen with the Pfizer, as well as the J&J. If you look at this, antibody activity remained high in all age groups out to 209 days in three serological assays. We are still working out the precise correlate of immunity, but antibodies delivered by vaccination persist at least through six months, and likely, from the shape of the curve, well beyond that. In that regard, ongoing studies are monitoring these immune responses beyond six months, as well as determining the effect of a booster dose to extend the duration and breadth of activity against not only wild type, but also emerging viral variants.

Vaccine Updates

Expansion of COVID-19 Vaccine Program: HHS Secretary Xavier Becerra today announced that all HRSA-funded health centers and Health Center Program look-alikes (LALs) will now be invited to participate in the Health Center COVID-19 Vaccine Program. These health centers will have the opportunity to join the program as soon as they are ready, increasing the total number of health centers that have been invited to 1,470 nationwide. This expansion will be made through the Health Resources and Services Administration (HRSA) and the Centers for Disease Control and Prevention (CDC). Approximately 70 percent of those who have received a vaccine through the Health Center COVID-19 Vaccine Program are racial or ethnic minorities.

Nearly 80 Percent of Educators At Least Partially Vaccinated: CDC issued a media release stating that nearly 80 percent of Pre-K-12 teachers, school staff, and childcare workers received at least their first shot of COVID-19 vaccine by the end of March. More than 2 million teachers, school staff, and childcare workers were vaccinated through the Federal Retail Pharmacy Program during the month of

March. Additionally, 5-6 million were vaccinated through their state programs through the end of March.

Getting Your Vaccine: CDC updated their information for people getting their COVID-19 vaccine. If you receive a Pfizer-BioNTech or Moderna COVID-19 vaccine, you will need 2 shots to get the most protection. COVID-19 vaccines are not interchangeable. If you received a Pfizer-BioNTech or Moderna COVID-19 vaccine, you should get the same product for your second shot. You should get your second shot even if you have side effects after the first shot, unless a vaccination provider or your doctor tells you not to get it.

Vaccine Adverse Event Reporting System: CDC provided information on their Vaccine Adverse Event Reporting System (VAERS), which is an early warning system used to monitor adverse events that happen after vaccination. VAERS is the frontline system of a comprehensive vaccine safety monitoring program in the United States . Millions of people in the United States have received COVID-19 vaccines. Other than rare reports of severe allergic reactions, analysis of VAERS reports has not detected any patterns that would indicate a safety problem with COVID-19 vaccines. More information on vaccine safety and monitoring here.

Testing and Treatment

FDA COVID-19 Update: The FDA released a testing update. As of April 6, 355 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 258 molecular tests and sample collection devices, 75 antibody and other immune response tests, and 22 antigen tests. There are 43 molecular authorizations and 1 antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home test, four over-the-counter (OTC) at-home antigen test, and one OTC molecular test. The FDA has authorized 6 antigen tests and 1 molecular test for serial screening programs.

Funding

CDC Awards $3 Billion to Expand COVID-19 Vaccine Programs: CDC has awarded funding to support local efforts to increase vaccine uptake by expanding COVID-19 vaccine programs and ensuring greater equity and access to vaccine by those disproportionately affected by SARS-CoV-2, the virus that causes COVID-19. The awards are part of $3 billion in funding that CDC has granted to 64 jurisdictions to bolster broad-based vaccine distribution, access, and administration efforts. The funding was made available by the American Rescue Plan and the Coronavirus Response and Relief Supplemental Appropriations Act and will provide critical support through CDC's existing immunization cooperative agreements in communities around the country. To ensure health equity and expanded access to COVID-19 vaccines: 75% of the total funding must focus on specific programs and initiatives intended to increase vaccine access, acceptance, and uptake among racial and ethnic minority communities; and, 60% must go to support local health departments, community-based organizations, and community health centers.

FEMA Vaccination Sites: FEMA has provided more than $4.5 billion to 42 states, Washington D.C., five tribes and five territories for expenses related to COVID-19 vaccination at 100% federal cost share. These funds cover critical supplies, staffing, training and transportation needs that support increased vaccination efforts. Furthermore, FEMA mobile vaccination units have begun operations. These vehicles can bring vaccinations to hard-to-reach and high-risk populations who cannot access services from fixed sites. Six units are operational: one in Connecticut, two in Maryland, two in Nevada and one in Oregon.

Information for Specific Populations

Employer Information for Office Buildings: CDC updated their guidance for office building employers, owners and managers, and operations specialists to create a safe and healthy workplace for workers and clients. CDC states that employers should perform enhanced cleaning and disinfection after anyone suspected or confirmed to have COVID-19 has been in the workplace within the last 24 hours, and to clean high-touch surfaces.

People with Moderate to Severe Asthma: CDC updated their guidance for people with asthma in order to protect themselves from COVID-19. People with moderate to severe asthma should continue to follow CDC guidelines and get a COVID-19 vaccine when it is available to them.

Community Health Workers Support of Home-Based Care: CDC updated their considerations intended for program managers and other public health officials supporting the COVID-19 response in low-resource non-US settings. Protecting community health workers' (CHWs) health and safety is critical, including during the COVID-19 pandemic. With training about prevention and appropriate infection prevention and control measures, CHWs can protect their own health while serving as good examples for how to prevent COVID-19 in the communities they serve. Relying on CHWs can help maximize available resources for managing and caring for people with more severe illness and can help maintain essential health services. CDC offers suggestions for CHWs in order to ensure their safety and the safety of their patients.

CMS Updates

The Value of Affordable Health Care: Secretary Becerra comments on the value of affordable health care , discussing his family's health scare in a time before health care reform. Secretary Becerra applauds both the Affordable Care Act (ACA) passed under the Obama-Biden administration, as well as the American Rescue Plan Act, signed last month by President Biden, as tools towards ensuring health care as a right and not as a privilege.

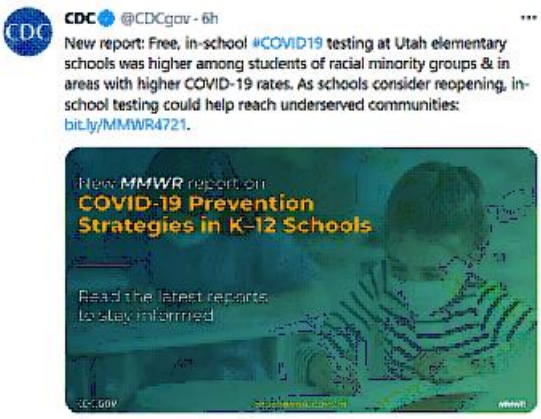
More than 500,000 Americans Have Enrolled in Marketplace Coverage During SEP: Today, HHS Secretary Xavier Becerra announced that more than half a million consumers have already signed up for health insurance through HealthCare.gov as a result of the Biden Administration's Special Enrollment Period (SEP) for the COVID-19 Public Health Emergency. The SEP, along with the additional financial assistance afforded by the American Rescue Plan (ARP), offers the opportunity for individuals and families to take advantage of significantly reduced premiums, increased savings, and quality, affordable health coverage through the Marketplaces using the Federal Platform. Today's report from the CMS, which covers plan selections from February 15 to March 31, also shows gains in enrollment among historically uninsured communities, including Black consumers and Americans near the poverty level. Of applicants who identified a race, 17% identified as Black – compared to about 11% in both 2020 and 2019 during the same time period. Among consumers requesting financial assistance, 41% report being at or slightly above the federal poverty level, compared to 38% in 2020 and 33% in 2019.

FY 2022 Proposed Medicare Payment and Quality Reporting Updates: On April 7, 2021, the CMS issued a proposed rule that would update Medicare payment policies and rates for the Inpatient Psychiatric Facility Prospective Payment System (IPF PPS) for Fiscal Year (FY) 2022 and propose changes to the IPF Quality Reporting (IPFQR) Program. For the FY 2023 payment determination and subsequent years, CMS is proposing to add the COVID-19 Vaccination Coverage Among Healthcare Personnel (HCP) measure to the IPFQR Program. The measure addresses the quality priority of "Promote Effective Prevention & Treatment of Chronic Disease" through the Meaningful Measures domain of Preventive Care. The process measure was developed by the Centers for Disease Control and Prevention (CDC) to track COVID-19 vaccination coverage among HCP in the IPF setting. This measure would be reported using the COVID-19 Modules on the CDC's National Healthcare Safety Network web portal.

Research

Study of Allergic Reactions to Moderna and Pfizer-BioNTech COVID-19 Vaccines: NIH begins a clinical trial to determine whether people who are highly allergic or have a mast cell disorder are at increased risk for an immediate, systemic allergic reaction to the Moderna or Pfizer-BioNTech COVID-19 vaccines. A systemic allergic reaction to a vaccine occurs in one or more parts of the body beyond the injection site. If such an allergic reaction occurs in study participants, investigators will assess whether the reactions are more frequent in participants who are highly allergic or have a mast cell disorder than in participants with no allergic history. In addition, investigators will examine the biological mechanism behind the reactions and whether a genetic pattern or other factors can predict who is at most risk. The study team will enroll 3,400 adults ages 18 to 69 years at up to 35 academic allergy-research centers nationwide.

Factors Associated with Participation in Elementary School-Based SARS-CoV-2 Testing: CDC released an *MMWR* on the factors associated with participation in elementary school-based SARS-CoV-2 testing in Salt Lake County, Utah. During December 3, 2020–January 31, 2021, CDC, in collaboration with the University of Utah Health and Economic Recovery Outreach Project, Utah Department of Health (UDOH), Salt Lake County Health Department, and one Salt Lake county school district, offered free, in-school, real-time reverse transcription–polymerase chain reaction (RT-PCR) saliva testing as part of a transmission investigation of SARS-CoV-2, the virus that causes COVID-19, in elementary school settings. Among 856 unique student contacts at 20 elementary schools, 594 who were exposed to 33 index patients at 13 elementary schools were analyzed. The *MMWR* describes the demographic breakdown of the participants in the study, and the potential of in-school specimen collection for SARS-CoV-2 testing to help reach underserved populations to reduce community transmission.



Trends in Geographic and Temporal Distribution of U.S. Children with MIS-C: JAMA Pediatrics published a study on the trends in geographic and temporal distribution of U.S. children with multisystem inflammatory syndrome (MIS-C) during the COVID-19 pandemic. In this cross-sectional study, 1,733 patients with MIS-C were identified with predominantly gastrointestinal, mucocutaneous, and cardiovascular manifestations, and a majority required intensive care. MIS-C peaks closely followed the peaks of COVID-19 and the spread of the pandemic from urban to rural communities. The data are consistent with observations that MIS-C resulted from delayed immunologic responses to infection by SARS-CoV-2.

Case Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 cases will remain stable or have an uncertain trend over the next 4 weeks, with 219,000 to 758,000 new cases likely reported in the week ending May 1, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of new reported cases per week will likely increase in 1 jurisdiction, which is indicated in the forecast plots below. Trends in numbers of future reported cases are uncertain or predicted to remain stable in the other states and territories. View previous case forecasts.

Hospitalization Forecasts: This week's national ensemble predicts that the number of new daily confirmed COVID-19 hospital admissions will

remain stable or have an uncertain trend over the next 4 weeks, with 2,400 to 11,000 new confirmed COVID-19 hospital admissions likely reported on May 3, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of daily confirmed COVID-19 hospital admissions will likely increase in 7 jurisdictions and decrease in 10 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported hospital admissions are uncertain or predicted to remain stable in the other states and territories. View previous hospitalization forecasts.

Death Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 deaths will remain stable or have an uncertain trend over the next 4 weeks, with 2,300 to 10,100 new deaths likely reported in the week ending May 1, 2021. The national ensemble predicts that a total of 568,000 to 588,000 COVID-19 deaths will be reported by this date. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of newly reported deaths per week will likely decrease in 3 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported deaths are uncertain or predicted to remain stable in the other states and territories. View previous death forecasts.

Marvin Figueroa, Director
Office of Intergovernmental and External Affairs
U.S. Department of Health and Human Services
Washington, D.C.

Subject: HHS COVID-19 Update - 4/8

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for April 8, 2021:

Vaccine Updates

Vaccination Toolkits: CDC updated their vaccination toolkits, which provide audience-specific information and language for healthcare teams and community administrators.

Getting Your COVID-19 Vaccine: CDC updated their information regarding getting your COVID-19 vaccine. CDC reiterated that COVID-19 vaccines are not interchangeable. If you received a Pfizer-BioNTech or Moderna COVID-19 vaccine, you should get the same product (or brand) for your second shot.

FEMA Vaccination Sites: Yesterday, federal pilot community vaccination centers opened in Gary, Indiana; Greenbelt, Maryland; St. Louis; Memphis, Tennessee and Milwaukee, with additional federal pilot community vaccination centers scheduled to open next week in Pueblo, Colorado; St. Paul, Minnesota; and Columbia, South Carolina. FEMA mobile vaccination units are now operating in Nevada, Oregon, Connecticut and Maryland, bringing vaccinations to hard-to-reach and high-risk populations who cannot access services from fixed sites. FEMA has now provided more than $4.5 billion for expenses related to COVID-19 vaccination at 100% federal cost share.

DOD Prioritizing COVID-19 Vaccinations to Those Deployed: The Defense Department is rapidly administering COVID-19 vaccines in a tiered priority process to service members, DOD contractors and civilians and their families who are stationed overseas and who wish to have them. Based on current projections of vaccine supplies and health care providers who administer them, the department projects that by the middle of May, all deployed personnel who want them will have had at least the initial vaccination dosage.

Testing and Treatment

Contact Tracing Resources for Health Departments: CDC updated their contact tracing resources for health departments in order to stop the spread of COVID-19. CDC added a resource on how to talk to your close contacts . It encourages people who have COVID-19 to notify their close contacts so that they can quarantine at home and get tested.

Reopening Guidance

Requirement for All Air Passengers Arriving in the U.S: CDC updated their fact sheet and Q&A regarding the requirement for proof of a negative COVID-19 test or recovery from COVID-19 for all air passengers arriving in the United States**.** If you plan to travel internationally, you will need to get tested no more than 3 days before you travel by air into the United States and show your negative result to the airline before you board your flight, or be prepared to show documentation of recovery (proof of a recent positive viral test and a letter from your healthcare provider or a public health official stating that you were cleared to travel).

Information for Specific Populations

Emergency Transportation for Tribal Communities: CDC updated their guidance for tribal communities in order to minimize risk of spreading COVID-19 when sharing personal vehicles.

Fraud Alert – COVID-19 Scams: The HHS Office of Inspector General is alerting the public about fraud schemes related to the novel coronavirus (COVID-19). Scammers are using telemarketing calls, text messages, social media platforms, and door-to-door visits to perpetrate COVID-19-related scams. Fraudsters are offering COVID-19 tests, HHS grants, and Medicare prescription cards in exchange for personal details, including Medicare information. However, these services are unapproved and illegitimate. If you suspect COVID-19 health care fraud, report it immediately online or call 800-HHS-TIPS (800-447-8477).

CMS Updates

FY 2022 Skilled Nursing Facility Prospective Payment System Proposed Rule: On April 8, 2021, CMS issued a proposed rule that would update Medicare payment policies and rates for skilled nursing facilities under the Skilled Nursing Facility (SNF) prospective payment system (PPS) for fiscal year (FY) 2022. In addition, the proposed rule includes proposals for the SNF Quality Reporting Program (QRP), and the SNF Value-Based Program (VBP) for FY 2022. CMS is proposing the adoption of the COVID-19 Vaccination Coverage among Healthcare Personnel (HCP) Measure beginning with the FY 2023 SNF QRP. This measure would require SNFs to report on COVID-19 HCP vaccination in order to assess whether SNFs are taking steps to limit the spread of COVID-19 among their HCP, reduce the risk of transmission within their facilities and help sustain the ability of SNFs to continue serving their communities throughout the COVID-19 PHE and beyond. Under this proposal, SNFs would report the vaccination data through the Centers for Disease Control and Prevention National Healthcare Safety Network beginning October 1, 2021.

FY 2022 Hospice Payment Rate Update Proposed Rule: On April 8, 2021, CMS issued a proposed rule (CMS-1754-P) that would provide routine updates to hospice base payments and the aggregate cap amount for FY 2022 in accordance with existing statutory and regulatory requirements. This proposed rule also includes a comment solicitation regarding hospice utilization. In addition, this rule proposes to rebase the hospice labor shares and clarify certain aspects of the hospice election statement addendum requirements. This rule proposes changes to the Hospice Conditions of Participation (CoPs) and Hospice Quality Reporting Program (HQRP). The proposed rule also includes a Home Health Quality Reporting Program (HH QRP) proposal to display publicly three quarters of certain outcome and assessment information set (OASIS) data

due to the COVID-19 public health emergency (PHE) exemptions of the 2020 first and second quarter data.

FY 2022 Inpatient Rehabilitation Facility Prospective Payment System Proposed Rule: On April 7, 2021, CMS issued a proposed rule that would update Medicare payment policies and rates for facilities under the Inpatient Rehabilitation Facility (IRF) Prospective Payment System (PPS) and the IRF Quality Reporting Program (QRP) for fiscal year (FY) 2022. In the ongoing efforts to address the COVID-19 public health emergency, CMS is proposing the adoption of the COVID-19 Vaccination Coverage among Healthcare Personnel (HCP) Measure to require IRFs to report COVID-19 HCP vaccinations in their facilities. This proposed measure is designed to assess whether IRFs are taking steps to limit the spread of COVID-19 among their HCP, reduce the risk of transmission within their facilities, and help sustain the ability of IRFs to continue serving their communities through the public health emergency and beyond.

PPE

Optimizing N95 Respirator Supplies: CDC updated information offering a series of strategies or options to optimize supplies of disposable N95 filtering facepiece respirators (commonly called "N95 respirators") in healthcare settings when there is limited supply. CDC adds clarifications on use of facemasks as a crisis capacity strategy and outlines the assumptions to implement contingency and crisis strategies.

Research

Post-COVID-19 Conditions: CDC released information on post-COVID-19 conditions, which include a wide range of health consequences that are present more than four weeks after infections with SARS-CoV-2. CDC outlines the types of post-COVID conditions including long COVID, multiorgan effects of COVID-19, and effects of COVID-19 treatment or hospitalization. There are ways to help manage post-COVID conditions, and many patients with these symptoms are getting better with time. CDC recommends that people get vaccinated regardless of whether they already had COVID-19. CDC continues active investigation into the full spectrum of COVID-19 illness, from the acute phase to longer term effects and conditions.

Accelerated Research to Address Concurrent HIV and COVID-19 Pandemics: In a review article published in the *Journal of Infectious Diseases*, Anthony S. Fauci, M.D., director of the National Institute of Allergy and Infectious Diseases, part of the NIH, and colleagues call for accelerated research to address concurrent HIV and COVID-19 pandemics. The COVID-19 pandemic is affecting people with or at risk for HIV both indirectly, by interfering with HIV treatment and prevention services, and directly, by threatening individual health. An effective response to these dual pandemics requires unprecedented collaboration to accelerate basic and clinical research, as well as implementation science to expeditiously introduce evidence-based strategies into real-world settings.

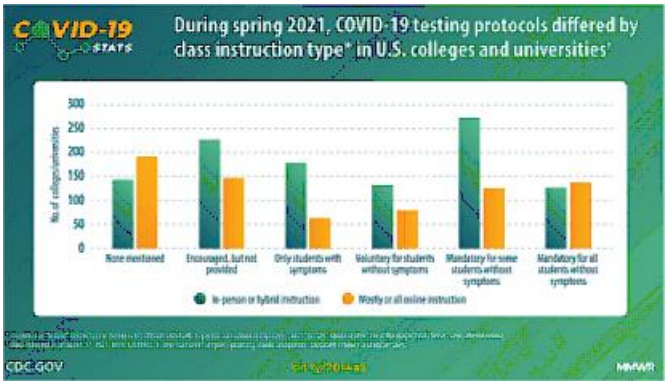
Substance Abuse Disorders During the COVID-19 Pandemic: NIH Director, Dr. Francis Collins, discusses his conversation with Dr. Nora Volkow, Director of NIH's National Institute on Drug Abuse, regarding the impact of the COVID-19 pandemic on people struggling with substance use disorders and those who are trying to help them . While the demands of the pandemic have been challenging for everyone, biomedical researchers have remained hard at work to address the opioid crisis. Among the many ways that NIH is supporting these efforts is through its Helping to End Addiction Long-Term (HEAL) Initiative, which is directing more than $1.5 billion to researchers and communities across the country.

COVID-19 Incidence and Mortality Among AI/AN and White Persons: CDC released an *MMWR* on COVID-19 incidence and mortality among American Indian or Alaska Native (AI/AN) and White persons in Montana from March 2020 – November 2020. Aggregate analyses of data from selected U.S. states indicate that COVID-19 incidence and mortality are higher among AI/AN persons than they are among White persons. COVID-19 incidence and mortality rates among AI/AN persons in Montana were 2.2 and 3.8 times, respectively, those among White persons. The case-fatality rate among AI/AN persons was 1.7 times that among White persons. These findings reinforce importance of using state-level surveillance to develop state and tribal COVID-19 vaccine allocation strategies and to inform local implementation of culturally appropriate public health measures that might help reduce COVID-19 incidence and mortality in AI/AN communities.

COVID-19 Transmission in the Blackfeet Tribal Reservation: CDC released an *MMWR* on the use of stay-at-home orders and mask mandates to control COVID-19 transmission in the Blackfeet Tribal Reservation in Montana from June 2020 – December 2020. Community mitigation measures (e.g., stay-at-home orders and mask use), coupled with case investigation and contact tracing with immediate isolation or quarantine, are primary approaches to preventing and controlling community SARS-CoV-2 transmission. In the Blackfeet Tribal Reservation, enforcement of stay-at-home orders and mandated use of face coverings in public, with potential fines and jail for noncompliance, were associated with a thirty-three-fold reduction in COVID-19 incidence from its peak of 6.40 cases per 1,000 residents per day on October 5 to 0.19 on November 7, 2020. Enforcement of stay-at-home orders and mask use mandates, coupled with robust public health investigations, have been shown to reduce COVID-19 incidence.

Spirit Lake Tribe COVID-19 Case Investigation and Contact Tracing Program: CDC released an *MMWR* with notes from the field on a COVID-19 case investigation and contact tracing program within the Spirit Lake Tribe in North Dakota from September 2020 – November 2020. Through the Spirit Lake Tribe case investigation and contact tracing program, the tribe's COVID-19 Incident Command System staff members conducted case investigations and contact tracing, provided COVID-19 education, followed up with patients regularly by telephone, and monitored daily symptoms of close contacts. Members of the Spirit Lake community served as contact tracers. Symptom monitoring was facilitated through CDC's Text Illness Monitoring system (version TIM²), using a free, two-way text-messaging platform to query enrolled contacts about daily COVID-19 symptoms. The system also alerted Spirit Lake Tribal Health authorities when participants reported symptoms or did not to respond. This tribally managed COVID-19 case investigation and contact tracing program effectively reached Spirit Lake tribal members to provide isolation, quarantine, symptom monitoring, and support services and contributed to timely case and contact management. This program might help guide similar programs in other tribes and the public health community.

College and University COVID-19 Stats: CDC released an *MMWR* on COVID-19 student testing protocols by mode of instruction at colleges and universities during the spring of 2021. As of March 17, 2021, a total of 899 (49%) of 1,849 public and private, nonprofit 4-year U.S. colleges and universities provided some type of COVID-19 testing for asymptomatic students, including 548 (30%) institutions conducting classes in-person or in a hybrid format. Among institutions providing testing for asymptomatic students, 389 (43%) had protocols that required periodic testing for various subgroups (e.g., athletes, fraternity and sorority activity participants, and a random sample of students); 287 (32%) mandated that all students receive testing (ranging from every other day to once every other week), which did not vary by public or private, nonprofit status or by mode of instruction. Among institutions, 18% (338 of 1,849) did not mention a COVID-19 testing protocol on their websites, including146 with in-person or hybrid instruction. Although asymptomatic transmission is estimated to account for approximately one half of SARS-CoV-2 transmission, a majority (950; 51%) of institutions did not publish a testing protocol for screening asymptomatic students in spring 2021.



Provisional Mortality Data: CDC updated an *MMWR* on provisional mortality data. This report was posted online as an *MMWR* Early Release on March 31. The COVID-19 pandemic caused approximately 375,000 deaths in the United States during 2020. The age-adjusted death rate increased by 15.9% in 2020. Overall death rates were highest among non-Hispanic Black persons and non-Hispanic American Indian or Alaska Native persons. COVID-19 was the third leading cause of death, and the COVID-19 death rate was highest among Hispanics. Provisional death estimates provide an early indication of shifts in mortality trends. Timely and actionable data can guide public health policies and interventions for populations experiencing higher numbers of deaths that are directly or indirectly associated with the COVID-19 pandemic.

COVID-19 Mortality Surveillance: CDC updated an *MMWR* on death certificate-based ICD-10 diagnosis codes for COVID-19 mortality surveillance. This report was posted online as an *MMWR* Early Release on March 31. Among 378,048 death certificates from 2020 listing COVID-19, 5.5% listed COVID-19 without codes for any other conditions. Among 357,133 death certificates with at least one other condition, 97% had a co-occurring diagnosis of a plausible chain-of-event condition (e.g., pneumonia or respiratory failure), or a significant contributing condition (e.g., hypertension or diabetes), or both. These findings support the accuracy of COVID-19 mortality surveillance in the United States using official death certificates. High-quality documentation of death certificate diagnoses is essential for an authoritative public record.

Community Transmission of SARS-CoV-2: CDC updated an *MMWR* on the community transmission of SARS-CoV-2 associated with a local bar opening event in Illinois. This report was posted online as an *MMWR* Early Release on April 5. Forty-six cases of COVID-19 were linked to an indoor bar opening event that occurred during February 2021 in a rural Illinois county. Event patrons were linked to secondary cases among household, long-term care facility, and school contacts, resulting in one hospitalization and one school closure affecting 650 students. Opening up settings such as bars, where mask wearing and physical distancing are challenging, can affect the community. As community businesses reopen, prevention measures should be emphasized, including limiting building occupancy, improving ventilation, prioritizing outdoor seating, enforcing correct mask wearing and physical distancing, staying home when ill, and encouraging COVID-19 vaccination to reduce transmission on site and within the community.

COVID-19 Science Update: CDC released a COVID-19 Science Update, presenting the latest COVID-19 research on a range of topics including but not limited to vaccine effectiveness, strategies for testing asymptomatic airline passengers, and the B.1.1.1.7 variant.

Healthcare Operations During the COVID-19 Pandemic: The HHS Assistant Secretary for Preparedness and Response (ASPR) program TRACIE – Technical Resources, Assistance Center, and Information Exchange – presents ways to address tough healthcare problems like supply chain issues, delays in emergency care, and the deferred elective procedures during the COVID-19 pandemic.

Non-COVID-19 Updates

Health Equity: CDC published a webpage to examine how racism is a serious threat to the public's health . The data show that racial and ethnic minority groups, throughout the United States, experience higher rates of illness and death across a wide range of health conditions, including diabetes, hypertension, obesity, asthma, and heart disease, when compared to their White counterparts. Additionally, the life expectancy of non-Hispanic/Black Americans is four years lower than that of White Americans. The COVID-19 pandemic, and its disproportionate impact among racial and ethnic minority populations is another stark example of these enduring health disparities.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- Early MMWRs - Vol. 70, No. 31 [Attachments, Links]
  - The **August 6** edition of CDC's Morbidity and Mortality Weekly Report (MMWR) includes the following COVID-related articles:
    - Rapid Increase in Circulation of the SARS-CoV-2 B.1.617.2 (Delta) Variant — Mesa County, Colorado, April–June 2021COVID-19 Vaccine Administration, by Race and Ethnicity — North Carolina, December 14, 2020–April 6, 2021
    - Reduced Risk of Reinfection with SARS-CoV-2 After COVID-19 Vaccination — Kentucky, May–June 2021
    - Effectiveness of COVID-19 Vaccines in Preventing Hospitalization Among Adults Aged ≥65 Years — 13 states, COVID-NET, February–April 2021
- New CDC Study: Vaccination Offers Higher Protection than Previous COVID-19 Infection [Link]
  - In response to today's MMWR on post-vaccination COVID-19 infection rates (linked here), CDC issued a media statement, announcing in part: "*In today's MMWR, a study of COVID-19 infections in Kentucky among people who were previously infected with SAR-CoV-2 shows that unvaccinated individuals are more than twice as likely to be reinfected with COVID-19 than those who were fully vaccinated after initially*

contracting the virus. These data further indicate that COVID-19 vaccines offer better protection than natural immunity alone and that vaccines, even after prior infection, help prevent reinfections."

- Read the CDC's full media statement here.

- Updated CDC Guidance for COVID-19 Prevention in K-12 Schools [Links]
  - On **August 5**, CDC updated its Guidance for COVID-19 Prevention in K-12 Schools to align with CDC's existing guidance for fully vaccinated people and assist K-12 schools in opening for in-person instruction and remaining open. Additionally, the Considerations for Case Investigation and Contact Tracing in K-12 Schools and Institutions of Higher Education (IHEs) has been updated to align with new CDC guidance.
  - The full updated Guidance is linked here.
- CDC COCA Call: Therapeutic Options to Prevent Severe COVID-19 in Immunocompromised People [Links]
  - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **Thursday, August 12** at **2:00 pm EDT** to discuss the FDA's role in issuing EUAs for certain monoclonal antibodies, options for compassionate use, the process for ordering and distributing monoclonal antibodies, and current data on using monoclonal antibodies for both non-hospitalized and immunocompromised patients. Presenters will also cover preventing, diagnosing, and treating COVID-19 in immunocompromised patients, including the role of monoclonal antibodies, serologic testing, and potential third dose of COVID-19 vaccinations.
    - Weblink: https://www.zoomgov.com/j/1612254638?pwd=SmNaNlJEUWt3YWdBMGtNRjhxRlZ1UT09
      Telephone: (646) 828-7666 or (669) 216-1590 or (551) 285-1373
      Webinar ID: 161 225 4638
      Passcode: 980771
      Access materials post-call:
      https://emergency.cdc.gov/coca/calls/2021/callinfo_081221.asp
- ELC & DOJ Webinar: Detection & Mitigation of COVID-19 in Confinement Facilities [Attachments, Link]
  - On **August 5**, CDC's Epidemiology and Laboratory Capacity for Infectious Diseases (ELC) and the Department of Justice (DOJ) hosted a webinar, "Detection & Mitigation of COVID-19 in Confinement Facilities."
  - In case you missed it, you may watch/download the full webinar here. Also attached are a transcript and summary of the Q&A portion of the webinar.
- Updated ELC Enhancing Detection Performance Measures Guidance [Attachment]
  - Today, **August 6**, CDC released an updated ELC Enhancing Detection Performance Measures Guidance document (attached) for this new budget year that started August 1, 2021.
  - This guidance provides details for all ELC Enhancing Detection performance measures including all data elements, reporting frequency, and reporting timelines.
- Updated CDC Public Health Science Priority Questions [Link]
  - The CDC's *Public Health Science Agenda* for COVID-19 articulates key areas of scientific inquiry and opportunities to guide the development of actionable, evidence-based public health guidance to limit the spread and impact of SARS-CoV-2 and ultimately end

the COVID-19 pandemic. As the evidence base and public health response to the COVID-19 pandemic continues to evolve, this Public Health Science Agenda has helped promote efforts to fill critical, time-sensitive scientific gaps and to inform evidence-based decision making.

- On **August 4**, a second update to the Priority Public Health Science Questions was released (linked here) to help achieve the objectives outlined in the Public Health Science Agenda for COVID-19. The newest update includes 15 Priority Public Health Science Questions that were systematically developed to be relevant, actionable near-term, and reflective of the evolving needs of the ongoing public health response.

Standing Updates

- CDC Partner Updates – August 4 & August 6 [Attachments]
  - Please see attached for the latest update from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – August 5 [Attachment]
  - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
  - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
  - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
  - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

August 4, 2021

CDC Resources

- **CDC Issues Eviction Order in Areas of Substantial and High Transmission:** CDC Director Dr. Rochelle Walensky signed an order determining the evictions of tenants for failure to make rent or housing payments could be detrimental to public health control measures to slow the spread of SARS-CoV-2. This order will expire on October 3, 2021 and applies in United States counties experiencing substantial and high levels of community transmission levels of SARS-CoV-2.
- **Overall US COVID-19 Vaccine Distribution and Administration Update as of Tue, 03 Aug 2021 06:00:00 EST**: CDC's COVID Data Tracker has updated maps, charts, and data for various vaccine-related metrics.
- **Laws and Regulations**: CDC has updated the most recent laws and regulations related to the COVID-19 pandemic.
- **Staffing Resources**: Recent update of the map shows CDC deployments and field staff.
- **Cruise Ship Color and Commercial Travel Status**: CDC has updated guidance for fully vaccinated people based on new evidence on the Delta variant.
- **What to Consider When Planning to Operate a COVID-19 Vaccine Clinic**: CDC shares strategies jurisdictions can use to plan, optimize, and maximize operations at all types of temporary COVID-19 vaccination clinics.
- **Families & Children**: CDC has updated guidance for parents, families, and organizations that care for children.
- **CDC Science Agenda for COVID-19**: CDC has updated a guide intended to strengthen the public health actions, guidance, and policy essential to limit the spread and impact of SARS-CoV-2 and ultimately end the COVID-19 pandemic.

Upcoming Meetings

- **CDC All-State, Tribal, Local, and Territorial (STLT) Update Call:** Monday, August 9th, 2:00-2:45 PM ET, CDC hosts a weekly national call series to provide state, tribal, local, and territorial partners with the latest information on the COVID-19 outbreak and U.S. preparedness efforts. If you would like to register for this event, please click here.

Additional Resources

- **Beyond School Supplies: Back to School Reminders & Readiness**
- **Find a COVID-19 vaccine near you:** Vaccines.gov is live – helping to make it easier for individuals to access COVID-19 vaccines. Powered by the trusted Vaccine Finder brand - Vaccines.gov is available in English and Spanish and will help connect Americans with locations offering vaccines near them.
    - **Individuals in the U.S. can now utilize a text messaging service to locate vaccine locations, available in both English and Spanish.** Individuals can text their ZIP code to 438829 (GETVAX) and 822862 (VACUNA) to find three locations nearby that have vaccines available.

August 6, 2021

Friday Feature: Race to End COVID-19 Partner Playbook

In collaboration with partners, CDC has developed a Race to End COVID Partner Playbook for planning and conducting community-based COVID-19 testing and vaccination events at racetracks. Race to End COVID events are envisioned as partnerships between state, tribal, local, and territorial (STLT) health departments, the National Association for Stock Car Auto Racing (NASCAR), and/or local racetracks, whether NASCAR-affiliated or independently owned.

An effective public health response to the COVID-19 pandemic involves the whole community, including the local, state, and/or tribal health authority and, potentially, members of the private sector. Public-private partnerships may offer a good way to promote public health messages and inform health behaviors to slow the spread of COVID-19. Please see the playbook for more details.

MMWR

- **Rapid Increase in Circulation of the SARS-CoV-2 B.1.617.2 (Delta) Variant — Mesa County, Colorado, April–June 2021.** Link here.
- **Reduced Risk of Reinfection with SARS-CoV-2 After COVID-19 Vaccination — Kentucky, May–June 2021.** Link here.
- **Effectiveness of COVID-19 Vaccines in Preventing Hospitalization Among Adults Aged ≥65 Years — COVID-NET, 13 States, February–April 2021.** Link here.

CDC Resources

Science and Data

- **CDC Science Agenda for COVID-19**: CDC has updated a guide intended to strengthen the public health actions, guidance, and policy essential to limit the spread and impact of SARS-CoV-2 and ultimately end the COVID-19 pandemic.
- **COVID Data Tracker Recent Updates - 2021-08-05 - The Vaccination Among People with Disabilities tab displays information on the number of vaccinated adults with disabilities in the United States:** CDC reports findings from a Household Pulse Survey of adults aged ≥18 years led by the U.S. Census Bureau, in partnership with multiple other federal statistical agencies, to measure household experiences during the COVID-19 pandemic.
- **COVID-19 and Animals:** Updated guidance on understanding the risk of animals spreading SARS-CoV-2, the virus that causes COVID-19, to people as well as spread from people to animals.

Work and School

- **Guidance for COVID-19 Prevention in Kindergarten (K)-12 Schools:** CDC has updated guidance for K-12 schools to recommend universal indoor masking and testing for fully vaccinated people in situations of known recent exposure to COVID-19.
- **Interim Guidance for Case Investigation and Contact Tracing in K-12 Schools:** CDC has updated guidance for K–12 schools and institutions of higher education, including considerations for people fully vaccinated against COVID-19 and situations when K–12 students are not considered close contacts.

- **What to do if a Student Becomes Sick at School or Reports a New COVID-19 Diagnosis Flowchart:** CDC shares guidance for situations when students show signs of infectious illness consistent with COVID-19, or confirmation of negative and/or positive COVID-19 test results.

Healthcare

- **What to Consider When Planning to Operate a COVID-19 Vaccine Clinic:** CDC shares strategies jurisdictions can use to plan, optimize, and maximize operations at all types of temporary COVID-19 vaccination clinics.

Community

- **Families with Vaccinated and Unvaccinated Members:** Updated guidance for families protecting unvaccinated members, those who have a condition or are taking medications that weaken their immune system, and choosing safer activities for the family.
- **CDC Issues Eviction Order in Areas of Substantial and High Transmission:** CDC Director Dr. Rochelle Walensky signed an order determining the evictions of tenants for failure to make rent or housing payments could be detrimental to public health control measures to slow the spread of SARS-CoV-2. This order will expire on October 3, 2021 and applies in United States counties experiencing substantial and high levels of community transmission levels of SARS-CoV-2.
- **Laws and Regulations:** CDC has updated the most recent laws and regulations related to the COVID-19 pandemic.
- **Families & Children:** CDC has updated guidance for parents, families, and organizations that care for children.

Upcoming Meetings

- **CDC All-State, Tribal, Local, and Territorial (STLT) Update Call:** Monday, August 9th, 2:00-2:45 PM ET, CDC hosts a weekly national call series to provide state, tribal, local, and territorial partners with the latest information on the COVID-19 outbreak and U.S. preparedness efforts. If you would like to register for this event, please click here.
- **Clinical Laboratory COVID-19 Response Calls:** Monday, August 9th, 3:00-4:00 PM ET, CDC's Division of Laboratory Systems hosts a biweekly call to discuss hot topics and to solicit the laboratory community's questions about the national response to the COVID-19 pandemic. To attends this call on August 9th, please click here and enter the following password: 048861a! To submit a question for consideration, email DLSinquiries@cdc.gov. For additional information, please contact LOCS@cdc.gov.
- **Understanding the Role of School Nurses in Supporting School Safety Before, During, and After an Emergency:** Tuesday, August 10th, 2:00-3:00 PM ET, the U.S. Department of Education (DOE), in partnership with multiple other educational agencies, will host a webinar with the National Association of School Nurses to highlight and discuss the role school nurses have in supporting overall school safety, security, emergency management, and preparedness before, during, and after an emergency. If you would like to register for this event, please click here.

ELC PERFORMANCE MEASURES GUIDANCE FOR PROJECT E: ENHANCING DETECTION

CDC-RFA-CK19-1904

CDC EPIDEMIOLOGY AND LABORATORY CAPACITY FOR PREVENTION AND CONTROL OF EMERGING INFECTIOUS DISEASES

August 2021

Contents

Introduction and Purpose 4

Organization of Guidance 5

Intended Use of Guidance 5

Updates in Guidance 6

Measure E.1: Median number of days from specimen collection date to date of report of final test result for COVID-19/SARS-CoV-2 molecular diagnostic tests 8

Measure E.2: Number of COVID-19/SARS-CoV-2 tests completed by test type, race/ethnicity, and result 10

Measure E.3: Proportion of COVID-19/SARS-CoV-2 laboratory test results submitted to CDC with complete information 12

Measure E.4: Biosafety outreach and guidance provided by PHLs and/or the health department to COVID-19/SARS-CoV-2 testing sites 14

Measure E.5: Percent of COVID-19 cases submitted to CDC that include complete and meaningful responses for key data elements. 16

Measure E.6: Proportion of COVID-19 cases with individual-level data submitted to CDC 18

Measure E.7: Median number of days from date of first positive specimen collection (or when not available, diagnosis date) to date COVID-19 case is reported to CDC 19

Measure E.8: Percent of facilities reporting emergency department (ED) visits to the National Syndromic Surveillance Program (NSSP) 20

Measure E.9: Completeness of priority data elements in ED visits reported to NSSP 21

Measure E.10: Percent of regularly reporting ILINet providers and the number of patient visits captured in ILINet each week both within and outside the Core Based Statistical Areas (CBSAs). 23

Measure E.11: Percent of labs reporting influenza and COVID-19/ SARS-CoV-2 via PHLIP 2.5.1 to CDC and the percent completeness of key data elements for respiratory virus specimens tested at the public health laboratory (PHL). 25

Measure E.12: Number of healthcare organizations engaged to implement electronic case reporting (eCR) 27

Measure E.12a: Number of conditions published to production in Reportable Conditions Knowledge Management System (RCKMS). 29

Measure E.13: Proportion of state reportable cases with an electronic initial case report (eICR) submitted 30

Measure E.14: Demonstration of automatic processing of electronic initial case reports (eICRs) in the jurisdiction integrated surveillance system(s) 31

Measure E.15: Proportion of test orders and results processed through Electronic Test Orders and Results Reporting (ETOR) at the PHL (this measure only applies to tests conducted at the public health laboratory) 32

Measure E.16: Systems/programs at the PHL with ETOR interfaces 34
Measure E.17: Caseload, number of cases per case investigator and number of contacts per contact tracer during the data collection period 35
Measure E.18: Timeliness, completeness, and effectiveness of case interviews among the cases sent for case investigation during the data collection period 37
Measure E.19: Timeliness of contact tracing during the data collection period 39
Measure E.20: Effectiveness of contact tracing to interrupt the transmission of COVID-19 during the data collection period 40
Measure E.21: Timeline of the case investigation process from specimen collection to contact notification during the data collection period 41
Measure E.22: Among contacts notified, proportion tested for COVID-19/SARS-CoV-2 at least once, within 14 days of notification during the data collection period 42
Measure E.23: Number of health department staff who can perform healthcare infection control assessments at the state and local level 43
Measure E.24: Number of proactive healthcare infection control assessments conducted by the health department or designee for COVID-19. 44
Measure E.25: Number of COVID-19 outbreaks and responses in healthcare settings 45
Measure E.26: Number of new or enhanced laboratory technologies procured, maintained, or implemented to improve laboratory response capacity 46
Measure E.27: Number of biothreat samples shipped to designated LRN reference laboratory or CDC 48
Measure E.28: Enhancing laboratory information infrastructure for LRN testing methodologies 49
Measure E.29: Number of SARS-CoV-2 specimens sent to CDC for sequencing per month 50
Appendix A. Reporting mechanism by measure 51
Appendix B. Reporting frequency (for recipient-reported measures only) 53
Appendix C. PM reporting timeline for measures reported via REDCap for Year 2 55

Introduction and Purpose

The goal of the Epidemiology and Laboratory Capacity for Prevention and Control of Emerging Infectious Diseases (ELC) is to support state, local, and territories' public health efforts to reduce morbidity and associated deaths caused by a wide range of infectious disease threats. The ELC provides annual funding, strategic direction, and technical assistance to domestic jurisdictions for strengthening core capacities in epidemiology, laboratory, and health information systems activities. In addition to strengthening core infectious disease capacities nationwide, this cooperative agreement also supports a myriad of specific infectious disease programs and projects and provides special appropriations in response to infectious disease emergencies (e.g., H1N1, Ebola, and Zika).

As part of the "Paycheck Protection Program and Health Care Enhancement Act of 2020 (P.L. 116-139, Title I)", the ELC awarded a total of $10.25 billion to recipient jurisdictions in a program-initiated component funding under the Emerging Issues (E) Project of CK19-1904, "ELC Enhancing Detection" supplement. In early 2021, an additional $19.11 billion from the "Coronavirus Response and Relief Supplemental Appropriations Act of 2021, H.R. 133", was provided to ELC recipients to provide additional critical support to jurisdictions as they continue to address COVID-19 within their communities. These funds are intended to provide critical resources to state, local, and territorial health departments in support of a broad range of COVID-19/SARS-CoV-2 testing and epidemiologic surveillance related activities, including the establishment of modernized public health surveillance systems. The work supported by ELC Enhancing Detection and the Enhancing Detection Expansion builds upon previous COVID-19 awards (ELC CARES and ELC Community-based Surveillance). These funds support the public health response to COVID-19 and lay the foundation for the future of public health surveillance.

This guidance provides information on performance measures for recipients of these supplemental funds. To reduce reporting burden on recipients, the performance measures for ELC Enhancing Detection and ELC Enhancing Detection Expansion encompass work being conducted for those receiving funds for ELC CARES and Community-based Surveillance.

The performance measures are intended to be used by ELC and recipients to help:

- Support continuous monitoring and examine opportunities to improve performance and implementation of activities
- Demonstrate accountability to stakeholders (e.g., funders, public) by showing how ELC funds are being spent
- Clarify ELC project expectations and priorities

The ELC realizes that there are limitations to using performance measures to evaluate the scope of public health work being conducted by the jurisdictions. For example, without a consideration of contextual factors, measures do not always fully represent how strongly or poorly a recipient is doing. Thus, it is important to have other ways of collecting project information to demonstrate performance (i.e., workplan/milestone updates, progress calls, success stories). The ELC will rely on a combination of these sources of information to assess progress more comprehensively throughout the duration of the project.

Organization of Guidance

For each measure, the following elements are described:

- *Measure:* Name of measure
- *Applicable recipients:* Recipients the measure applies to
- *Rationale:* Provides the context and reasoning for monitoring this measure
- *Data elements:* Specific variables that will be reported by recipient or monitored by ELC
- *Additional guidance:* Additional information to help understand the measure such as definitions for specific terms, inclusion/exclusion criteria, limitations to the measure, and other applicable information
- *Target:* Recommended recipient target for this measure, where applicable. Targets are used to provide guidance to recipients on the desired level of performance from ELC. They will also be used in discussions between ELC and recipients to identify gaps and opportunities to provide technical assistance.
- *Recommended data source:* Source the recipient or ELC may use to retrieve data
- *Reporting frequency:* Specifies how often the measure will be reported
- *Reporting mechanism:* Describes how data will be reported

Intended Use of Guidance

Please take some time to review the guidance and share it with the appropriate staff members in your jurisdiction who are involved in the implementation of these activities. Ensure that you and your staff members understand each measure and how it applies to your jurisdiction. Some of these measures will be monitored through data reporting that recipients already submit to CDC. ELC recommends that you develop a plan for how you will collect, organize, and synthesize this information for reporting.

While ELC has made every effort to consolidate data submission intervals, please note that some measures require more frequent reporting than others. Furthermore, due to the relatively long (30 month) project period, recipients should anticipate and work with ELC to re-evaluate and potentially modify some measures to accommodate shifts in priorities during the timeframe of this project and to improve the ability to monitor performance. Some additional data collection for other measures may be required, and some measures may eventually become obsolete. ELC will make every effort to keep these changes minimal.

If you have questions related to these performance measures, please contact elcevaluation@cdc.gov, or your ELC Project Officer.

Updates in Guidance

The updated version of the guidance includes several updates and revisions that ELC recommends awardees pay particular attention to:

- **Measure E.10:** Percent of regularly reporting ILINet providers and the number of patient visits captured in ILINet each week both within and outside the Core Based Statistical Areas (CBSAs).
    - Numerator has been updated to the number of CBSA's with at least **200** patient visits each week from regularly reporting ILINet providers per 100,000 population
    - The target has been updated to at least **200** patient visits per 100,000 population within each CBSA, captured in ILINet each week after 12 months.
- **Measure E.12:** Number of healthcare organizations engaged to implement electronic case reporting (eCR)
    - Question 1 has been modified to only include the types of recruitment for **new** in-jurisdiction providers to onboard to eCR rather than the quantity.
    - Three new questions:
        - Did you confirm that your answer to question 1 is consistent with the monitoring question available on the Site Overview monitoring form? (Y/N)
        - Please share any successful recruitment strategies or any challenges to recruitment.
        - If you offered incentives to healthcare organizations for participating in eCR, what has been the impact of those incentives?
    - Former Question 3 (now Question 5): New categories added to the levels of engagement in eCR between public health and healthcare organizations
        - Testing for COVID-19 only
        - In production and parallel reporting for COVID-19 only
        - In production with no manual reporting for COVID-19 only
        - Testing for all conditions
        - In production and parallel reporting for all conditions
        - In production with no manual reporting for all conditions
- **NEW MEASURE - Measure E.12a:** Number of conditions published to production in Reportable Conditions Knowledge Management System (RCKMS).
- **Measure E.14:** Demonstration of automatic processing of electronic initial case reports (eICRs) in the jurisdiction integrated surveillance system(s)
    - Rather than providing a numerator and denominator, the recipient will indicate the percent of eICRs that are received by the jurisdiction and populated into the system without entering an error queue in the production environment for each surveillance system where applicable.
    - Two new questions:
        - Did you confirm that your answers for question 1 are consistent with the monitoring question available on the Site Overview monitoring form? (Y/N)
        - Please provide any qualitative information about your progress on processing eICRs into the surveillance system. Are there any successes, challenges, or status changes that you would like to share?
- **Measure E.15:** Proportion of test orders and results processed through Electronic Test Orders and Results Reporting (ETOR) at the PHL (this measure only applies to tests conducted at the public health laboratory)
    - This measure has been broken out to examine test orders and results by web portal versus direct and indirect systems integration.

- **Measure E.17:** Caseload, number of cases per case investigator and number of contacts per contact tracer during the data collection period
    - "Number of cases sent to the case investigation team" has been removed
- **Measure E.19:** Timeliness of contact tracing during the data collection period
    - "Number of contacts notified" has been added
    - "Number of contacts notified between 1 and 3 days of case interview" has been removed
    - "Number of contacts notified after 3 days of case interview" has been removed
- **Measure E.20:** Effectiveness of contact tracing to interrupt the transmission of COVID-19 during the data collection period
    - "Number of contacts that agree to have their symptoms monitored" has been removed
- **Measure E.29:** Number of SARS-CoV-2 specimens sent to CDC for sequencing per month
    - These data will be collected from an existing source, and recipients will not be required to report.
- **Appendix C:** PM reporting timeline for measures reported via REDCap for Year 2
    - **All data collection and data submission dates have been updated.**

Measure E.1: Median number of days from specimen collection date to date of report of final test result for COVID-19/SARS-CoV-2 molecular diagnostic tests

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	Laboratory turnaround time can impact public health's ability to respond to events in a timely manner. Whether or not tests are being conducted in a timely manner may help identify areas for improvement or point to gaps in the process to help achieve more timely detection and reduce the spread of COVID-19. Public health may have limited control over tests conducted by non-PHL laboratories/community testing sites and the quality of specimens sent to public health. However, since the majority of COVID-19/SARS-CoV-2 testing is performed outside of the PHL, assessing all laboratories ability to perform timely testing and reporting is a critical component in the success of our public health response. These data will be used to guide discussions between ELC and the recipient on how to work together to improve testing timeliness, where needed.
Data Elements	For the PHL: 1. Median number of days and range from **specimen collection date** to **receipt of specimen at the laboratory** for COVID-19/SARS-CoV-2 molecular tests conducted in the PHL a. Minimum b. Median c. Maximum d. Percent of specimens **received at the PHL** for COVID-19/SARS-CoV-2 molecular testing **within 2 days of the specimen collection date** i. Numerator: The number of specimens that were received at the PHL for COVID-19/SARS-CoV-2 molecular testing within 2 days of the specimen collection date ii. Denominator: The total number of specimens that were received at the PHL for COVID-19/SARS-CoV-2 molecular testing 2. Median number of days and range **from receipt of specimen** to **date of report of final test result** for COVID-19/SARS-CoV-2 molecular tests conducted in the PHL a. Minimum b. Median c. Maximum d. Percent of specimens for which **final test results were reported** for COVID-19/SARS-CoV-2 molecular testing **within 2 days** of the **date the specimen was received** at the PHL i. Numerator: The number of specimens for which final test results were reported for COVID-19/SARS-CoV-2 molecular testing within 2 days of the date the specimen was received at the PHL ii. Denominator: The number of specimens for which final test results were reported for COVID-19/SARS-CoV-2 molecular testing at the PHL For non-PHL laboratories/community testing sites: 3. Median number of days and range from specimen collection date to date of report of final test result for COVID-19/SARS-CoV-2 molecular tests conducted outside of the PHL a. Median b. Minimum

	c. Maximum d. Proportion of specimens for which final test results were reported for COVID-19/SARS-CoV-2 molecular testing within 4 days of the specimen collection date for tests conducted outside of the PHL i. Numerator: The number of specimens for which final test results were reported for COVID-19/SARS-CoV-2 molecular testing within 4 days of the specimen collection date for tests conducted outside of the PHL ii. Denominator: The number of specimens for which final test results were reported for COVID-19/SARS-CoV-2 molecular testing outside of the PHL
Additional Guidance	This measure applies to molecular tests conducted covering the entire jurisdiction. If the date of report of final test result is missing, please use the date the test result was determined. The median number of days and range should include weekend days. *Specimen collection to receipt of specimen:* This includes the time from collection of specimen to receipt of the specimen in the laboratory. *Receipt of specimen to final test result:* This includes the time from receipt of specimen, obtaining laboratory test results, and then reporting the result to public health.
Target	≤ 2-day from specimen collection to receipt of specimen. ≤ 2-day from receipt of specimen to date of report of final test result.
Recommended Data Source	LIMS
Reporting Frequency	Quarterly
Reporting Mechanism	☒ REDCap for PHLs ☒ CDC currently has this data for non-PHL laboratories/community testing sites and there is no need to report it at this time.

Measure E.2: Number of COVID-19/SARS-CoV-2 tests completed by test type, race/ethnicity, and result

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	A major purpose of this funding is to ensure a robust testing program for COVID-19/SARS-CoV-2 is in place. Recipients are expected to expand testing capacity, including working with non-PHL laboratories/community testing sites, to enable the jurisdiction to test sufficient numbers of its population in accordance with CDC guidelines and in alignment with a jurisdiction's testing plan. This measure looks at the volume of COVID-19/SARS-CoV-2 testing conducted across a jurisdiction and may be used in conjunction with percent of positive molecular tests to indicate whether a jurisdiction is sufficiently testing its population. Volume will also be assessed by race/ethnicity to determine whether all racial/ethnic groups are being testing
Data Elements	1. Number of COVID-19/SARS-CoV-2 molecular tests conducted, total and by race/ethnicity 2. Number of COVID-19/SARS-CoV-2 serology tests conducted, total and by race/ethnicity 3. Number of COVID-19/SARS-CoV-2 antigen tests conducted, total and by race/ethnicity 4. Number of COVID-19/SARS-CoV-2 molecular tests conducted that were positive 5. Number of COVID-19/SARS-CoV-2 serology tests conducted that were positive 6. Number of COVID-19/SARS-CoV-2 antigen tests conducted that were positive 7. Number of individuals planned to be tested (molecular)
Additional Guidance	This measure is about the total number of tests conducted. Numbers are inclusive of all tests conducted in your jurisdiction regardless of testing site. We understand there may or may not be a substantial discrepancy between the number of tests conducted and number of individuals tested; however, at this point in time, there is no way to differentiate between these two numbers through the CELR line-level data received by CDC. We encourage jurisdictions to de-duplicate test results whenever possible in order to better understand the burden of COVID-19 within the population. There are limitations to using percent positivity as an indicator of adequate testing capacity, and results will be contextualized with other factors. For example, a high percentage of positive test results may indicate that testing is occurring among a disproportionately high-risk population, or there is a high prevalence of COVID-19/SARS-CoV-2 overall circulating within the population. The percent of positive test results among all molecular test results may also be used to help gauge whether a jurisdiction has sufficient testing capacity in place, especially when it is applied to specific populations (e.g. high-risk demographics) and geographical areas (e.g. densely populated urban areas) *Number of tests conducted:* These include all tests (molecular, antigen, serology) and all test results (positive, negative and indeterminant). *Number of individuals planned to be tested:* This information is collected via the Jurisdictional Testing Plans as mandated by legislative language.

Target	≥ 2% of population tested per month (diagnostic testing) for the first year of funding during the remainder of calendar year 2020. While the target applies to diagnostic testing only, jurisdictions should evaluate and implement appropriate use of serology to better understand their population. This target may change over time.
Recommended Data Source	LIMS (#1-3) Jurisdictional Testing Plans (#4)
Reporting Frequency	Monthly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.3: Proportion of COVID-19/SARS-CoV-2 laboratory test results submitted to CDC with complete information

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	Assuring a rapid and thorough public health response to the COVID-19 pandemic necessitates comprehensive laboratory testing data. These data contribute to understanding disease incidence and trends, availability and use of testing resources, and identification of supply chain issues for reagents and other material. Particularly important for identifying and addressing health disparities, ascertaining race/ethnicity among cases is a high priority in the guidance and that efforts should focus on those variables. Laboratory testing data, in conjunction with case reports and other data, also provide vital guidance for mitigation and control activities. The intent of this measure is to look at the extent to which laboratory test result information being submitted to CDC through the CELR line-level data is complete, resulting in a more detailed and timelier national picture of testing surveillance. ELC understands that completeness of these data may be reliant on the ordering provider; these data will be used to guide discussions between ELC and the recipient on how to work with ordering providers and clinical labs to improve data completeness.
Data Elements	For tests conducted within the PHL: 1. Proportion of COVID-19/SARS-CoV-2 laboratory test results submitted to CDC with complete information a. Numerator: Number of laboratory test results with complete information b. Denominator: Number of laboratory test results For tests conducted at non-PHL laboratories/community testing sites: 2. Proportion of COVID-19/SARS-CoV-2 laboratory test results submitted to CDC with complete information a. Numerator: Number of laboratory test results with complete information b. Denominator: Number of laboratory test results
Additional Guidance	This includes tests for all results. *Complete information:* A COVID-19/SARS-CoV-2 laboratory report with these critical data elements (as defined here: https://www.hhs.gov/sites/default/files/covid-19-laboratory-data-reporting-guidance.pdf) completed and sent to CDC will be considered "complete" for the following data elements: 1. Test order identifier (universal service identifier/universal service description) 2. Test result 3. Test Result date 4. Accession #/Specimen ID (filler order number namespace/filler order number OID) 5. Age 6. Patient race 7. Patient ethnicity 8. Patient gender 9. Patient residence zip code 10. Patient residence county 11. Ordering provider name and NPI (as applicable) 12. Ordering provider zip

	13. Performing Laboratory name or CLIA number, if known 14. Performing Laboratory zip code 15. Specimen Source - use appropriate LOINC, SNOMED-CT, SPM4 codes, or equivalently detailed alternative codes 16. Date specimen collected (date format) 17. Test report date
Target	ELC plans to baseline completeness percentages for all data elements and use that information to develop strategies for improvement. The ELC acknowledges that current percentages for completeness may be low.
Recommended Data Source	LIMS
Reporting Frequency	Quarterly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.4: Biosafety outreach and guidance provided by PHLs and/or the health department to COVID-19/SARS-CoV-2 testing sites

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	Safety of testing for COVID-19/SARS-CoV-2, in both laboratory and non-laboratory testing sites (e.g., prisons, nursing homes, drive-through testing sites), is an important concern. Public health departments are expected to conduct outreach and engage with testing facilities to improve safety of testing. This measure looks at the extent and breadth of outreach and engagement efforts on improving safety in non-PHL laboratories/community testing sites to help ensure that testing is done safely to protect personnel involved in collecting and processing specimens.
Data Elements	1. Please describe what external outreach steps are being taken to provide consultation and training on biosafety. 2. Do you have a dedicated team in the PHL to address issues around laboratory safety, including inventory management of PPE, specimen management, diagnostic and surveillance testing, and reporting results? (Yes/No) a. If no, do you have plans to develop such a team? (Yes/No) 3. Do you have a biosafety officer (BSO)? (Yes/No) a. If yes, is your BSO part-time or full-time? 4. Do you have a biosafety outreach officer (BOO) to provide biosafety guidance to external institutions? (Yes/No) a. If no, do you have plans to hire one? (Yes/No) b. If yes, is your BOO part-time or full-time? 5. Does your BSO/BOO/biosafety team engage **non-PHL laboratories**? (Yes/No) a. If yes, how does your BSO/BOO/biosafety team engage non-PHL laboratories* (select all that apply)? i. Provides in-person training • If yes, what kind of in-person training did you provide? (Open-ended) ii. Provides virtual training • If yes, what kind of virtual training did you provide? (Open-ended) iii. Facilitates access to training opportunities iv. Facilitates routine conference calls/discussions v. Conducts site visits vi. Supplies biosafety materials to laboratories for reading vii. Shares videos with biosafety guidance (YouTube) viii. Other (please specify) b. If your team does not engage non-PHL laboratories, why not? (open-ended) 6. Percent of non-PHL laboratories performing testing for COVID-19/SARS-CoV-2 with which the PHL has engaged in any outreach a. Numerator: Number of non-PHL laboratories performing testing for COVID-19/SARS-CoV-2 with which the PHL has engaged in any outreach b. Denominator: Number of non-PHL laboratories performing testing for COVID-19/SARS-CoV-2 7. Does your PHL/Health Department/Infection Prevention and Control team** engage **non-traditional testing sites**? (Yes/No)

	a. If yes, how has your PHL/health department/Infection Prevention and Control team engaged non-traditional testing sites (select all that apply)? i. Provides in-person training • If yes, what kind of in-person training did you provide? (Open ended) ii. Provides virtual training • If yes, what kind of virtual training did you provide? (Open ended) iii. Facilitates access to training opportunities iv. Facilitates routine conference calls/discussions v. Conducts site visits vi. Supplies biosafety materials to laboratories for reading vii. Shares videos with biosafety guidance (YouTube) viii. Other (please specify) b. If your team does not engage non-traditional testing sites, why not? (open-ended)
Additional Guidance	This measure should include only sites performing any COVID-19/SARS-CoV-2 testing, not collection sites. Sites performing POC testing are considered testing sites. *A clinical laboratory is defined by CLIA as any facility which performs laboratory testing on specimens obtained from humans for the purpose of providing information for health assessment and for the diagnosis, prevention, or treatment of disease. **Depending on the structure of public health within the jurisdiction, non-traditional testing sites may be monitored by the health department/infection prevention rather than the PHL. Please engage with the health department if the PHL in your jurisdiction does not communicate directly with non-traditional testing sites. *Outreach:* Outreach can include training (virtual and in-person), communications (e-mail, phone calls, newsletters, flyers, site visit, routine meetings. Additional guidance on biosafety practices around handling and processing COVID-19/SARS-CoV-2 specimens is provided here: https://www.cdc.gov/coronavirus/2019-ncov/lab/lab-biosafety-guidelines.html APHL Biosafety and Biosecurity Resources: https://www.aphl.org/programs/preparedness/Pages/Biosafety-Biosecurity-Resources.aspx
Target	
Recommended Data Source	
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.5: Percent of COVID-19 cases submitted to CDC that include complete and meaningful responses for key data elements.

Applicable Recipients	All states, NYC, DC, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	The intent of this measure is to monitor the completeness of case surveillance data that jurisdictions submit to CDC. The analysis will also include a review of data with a meaningful response, defined as responses other than 'unknown', in order to understand the challenges in reporting this data and identify potential areas for improvement. Over time, efficient detection and reporting strategies (e.g., eCR, ELR, NNDSS MMGs), and additional staffing for case investigation and disease control should improve this data. Jurisdictions should strive to ensure that maximum completeness and validity, as well as meaningful data are achieved for the key data elements listed below.
Data Elements	1. Percent completeness* of priority 1 and priority 2 data elements. a. Numerator: Number of COVID cases with complete data b. Numerator: Number of COVID cases with missing data c. Denominator: Total number of COVID cases submitted to CDC 2. Percent of data with a meaningful response for priority 1 *and* priority 2 data elements. a. Numerator: Number of COVID cases with responses other than 'unknown' for priority 1 and 2 data elements b. Denominator: Total number of COVID cases submitted to CDC *Priority 1 Data Elements:* a. Race b. Ethnicity c. Healthcare Occupation d. Hospitalization *Priority 2 Data Elements:* e. Onset date
Additional Guidance	Initial reports should strive to capture and send basic demographic data and case status without delay. It is understood that other data elements that require more case follow-up to occur (e.g. interview, access to med records, etc.) may be delayed. Priority 2 data elements will be evaluated for completeness after jurisdictions submit priority 1 data elements consistently for several submissions. *Completeness: It is important to note that in this context, completeness for ***Priority 1 Data elements*** is an analysis of data that has passed validation checks. Because of built-in validation checks, the data reported must be valid to be accepted. Any invalid data reported for ***Priority 1 Data elements*** will be coded as 'missing'. Resources to support jurisdictional health departments submit COVID-19 case data to CDC:

	Information for Health Departments on Reporting Cases of COVID-19 | CDC COVID PUI Form: May 2020: https://www.cdc.gov/coronavirus/2019-ncov/downloads/pui-form.pdf Jan 2021: https://www.cdc.gov/coronavirus/2019-ncov/downloads/php/COVID19-Worksheet-CSV-annotated-20201Jan15.pdf COVID Message Mapping Guide: https://wwwn.cdc.gov/nndss/case-notification/message-mapping-guides.html
Target	≥ 90% for each data element Jurisdictions should strive for high levels of completeness, validity, and 'meaningful' responses for all data elements.
Recommended Data Source	Data quality reports produced from case surveillance data received at CDC
Reporting Frequency	Monthly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.6: Proportion of COVID-19 cases with individual-level data submitted to CDC

Applicable Recipients	All states, NYC, DC, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	Aggregate counts submitted by jurisdictions to CDC limit CDC's ability to understand disease trends and patterns. This measure captures improvement in data quality related to electronic data flows. The intent of this measure is to monitor the extent to which jurisdictions provide case-level data on COVID-19 cases to CDC by comparing to the aggregate case counts.
Data Elements	1. Proportion of COVID-19 cases with individual-level data submitted to CDC a. Numerator: Cases with individual-level case information received at CDC b. Denominator: Aggregate case counts
Additional Guidance	https://www.cdc.gov/coronavirus/2019-ncov/downloads/pui-form.pdf A link to the COVID-19 MMG will be provided once available.
Target	≥ 98%
Recommended Data Source	1. Numerator: NNDSS and DCIPHER 2. Denominator: Aggregate case counts
Reporting Frequency	Monthly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.7: Median number of days from date of first positive specimen collection (or when not available, diagnosis date) to date COVID-19 case is reported to CDC

Applicable Recipients	All states, NYC, DC, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	The intent of this measure is to monitor improvements in the timeliness of COVID-19 case reporting to CDC. Recipients are expected to work with reporters to improve the speed with which COVID-19 cases are identified and reported to public health and the speed with which initial notification is provided to CDC. Timely data ensures that public health has up-to-date information on which to base decisions and actions.
Data Elements	1. Median number of days from date of first positive specimen collection (or when not available, diagnosis date) to date COVID-19 case is reported to CDC
Additional Guidance	To the best of the jurisdiction's ability, initial reports should strive to capture and send basic demographic data and case status without delay. It is understood that other data elements that require more case follow up to occur (e.g. interview, access to med records, etc.) may be delayed. If both date of diagnosis and specimen collection date are available, the earlier of the two dates will be used for the calculation. https://www.cdc.gov/coronavirus/2019-ncov/downloads/pui-form.pdf https://wwwn.cdc.gov/nndss/case-notification/message-mapping-guides.html
Target	≤ 5 days
Recommended Data Source	Calculations based on COVID-19 case notifications to CDC through NNDSS and DCIPHER.
Reporting Frequency	Monthly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.8: Percent of facilities reporting emergency department (ED) visits to the National Syndromic Surveillance Program (NSSP).

Applicable Recipients	All states, DC
Rationale	Syndromic surveillance provides public health with a timely system for detecting, understanding, and monitoring health events, including COVID-19. Recipients are expected to work with EDs in their jurisdiction to increase the number submitting syndromic surveillance data or increase the ED data transmitted to NSSP. The intent of this measure is to monitor the extent to which syndromic surveillance coverage of ED visits increases over time. From a jurisdiction and national perspective, full coverage of ED visits ensures that valid conclusions can be drawn for all geographic and population areas and that important findings are not missed due to coverage gaps.
Data Elements	1. Percent of facilities that are reporting emergency department (ED) visits to the National Syndromic Surveillance Program (NSSP). a. Numerator: The number of non-federal emergency departments that sent at least one valid message in production to NSSP in the last 12 months b. Denominator: Total number of non-federal emergency departments
Additional Guidance	Source for total number of ED visits can be an estimation from American Hospital Association or a state-specific source.
Target	Recipients should aim to have > 90% of facilities reporting by the end of 2022
Recommended Data Source	NSSP calculations of ED visit coverage
Reporting Frequency	Quarterly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.9: Completeness of priority data elements in ED visits reported to NSSP

Applicable Recipients	All states, DC, NYC and Los Angeles County
Rationale	Recipients are expected to work with facilities submitting ED data to improve data element completeness. The intent of this measure is to monitor the completeness of ED visit data, focusing on NSSP Priority 1 and 2 data elements. Increased completeness of information in the syndromic surveillance records improves public health's ability to detect and describe health events and the affected population groups and geographic areas.
Data Elements	1. Completeness of priority1 and 2 data elements in ED visits reported to NSSP a. Numerator: Number of ED visits with complete data b. Denominator: Total number of ED visits reported to NSSP *Priority 1 Data Elements:* • Admit_Reason_Code • Admit_Reason_Description • C_Chief_Complaint • Chief_Complaint_Text • Diagnosis_Code • Diagnosis_Description • C_Patient_Age • C_Patient_Age_Years • Patient_Zip • C_Biosense_Facility_ID • C_Facility_ID • Facility_Type_Code • Sending_Facility_ID • Treating_Facility_ID • C_Unique_Patient_ID • Visit_ID • Arrived_Date_Time • Admit_Date_Time • C_Visit_Date • C_Visit_Date_Time • C_Death • C_FacType_Patient_Class • C_Patient_Class • Patient_Class_Code *Priority 2 Data Elements:* • Chief_Complaint_Code • Diagnosis_Type • Administrative_Sex • Age_Reported • Age_Units_Reported • C_Patient_County • Ethnicity_Code

	• Ethnicity_Description • Patient_City • Patient_Country • Medical_Record_Number • Patient_State • Race_Code • Sending_Facility_ID_Source • First_Patient_ID • Message_Profile_ID • Message_Structure • Message_Type • Processing_ID • Trigger_Event • Version_ID • Message_Date_Time • Recorded_Date_Time • Discharge_Date_Time • Discharge_Disposition
Additional Guidance	Please review pages 27-28 of the BioSense Platform User Manual for Data-Quality-on-Demand-Programs (https://www.cdc.gov/nssp/biosense/docs/Data-Quality-On-Demand_User_Manual.pdf) for a list of key data elements.
Target	≥ 90% completeness
Recommended Data Source	NSSP Data Quality Dashboard
Reporting Frequency	Quarterly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.10: Percent of regularly reporting ILINet providers and the number of patient visits captured in ILINet each week both within and outside the Core Based Statistical Areas (CBSAs).

Applicable Recipients	All states, NYC, DC, Chicago, Puerto Rico, and US Virgin Islands. Other recipients may enroll providers if interested.
Rationale	The Outpatient Influenza-like Illness Surveillance Network, or ILINet, consists of volunteer sentinel outpatient providers, urgent care centers, and emergency departments. Providers who participate in the ILINet program collect and report information about the number of influenza-like illness (ILI) visits to their practice/facility each week. Mild to moderate COVID-19 illness presents with symptoms similar to ILI, so ILINet is now also being used to track trends of mild COVID-19 illness and allows for comparison with prior influenza seasons. There are currently more than 2,900 ILINet sentinel providers covering all 50 states, Puerto Rico, the District of Columbia, and the U.S. Virgin Islands. Data reported by ILINet providers provide a national picture of ILI activity in the U.S. Expanding the geographic distribution of ILINet providers and increasing their reporting frequency, as well as volume of patient visits, will improve our ability to detect and monitor community spread of SARS-CoV-2 and influenza. Establishing or maintaining one or more regularly reporting ILINet sites within each CBSA that, in aggregate, see at least 200 patients per 100,000 population each week, will help each jurisdiction obtain more complete geographic coverage for syndromic surveillance for respiratory illnesses. For non-CBSA areas within a state, ILINet sites and patient visits should be commensurate with population size.
Data Elements	1. Percent of CBSA's with at least 200 patient visits per 100,000 population captured in ILINet each week a. Numerator: Number of CBSA's with at least 200 patient visits each week from regularly reporting ILINet providers per 100,000 population b. Denominator: Total number of CBSA's 2. Average number of patient visits reported each week by regularly reporting ILINet sites that are **not** within the CBSAs a. Non-CBSA area population estimate (state population- population of all CBSAs) b. Average number of patient visits per week from regularly reporting providers not in the CBSA 3. Percent of enrolled ILINet providers that regularly report a. Numerator: Number of regularly reporting ILINet providers b. Denominator: Number of enrolled ILINet providers
Additional Guidance	*Core-Based Statistical Area:* Metropolitan and Micropolitan Statistical Areas are collectively referred to as Core-Based Statistical Areas[1]. They are defined by the Office of Management and Budget (OMB) and consist of the county or counties or equivalent entities associated with at least one urban core (urbanized area or urban cluster) of at least 10,000 population, plus adjacent counties having a high degree of social and economic integration with the core as measured through commuting ties with the counties containing the core. *ILINet provider types:* Providers in many types of practices may be ILINet providers, including: • Emergency medicine

[1] https://www.census.gov/topics/housing/housing-patterns/about/core-based-statistical-areas.html

	• Family practice • Infectious disease • Internal medicine • OB/GYN • Pediatrics • Student health • Urgent care
Target	• Within each CBSA, at least 200 patient visits per 100,000 population captured in ILINet each week after 12 months • For non-CBSA areas of a state, maintain the number of providers and patient visits commensurate with the population. • 80% of ILINet sites routinely report each quarter. “Routinely report” is defined as reporting at least 12 out of 13 weeks in the quarter.
Recommended Data Source	ILINet
Reporting Frequency	Quarterly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Measure E.11: Percent of labs reporting influenza and COVID-19/ SARS-CoV-2 via PHLIP 2.5.1 to CDC and the percent completeness of key data elements for respiratory virus specimens tested at the public health laboratory (PHL).

Applicable Recipients	All states, NYC, DC, Guam, and Puerto Rico
Rationale	Improving the completeness and validity of laboratory reporting for respiratory viruses will help CDC gain a better understanding of the community and seasonal spread of COVID-19/SARS-CoV-2 vis-à-vis other respiratory viruses. Laboratory reporting for respiratory viruses, including SARS-CoV-2/COVID-19, influenza, RSV and others, must have complete and valid data for all key data elements to inform epidemiologic case investigations and follow up and to monitor trends in virus circulation. Submitting all public health laboratory reports for respiratory virus testing to CDC will ensure that PHL data can be used most effectively. This measure focuses on laboratory reporting for all respiratory virus specimens tested at the public health laboratory. ELC will collect a complementary measure (E.3) that focuses on reporting for COVID-19/ SARS-CoV-2 specimens tested at all laboratories, including at the public health laboratory and clinical laboratories.
Data Elements	1. Percent of labs reporting influenza and COVID-19/ SARS-CoV-2 via PHLIP 2.5.1 a. Numerator: Number of labs reporting influenza and COVID-19 via PHLIP 2.5.1 b. Denominator: Total number of PHLs 2. Percent of labs reporting other respiratory viruses via PHLIP 2.5.1 a. Numerator: Number of labs reporting other respiratory viruses via PHLIP 2.5.1 b. Denominator: Total number of PHLs 3. Percent completeness* of the following key data elements reported to CDC for Influenza and COVID-19/SARS-CoV2 specimens tested at the PHL: • Patient DOB (or age if DOB is not available) • Patient race/ethnicity • Patient zip code or county of residence (or zip code or county of submitting facility) • Specimen collection date • Virus test results • Level of care (inpatient/outpatient), when possible • Illness onset date, when possible • Specimen source, when possible • Gender, when possible Additional data element for respiratory specimens submitted by ILINet providers: • ILINet provider ID a. Numerator: Number of influenza specimens with complete* data for each key data element above. b. Denominator: Total number of influenza specimens reported c. Numerator: Number of COVID-19/ SARS-CoV-2 specimens with complete* data for each key data element above. d. Denominator: Total number of COVID-19/ SARS-CoV-2 specimens reported
Additional Guidance	*PHLIP:* The Public Health Laboratory Interoperability Project (PHLIP) is a collaborative effort between the Association of Public Health Laboratories, CDC, and state public health

	laboratories (PHLs) to advance automated electronic data flows from PHLs to CDC.[2] *Completeness: It is important to note that in this context, completeness is an analysis of data that has passed validation checks. Because of built-in validation checks, the data reported must be valid to be accepted. However, blank (missing) data is also accepted.
Target	• 100% of labs reporting influenza and COVID-19 to CDC are using PHLIP 2.5.1. • 100% of labs reporting other respiratory viruses to CDC are using PHLIP 2.5.1 • Reports for all respiratory virus testing at the public health laboratory include data that are at least 80% complete* for each key data element.
Recommended Data Source	PHLIP
Reporting Frequency	Quarterly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

[2] https://www.aphl.org/programs/informatics/Documents/INF_2013May15_ELSM-Overview.pdf

Measure E.12: Number of healthcare organizations engaged to implement electronic case reporting (eCR)

Applicable Recipients	All recipients
Rationale	Jurisdictions must demonstrate that they are making electronic case reporting implementation with healthcare organizations a priority focus area through this funding. Recipients are expected to recruit and work with healthcare organizations in their jurisdictions that submit reportable condition reports to implement electronic case reporting. The intent of this measure is to monitor the extent to which the number of healthcare organizations submitting electronic case reports to the jurisdiction increases over time. From a jurisdiction and national perspective, full coverage of healthcare organizations ensures that all cases of reportable conditions are identified for public health action.
Data Elements	1. How are you recruiting new in-jurisdiction providers to onboard to eCR? (Select all that apply.) ☐ Sending recruitment letters or e-mails ☐ Hosting or participating in recruitment group calls or eCR webinars to in-jurisdiction providers ☐ Targeted discussions (calls with one or more healthcare organizations, HIE, or HIN for recruitment) ☐ Passive recruitment – accepting providers who reach out to the eCR team ☐ Not recruiting (if this is checked, must provide a date for when recruitment will begin in question 1a) 1a. If not currently recruiting, what date will you start recruiting? (D-M-Y) 2. Did you confirm that your answer to question 1 is consistent with the monitoring question available on the Site Overview monitoring form? (Y/N) 3. Please share any successful recruitment strategies or any challenges to recruitment. 4. List priority healthcare organizations for **recruitment** who have not yet implemented eCR at this time. Ideally, include at least 15 organizations and accompanying information listed below. List organizations you have prioritized for eCR recruitment and implementation. Indicate whether you have reached out to recruit this organization. Do not include any organizations already in testing or live with eCR. (Please enter the information in the spreadsheet template provided in REDCap.) • Organization name • Name of EHR vendor (if known) • Date last contacted 5. For healthcare organizations actively **engaged** in eCR with the public health agency, please indicate the following for level of engagement. (Please enter the information in the spreadsheet template provided in REDCap.) • Testing for COVID-19 only • In production and parallel reporting for COVID-19 only • In production with no manual reporting for COVID-19 only • Testing for all conditions • In production and parallel reporting for all conditions • In production with no manual reporting for all conditions 6. If you offered incentives to healthcare organizations for participating in eCR, what has been the impact of those incentives?

Additional Guidance	The agreed upon priority list of healthcare organizations in the jurisdiction will be used at quarterly calls between jurisdiction and the ELC HIS Implementation and Monitoring Team to track status of organization's implementation progress. Questions 4 and 5 will be reported using the spreadsheet template available for download in REDCap. Question 5 is cumulative. Recipients may update the engagement list (in Excel) and status each quarter of reporting. Healthcare organizations may change status over time.
Target	Quarterly reporting on engagement status
Recommended Data Source	CDC will assist with providing an initial list of healthcare organizations in the jurisdiction if desired.
Reporting Frequency	Quarterly
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.12a: Number of conditions published to production in Reportable Conditions Knowledge Management System (RCKMS).

Applicable Recipients	All recipients
Rationale	Using this RCKMS allows public health jurisdictions to define reporting criteria, and helps healthcare organizations using electronic case reporting send the appropriate initial case reports to respective public health agencies. Increasing the number of reportable conditions published to production in RCKMS ensures efficient and timely disease surveillance, ultimately leading to more timely identification of clusters or outbreaks of disease and resulting in more rapid public health response.
Data Elements	1. Per the guidance, each jurisdiction should have at least 36 conditions authored each quarter, for a total of 144 conditions authored to production by the end of the year. How many conditions has your jurisdiction currently published to production in RCKMS?
Additional Guidance	
Target	36 conditions authored each quarter, for a total of 144 conditions authored to production by the end of the year
Recommended Data Source	
Reporting Frequency	Quarterly
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.13: Proportion of state reportable cases with an electronic initial case report (eICR) submitted

Applicable Recipients	All recipients
Rationale	Recipients are expected to work with healthcare organizations in their jurisdictions that submit reportable condition reports to increase the number submitting reports electronically. The intent of this measure is to monitor the extent to which cases in the jurisdiction have associated electronic case reports – either case was started by an eICR, an eICR was received and helped define the case status, or eICR received provided additional data to support the case. From a jurisdiction and national perspective, submission of electronic reports that are timely and complete will allow for more efficient and speedy public health action.
Data Elements	1. Percent of state reportable cases with an electronic initial case report (eICR) submitted during the last 6 months a. Numerator: Number of reportable cases with at least one associated electronic initial case report (see additional guidance below) b. Denominator: Total number of reportable cases known by the jurisdiction from all reporting mechanisms for all state reportable conditions
Additional Guidance	For 1a: This is not the number of electronic initial case reports (eICRs) received, but the unique number of case reports that have **one or more** eICR associated with them (e.g deduplicated eICRs) Jurisdiction must maintain production connection with AIMS to receive eICRs
Target	50% by August 2021; overall target > 90%
Recommended Data Source	
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.14: Demonstration of automatic processing of electronic initial case reports (eICRs) in the jurisdiction integrated surveillance system(s)

Applicable Recipients	All recipients
Rationale	Recipients are expected to ensure that their surveillance systems have capability to accept, process and present the data in electronic initial case reports (eICRs) and reportability responses (RRs) for use by users of the surveillance system. The intent of this measure is to monitor the surveillance system(s) ability to fully process the electronic case report data. Increased capacity to process electronic data improves public health's ability to identify and response to health events and the affected population groups and geographic areas.
Data Elements	1. List each surveillance system that is used to manage cases of reportable conditions a. For each surveillance system, indicate the percent of eICRs that are received by the jurisdiction and populated into the system without entering an error queue in the production environment. b. What are the start and end dates for this metric? i. What is the start date for this metric? (Month, day, year) ii. What is the end date for this metric? (Month, day, year) 2. Did you confirm that your answers for question 1 are consistent with the monitoring questions available on the Site Overview monitoring form? (Y/N) 3. Please provide any qualitative information about your progress on processing eICRs into the surveillance system. Are there any successes, challenges, or status changes that you would like to share?
Additional Guidance	Data from RR are needed to process eICR. Report measure for each surveillance system being used for managing reportable conditions. Conditions may vary by jurisdictions.
Target	Processing of > 50% of eICRs by the surveillance system
Recommended Data Source	
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.15: Proportion of test orders and results processed through Electronic Test Orders and Results Reporting (ETOR) at the PHL (this measure only applies to tests conducted at the public health laboratory)

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County
Rationale	Electronic Test Orders and Results (ETOR) enable laboratories and healthcare providers to electronically exchange standardized test orders and results. Recipients are expected to work on enhancing laboratory test ordering and reporting capability with this project. The volume of orders and results data exchanged through ETOR by jurisdiction provides CDC an understanding of ETOR implementation occurring across the nation.
Data Elements	1. Number of **test orders** processed through Electronic Test Orders and Results (ETOR) established through the PHL LIMS and/or a centralized platform and/or web portal a. Number of test orders received by the PHL through a web portal b. Number of test orders sent or received by the PHL through direct systems integration ETOR c. Number of test orders sent or received by PHL through indirect systems integration ETOR d. Number of all test orders sent or received by the PHL 2. Number of **test results** processed through Electronic Test Orders and Results (ETOR) established through the PHL LIMS and/or a centralized platform and/or web portal a. Number of test results received by the PHL through a web portal b. Number of test results sent or received by the PHL through direct systems integration ETOR c. Number of test results sent or received by PHL through indirect systems integration ETOR d. Number of all test results sent or received by the PHL
Additional Guidance	This measure only applies to tests conducted at the public health laboratory. *Number of test orders/results exchanged through a web portal:* Includes all orders received and results sent by the laboratory using a web portal. The web portal needs to be directly integrated to the LIMS to be considered valid for counting as "received and sent through a web portal". Please do not count tests which are transferred from portal to LIMS or vice versa by staff using mechanisms such as copy pasting or exporting to files by portal and upload to LIMS or other similar means for both orders and result reporting). *Number of test orders/results exchanged through direct systems integration ETOR:* Includes all orders received and results sent by the laboratory through direct systems integration. Systems (EHR and LIMS) are integrated, and data is exchanged using HL7 messaging or other file formats. Data translation for integration is managed through integration engines such as Rhapsody, Mirth, within the PHL No manual data entry is involved in sending or receiving data. *Number of test orders/results exchanged through indirect systems integration ETOR:* Includes all orders received and results sent by the laboratory through indirect systems integration. Sending and receiving systems (EHR and LIMS) exchange data using an

	external system such as a centralized platform. This external system translates the messages for integration. No manual work is involved in sending or receiving data. *Number of test results/orders:* This includes all test orders/results exchanged by the laboratory through all mechanisms (e.g., paper form, PDF Form, Email, through phone, mail, web portal, HL7 based message.
Target	None at this time.
Recommended Data Source	LIMS
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.16: Systems/programs at the PHL with ETOR interfaces

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County
Rationale	Electronic Test Orders and Results (ETOR) implementation is aimed at process automation within public health laboratories. This allows enhanced testing capacity by load management and reduction of errors due to manual data entry. The number of different programs/ systems connected electronically with healthcare providers is an indicator of the amount of process automation within the laboratory.
Data Elements	1. List of systems and/or programs within your public health laboratory that currently have fully implemented ETOR interfaces with any healthcare provider.
Additional Guidance	This measure only applies to systems/programs within the public health laboratory. Please list system/program if ETOR has been fully established with at least one healthcare provider. *Systems/programs:* This could include how the public health laboratory is categorized administratively or based on how LIMS implementations are divided.E.g., Infectious Disease Program, Microbiology Laboratory, Newborn Screening Laboratory, Pathology Laboratory. Recipients are encouraged to provide a list of systems/programs within their public health laboratory at the start of measurement period. *Healthcare providers:* Hospitals, Hospital systems, Physicians' offices or other entities receiving services from the public health laboratory. *Fully Implemented ETOR:* Systems where at least 80% of routine orders and/or results are exchanged electronically using web portal, direct or indirect integration
Target	None at this time.
Recommended Data Source	Administrative System
Reporting Frequency	Annually
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.17: Caseload, number of cases per case investigator and number of contacts per contact tracer during the data collection period

Applicable Recipients	All recipients
Rationale	This measure is essential for monitoring capacity and identifying case investigation and contact tracing staffing needs. This data will help provide important information about variations in workload over time and across jurisdictions.
Data Elements	1. Number of cases reported to the health department (confirmed and, if possible, probable) 2. Number of case Investigators 3. Number of contacts identified through case investigations 4. Number of contact tracers
Additional Guidance	If exact numbers are difficult to obtain, please provide the best estimate for these data elements and provide an explanation in the note section. Case investigators and contact tracers are not expected to be mutually exclusive or spend 100% of their time on one these tasks. It is understood that case investigators may perform some contact tracing activities and vice versa. *Definitions:* Total number of cases should include all confirmed and, if possible, probable. “Number of case investigators” is the total number of staff who were assigned cases to contact for an interview “Number of contacts” is the total number of contacts identified through case interviews. “Number of contact tracers” is the total number of staff assigned to follow up on contacts *Potential Calculations (performed by ELC):* 1. Caseload per case investigator 2. Caseload per contact tracer
Target	No target
Recommended Data Source	Case investigation management system, Contact tracing management system
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)

Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.18: Timeliness, completeness, and effectiveness of case interviews among the cases sent for case investigation during the data collection period

Applicable Recipients	All recipients
Rationale	The intent of this measure is to monitor the timeliness of completion of case interviews following the report of a case to the health department. Conducting timely case interviews increases the likelihood of quickly identifying and notifying contacts, allowing for more timely detection of additional COVID-19 cases. Rapid case follow- up is essential to mitigate the spread of disease.
Data Elements	1. Number of cases that completed an interview 2. Number of cases interviewed within 1 day of report to case investigations team 3. Number of cases that provided at least one contact 4. Number of cases that were successfully contacted but did not complete an interview 5. Number of cases that did not respond to contact attempts
Additional Guidance	If exact numbers are difficult to obtain, please provide the best estimate for these data elements and provide an explanation in the note section. *Definitions:* "Cases that completed an interview" is defined as the active engagement with a case or proxy to conduct an interview, beyond notification of positive result or scheduling a time for interview. This can also include interviews that do not result in contact tracing efforts based on prioritization algorithms. "Successfully contacted but did not complete interview" refers to a case who responded to outreach attempts from the health department but was unable to (or refused to) complete an interview "Did not respond to contact attempts" refers to when one or more attempt was made by the health department to contact the case, but the attempt was unsuccessful. *Potential calculations (performed by ELC):* 1. Percent of cases that completed an interview among the total cases sent to the health department 2. Percent of cases that completed an interview within 1 day of report among those who completed an interview 3. Percent of cases that did not complete an interview among those that were successfully contacted 4. Percent of cases that provided contacts among those that complete an interview 5. The average number of contacts provided by cases that completed an interview
Target	The target for this measure is still under development; there is a need to see what is realistic and how this target needs to change over time, depending on epidemiology and capacity. There is no expectation that 100% of cases would be interviewed.

Recommended Data Source	Case investigation data system
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.19: Timeliness of contact tracing during the data collection period

Applicable Recipients	All recipients
Rationale	The intent of this measure is to monitor the timeliness of contact notification following a case report to the health department. Identifying and notifying contacts of cases in a timely manner allows for detection and mitigation of possible transmission.
Data Elements	1. Total number of contacts notified 2. Number of contacts notified within 1 day of case interview
Additional Guidance	If exact numbers are difficult to obtain, please provide the best estimate for these data elements and provide an explanation in the note section. *Definitions:* "Notified" means that a person is informed of their potential exposure to a COVID-19 case. Method of notification is not defined and can vary depending on notification methods (text, phone, email, other). Notification does not necessarily require an interview.
Target	The target for this measure is still under development; there is a need to see what is realistic and how this target needs to change over time, depending on epidemiology and capacity. There is currently no expectation that 100% of contacts would be notified within 1 day.
Recommended Data Source	Contact tracing data system
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.20: Effectiveness of contact tracing to interrupt the transmission of COVID-19 during the data collection period

Applicable Recipients	All recipients
Rationale	Contacts enrolling in symptom monitoring program and the capacity to reach contacts to recommend quarantine or isolation and monitor symptoms is important to interrupt the transmission of CoVID-19. The number of cases that were known to be contacts is an important metric to collect because new cases that are not identified as contacts in the previous 14 days could indicate spread of COVID-19 in the community that is unknown to the health department. This could reduce the effectiveness of case investigations and contact tracing efforts.
Data Elements	1. Number of new cases that were identified (or known) as contacts in the previous 14 days
Additional Guidance	If exact numbers are difficult to obtain, please provide the best estimate for these data elements and provide an explanation in the note section. *Potential calculations (performed by ELC):* 1. Percent of new cases that were identified (or known) as contacts in the previous 14 days among the number of cases.
Target	The target for this measure is still under development; there is a need to see what is realistic and how this target needs to change over time, depending on epidemiology and capacity. There is currently no expectation that 100% of contacts would agree to symptom monitoring.
Recommended Data Source	Case surveillance and contact tracing data system
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.21: Timeline of the case investigation process from specimen collection to contact notification during the data collection period

Applicable Recipients	All recipients
Rationale	The timeliness of sample collection to contact notification to mitigate the spread of CoVID-19 is dependent on several different points within the case investigation process. These different points can be used to identify areas where contact tracing is being delayed.
Data Elements	1. Median and range for the number of days between specimen collection and report of case to the health department 2. Median and range for the number of days between the report of the case to the health department to a case interview completion 3. Median and range of the number of days between when a case interview is completed to when any identified contacts were notified
Additional Guidance	
Target	No target at this time.
Recommended Data Source	Laboratory reports, case surveillance and contact tracing systems
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.22: Among contacts notified, proportion tested for COVID-19/SARS-CoV-2 at least once, within 14 days of notification during the data collection period

Applicable Recipients	This measure will no longer be collected.
Rationale	Obtaining information on the extent of testing among contacts is important because it reflects both testing capacity and public health intervention to reduce the spread of COVID-19. Monitoring the extent of testing conducted within contact tracing process is important for better understanding how contact tracing programs are implemented and evolve over time, across jurisdictions.
Data Elements	1. Number of contacts tested for COVID-19/SARS-CoV-2 at least once, within 14 days of notification out of the number of contacts notified
Additional Guidance	"Testing" can be by self-report or lab result received (assuming negative lab results come to recipient). Tested using a diagnostic test, for current/active infection, not antibody testing. Antibody testing should not be included in this measure. Testing capacity and testing protocols vary across recipients, so it may be difficult to compare this measure across recipients. Some contacts may be appropriately managed without testing, so this measure does not reflect the percent of contacts who were appropriately managed. Some testing may be difficult to capture, if the contact is tested on their own or if there are gaps in reporting of testing to the health department (by testing agencies or the contact).
Target	No target at this time.
Recommended Data Source	Contact tracing data system
Reporting Frequency	Monthly (Schedule included in Appendix C of the guidance)
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.23: Number of health department staff who can perform healthcare infection control assessments at the state and local level

Applicable Recipients	All recipients
Rationale	Strengthening the infection prevention and control expertise can influence a health department's ability to respond to COVID-19 and other infectious diseases outbreaks. Tracking the number of people who can perform infection control assessments in healthcare settings is an essential component of monitoring progress and identify areas for improvement or point to gaps in IPC workforce development at the state and local level.
Data Elements	1. Number of staff who can independently and capably perform an infection control assessment in healthcare facilities, provide prevention and outbreak response recommendations to facilities, and follow-up with facilities to ensure gaps have been mitigated. a. Number of state HD staff b. Number of local HD staff c. Number of other staff (e.g., staff working at medical schools, nursing schools, regional teams, partnerships etc.)
Additional Guidance	Health department staff can include hired and/or contracted by the HD. Please refer to the REDCap user guide on HAI/AR Performance Measured for step-by-step instructions on completing this form.
Target	N/A
Recommended Data Source	N/A
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap (**HAI/AR Performance Measures 2020 - 2021 (BP2)** REDCap Project) ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.24: Number of proactive healthcare infection control assessments conducted by the health department or designee for COVID-19.

Applicable Recipients	All recipients
Rationale	The health department plays a critical role in responding to possible COVID-19 HAI/AR outbreaks. Understanding the proactive assessments conducted allows CDC and the HDs to track IPC issues requiring the greatest public health support. Beyond the infection control assessments, HDs should follow up after the assessment to support healthcare settings in implementing recommendations.
Data Elements	1. Number of healthcare facilities where a proactive (prevention-based) infection control assessment was conducted by the health department or designee, by method: a. Remote (e.g., Tele-ICAR, video-ICAR) b. On-site
Additional Guidance	Provision of remote/onsite assistance to assess infection control issues may be done directly by the Recipient or through the support of a local health department, academic partner, contractor, consultant, or other entity (designee) for which the Recipient can assure the quality of services provided. Prevention-based assessments require use of a structured form for data collection, such as CDC tele-ICAR tool (or similar state/local developed tool). Proactive infection control assessments are those that focus on facilities considered to be at high risk for COVID-19 outbreaks, with the goal of improving infection control practices to reduce transmission of COVID-19. This type of infection control assessment is distinct from response-driven infection control assessments that are focused on facilities where COVID-19 or other HAI/AR infections outbreaks have been identified. Please refer to the REDCap user guide on HAI/AR Performance Measured for step-by-step instructions on completing this form.
Target	N/A
Recommended Data Source	N/A
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap (**HAI/AR Performance Measures 2020 - 2021 (BP2)** REDCap Project) ☐ CDC currently has this data and there is no need to report it currently.

Measure E.25: Number of COVID-19 outbreaks and responses in healthcare settings

Applicable Recipients	All recipients
Rationale	Rapid and structured response is critical to the successful containment of COVID-19 in all healthcare settings. An understanding of this information can help CDC and HD quantify the extent of the issue and assess whether timely and efficient response is implemented.
Data Elements	1. Number of possible COVID-19 outbreaks that met the threshold for additional investigation 2. Of the possible COVID-19 outbreaks, number for which any response was provided
Additional Guidance	Response refers to a series of actions on the part of public health authorities to assess specific, acute HAI/AR risks and prevent further harm. Response efforts may take the form of consultation regarding IPC activities, remote or on-site assessments, or other IPC technical assistance (e.g. cohorting or testing strategies, return to work criteria, PPE optimization, mitigating staffing shortages), to facilities with COVID-19 infections among residents/patients or HCP. Note that definition of “outbreak”, “responded to” and “specified time period” is defined in the REDCap reporting template. Please refer to the REDCap user guide on HAI/AR Performance Measured for step-by-step instructions on completing this form.
Target	N/A
Recommended Data Source	N/A
Reporting Frequency	Twice per year
Reporting Mechanism	☒ REDCap (**HAI/AR Performance Measures 2020 - 2021 (BP2)** REDCap Project) ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.26: Number of new or enhanced laboratory technologies procured, maintained, or implemented to improve laboratory response capacity

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	When PHLs have the capacity to conduct multiple types of tests in a timely manner, public health is better able to detect SARS-CoV-2, respond to areas of increased incidence of COVID-19, and identify populations that require more thorough mitigation measures. Current funding opportunities allow PHLs to bolster their laboratory technology, including adding new equipment, maintaining existing equipment, and managing service agreements for both new and existing equipment. These data will serve initially as a baseline for current testing capacity in terms of technology and will allow CDC to monitor how funds have been used to build on that technology over the course of the project.
Data Elements	1. Have any of the following automated and/or high-throughput laboratory platforms, service agreements, and/or reagents been procured by your public health laboratory using Strengthening PHL Preparedness funds? Please select "yes" for all platforms that apply. If platform is not listed in the table, please add to "Other".

	Platforms	Number of platforms	Service Agreements	Reagents /Supplies
Bruker MALDI-TOF Microflex System	☐	(drop down menu 1,2)	Number for Newly Acquired Equipment (drop down 0,1,2) Number for Existing Equipment (drop down 0,1,2)	☐
KingFisher FLEX (96 well Deep Head) System	☐	(drop down menu 1,2)	Number for Newly Acquired Equipment (drop down 0,1,2) Number for Existing Equipment (drop down 0,1,2)	☐
Sequencer - MinION - Illumina Iseq100 - GridION - MiniSeq - NextSeq - Others (please specify)	☐	(drop down menu 0, 1,2,3,4 or more)	Number for Newly Acquired Equipment (drop down 0,1,2,3,4 or more) Number for Existing Equipment (drop down 0,1,2,3,4 or more)	☐
Extraction platform - Qiagen EZ1 Advanced XL - Roche MagNAPure 24 - Roche MagNA Pure 96 - Others (please specify)	☐	(drop down menu 0, 1,2,3)	Number for Newly Acquired Equipment (drop down 0,1,2,3) Number for Existing Equipment (drop down 0,1,2,3)	☐
Other _____ (Should include other instruments such as liquid handlers/robotics)	☐	(drop down menu 1,2,3)	Number for Newly Acquired Equipment (drop down 0,1,2,3) Number for Existing Equipment (drop down 0,1,2,3)	☐

<table>
<tr><td></td><td>2. Have any of the following bioinformatics enhancements been procured by your public health laboratory using Strengthening PHL Preparedness funds? Select all that apply. If not applicable, please leave blank and provide explanation in the comments.

Measure E.27: Number of biothreat samples shipped to designated LRN reference laboratory or CDC

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	By sending samples for further characterization of biothreat samples, PHLs help strengthen response capabilities by contributing to laboratory testing infrastructure. CDC will use this measure to monitor the amount of funding recipients need to adequately ship samples when necessary.
Data Elements	1. Were any samples sent to a LRN reference laboratory? (Yes/No/Not Applicable) a. If yes, how many samples were sent to a LRN reference laboratory? 2. Were any samples sent to CDC? (Yes/No) a. If yes, how many samples were sent to CDC?
Additional Guidance	Shipment of biothreat isolates or specimens to an LRN reference laboratory or to CDC for further rule out testing or characterization is acceptable.
Target	
Recommended Data Source	
Reporting Frequency	Quarterly
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.28: Enhancing laboratory information infrastructure for LRN testing methodologies

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	Enhancement and expansion of laboratory information infrastructure between local, state, and national laboratories will enable faster, dynamic, and more complete data exchange and reporting. With more efficient reporting practices, public health is better able to detect SARS-CoV-2, respond to areas of increased incidence of COVID-19, and identify populations that require more thorough mitigation measures. These data inform CDC on how LRN methodologies are being prioritized in the context of information exchange.
Data Elements	1. Has your laboratory implemented ELR for LRN testing methodologies? (Yes/In Progress/No/Not Applicable) a. If no, please explain limitations or challenges in implementing ELR for LRN testing methodologies. 2. What enhancements have been accomplished within your laboratory information system infrastructure within this reporting period using Strengthening PHL Preparedness funds? 3. Please explain the plan for enhancements for the reporting period.
Additional Guidance	
Target	Implementation of ELR for LRN testing methodologies, when applicable
Recommended Data Source	
Reporting Frequency	Semi-annual
Reporting Mechanism	☒ REDCap ☐ CDC currently has this data and there is no need to report it at this time.

Measure E.29: Number of SARS-CoV-2 specimens sent to CDC for sequencing per month

Applicable Recipients	All states, NYC, DC, Philadelphia, Houston, Los Angeles County, American Samoa, Guam, Marshall Islands, Northern Mariana Islands, Federated States of Micronesia, Palau, Puerto Rico, and US Virgin Islands
Rationale	As SARS-CoV-2 continues to evolve and more variants of the virus are identified, the ability for laboratories to sequence SARS-CoV-2 specimens allows public to identify where those variants exist and how public health should respond. PHLs should aim to increase the number of SARS-CoV-2 specimens sent to CDC for sequencing for that effort. This performance measure will indicate growth of sequencing and facilitate the use of genomic sequence data in the response to SARS-CoV-2 and other emerging pathogens on a national level.
Data Elements	1. The number of SARS-CoV-2 specimens sent to CDC for sequencing each month. The following information must be submitted for cases: a. Viral Ct value b. Host control Ct (RNase or whatever is used in the assay) c. Sample collection date d. Patient information: i. Residence by country and (where relevant) state and county ii. Race/ethnicity iii. Age in years iv. Gender vi. Hospitalized (yes/no/unknown) vii. Death (yes/no/unknown) viii. Optional: Other relevant information
Additional Guidance	The number of specimens sent to CDC should be counted starting from February 2021. This measure still applies to all jurisdictions, including those with very few or no COVID cases. It is understood these jurisdictions may or may not make targets.
Target	Minimum: 20 specimens sent to CDC per month Based on population size, the ultimate target by state is listed in Appendix 2 of this doc: NS3-Submission-Guidance.pdf (aphl.org)
Recommended Data Source	LIMS
Reporting Frequency	Monthly
Reporting Mechanism	☐ REDCap ☒ CDC currently has this data and there is no need to report it at this time.

Appendix A. Reporting mechanism by measure

ID	Measure	REDCap	CDC has data and will share with recipients
E.1	Median number of days from specimen collection date to date of report of final test result for COVID-19/SARS-CoV-2 molecular diagnostic tests	X	X
E.2	Number of COVID-19/SARS-CoV-2 tests completed by test type, race/ethnicity, and result		X
E.3	Proportion of COVID-19/SARS-CoV-2 laboratory test results submitted to CDC with complete information		X
E.4	Biosafety outreach and guidance provided by PHLs and/or the health department to COVID-19/SARS-CoV-2 testing sites	X	
E.5	Percent of COVID-19 cases submitted to CDC that include complete and meaningful responses for key data elements.		X
E.6	Proportion of COVID-19 cases with individual-level data submitted to CDC.		X
E.7	Median number of days from date of first positive specimen collection (or when not available, diagnosis date) to date COVID-19 case is reported to CDC		X
E.8	Percent of facilities reporting emergency department (ED) visits to the National Syndromic Surveillance Program (NSSP).		X
E.9	Completeness of priority data elements in ED visits reported to NSSP		X
E.10	Percent of regularly reporting ILINet providers and the number of patient visits captured in ILINet each week both within and outside the Core Based Statistical Areas (CBSAs)		X
E.11	Percent of labs reporting influenza and COVID-19/ SARS-CoV-2 via PHLIP 2.5.1 to CDC and the percent completeness of key data elements for respiratory virus specimens tested at the public health laboratory (PHL)		X
E.12	Number of healthcare organizations engaged to implement electronic case reporting (eCR)	X	
E.12a	Number of conditions published to production in Reportable Conditions Knowledge Management System (RCKMS).	X	
E.13	Proportion of state reportable disease cases with an electronic initial case report (eICR) submitted	X	
E.14	Demonstration of automatic processing of electronic initial case reports (eICRs) in the jurisdiction integrated surveillance system(s)	X	
E.15	Proportion of test orders and results processed through Electronic Test Orders and Results Reporting (ETOR) at the PHL (this measure only applies to tests conducted at the public health laboratory)	X	
E.16	Systems/programs at the PHL with ETOR interfaces	X	
E.17	Caseload, number of cases per case investigator and number of contacts per contact tracer during the data collection period	X	
E.18	Timeliness, completeness, and effectiveness of case interviews among the cases sent for case investigation during the data collection period	X	
E.19	Timeliness of contact tracing during the data collection period	X	
E.20	Effectiveness of contact tracing to interrupt the transmission of COVID-19 during the data collection period	X	

ID	Measure	REDCap	CDC has data and will share with recipients
E.21	Timeline of the case investigation process from specimen collection to contact notification during the data collection period	X	
E.22	Among contacts notified, proportion tested for COVID-19/SARS-CoV-2 at least once, within 14 days of notification during the data collection period	X	
E.23	Number of health department staff who can perform healthcare infection control assessments at the state and local level	X	
E.24	Number of proactive healthcare infection control assessment and response (ICAR) conducted by the health department or designee for COVID-19.	X	
E.25	Number of COVID-19 outbreaks and responses in healthcare settings	X	
E.26	Number of new or enhanced laboratory technologies procured, maintained, or implemented to improve laboratory response capacity	X	
E.27	Number of biothreat samples shipped to designated LRN reference laboratory or CDC	X	
E.28	Enhancing laboratory information infrastructure for LRN testing methodologies	X	
E.29	Number of SARS-CoV-2 specimens sent to CDC for sequencing per month		X

Appendix B. Reporting frequency (for recipient-reported measures only)

ID	Measure	Reporting Frequency
E.1	Median number of days from specimen collection date to date of report of final test result for COVID-19/SARS-CoV-2 molecular diagnostic tests	Quarterly
E.4	Proportion of COVID-19/SARS-CoV-2 testing sites that received biosafety guidance and conducted laboratory risk assessments	Twice per year
E.12	Number of healthcare organizations engaged to implement electronic case reporting (eCR)	Quarterly
E.12a	Number of conditions published to production in Reportable Conditions Knowledge Management System (RCKMS).	Quarterly
E.13	Proportion of state reportable disease cases with an electronic initial case report (eICR) submitted	Twice per year
E.14	Demonstration of automatic processing of electronic initial case reports (eICRs) in the jurisdiction integrated surveillance system(s)	Twice per year
E.15	Proportion of test orders and results processed through Electronic Test Orders and Results Reporting (ETOR) at the PHL (this measure only applies to tests conducted at the public health laboratory)	Twice per year
E.16	Systems/programs at the PHL with ETOR interfaces	Annually
E.17	Caseload, number of cases per case investigator and number of contacts per contact tracer during the data collection period	Monthly
E.18	Timeliness, completeness, and effectiveness of case interviews among the cases sent for case investigation during the data collection period	Monthly
E.19	Timeliness of contact tracing during the data collection period	Monthly
E.20	Effectiveness of contact tracing to interrupt the transmission of COVID-19 during the data collection period	Monthly
E.21	Timeline of the case investigation process from specimen collection to contact notification during the data collection period	Monthly
E.22	Among contacts notified, proportion tested for COVID-19/SARS-CoV-2 at least once, within 14 days of notification during the data collection period	Monthly
E.23	Number of health department staff who can perform healthcare infection control assessments at state and local level	Twice per year
E.24	Number of proactive healthcare infection control assessment and response (ICAR) conducted by the health department or designee for COVID-19.	Twice per year
E.25	Number of COVID-19 outbreaks and responses in healthcare settings	Twice per year

ID	Measure	Reporting Frequency
E.26	Number of new or enhanced laboratory technologies procured, maintained, or implemented to improve laboratory response capacity	Twice per year
E.27	Number of biothreat samples shipped to designated LRN reference laboratory or CDC	Quarterly
E.28	Enhancing laboratory information infrastructure for LRN testing methodologies	Twice per year

Subject: HHS COVID-19 Update - 8/5

Dear Partner:

HHS Office of Intergovernmental and External Affairs COVID-19 update for August 5, 2021:

Highlights from President Biden's August 3rd Remarks on Fighting the COVID-19 Pandemic

- **Delta Variant and Transmissibility:** President Biden stated that because the Delta variant is highly transmissible, it is causing a new wave of cases, accounting for over 80% of cases in the United States today, with a likelihood of an increase in cases in the future. Biden states that the predicted increase is "a largely preventable tragedy that will get worse before it gets better."
- **COVID-19 and Vaccines:** Biden stated that the best way to protect yourself from COVID-19 is to get vaccinated; if vaccinated, it is highly unlikely to get COVID-19 and, if you contract the virus, you will likely experience mild symptoms if any. The data shows that the vast majority of cases, hospitalizations, and deaths due to COVID-19 are from the unvaccinated population. Biden commented, "The best line of defense against the virus is the vaccine… We have a pandemic of the unvaccinated."
- **Data of Increased Vaccination:** Biden reported a 55 percent increase in the average number of new people getting vaccinated every day in the past two weeks, and the highest seven-day total in a month. The eight states with the highest current case rates have seen a doubling of the number of people newly vaccinated each day. Biden declared that "we have to continue our aggressive efforts to vaccinate the unvaccinated."
- **Federal Steps to Incentivize Vaccination:** Biden outlined steps taken by his administration and other government-affiliated organizations to increase vaccinations. Places that have offered $100 to get vaccinated have seen an uptick of 25 percent of daily vaccination rates. Biden reiterated his plan to reimburse small- and medium-sized businesses who give paid time off to their employees to get vaccinated, to work with the Pentagon on adding COVID-19 to required vaccines for troops, and to require healthcare workers in the Department of Veterans Affairs to be vaccinated. Biden stated that these restrictions are "tough, unpopular steps to keep people safe and our economy strong."
- **States' Lack of Action on COVID:** President Biden stated that many states' harmful laws on mask mandates is disappointing and harmful; seven states have both banned mask mandates statewide and in schools while many students are not yet eligible to be vaccinated. The president cited these measures and accompanying low vaccination rates as the cause of the rise of cases, citing Florida and Texas as accounting for a third of all new cases. Biden declared that "COVID-19 is a national challenge, and we must come together — we have to come together — all of us together, as a country, to solve it."
- **Vaccination Abroad:** Biden stated that a global attack on the virus is in the United States' national interest. New, potentially more dangerous variants (such as the Delta variant) can mutate outside of the United States and threaten the country if a global approach is not taken. Biden highlighted American action in global vaccination, announcing that he will purchase and donate 500 million doses from Pfizer; he also stated that the U.S. has domestically manufactured 110 million doses for global vaccination. Biden reiterated that he's "been very clear-eyed that we need to attack this virus globally, not just at home, because it's in America's self-interest to do so."

Highlights from the White House COVID-19 Response Team Briefing

Jeff Zients

- **Update on Progress in the Fight Against COVID:** Mr. Zients highlighted how, driven by the Delta variant, cases are continuing to rise, especially among the unvaccinated. Zients states that over the past seven days, seven states — among the leaders in unvaccinated percentage — accounted for half of the new cases and hospitalizations despite holding less than a quarter of US population; vaccines are the best way to protect against COVID. Vaccinations are on the rise; the past 24 hours served as the greatest number of vaccinations in a single day since July 3 and the daily average of vaccinations has increased for the fourth week in a row. Zients said that "clearly Americans are seeing the impact of being unvaccinated and unprotected and they respond by doing their part, rolling up their sleeve, and getting vaccinated."
- **Action on Vaccination Requirements:** Mr. Zients reiterated President Biden's call for federal workers and contractors to get vaccinated and notes the further requests for similar requirements in the private sector. Zients stated that over 650 colleges and universities are requiring students and staff on campus to be vaccinated and nationwide, over 100 hospitals and healthcare systems are requiring healthcare professionals to be vaccinated. "America's businesses, large and small, universities and medical schools, and many other institutions are stepping up on vaccination requirements and our message is quite simple: we support these vaccination requirements to protect workers, communities, and the country," Zients said.
- **COVID-19 Surge Response Teams:** Mr. Zients stated that the COVID-19 Surge Response Teams are in 16 states and addressing each state's specific needs, whether that is increased testing, mobile vaccination clinics, or hospital capacity. Zients noted the hundreds of federal employees deployed to the states that are assisting in combatting COVID. "Our whole of government response," Zients said, "will continue its relentless efforts to end this pandemic and deliver progress each and every day."

Dr. Walensky

- **COVID-19 Case Update:** Dr. Walensky stated that on August 3, the CDC reported 103,455 new cases of COVID with a 7-day average of about 89,463 cases per day, representing an increase of 43.3% from last week. Hospitalizations and deaths from this week compared to the last increased significantly; deaths rose 39.3 percent. Walensky stated that 83% of counties within the United States are experiencing moderate or high transmission. Those at high risk remain people who have not yet been vaccinated. Walensky said that "now is the time to get vaccinated. We know these vaccines are working and we know that they save lives."

Dr. Fauci

- **Vaccine Hesitancy and Concern Over Development Speed:** In response to Americans worried about the speed of the development of the vaccine, Dr. Fauci outlined the various ways in which the vaccine is safe and not rushed: the investment of logistics and resources, the decades of prior research (both in platform technology and immunogen), the non-sequential investment in vaccine development, and the reuse of clinical trial sites originally built for HIV and influenza further sped the development. Fauci said that the vaccine "did not go too

fast; it was a major investment both in the logistics, the resources, and the clinical and basic research."

Dr. Murthy

- **Vaccine Efficacy:** Dr. Murthy stated that the COVID-19 vaccines protect against the Delta variant, both at reducing the risk of infection and the severity if infected. Murthy said that "breakthrough infections of vaccinated people are the exception, not the rule."
- **Meeting of Living Surgeons General:** Yesterday, Dr. Murthy met with the living former surgeons general to discuss the vaccination effort with equity being at the forefront. The meeting covered health misinformation, ensuring that communities of color and rural areas are not left behind, and engaging with trusted community messengers. Murthy stated that "this gathering of surgeons general reflected the diversity of our nation, and it was emblematic of what we have to do together to defeat the virus."

Testing and Treatment

FDA Testing Updates: As of August 3, 398 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 279 molecular tests and sample collection devices, 87 antibody and other immune response tests and 32 antigen tests. There are 53 molecular authorizations and one antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, three antigen prescription at-home tests, six antigen over-the-counter (OTC) at-home tests and two molecular OTC at-home tests. The FDA has authorized 13 antigen tests and eight molecular tests for serial screening programs. The FDA has also authorized 595 revisions to EUA authorizations.

Funding

FEMA COVID-19 Funeral Assistance Tops $888 Million: FEMA announced that COVID-19 funeral assistance has now increased to over $888 million to more than 135,000 people to assist with COVID-19-related funeral costs for deaths occurring on or after Jan. 20, 2020. The assistance, easing financial stress, comes from the Coronavirus Response and Relief Supplemental Appropriations Act of 2021 and the American Rescue Plan Act of 2021. Eligibility determinations are not driven by state/location; instead, they are based on when the applicant submits all required documentation.

Information for Specific Populations

CDC Issues Eviction Order in Areas of Substantial and High Transmission: CDC announced that Director Dr. Rochelle Walensky signed an order on August 3rd determining the evictions of tenants for failure to make rent or housing payments could be detrimental to public health control measures to slow the spread of SARS-CoV-2, the virus that causes COVID-19. This order will expire on October 3, 2021 and applies in United States counties experiencing substantial and high levels of community transmission levels of SARS-CoV-2: This temporary protection from eviction in counties with heightened levels of community transmission exists in order to respond to recent, unexpected developments in the trajectory of the COVID-19 pandemic, including the rise of the Delta variant. It is intended to target specific areas of the country where cases are rapidly increasing, which likely would be exacerbated by mass evictions.

CDC Extends Order at the Southern and Northern Land Borders: The Centers for Disease Control and Prevention (CDC) has issued an order under Sections 362 and 365 of the Public Health Service Act, and associated implementing regulations, that temporarily suspends the introduction of certain noncitizens. The order is based on the Director's determination that introduction of such noncitizens, regardless of their country of origin, migrating through Canada and Mexico into the United States creates a serious danger of the introduction of COVID-19 into the United States, and the danger is so increased by the introduction of such noncitizens that a temporary suspension is necessary to protect the public health. Unaccompanied noncitizen children already excepted under a July 16, 2021, order, remain excepted from the order's coverage.

Readout of the Sixth Covid-19 Health Equity Task Force Meeting: HHS released a readout on Friday, July 30's, sixth COVID-19 Health Equity Task Force meeting to consider interim recommendations addressing future pandemic preparedness. Task Force Members discussed and voted favorably on interim recommendations, including but not limited to exploring strategies that meet local and regional staffing needs during pandemic response, expanding adequate and evidence-based healthcare access and funding infrastructure to treat patients in congregate settings, establishing and adjusting national standards as well as strategically target funding for water, sewage, and air quality to where it's needed, based on data from reliable equity indicators.

What to Consider When Planning to Operate a COVID-19 Vaccine Clinic: CDC released information regarding what to consider when planning to operate a COVID-19 vaccine clinic. The informational sheet provides guidance to conduct a gap analysis to determine specific geographic areas and specific populations that may benefit from additional sites to improve access to vaccination, work with community leaders and trusted members of the community to help with the success of vaccination clinics, and assess the optimal time to activate a vaccination site and consider the benefits of focused vaccination efforts. The page also page also provides a checklist of best practices for vaccination clinics held at satellite, temporary, or off-site locations.

Know What to Expect at Your Child's K- 12 School or Child Care Program: CDC released information for parents on what to expect for K-12 school or childcare programs. The page provides information for factors that a child's school or care program may consider, prevention strategies for these programs, and vaccination and masking.

CMS Updates

Fiscal Year (FY) 2022 Medicare Hospital Inpatient Prospective Payment System (IPPS) and Long Term Care Hospital (LTCH) Rates Final Rule (CMS-1752-F): CMS announced that, on August 2, 2021, it issued the final rule for fiscal year (FY) 2022 Medicare Hospital Inpatient Prospective Payment System (IPPS) and Long-Term Care Hospital (LTCH) Prospective Payment System (PPS). The final rule updates Medicare payment policies and rates for operating and capital-related costs of acute care hospitals and for certain hospitals and hospital units excluded from the IPPS for FY 2022. The policies in this IPPS and LTCH PPS final rule build on key priorities to close health care equity gaps and support greater access to life-saving diagnostics and therapies during the COVID-19 public health emergency (PHE) and beyond. To continue to mitigate potential financial disincentives for hospitals to provide new COVID-19 treatments and to minimize any potential payment disruption immediately following the end of the PHE, CMS is extending the New COVID-19 Treatment Add-on Payment for eligible COVID-19 products through the end of the fiscal year in which the PHE ends.

Research

Outbreak of SARS-CoV-2 Infections, Including COVID-19 Vaccine Breakthrough Infections, Associated with Large Public Gatherings: CDC released an *MMWR* on the outbreak of SARS-CoV-2 infections, including COVID-19 vaccine breakthrough infections, associated with large public gatherings in Barnstable County, Massachusetts in July, 2021. This report was released as an *MMWR* Early Release on July 30. Variants of SARS-CoV-2 continue to emerge. The B.1.617.2 (Delta) variant is highly transmissible. In July 2021, following multiple large public events in a Barnstable County, Massachusetts, town, 469 COVID-19 cases were identified among Massachusetts residents who had traveled to the town during July 3–17; 346 (74%) occurred in fully vaccinated persons. Testing identified the Delta variant in 90% of specimens from 133 patients. Cycle threshold values were similar among specimens from patients who were fully vaccinated and those who were not. Jurisdictions might consider expanded prevention strategies, including universal masking in indoor public settings, particularly for large public gatherings that include travelers from many areas with differing levels of SARS-CoV-2 transmission. CDC Director Rachelle Walensky, MD, MPH, released an accompanying statement on the MMWR.

COVID-19 Vaccine Safety in Adolescents Aged 12–17: CDC released an *MMWR* on COVID-19 vaccine safety in adolescents aged 12–17 in the United States from December 14, 2020 - July 16, 2021. This report was released as an *MMWR* Early Release on July 30. In preauthorization trials of the Pfizer-BioNTech COVID-19 vaccine, adolescents aged 12–17 years reported local and systemic mild and moderate reactions. Myocarditis has been observed after vaccination with mRNA vaccines in post authorization monitoring. Local and systemic reactions after vaccination with Pfizer-BioNTech vaccine were commonly reported by adolescents aged 12–17 years to U.S. vaccine safety monitoring systems, especially after dose 2. A small proportion of these reactions are consistent with myocarditis. Mild local and systemic reactions are common among adolescents following Pfizer-BioNTech vaccine, and serious adverse events are rare. The Advisory Committee on Immunization Practices conducted a risk-benefit assessment and continues to recommend the Pfizer-BioNTech COVID-19 vaccine for all persons aged ≥12 years.

Full-dose Blood Thinners Reduce the Need for Organ Support in Moderately Ill COVID-19 Patients, but Not in Critically Ill Patients: NIH released a report on full-dose blood thinners reducing the need for organ support in moderately ill COVID-19 patients, but not critically ill patients. In April 2020, hospitalized COVID-19 patients received either a low or full dose of heparin, a blood thinner, for up to 14 days after enrollment. By December 2020, interim results indicated that full-dose anticoagulation did not reduce the need for organ support and may even cause harm in critically ill patients. However, one month later, interim results indicated that full doses of heparin likely benefited moderately ill patients. The full study can be viewed here.

Long-Term Study of Brain Development Records Pandemic Life: NIH released a report on the analysis of adolescent brains to examine the long-term health impacts caused by the COVID-19 pandemic and shutdowns. Through surveys and tests, the study, from Adolescent Brain Cognitive Development (ABCD) Study and funded by NIH, is capturing the impact of the COVID-19 pandemic on children using an MRI.

Case Forecasts: This week's national ensemble predicts that 350,000 to 1,800,000 new cases will likely be reported in the week ending August 28, 2021. Over the last several weeks, more reported cases have fallen outside of the forecasted prediction intervals than expected. This suggests that current forecast prediction intervals may not capture the full range of uncertainty. Because of this, case forecasts for the coming weeks should be interpreted with caution. View previous case forecasts.

Hospitalization Forecasts: This week's national ensemble predicts that the number of new daily confirmed COVID-19 hospital admissions will likely increase over the next 4 weeks, with 6,700 to 24,000 new confirmed COVID-19 hospital admissions likely reported on August 30, 2021. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of daily confirmed COVID-19 hospital admissions will likely increase in 38 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported hospital admissions are uncertain or predicted to remain stable in the other states and territories. View previous hospitalization forecasts.

Death Forecasts: This week's national ensemble predicts that the number of newly reported COVID-19 deaths will likely increase over the next 4 weeks, with 2,300 to 9,100 new deaths likely reported in the week ending August 28, 2021. The national ensemble predicts that a total of 624,000 to 642,000 COVID-19 deaths will be reported by this date. The state- and territory-level ensemble forecasts predict that over the next 4 weeks, the number of newly reported deaths per week will likely increase in 17 jurisdictions, which are indicated in the forecast plots below. Trends in numbers of future reported deaths are uncertain or predicted to remain stable in the other states and territories. View previous death forecasts.

Top Military Medical Doctor Predicts Coronavirus Longevity: DoD released a report on the analysis of COVID-19 longevity according to director of Defense Health Agency, Army Lt. Gen. Ronald J. Place. Place stated his belief that COVID-19 and other such coronaviruses likely will stay in the environment and continue to mutate. Vaccines serve as the way to protect oneself from this lingering threat.

Reduced Risk of Reinfection with SARS-CoV-2 After COVID-19 Vaccination — Kentucky, May–June 2021

Alyson M. Cavanaugh, DPT, PhD[1,2]; Kevin B. Spicer, MD, PhD[2,3]; Douglas Thoroughman, PhD[2,4]; Connor Glick, MS[2]; Kathleen Winter, PhD[2,5]

Although laboratory evidence suggests that antibody responses following COVID-19 vaccination provide better neutralization of some circulating variants than does natural infection (*1*,*2*), few real-world epidemiologic studies exist to support the benefit of vaccination for previously infected persons. This report details the findings of a case-control evaluation of the association between vaccination and SARS-CoV-2 reinfection in Kentucky during May–June 2021 among persons previously infected with SARS-CoV-2 in 2020. Kentucky residents who were not vaccinated had 2.34 times the odds of reinfection compared with those who were fully vaccinated (odds ratio [OR] = 2.34; 95% confidence interval [CI] = 1.58–3.47). These findings suggest that among persons with previous SARS-CoV-2 infection, full vaccination provides additional protection against reinfection. To reduce their risk of infection, all eligible persons should be offered vaccination, even if they have been previously infected with SARS-CoV-2.*

Kentucky residents aged ≥18 years with SARS-CoV-2 infection confirmed by positive nucleic acid amplification test (NAAT) or antigen test results† reported in Kentucky's National Electronic Disease Surveillance System (NEDSS) during March–December 2020 were eligible for inclusion. NEDSS data for all Kentucky COVID-19 cases were imported into a REDCap database that contains laboratory test results and case investigation data, including dates of death for deceased patients reported to public health authorities (*3*). The REDCap database was queried to identify previously infected persons, excluding COVID-19 cases resulting in death before May 1, 2021. A case-patient was defined as a Kentucky resident with laboratory-confirmed SARS-CoV-2 infection in 2020 and a subsequent positive NAAT or antigen test result during May 1–June 30, 2021. May and June were selected because of vaccine supply and eligibility requirement considerations; this period was more likely to reflect resident choice to be vaccinated, rather than eligibility to receive vaccine.§ Control participants were Kentucky residents with laboratory-confirmed SARS-CoV-2 infection in 2020 who were not reinfected through June 30, 2021. Case-patients and controls were matched on a 1:2 ratio based on sex, age (within 3 years), and date of initial positive SARS-CoV-2 test (within 1 week). Date of initial positive test result refers to the specimen collection date, if available. The report date in NEDSS was used if specimen collection date was missing. Random matching was performed to select controls when multiple possible controls were available to match per case (*4*).

Vaccination status was determined using data from the Kentucky Immunization Registry (KYIR). Case-patients and controls were matched to the KYIR database using first name, last name, and date of birth. Case-patients were considered fully vaccinated if a single dose of Janssen (Johnson & Johnson) or a second dose of an mRNA vaccine (Pfizer-BioNTech or Moderna) was received ≥14 days before the reinfection date. For controls, the same definition was applied, using the reinfection date of the matched case-patient. Partial vaccination was defined as receipt of ≥1 dose of vaccine, but either the

* https://www.cdc.gov/vaccines/covid-19/clinical-considerations/covid-19-vaccines-us.html?CDC_AA_refVal=https%3A%2F%2Fwww.cdc.gov%2Fvaccines%2Fcovid-19%2Finfo-by-product%2Fclinical-considerations.html#CoV-19-vaccination

† https://www.cdc.gov/coronavirus/2019-ncov/hcp/testing-overview.html

§ May and June were selected for two primary reasons. First, when vaccination supplies were low, some previously infected persons were deferring vaccination for 90 days to allow never-infected persons priority for available vaccine; however, by May 2021, deferral for 90 days was no longer a reason for those infected in 2020 to remain unvaccinated. Second, although vaccination eligibility was initially restricted based on age, comorbidities, and occupation, by April 5, 2021, all Kentucky residents aged ≥16 years became eligible for vaccination (https://chfs.ky.gov/agencies/dph/covid19/Cv19VaccineFAskedQ.pdf). Thus, vaccination status in May or June 2021 might more accurately reflect choice rather than eligibility to be vaccinated.

Summary

What is already known about this topic?

Reinfection with human coronaviruses, including SARS-CoV-2, the virus that causes COVID-19, has been documented. Currently, limited evidence concerning the protection afforded by vaccination against reinfection with SARS-CoV-2 is available.

What is added by this report?

Among Kentucky residents infected with SARS-CoV-2 in 2020, vaccination status of those reinfected during May–June 2021 was compared with that of residents who were not reinfected. In this case-control study, being unvaccinated was associated with 2.34 times the odds of reinfection compared with being fully vaccinated.

What are the implications for public health practice?

To reduce their likelihood for future infection, all eligible persons should be offered COVID-19 vaccine, even those with previous SARS-CoV-2 infection.

vaccination series was not completed or the final dose was received <14 days before the case-patient's reinfection date. Using conditional logistic regression, ORs and CIs were used to compare no vaccination and partial vaccination with full vaccination among case-patients and controls. SAS (version 9.4; SAS Institute) was used for matching and statistical analyses. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.¶

Overall, 246 case-patients met eligibility requirements and were successfully matched by age, sex, and date of initial infection with 492 controls. Among the population included in the analysis, 60.6% were female, and 204 (82.9%) case-patients were initially infected during October–December 2020 (Table 1). Among case-patients, 20.3% were fully vaccinated compared with 34.3% of controls (Table 2). Kentucky residents with previous infections who were unvaccinated had 2.34 times the odds of reinfection (OR = 2.34; 95% CI = 1.58–3.47) compared with those who were fully vaccinated; partial vaccination was not significantly associated with reinfection (OR = 1.56; 95% CI = 0.81–3.01).

Discussion

This study found that among Kentucky residents who were previously infected with SARS-CoV-2 in 2020, those who were unvaccinated against COVID-19 had significantly higher likelihood of reinfection during May and June 2021. This finding supports the CDC recommendation that all eligible persons be offered COVID-19 vaccination, regardless of previous SARS-CoV-2 infection status.

Reinfection with SARS-CoV-2 has been documented, but the scientific understanding of natural infection-derived immunity is still emerging (*5*). The duration of immunity resulting from natural infection, although not well understood, is suspected to persist for ≥90 days in most persons.** The emergence of new variants might affect the duration of infection-acquired immunity, and laboratory studies have shown that sera from previously infected persons might offer weak or inconsistent responses against several variants of concern (*2,6*). For example, a recent laboratory study found that sera collected from previously infected persons before they were vaccinated provided a relatively weaker, and in some cases absent, neutralization response to the B.1.351 (Beta) variant when compared with the original Wuhan-Hu-1 strain (*1*). Sera from the same persons after vaccination showed a heightened neutralization response to the Beta variant, suggesting that vaccination enhances the immune response even to a variant to which the infected person had not been previously exposed. Although such laboratory evidence continues to suggest that vaccination provides improved neutralization of SARS-CoV-2 variants, limited evidence in real-world settings to date corroborates the findings that vaccination can provide improved protection for previously infected persons. The findings from this study suggest that among previously infected persons, full vaccination is associated with reduced likelihood of reinfection, and, conversely, being unvaccinated is associated with higher likelihood of being reinfected.

The lack of a significant association with partial versus full vaccination should be interpreted with caution given the small numbers of partially vaccinated persons included in the analysis (6.9% of case-patients and 7.9% of controls), which limited statistical power. The lower odds of reinfection among the partially vaccinated group compared with the unvaccinated group is suggestive of a protective effect and consistent with findings from previous studies indicating higher titers after the first mRNA vaccine dose in persons who were previously infected (*7,8*).

The findings in this report are subject to at least five limitations. First, reinfection was not confirmed through whole genome sequencing, which would be necessary to definitively prove that the reinfection was caused from a distinct virus relative to the first infection. Although in some cases the repeat positive test could be indicative of prolonged viral shedding or failure to clear the initial viral infection (*9*), given the time between initial and subsequent positive molecular tests among participants in this study, reinfection is the most likely explanation. Second, persons who have been vaccinated are possibly less likely to get tested. Therefore, the association of reinfection and lack of vaccination might be overestimated. Third, vaccine doses administered at federal or out-of-state sites are

TABLE 1. Demographic characteristics of COVID-19 patients with reinfection (case-patients) and COVID-19 patients who were not reinfected (control participants) — Kentucky, May–June 2021

Characteristic	No. (%) Case-patients* (n = 246)	Control participants† (n = 492)
Age group, yrs		
18–29	46 (18.7)	89 (18.1)
30–39	37 (15.0)	83 (16.9)
40–49	43 (17.5)	80 (16.3)
50–59	44 (17.9)	88 (17.9)
60–69	27 (11.0)	51 (10.4)
70–79	28 (11.4)	58 (11.8)
≥80	21 (8.5)	43 (8.7)
Sex		
Female	149 (60.6)	298 (60.6)
Month of initial infection in 2020		
March	0 (0)	3 (0.6)
April	7 (2.8)	11 (2.2)
May	2 (0.8)	2 (0.4)
June	4 (1.6)	11 (2.2)
July	8 (3.3)	17 (3.5)
August	8 (3.3)	13 (2.6)
September	13 (5.3)	22 (4.5)
October	36 (14.6)	78 (15.9)
November	72 (29.3)	141 (28.7)
December	96 (39.0)	194 (39.4)

* Case-patients were eligible for inclusion if initial infection occurred during March–December 2020, and a subsequent positive nucleic acid amplification or antigen test result was received during May–June 2021 (using date of specimen collection). Cases for analyses were restricted to persons aged ≥18 years at time of reinfection.
† Controls were matched by sex, age (within 3 years), and time of initial infection diagnosis (within 7 days).

not typically entered in KYIR, so vaccination data are possibly missing for some persons in these analyses. In addition, inconsistencies in name and date of birth between KYIR and NEDSS might limit ability to match the two databases. Because case investigations include questions regarding vaccination, and KYIR might be updated during the case investigation process, vaccination data might be more likely to be missing for controls. Thus, the OR might be even more favorable for vaccination. Fourth, although case-patients and controls were matched based on age, sex, and date of initial infection, other unknown confounders might be present. Finally, this is a retrospective study design using data from a single state during a 2-month period; therefore, these findings cannot be used to infer causation. Additional prospective studies with larger populations are warranted to support these findings.

These findings suggest that among persons with previous SARS-CoV-2 infection, full vaccination provides additional protection against reinfection. Among previously infected Kentucky residents, those who were not vaccinated were more than twice as likely to be reinfected compared with those with full vaccination. All eligible persons should be offered vaccination, including those with previous SARS-CoV-2 infection, to reduce their risk for future infection.

TABLE 2. Association of SARS-CoV-2 reinfection* with COVID-19 vaccination status — Kentucky, May–June 2021

Vaccination status	No. (%) Case-patients	Control participants	OR (95% CI)†
Not vaccinated	179 (72.8)	284 (57.7)	2.34 (1.58–3.47)
Partially vaccinated¶	17 (6.9)	39 (7.9)	1.56 (0.81–3.01)
Fully vaccinated§	50 (20.3)	169 (34.3)	Ref
Total	**246 (100)**	**492 (100)**	—

Abbreviations: CI = confidence interval; NAAT = nucleic acid amplification test; OR = odds ratio; Ref = referent group.
* All case-patients (reinfected) and control participants (not reinfected) had previous SARS-CoV-2 infection documented by positive NAAT or antigen test results during March–December 2020. Reinfection was defined as receipt of positive NAAT or antigen test results during May 1–June 30, 2021.
† Estimated based on conditional logistic regression.
§ Case-patients were considered partially vaccinated if ≥1 dose of vaccine was received, but the vaccination series was either not completed or the final dose was received <14 days before their reinfection date. For control participants, the same criteria were applied, using the matched case-patient's reinfection date.
¶ Case-patients and control participants were considered fully vaccinated if a complete COVID-19 vaccine series was received ≥14 days before the case-patient's reinfection date.

Early Release / Vol. 70
August 6, 2021

Rapid Increase in Circulation of the SARS-CoV-2 B.1.617.2 (Delta) Variant — Mesa County, Colorado, April–June 2021

Rachel Herlihy, MD[1]; Wendy Bamberg, MD[1]; Alexis Burakoff, MD[1]; Nisha Alden, MPH[1]; Rachel Severson, MS[1]; Eric Bush, DVM[1]; Breanna Kawasaki, MPH[1]; Brynn Berger, MPH[1]; Elizabeth Austin, MPH[1]; Meghan Shea, MPH[1]; Eduardo Gabrieloff, MFA[1]; Shannon Matzinger, PhD[1]; April Burdorf, MPH[1]; Janell Nichols[1]; Kim Goode[1]; Alana Cilwick, MPH[1]; Chelsea Stacy, MPH[2]; Erin Staples, MD, PhD[3]; Ginger Stringer, PhD[1]

On May 5, 2021, the Colorado Department of Public Health and Environment (CDPHE) identified the first five COVID-19 cases caused by the SARS-CoV-2 B.1.617.2 (Delta) variant in Mesa County in western Colorado (population 154,933, <3% of the state population). All five initial cases were associated with school settings. Through early June, Mesa County experienced a marked increase in the proportion of Delta variant cases identified through sequencing: the 7-day proportion of sequenced specimens identified as B.1.617.2 in Mesa County more than doubled, from 43% for the week ending May 1 to 88% for the week ending June 5. As of June 6, more than one half (51%) of sequenced B.1.617.2 specimens in Colorado were from Mesa County. CDPHE assessed data from surveillance, vaccination, laboratory, and hospital sources to describe the preliminary epidemiology of the Delta variant and calculate crude vaccine effectiveness (VE). Vaccination coverage in early May in Mesa County was lower (36% of eligible residents fully vaccinated) than that in the rest of the state (44%). Compared with that in all other Colorado counties, incidence, intensive care unit (ICU) admissions, and COVID-19 case fatality ratios were significantly higher in Mesa County during the analysis period, April 27–June 6, 2021. In addition, during the same time period, the proportion of COVID-19 cases in persons who were fully vaccinated (vaccine breakthrough cases) was significantly higher in Mesa County compared with that in all other Colorado counties. Estimated crude VE against reported symptomatic infection for a 2-week period ending June 5 was 78% (95% confidence interval [CI] = 71%–84%) for Mesa County and 89% (95% CI = 88%–91%) for other Colorado counties. Vaccination is a critical strategy for preventing infection, serious illness, and death from COVID-19. Enhanced mitigation strategies, including masking in indoor settings irrespective of vaccination status, should be considered in areas with substantial or high case rates.

Whole genome sequencing is performed in the CDPHE laboratory on specimens submitted as part of sentinel surveillance (38 sites across Colorado, including one acute care hospital in Mesa County), as well as for cluster and outbreak response and on suspected variants (reverse transcription–polymerase chain reaction [RT-PCR]–positive specimens with S-gene target failure associated with the B.1.1.7 lineage) (*1*). The Colorado Electronic Disease Reporting System (CEDRS), a surveillance system managed by CDPHE, was used to identify reported confirmed or probable cases of COVID-19 occurring from April 27, the date of illness onset for the first Delta variant case in Mesa County, to June 6, when sequencing identified B.1.617.2 as the dominant variant in Colorado (*2*). The Colorado Immunization Information System (CIIS) was used to verify COVID-19 vaccination status; vaccine breakthrough infections were identified using personally identifying information to match cases in CEDRS to CIIS entries* (*3*). Crude VE against reported symptomatic infection was estimated and compared among Mesa County and all other Colorado counties using a screening method outlined by the World Health Organization† as a rapid tool to assess whether a vaccine is performing as expected (*4*). To better determine settings where the Delta variant was spreading, outbreak data

* SARS-CoV-2 RNA or antigen in a respiratory specimen collected from a person ≥14 days after they have completed all recommended doses of the primary series for a Food and Drug Administration–authorized COVID-19 vaccine.

† Crude VE was estimated as (1-[{PCV/(1-PCV)}/{PPV/(1-PPV)}]) following World Health Organization interim guidance on conducting VE evaluations in the setting of new SARS-CoV-2 variants where PCV is the observed percentage of cases in persons who are vaccinated and PPV is the percentage of a comparable group in the population who are vaccinated. The PPV used in the calculations for Mesa County and other Colorado counties was from May 7, 2021, approximately 2 weeks before the anticipated onset for cases included in the PCV estimate. PPV included only vaccine-eligible persons and PCV was limited to symptomatic persons who were vaccine-eligible.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-001955

during April 22–June 26 were obtained from the CDPHE outbreak database, which contains information on all reported COVID-19 outbreaks in Colorado and outbreak line lists.[§] Residential care facility vaccination data were obtained from EMResource, a capacity planning tool used by CDPHE for facility-level reporting of aggregate COVID-19 vaccinations. Incidence of SARS-CoV-2 infection and proportions of outcomes and vaccination rates among patients living in Mesa County and all other Colorado counties were compared and p-values were calculated using chi-square or Fisher's exact tests. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[¶]

During April 27–June 6, a total of 1,945 COVID-19 cases were reported in Mesa County through CEDRS (incidence = 1,255 per 100,000). Compared with that in all other Colorado counties, incidence, overall ICU admissions, and overall case fatality ratios were significantly higher in Mesa County (Table). In addition, the proportion of breakthrough cases was significantly higher in Mesa County than in all other Colorado counties. In Mesa County, the proportion of persons aged ≥65 years with COVID-19 who were fully vaccinated (27.5%) was significantly higher than that in all other Colorado counties (17.4%). The crude VE against reported symptomatic infection for a 2-week period ending June 5 was 78% (95% CI = 71%–84%) for Mesa County and 89% (95% CI = 88%–91%) for all other Colorado counties.[**]

Among 18,475 sequenced specimen results reported in Colorado through June 6, a total of 783 infections with the Delta variant were identified; more than one half (400; 51.1%) of these occurred among Mesa County residents, even though the county accounts for <3% of the state's population. Symptomatic illness was reported in 304 (76.0%) of the 400 Delta variant infections in Mesa County residents and 251 (65.5%) of 383 Delta variant infections in other counties. The 7-day percentage of sequenced sentinel specimens identified as SARS-CoV-2 B.1.617.2 in Mesa County increased from 43% for the week ending May 1 to 88% for the week ending June 5 (Figure). During the 5-week period, 67% (51 of 76) of sentinel surveillance specimens in Mesa County were identified as B.1.617.2 compared with 15% (248 of 1,637) of specimens from all other Colorado counties sequenced over the same time frame.

During April 22–June 26, a total of 37 COVID-19 outbreaks were reported in Mesa County; 13 (35%) in residential care facilities, 11 (30%) in schools, two (5%) in correctional facilities, and 11 (30%) in other settings. Twelve outbreaks, including seven in residential care facilities, had at least one Delta variant case. Average vaccination coverage in these seven residential facilities was 87% among residents (range = 50%–97%) and 50% among staff members (range = 6%–69%); attack rates among residents ranged from 0% to 54.6% (median = 1.2%) and among staff members from 2.2% to 25.5% (median = 10.0%). Five of these seven outbreaks involved at least one case in a fully vaccinated resident or staff member.[††]

Discussion

The Delta variant is highly transmissible; within 5 weeks of first identification, the Delta variant became the dominant SARS-CoV-2 variant in Mesa County, Colorado and is also now the predominant variant in the United States (*5*). Higher ICU admissions and case fatality ratios in Mesa County compared with those in the rest of the state are consistent with previous reports that infections with the Delta variant might result in more severe outcomes (*6*,*7*). The slightly lower crude VE estimate against symptomatic infection in Mesa County may lend support to previous findings that COVID-19 vaccines provide modestly lower protection against symptomatic infection with the Delta variant (*8*). Alternatively, because the Delta variant was circulating at higher levels in Mesa County than in other Colorado counties, the lower VE in Mesa County might reflect the much higher exposure to circulating virus among vaccinated persons.

The findings in this report are subject to at least four limitations. First, lack of genetic sequencing for all SARS-CoV-2 isolates likely affected estimated rates and proportions; the number of outbreaks involving the Delta variant might be underreported for this reason. Second, sentinel surveillance might not provide a fully representative sample of sequence types in Colorado because the specimens originate from hospitals and likely include more specimens from inpatients and

[§] An outbreak in a residential care facility (skilled nursing facility, assisted living residence, intermediate care facility, or group home) is defined as the occurrence of two or more confirmed cases of COVID-19 among residents and staff members in a facility within 14 days, or one confirmed case and two or more probable cases of COVID-19 among residents and staff members in a facility within 14 days. Until May 31, 2021, the definition of a school outbreak was defined as two or more confirmed COVID-19 cases among students, teachers, and staff members from separate households within 14 days in a single classroom, cohort, or activity or other close contact in the school setting; or one confirmed case and two or more probable cases of COVID-19 among students, teachers, and staff members from separate households within 14 days in a single classroom, cohort, or activity or other close contact in the school setting. Starting June 1, the definition changed from two or more to five or more cases of COVID-19, of which at least one patient has had a positive molecular amplification test or antigen test, among students, teachers, and staff members from separate households within 14 days in a single classroom, cohort, or activity or other close contact in the school setting.

§ A fully vaccinated person is one who has completed all recommended doses of a Food and Drug Administration–authorized COVID-19 vaccine, including Pfizer-BioNTech, Moderna, and Janssen (Johnson & Johnson) ≥14 days before a positive SARS-Co-V-2 test result.
¶ Vaccination status was missing for 97 persons.

emergency department patients compared with specimens from other testing sites. Third, the screening method provides rapid crude VE estimates that do not control for possible effects of confounding or clustering. Some of the differences between VE and severity of illness in Mesa County and that in other counties might be due to differences in the age distribution of patients and the inclusion of cases associated with outbreaks in congregate settings. However, CDPHE estimates that fewer than 10% of cases during the time period occurred in congregate settings. Finally, differences in vaccination coverage in some of these populations might be an additional confounding factor when estimating crude VE at the county and state levels. VE studies with more rigorous methods and the power to estimate protection against severe outcomes are needed to better understand the potential impact of the Delta variant.

Vaccination is a critical strategy for preventing infection, serious illness, and death associated with SARS-CoV-2 (including the Delta variant). Additional targeted prevention strategies (e.g., masking in indoor settings irrespective of vaccination status) and adherence to prevention strategies (e.g., surveillance testing and infection prevention and control procedures) are prudent in areas with high circulation of the Delta variant and in higher risk settings, such as residential care facilities.

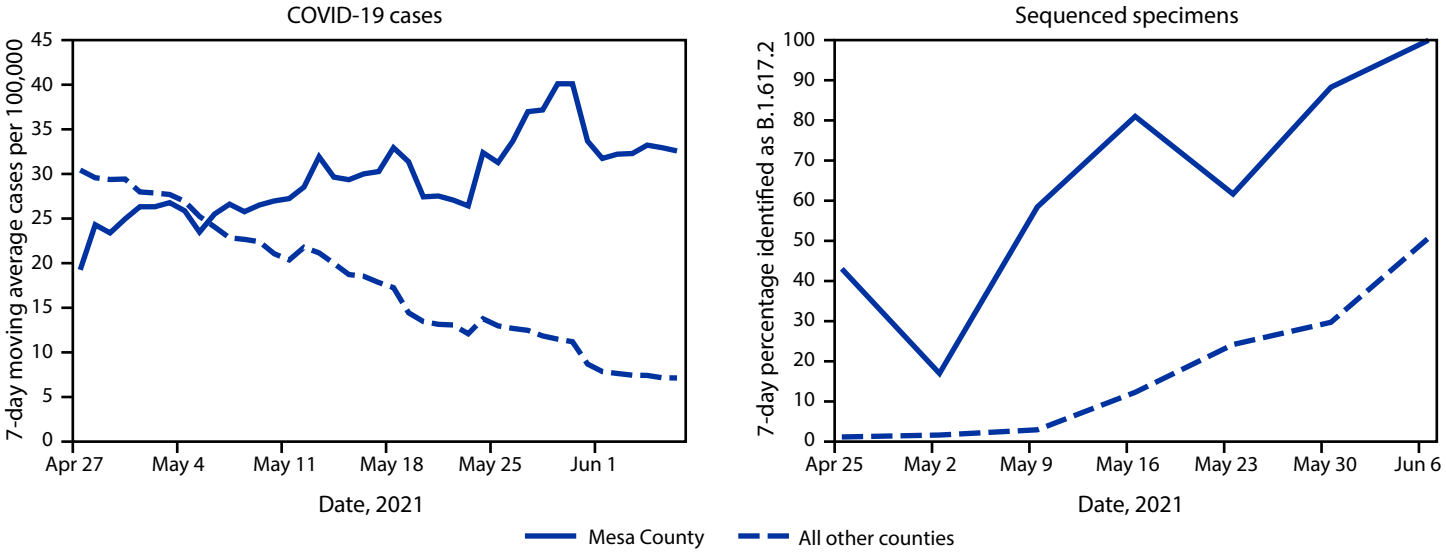
FIGURE. Number of COVID-19 cases and proportion of B.1.617.2 (Delta) variant infections in Mesa and other counties — Colorado, April 27–June 6, 2021



Summary

What is already known about this topic?

The highly transmissible B.1.617.2 (Delta) variant of SARS-CoV-2 has become the predominant circulating U.S. strain.

What is added by this report?

During April–June 2021, COVID-19 cases caused by the Delta variant increased rapidly in Mesa County, Colorado. Compared with that in other Colorado counties, incidence, intensive care unit admissions, COVID-19 case fatality ratios, and the proportion of cases in fully vaccinated persons were significantly higher in Mesa County. Crude vaccine effectiveness against symptomatic infection was estimated to be 78% for Mesa County and 89% for other Colorado counties.

What are the implications for public health practice?

Vaccination is critical for preventing infection, serious illness, and death associated with SARS-CoV-2 infection (including the Delta variant). Multicomponent prevention strategies, such as masking in indoor settings irrespective of vaccination status as well as optimal surveillance testing and infection prevention and control, should be considered in areas of high incidence.

Clinical trials of COVID-19 vaccines currently authorized for emergency use in the United States (Pfizer-BioNTech, Moderna, and Janssen [Johnson & Johnson]) indicate that these vaccines have high efficacy against symptomatic disease, including moderate to severe illness (*1*–*3*). In addition to clinical trials, real-world assessments of COVID-19 vaccine effectiveness are critical in guiding vaccine policy and building vaccine confidence, particularly among populations at higher risk for more severe illness from COVID-19, including older adults. To determine the real-world effectiveness of the three currently authorized COVID-19 vaccines among persons aged ≥65 years during February 1–April 30, 2021, data on 7,280 patients from the COVID-19–Associated Hospitalization Surveillance Network (COVID-NET) were analyzed with vaccination coverage data from state immunization information systems (IISs) for the COVID-NET catchment area (approximately 4.8 million persons). Among adults aged 65–74 years, effectiveness of full vaccination in preventing COVID-19–associated hospitalization was 96% (95% confidence interval [CI] = 94%–98%) for Pfizer-BioNTech, 96% (95% CI = 95%–98%) for Moderna, and 84% (95% CI = 64%–93%) for Janssen vaccine products. Effectiveness of full vaccination in preventing COVID-19–associated hospitalization among adults aged ≥75 years was 91% (95% CI = 87%–94%) for Pfizer-BioNTech, 96% (95% CI = 93%–98%) for Moderna, and 85% (95% CI = 72%–92%) for Janssen vaccine products. COVID-19 vaccines currently authorized in the United States are highly effective in preventing COVID-19–associated hospitalizations in older adults. In light of real-world data demonstrating high effectiveness of COVID-19 vaccines among older adults, efforts to increase vaccination coverage in this age group are critical to reducing the risk for COVID-19–related hospitalization.

COVID-NET includes data on laboratory-confirmed COVID-19–associated hospitalizations in 99 U.S. counties in 14 states, representing approximately 10% of the U.S. population.[†] COVID-NET cases were hospitalizations that occurred in residents of a designated COVID-NET catchment area who were admitted within 14 days of a positive SARS-CoV-2 test result. COVID-NET program personnel collected information on COVID-19 vaccination status (vaccine product received, number of doses, and administration dates) from state IISs for all sampled COVID-NET cases.[§] Some sites expanded collection of information on vaccination status to all reported COVID-NET cases, not only sampled cases, which were included for analysis if all cases in a single month had vaccination status available. Data from 13 sites were included for analysis; one site (Iowa) does not have access to the state IIS and cannot collect vaccination data.[¶] Population-level vaccination coverage was determined using deidentified person-level COVID-19 vaccination data reported to CDC by jurisdictions, pharmacies, and federal entities through the

IISs,** Vaccine Administration Management System,†† or direct data submission.§§

The study was restricted to adults aged ≥65 years and included the period February 1–April 30, 2021. The Janssen vaccine was authorized for use during the study period beginning March 15, 2021.¶¶ Patients were classified as 1) unvaccinated (no IIS record of vaccination), 2) partially vaccinated (1 dose of Moderna or Pfizer-BioNTech received ≥14 days before hospitalization or 2 doses, with the second dose received <14 days before hospitalization), or 3) fully vaccinated (receipt of both doses of Moderna or Pfizer-BioNTech with second dose received ≥14 days before hospitalization or receipt of a single dose of Janssen ≥14 days before hospitalization). Patients with only 1 dose of any COVID-19 vaccine received <14 days before hospitalization were excluded. Daily county-level coverage data for adults aged 65–74 and ≥75 years in the COVID-NET catchment area were estimated using population denominators from the U.S. Census Bureau; vaccination status was classified as described for hospitalized cases.*** For vaccine records missing county of residence, county of vaccine administration was used.

To estimate vaccine effectiveness and corresponding 95% CIs, methods were adapted based on previously published literature (*4*). Poisson regression was used to compare case counts by vaccination status (outcome) and the proportion of the population vaccinated and unvaccinated (offset).††† Data were stratified by age group because of the potential for confounding by age, and adjusted for COVID-NET site, time (number of weeks since the start of the study period as a categorical covariate), and monthly site-specific sampling frequency.§§§ Vaccine effectiveness was calculated as one minus the exponent of the estimated coefficient of the exposure (vaccination status) variable. For estimating effectiveness of full vaccination, partially vaccinated persons were excluded; for estimating effectiveness of partial vaccination, fully vaccinated persons were excluded. Vaccine product–specific estimates excluded persons who had received other COVID-19 vaccines. To account for the interval between infection and hospitalization, sensitivity analyses were conducted using a reference date 1 week and 2 weeks before admission, rather than admission date, for classification of vaccination status for cases (i.e., adding 7 and 14 days, respectively between last vaccine dose and hospital admission date); the same adjustment was included for population vaccination coverage. Statistical analyses were conducted using SAS software (version 9.4; SAS Institute). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.¶¶¶

During February 1–April 30, 2021, among 7,280 eligible COVID-NET patients, 5,451 (75%) were unvaccinated, 867 (12%) were partially vaccinated, and 394 (5%) were fully vaccinated; 568 (8%) who received a single vaccine dose <14 days before hospitalization were excluded from the analysis (Table). Vaccination coverage in the population increased rapidly during this period among persons aged ≥65 years and varied by age and vaccine product (Figure 1). Among adults aged ≥65 years in the COVID-NET catchment area, full vaccination coverage from any of the three authorized vaccines ranged from 0.7% on February 1, 2021, to 72% on April 30, 2021.

Effectiveness of full vaccination in preventing hospitalization among adults aged 65–74 years was estimated at 96% (95% CI = 94%–98%) for Pfizer-BioNTech, 96% (95% CI = 95%–98%) for Moderna, and 84% (95% CI = 64%–93%) for Janssen vaccine products. Among adults aged ≥75 years, effectiveness of full vaccination was 91% (95% CI = 87%–94%) for Pfizer-BioNTech, 96% (95% CI = 93%–98%) for Moderna, and 85% (95% CI = 72%–92%) for Janssen vaccine products (Figure 2). Effectiveness of partial vaccination among adults aged 65–74 years was 84% (95% CI = 76%–89%) for Pfizer-BioNTech and 91% (95% CI = 87%–93%) for Moderna vaccine products. Among those aged ≥75 years, effectiveness

** IISs are confidential, computerized, population-based systems that collect and consolidate vaccination data from providers in 64 public health jurisdictions nationwide and can be used to track administered vaccines and measure vaccination coverage. https://www.cdc.gov/vaccines/covid-19/reporting/overview/IT-systems.html

††† Population vaccine effectiveness is defined as the reduction in disease risk among vaccinated versus unvaccinated persons in the population. Vaccine effectiveness is typically estimated by examining the proportion of persons with disease among those who are vaccinated and the proportion of persons with disease among those who are unvaccinated. If these numbers are difficult to measure or estimate and only case vaccination information is available, then an alternative approach, called the "screening method," uses estimates of 1) the proportion of persons with disease who are vaccinated and 2) the proportion of persons in the population who are vaccinated. This analysis applied a variation of the screening method through a Poisson regression model, which allows the estimates to account for potential confounding. Specifically, the Poisson regression model uses case counts (both vaccinated and unvaccinated) as the outcome, vaccination status as the exposure variable, and the logarithms of the proportion of vaccinated and unvaccinated persons in the population as offsets. The Poisson model includes the potential confounders time and COVID-NET site as fixed effects because vaccination coverage data are available in each time-by-site stratum. A generalized estimating equation approach with autoregressive correlation structure accommodated daily variations of disease rates and vaccine coverage because this study occurred during a time of very rapid change. Finally, the adjusted vaccine effectiveness estimate was calculated as 1 - exp(β), in which β is the regression coefficient of the vaccination status exposure variable.

§§§ Sampling weights were created based on the probability of selection. Weights were adjusted for nonresponse; adjusted to population catchment totals based on combinations of surveillance site, time period of admission, age, sex, and race/ethnicity via raking procedures; and trimmed to reduce variability.

Abbreviation: COVID-NET = Coronavirus Disease 2019–Associated Hospitalization Surveillance Network.

* Among 7,280 eligible COVID-NET patients, 568 patients (251 aged 65–74 years and 317 aged ≥75 years) who received only 1 dose of any COVID-19 vaccine <14 days before hospitalization were excluded from analysis.

† COVID-NET data included in this analysis were from the following states: California, Colorado, Connecticut, Georgia, Maryland, Michigan, Minnesota, New Mexico, New York, Ohio, Oregon, Tennessee, and Utah.

§ Partially vaccinated patients received 1 dose of Moderna or Pfizer-BioNTech vaccine ≥14 days before hospitalization or 2 doses, with the second dose received <14 days before hospitalization.

¶ Fully vaccinated patients received both doses of Moderna or Pfizer-BioNTech vaccine, with second dose received ≥14 days before hospitalization, or receipt of a single dose of Janssen (Johnson & Johnson) vaccine ≥14 days before hospitalization.

** The Janssen vaccine was authorized for use after the study began; cases were included during March 15–April 30, 2021.

of partial vaccination was 66% (95% CI = 48%–77%) for Pfizer-BioNTech and 82% (95% CI = 76%–86%) for Moderna vaccine products. Sensitivity analyses accounting for interval between infection and hospitalization did not yield notably different vaccine effectiveness estimates, with point estimates varying by <1% for Pfizer-BioNTech and Moderna vaccine models. Point estimates for Janssen COVID-19 vaccine models varied by <10%, with few cases eligible for inclusion and wide CIs.

Discussion

In this analysis of 7,280 laboratory-confirmed COVID-19–associated cases among hospitalized adults aged ≥65 years, all three COVID-19 vaccine products currently authorized for use in the United States had high effectiveness in preventing laboratory-confirmed COVID-19–associated hospitalizations. The effectiveness of full vaccination with mRNA vaccines (Pfizer BioNTech and Moderna) was ≥91% and of Janssen was ≥84% among adults aged ≥65 years. These findings are consistent with estimates from other observational studies of the mRNA vaccines and provide an early estimate of the effectiveness of Janssen in preventing COVID-19–associated hospitalization (*1*–*3*,*5*). Although the method used in this analysis does not account for many important potential confounders and results should be interpreted with caution, taken together, these findings provide additional evidence that available vaccines are highly effective in preventing COVID-19–associated hospitalizations and demonstrate that performance of COVID-19 vaccines can be assessed using existing disease surveillance and immunization data.

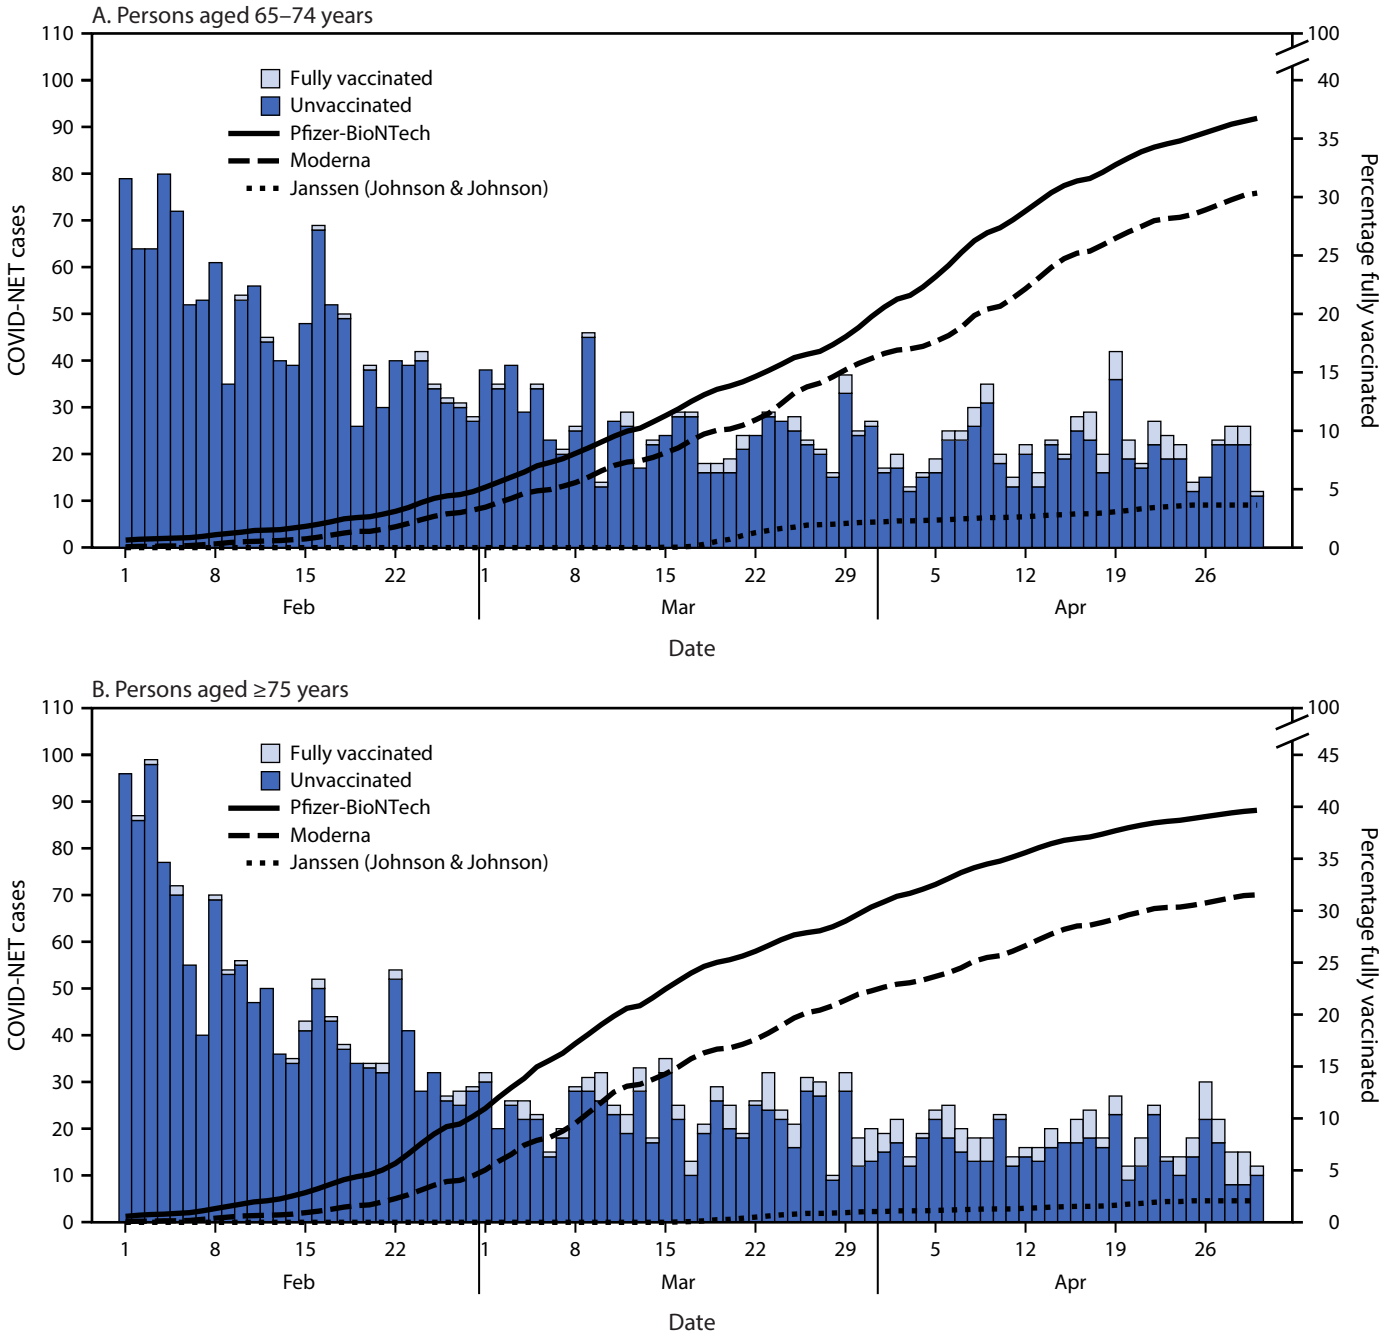
This analysis provides an early estimate of the Janssen vaccine effectiveness in preventing hospitalization in older adults, adding to the limited observational data available assessing Janssen vaccine effectiveness.**** These findings are consistent with clinical trial efficacy data, which found an efficacy of 76.7% for prevention of moderate to severe disease ≥14 days after vaccination (*3*). The relatively few cases and low population vaccination coverage with Janssen in this analysis likely contributed to the wide CIs for the vaccine effectiveness estimate. In addition, given vaccine prioritization for populations at high risk, older adults receiving the Janssen product were more likely to be at lower risk and differ substantially from those receiving products available earlier in the vaccine rollout. Other observational studies have demonstrated variability in the effectiveness of partial vaccination with mRNA vaccines in preventing hospitalization, with point estimates of effectiveness of 64% to 91% (*5*,*6*). Variation in estimates of effectiveness of partial vaccination between Pfizer-BioNTech and Moderna in this analysis might represent confounding from differences among the persons receiving these products. Residents of long-term care facilities (LTCFs) were prioritized early in the vaccine rollout and were more likely to receive Pfizer-BioNTech than Moderna.†††† The underlying risk for severe illness from COVID-19 in this medically fragile population could contribute to lower vaccine effectiveness among LTCF residents than among the general population of older adults and to an apparently lower effectiveness of Pfizer-BioNTech. Moreover, if partial protection increases between the third and fourth week after receipt of the first dose, it is possible that the timing of the second Pfizer-BioNTech and Moderna doses (21 and 28 days after the first dose, respectively) could affect the observed effectiveness of partial vaccination. Therefore, these results should not be interpreted as definitive evidence of a difference in the effectiveness of partial vaccination between the two mRNA vaccines, but rather as an indication that further evaluation is warranted.

**** https://www.medrxiv.org/content/10.1101/2021.04.27.21256193v1

†††† Among COVID-NET patients living in LTCFs, more residents received Pfizer-BioNTech vaccine than received Moderna vaccine, consistent with state distribution through the federal Pharmacy Partnership for Long-Term Care Program. https://www.cdc.gov/vaccines/covid-19/long-term-care/pharmacy-partnerships-faqs.html

MS-DOH-21-1816-A-001961

FIGURE 1. COVID-NET* cases and full vaccination coverage among persons aged 65–74 years (A) and persons aged ≥75 years (B) — 13 states, February 1–April 30, 2021

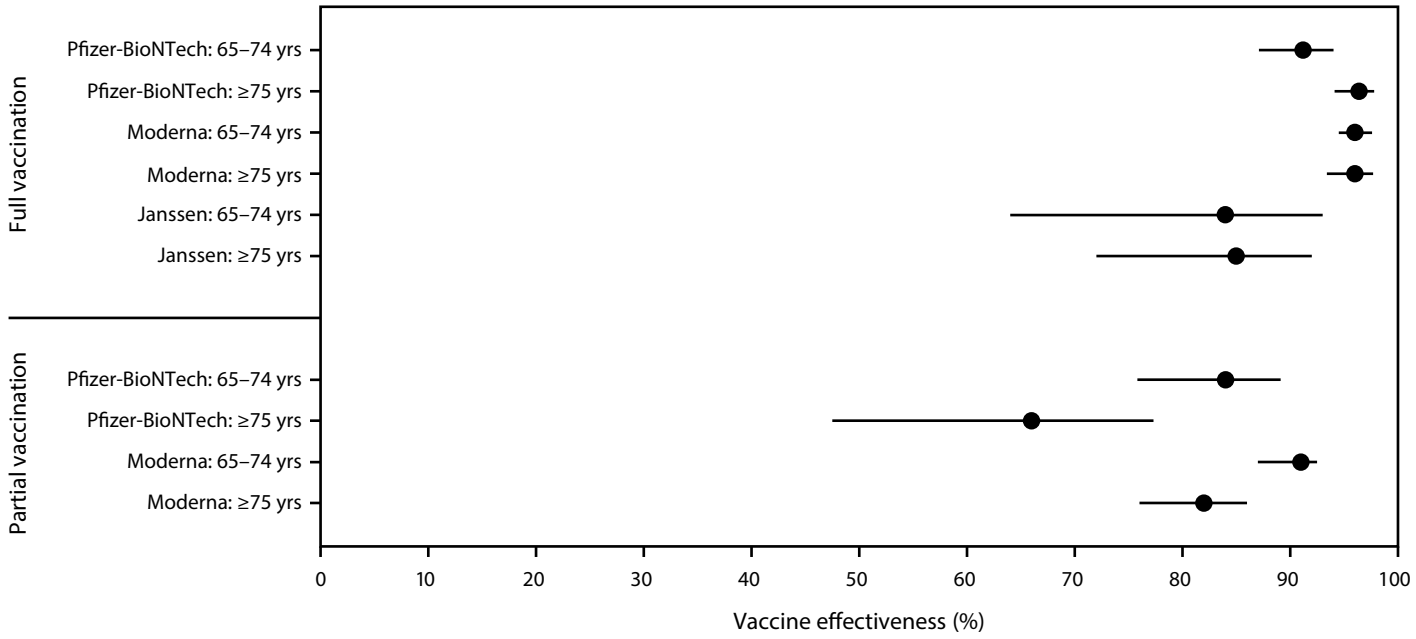


Abbreviation: COVID-NET = Coronavirus Disease 2019–Associated Hospitalization Surveillance Network.
* COVID-NET data included in this analysis were from the following states: California, Colorado, Connecticut, Georgia, Maryland, Michigan, Minnesota, New Mexico, New York, Ohio, Oregon, Tennessee, and Utah.

The findings in this report are subject to at least four limitations. First, although adjustments were made for time and site, the analysis did not adjust for other potential confounders, such as chronic conditions, because person-level data were not available for the catchment population. In addition, although the analysis was stratified by age and adjusted for time and site, the heterogeneity of disease risk, vaccination coverage within each site, and differences in the populations who received different vaccine products might confound estimates of vaccine effectiveness. Second, the study period for this analysis

MS-DOH-21-1816-A-001962

FIGURE 2. Estimates of vaccine effectiveness in preventing COVID-19–associated hospitalization among patients aged ≥65 years for the COVID-NET catchment area, by vaccine product and age group using the screening method — COVID-NET, 13 states,* February 1–April 30, 2021†



Abbreviation: COVID-NET = Coronavirus Disease 2019–Associated Hospitalization Surveillance Network; Janssen = Janssen (Johnson & Johnson).
* COVID-NET data included in this analysis were from the following states: California, Colorado, Connecticut, Georgia, Maryland, Michigan, Minnesota, New Mexico, New York, Ohio, Oregon, Tennessee, and Utah.
† Confidence intervals indicated by error bars.

Summary

What is already known about this topic?

Clinical trials of COVID-19 vaccines currently authorized for emergency use in the United States (Pfizer-BioNTech, Moderna, and Janssen [Johnson & Johnson]) have shown high efficacy in preventing symptomatic (including moderate to severe) COVID-19.

What is added by this report?

Among adults aged 65–74 years, effectiveness of full vaccination for preventing hospitalization was 96% for Pfizer-BioNTech, 96% for Moderna, and 84% for Janssen COVID-19 vaccines; among adults aged ≥75 years, effectiveness of full vaccination for preventing hospitalization was 91% for Pfizer-BioNTech, 96% for Moderna, and 85% for Janssen COVID-19 vaccines.

What are the implications for public health practice?

Efforts to increase vaccination coverage are critical to reducing the risk for COVID-19–related hospitalization, particularly in older adults.

occurred before the predominance of the B.1.617.2 (Delta) variant; changes in circulating SARS-CoV-2 variants might affect vaccine effectiveness when assessed over time. Third, persons choosing to receive vaccine later in the rollout might have different risk characteristics than do those vaccinated earlier and might have experienced differences in access to vaccine products by time and location. Finally, this analysis was limited to adults aged ≥65 years, and the results are not generalizable to younger age groups.

This analysis found that all COVID-19 vaccines currently authorized in the United States are highly effective in preventing COVID-19–associated hospitalizations in older adults and also demonstrates the utility of this method in generating a relatively rapid assessment of vaccine performance in the setting of high-quality surveillance and vaccine registry data. Efforts to increase vaccination coverage are critical to reducing the risk for COVID-19–related hospitalization, particularly in older adults.

Detection & Mitigation of COVID-19 in Confinement Facilities

Thursday, August 5, 2021

Welcome	Angelica O'Connor, ELC
Background	Ruby Qazilbash, Department of Justice
Purpose	
Required & optional activities	
Technical assistance	
Reporting requirements	Dr. Jason Snow, ELC
Grants management	
Questions	

Welcome

Angelica O'Connor

ELC Program Coordinator

Detection & Mitigation of COVID-19 in Confinement Facilities

Ruby Qazilbash

Associate Deputy Director, Bureau of Justice Assistance, U.S. Department of Justice

Background

- $700M made available through *American Rescue Plan Act of 2021*
- Project period: August 1, 2021 – July 31, 2024 (36 months)
- All 64 ELC recipients to respond to COVID-19 in confinement facilities*
  - *Defined as adult prisons and jails; juvenile confinement facilities; police lock-ups; and community confinement facilities
- Award formula = $\frac{\text{recipient's incarcerated population}}{\text{total national incarcerated population}}$

Purpose

- From March to June 2020, 11% of COVID tests in jails were positive
- By December 2020, state & federal prisoners' COVID positivity rate was four times higher than the general population
- As facilities now open for visitors and service/care providers, mitigation of new transmission of COVID must be addressed

Required Activity

1. Assist confinement facilities in establishing and implementing COVID diagnostic and screening testing programs for residents / detainees / inmates, staff, and visitors

Optional Activities

- Conduct COVID-19 testing and contact tracing within confinement facilities.
- Support facilities in planning and implementing recommended isolation and quarantine strategies including for confirmed and suspected cases and close contacts.
- Implement distancing policies and support staff training to maintain distancing practices.
- Support staffing strategies that reduce the risk of virus transmission (e.g., organize staff assignments so that the same staff are assigned to the same areas of the facility over time).
- Support transportation policies and practices consistent with recommendations to reduce transmission.
- Implement visitor policies consistent with recommendations to reduce virus risk.
- Implementation of infection control practices inside facilities.
- Develop and implement procedures and systems to improve confinement facility preparedness and response efforts.
- Coordinate preparedness and response efforts with state, local, tribal, and territorial public health departments to prevent, prepare for, and respond to COVID-19 within confinement facilities.
- Enhance/improve the practices of confinement facilities to mitigate the spread of COVID-19, and to reduce the risk of virus transmission and exposure to environmental health hazards.

Optional Activities (continued)

- Purchase of additional supplies to sanitize and clean the confinement facilities. Funding must not supplant existing expenditures on such supplies and can only be used to support enhanced cleaning efforts.

- Educate and train confinement facility staff and residents/detainees/inmates on sanitation and minimizing the spread of infectious diseases.

- Implement COVID-19 mitigation practices to minimize potential opportunities for exposure including video conferencing technology and other measures for attorney/client purposes, court appearances, family visiting, and programming.

- Based on state and local laws and regulations, and training and technical assistance provided by the DOJ, review and analyze policies and practices and implement policy and practice changes to safely reduce populations in confinement facilities to mitigate the spread of COVID-19. This could include creating policies and practices that may divert individuals from confinement, determine the optimal population for the facility given physical plant/structure and public health guidelines, and the revision of appropriate release practices. The DOJ will make training and technical assistance available to grantees to help ensure these activities comport with state and local laws and evidence-based practices and are administered solely by state and local correctional agencies.

Technical Assistance

- CDC guidance on the Management of COVID-19 in Correctional and Detention Facilities
- ELC as a source of regular program management and oversight support
- Bureau of Justice Assistance as a source of support with:
  - Technical assistance during workplan development, upon request
  - Workplans and budgets review alongside ELC team
  - Technical assistance during implementation, upon request
  - BJA hiring designated term position to assist recipients and their health departments

Detection & Mitigation of COVID-19 in Confinement Facilities

Jason Snow

Program Manager, ELC Cooperative Agreement

Allowable Costs (See guidance for full listing)

- Personnel (term, temporary, students, overtime, consultant and/or contract staff, etc.) related to testing and mitigation efforts.
- Laboratory equipment used for COVID-19 testing and necessary maintenance contracts.
- Collection supplies, test kits, reagents, consumables, and other necessary supplies for existing or new screening testing or onboarding new platforms to support testing.
- Personal Protective Equipment (PPE) (e.g., masks, gloves, gowns) for those collecting samples and/or conducting testing.
- Hardware and software necessary for reporting to public health and communication and coordination of follow up on any positive cases detected.
- Testing & mitigation effort outreach expenses
- Resident, inmate, or detainee needs resulting from COVID-19-related restricted access to and/or limited mobility within the facility
  - Includes communication access to/by family, legal representation, & service providers

Grants Management - Budget

- Funds will be awarded
  - In the *Project E: Emerging Issues* tab of the ELC budget workbook
  - On line 'E.1_O1' in the 'Other' cost category section

- At time of NOA issuance, funds will be accessible in the Payment Management System (PMS) and can be used, in accordance with guidance, during the 90-day period for preparing the workplan & budget.

Grants Management – Budget (continued)

- Within 90 days of receiving the NOA, submit your 'Budget Revision Amendment' in GrantSolutions. Your Amendment must include:
  - Revised budget using the ELC budget workbook that was provided in GrantSolutions as a Grant Note
  - Budget Information SF-424A using the form generated by ELC budget workbook or a PDF – **not the e-form in GrantSolutions**
  - Cover letter signed by the Authorized Official of record

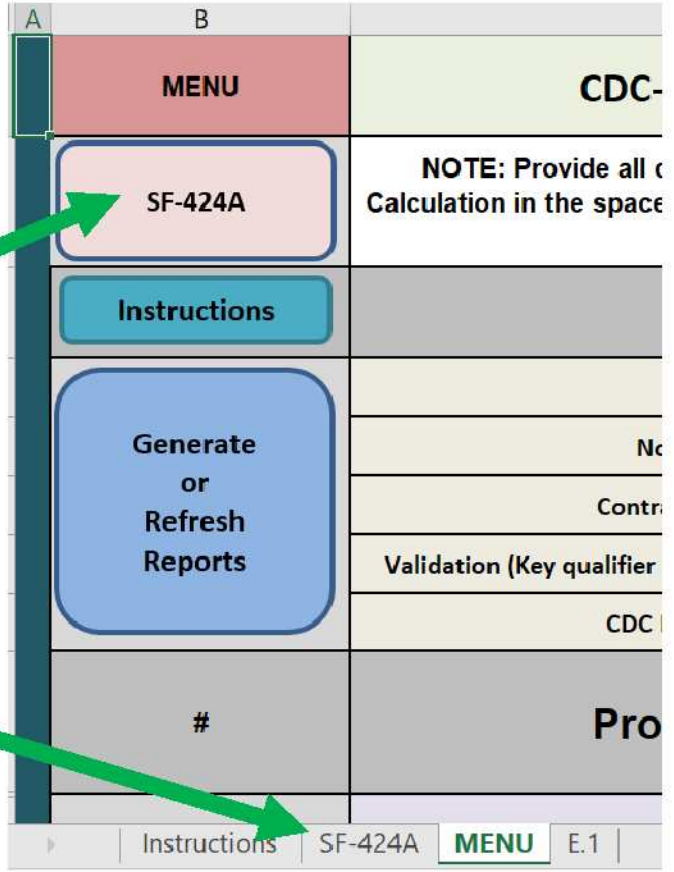
- If a recipient does not have written approval for an extension from CDC and misses the 90-day deadline for workplan and revised budget submission, their PMS account **may be restricted**.

Reminder - SF-424A

- Do not use the hyperlink for the SF-424A in GrantSolutions as it creates issues for award processing.

- ELC budget workbook
  1. Use the 'SF-424A' button on the 'Menu' page to generate.
  2. Go to the 'SF-424A' tab.
  3. Print the tab as a PDF.
  4. Upload in GrantSolutions under the 'SF-424A' in the amendment submission section.

Note: clicking the 'refresh and generate reports' button in Excel will create reports of *all* worksheets. Follow steps 1-4 here to generate a report for *only* this budget worksheet.



Grants Management - Workplan

- Within 90 days of receiving the NOA, submit your workplan into REDCap's 'Detection & Mitigation of COVID-19 in Confinement Facilities' portal.

- A letter signed by all ELC Governance Team members indicating that they have each contributed to and agreed upon the workplan *and* revised budget must be submitted in REDCap.

- Reminder: 1 required activity and up to 14 optional activities

Reporting Requirements

Authorized Official's signed Acknowledgement of Guidance letter through a GrantSolutions Grant Note	Due 5 days after NOA is received
Financial reporting	Due the 5th of each month, starting October 5th
Any applicable performance measures	TBD
Workplan, revised budget, & agreement letter signed by all ELC Governance Team members	Due 90 days after NOA is received, likely mid-November
Quarterly workplan/milestone progress reporting	Due quarterly, starting January 31st

Questions & Answers

Webinar recording and slides will be sent tomorrow, August 6th

Weekly Office Hours

To address recipients' questions and provide regular technical assistance, the DOJ and ELC will cohost weekly Office Hours.

Office hours will be held each Thursday, 4:00-5:00pm ET, August 26 through Thursday, September 23.

A recurring calendar invitation to these optional Office Hours will be sent from the ELC mailbox. Please not these Office Hours are intended for ELC recipients only.

Detection & Mitigation of COVID-19 in Confinement Facilities

Webinar Q&A Summary

If you'd like to listen to our full Q&A session, it begins at the 23-minute mark of the webinar recording.

The ELC will be providing funding directly to its 64 recipients. These recipients (i.e., state, large local, and territorial and freely associated state health departments) will then develop workplans and budgets that address the needs of their own jurisdictions' state, tribal, or locality's correctional and confinement facility's needs. Federal confinement facilities are not eligible to receive financial or programmatic support under this supplement.

The project period is August 1, 2021 – July 31, 2024. 85% of the total funding a recipient receives must go towards direct financial support for COVID-19 detection & mitigation efforts in confinement facilities (defined as any of these facilities), which also includes staffing to support supplement activities whether in the health department or confinement facility. 15% of the total funding a recipient receives must go towards expenses associated with reporting, managing, and other associated costs in launching and maintaining efforts under this supplement.

It is each ELC recipient's discretion how they prioritize selecting, distributing funding, and engaging with specific stakeholders (including state associations of counties, departments of corrections, state sheriff's associations, etc.); confinement facilities (defined as any of these facilities), and populations; the guidance does require, however, that recipients strive to support the largest extent of eligible confinement facilities as possible in their jurisdiction. The Department of Justice is available to provide technical assistance and support as recipients make these decisions.

Examples of costs that would be **in scope** for this award,
as asked about during the webinar:

- Hiring of infection prevention coordinators within confinement facilities
- Gloves, masks, gowns, and other PPE for those collecting samples/conducting testing
- Financial support to organizations that provide guidance and oversight to county detention facilities,
- Personnel to conduct testing or collect samples
- Ventilation upgrades that support the mitigation and prevention of COVID in confinement facilities
- Interoperable data systems for surveillance of testing efforts
- Telehealth systems to mitigate restricted access to and/or limited mobility within facilities, including communication access to/by family, legal representation, & service providers

Examples of costs that would be **out of scope** for this award,
as asked about during the webinar:

- Sick leave and/or personal time off required of confinement facility staff after exposure to a suspected or confirmed COVID case
- Direct incentives (e.g., monetary gift) to increase testing in confinement facilities
- Any costs to support isolation and/or quarantine of staff and/or residents of confinement facilities (including but not limited to food, paid leave, bill payment, medical supplies, etc.)
- Anti-human trafficking efforts, including but not limited to safe houses
- Clinical services of any kind, including administering vaccines and providing medical care

Additional examples of allowable costs can be found in the supplement's guidance. Where activities or costs overlap with other existing ELC supplements, workplans and budgets must clearly state how they are not duplicative (e.g., if including whole genome sequencing under this supplement, the recipient must provide evidence of how this does not duplicate *ELC AMD Sequencing and Analytics* activities). Spending can begin as soon as NOAs are granted.

Please contact your ELC Project Officer, the ELC mailbox (elc@cdc.gov) with any questions, concerns, or requests for technical assistance from the Department of Justice.

DETECTION AND MITIGATION OF COVID-19 IN CONFINEMENT FACILITIES
WEBINAR TRANSCRIPT

Cameron Warner: Today, we will be discussing the newest supplemental award administered through the ELC, Detection and Mitigation of COVID-19 in Confinement Facilities. This effort really represents a partnership between HHS and the Department of Justice that we hope will provide much needed support to confinement facilities. I want to thank our colleague and SMEs from the Department of Justice that are on the line for joining in particular Ruby Qazilbash. She's been a great partner to work with already.

Cameron Warner: I'll turn things over to her to cover the background and purpose of the funding and the activities and technical assistance. Then she'll turn it over to Jason for reporting requirements and grants management. Of course, we will also have time at the end for questions. Without further ado, here's Ruby.

Ruby Qazilbash: Thanks so much Cameron and Angelica. Good afternoon everyone Thank you so much for joining us. Today, perhaps you're joining today, or perhaps you're listening or watching a recording afterwards day today, which is Thursday August 5.

Ruby Qazilbash: It was recently announced, and why you're tuning in, by the White House that CDC is making $700 million available through the American Rescue Plan Act. And this is to respond specifically to the disproportionate impact of on the nation's confinement facilities. These funds are awarded, as you know, to the 64 current ELC cooperative agreement recipients. For those on today's webinar - or listening after the fact, who are not current recipients - ELC is the Epidemiology and Laboratory Capacity for Prevention and Control of Emerging Infectious Diseases Program. At the CDC the 64 current ELC cooperative agreement recipients are the public health authorities in the states, the territories, District of Columbia, and the eight most populous U.S. local jurisdictions. And important to note that the formula for determining the allocation for these funds per recipient was determined by the recipient share of the total national custodial or incarcerated population.

Ruby Qazilbash: And then, with regard to confinement facilities, how are we defining them or what do we rely on? The guidance sites title 28 section 115.5 for the definition of confinement facilities and it includes adult prisons and jails, juvenile confinement facilities, police lockups, and community confinement facilities. But the guidance also really importantly outlines that state recipients must support units of local government within their jurisdiction to reach the fullest complement of confinement facilities within the state. In order to do that, cooperative agreement recipients of these funds will need to determine the best strategy. We hope to provide support for that. As we see it, this could include the recipient partnering with their public safety authority or state administering agencies - those are designated by the nation's governors and the states and territories; a component of the governor's or the mayor's office; a freestanding criminal justice planning entity; or a division of the state’s department of public safety. At the local level, criminal justice coordinating Councils might be the appropriate or an appropriate partnering authority.

Ruby Qazilbash: We really want to get up the purpose, and I'd like to say, on behalf of the Department of Justice, and specifically the Bureau of justice assistance, that we're really honored to be a partner of the ELC program at the CDC on this effort. We have seen the disproportionate impact of COVID on the nation's confinement facilities. From March to June of 2020, 11% of covert tests in jails were positive. By December of 2020, state and federal prisoners’ COVID positivity rate was four times higher than that of the general US population. Detainees -- residences of confinement facilities have been heavily impacted, our public safety staff who work in confinement facilities have been heavily impacted. These are congregate settings that we're talking about. Most of them, jails, prisons, community confinement facilities, juvenile detention facilities, these are 24-hour environments, with people living in them and people working all three shifts to staff them. As COVID entered and moved through facilities, leadership and staff implemented protocols, including testing upon booking, quarantining prior to entry into the general facility population, separating individuals that tested positive.

Ruby Qazilbash: Many facilities that didn't already have strong partnerships with public health authorities learned to work together pretty quickly to test, to track, to report, to coordinate vaccine distribution when vaccines became available… All working to keep people safe. There was immense impact on the daily operations of these facilities, both for people living in them, and certainly for people working in them. For many, there was a stop to a lot of things - to visitors, in-person programming, in-person court appearances. For many, there was extreme limitation on movement within facilities to keep people safe. So as facilities are now beginning to open back up again to visitors, to service and care providers, mitigation of new transmission of COVID has really got to be addressed and that is what the intention is of this funding.

Ruby Qazilbash: It's really important to note that, under this guidance, there is one required activity and 14 optional activities that are outlined within the guidance. All activities pertain to COVID-19 detection and mitigation. The funds do not support vaccinations or clinical care. The, as listed here, the required activity is to assist confinement facilities in establishing and implementing COVID diagnostic and screening testing programs for the people who live, work, and visit these facilities.

Ruby Qazilbash: The first set of optional activities include conducting COVID-19 testing and contact tracing, supporting facilities in planning and implementing recommended isolation and quarantine strategies, implementing distancing policies and training staff on them, supporting staffing transportation and visiting strategies that reduce the risk of virus transmission, implementation of infection control practices inside the facilities and coordinating those preparedness and response efforts with the relevant state, local, tribal, or territorial public health departments, and enhancing and improving the practices of confinement facilities to mitigate the spread of COVID. There are other optional activities that really have more to do with mitigation, I would say: purchase of additional supplies around sanitizing and cleaning, educating and training staff - as well as residents/detainees -on sanitation. We're interested to see the plans that you all come up with, but some ideas that we've listed here are ways that you can implement mitigation practices to minimize potential opportunities for exposure. That could mean implementation of technology to make things that need to happen able to happen, such as measures for attorney client purposes for court appearances, to facilitate family and other visiting, as well as programming, that's really taken a hit during the lockdown and facilities. Lastly here, importantly, recommendations from the national academies of sciences special report: jurisdictions can implement mitigation strategies that reduce the size of the population in custody and part as a way to achieve greater physical distance between individuals within facilities. And this can include creating and implementing policies and practices that may divert people from confinement, to determine and take strategies to determine the optimal population for the facility given its particular physical plant or structure and the current public health guidelines locally, and then revising release practices to achieve a reduction in the number of people confined within those facilities. It's important to know that this last option will obviously need to take state and local laws and regulations into account.

Ruby Qazilbash: With regard to technical assistance, we want to make a distinction of where and from whom recipients and sub recipients will and can receive it. So, as these are CDC awards, ELC will continue as the source or regular program management and oversight, so including compliance with terms and conditions, the award fiscal performance, and programmatic oversight. The Bureau of Justice Assistance is for the provision of technical assistance: to do things like help inform partnerships to ensure that the funds get to the confinement facilities that they're intended to reach as expeditiously as possible. We'll also review work plans and budgets, alongside the ELC team, and will provide ongoing technical assistance during implementation. I'm going to pass the baton to Dr. Jason Snow, who's going to review those allowable costs and then other aspects of grants management for these awards.

Jason Snow: Thank you very much. Ruby. Good afternoon, this is Jason Snow. I'm the ELC Program Manager. The ELC, in coordination with our colleagues in the Office of Grants Services, are completing a process this week of finalizing our End of Year - also referred to EOY - notice of awards. Awards have already started going out today, and they will continue on a rolling basis through the first part of next week. As in prior

years, our End of Year awards are made up using fallout funds from various programs and projects under the ELC, to augment funds that were previously provided in the last month in the budget period three funding. Part of the end of your awards this year consist of special COVID funds to support two different projects. The first project is this one, the Detection and Mitigation of COVID-19 in Confinement Facilities award. The second project that you will find in your budget is going to be the Accelerating Data Modernization in Jurisdictions award, which was issued under the project C2 Data Modernization tab of the ELC budget workbook. There's a separate webinar scheduled for next Wednesday August 11 at 3pm which will cover that particular award in more detail.

Jason Snow: In the guidance document on pages two and three, you will find a listing of allowable costs. This slide contains some, but not all, the costs listed in the guidance. As you develop your work plan and budget, common allowable costs would likely include hiring staff or supporting the reallocation of existing staff to conduct testing and or overseeing mitigation efforts. For mitigation efforts, please ensure the details are included in the work plan and in the budget justification section. This is a broad category and not all possible mitigation strategies might be within scope for this particular award. Laboratory equipment is another likely cost to include in the budget. However, if a similar piece of equipment was included in a prior ELC budget, such as in enhancing detection and enhancing detection expansion, or the recently awarded reopening schools award, please indicate in the budget justification for this award how the lab equipment request differs and does not duplicate from prior requests. With the hardware and software necessary for reporting positive cases to public health and related follow up. Please keep in mind that a strong budget justification in this area would incorporate how these lab systems and health information system enhancements will assess, not only for the immediate COVID response, but for ongoing public health surveillance. Additionally, details around how these systems would ensure capture and transmission of key data elements such as race and ethnicity, are important to include. Similar to the comment made about staffing for costs around testing and mitigation outreach expenses, please specify the mitigation efforts that will be addressed when completing the budget justification for these associated costs. Included in the outreach category could be items such as health communications and educational efforts that are tailored for residence inmates, detainees, correctional officers, other facility staff, as well as family members and other visitors. The last item on this list pertains to residents and maintaining needs resulting from restricted access due to COVID-19. Should questions arise around possible associated costs, please feel free to reach out to your ELC project officer, who can connect you to the appropriate DOJ subject matter expert as well as for determination if the request would be in scope.

Jason Snow: For the Detection and Mitigation of COVID-19 in Confinement Facilities award, you will find the awarded amount under your project the emerging issues tab in the ELC budget workbook. When the end of year notices of awards are issued and released, your ELC project officer will release the associated grant note in GrantSolutions. It will be in this grant note that you will find your budget workbook, which is an excel file, along with the ELC funding spreadsheet, which shows the various sources across categories that are pertinent to the end of year funding. Once the award is released and issued, the entirety of this award will be made available to the recipients in the payment management system for immediate use. As with prior ELC awards, please note that funds must be used in accordance with the guidance. Any questions about if a cost is within scope should be directed to your ELC project officer to ensure that funds are being used appropriately and will not end up having to be paid back from non-federal sources at a later date.

Jason Snow: On July 27, CDC published the guidance for this award in GrantSolutions as a grant note. We also sent out an email the week prior on July 22 that provided recipients with advanced copy of this guidance. The guidance can also be found on our website under the resources section and then look under the ELC COVID-19 supplemental words guidance section. On both the cover page and page with the section header background and purpose, you will find a reminder that this award can be found under your project E emerging issues on the ELC budget workbook. It will be on the same tab that you will need to complete your budget for revision. Within 90 days from the time the recipient receives the notice of award, you work plan and budget must be completed and submitted to CDC. To submit budget revisions, you will do so through the budget revision amendment option in GrantSolutions. As part of the budget revision amendment, please include your ELC budget workbook in the original excel format. Please do not submit a word, PDF, or budget that does not

utilize the ELC budget workbook that was provided in a grant note at time of award. Doing so will result in the action being returned. Also, when completing the budget revision, do not use the hyperlink in grant solutions to create a SF424-a online. Doing so creates issues on the CDC side when processing or revise notice of award. ELC budget workbooks will generate the SF424a PDF once the budget has been completed.

Jason Snow: This is a screenshot of the menu tab on an ELC budget workbook. Once the budget has been completed and you've checked the summary table at the bottom to ensure that your requested total matches your approved total - which comes from the original award line of E 101, go to your menu. In the upper left you will find the SF424a button. Select this, and the budget workbook will take all the requested line items and generate the SF424a for you. Next, go to the SF424a tab which could be found at the bottom of the workbook, just left of the menu tab. On the SF424a tab, you can print a PDF to create the file that will be needed to upload into GrantSolutions as part of your budget revision amendment.

Jason Snow: Within 90-days, recipients are going to need to go into REDCap and complete the workplan. As Ruby mentioned previously, there is one required activity, which is to assist facilities in establishing and implementing diagnostic and screening testing programs for residents, detainees, staff, and visitors. In cases where this activity has already been addressed, recipients would simply need to note in the workplan, using the implementation plan section, providing the details on how this has been addressed to date and the plans for continued support through the project period. The remaining 14 activities are optional and should be addressed as needed and appropriate to meet the needs within the recipient's jurisdiction. By the 90-day response window, recipients will need to submit a budget revision into GrantSolutions that includes a completed ELC budget workbook in the original excel format, a PDF of the workplan - which could be printed off from REDCap once completed - and a letter of support that is signed by the ELC governance team members. And please remember this letter needs to be on agency letterhead.

Jason Snow: This slide provides a summary of the various due dates for this award. The acknowledgement letter must be signed by the authorizing official on record in GrantSolutions. It must be submitted in GrantSolutions as a grant and within five days of the notice of award being issued. As of today, actually right before this webinar, I have already seen numerous grant notices come through that have either followed the early release of the guidance, by way of the ELC mailbox, or after OGS published the guidance in GrantSolutions on July 27. If you've already submitted the letter when the notice of award was officially issued and released to you, you do not need to resubmit. Those proactive early submissions will still meet the five-day requirement. Financial Reporting on this award will start October 5 and will continue monthly. As with prior ELC COVID awards monthly reporting is required until all funds are extended. Workplan completion in REDCap and budget completion in the ELC budget workbook - that will be available in GrantSolutions as a grant note after the award is issued – are both due within 90 days from the issuance of the award. Please remember to make your workplan, ELC governance team letter, and the completed ELC budget workbook in the original excel format, as a budget revision amendment in GrantSolutions. The performance measures for this award are still being discussed and developed. When we finalize this information, any reporting requirements will be shared with recipients. Quarterly workplan monitoring will begin and align with the ELC budget period three, quarterly reporting cycle, which is January 2022. And if I recall correctly, the next slide opens up our question-and-answer portion.

Cameron Warner: As Jason mentioned, if we're unable to answer your question today or questions arise as you complete your work plan and revised budget, the ELC and Department of Justice will be hosting weekly office hours beginning August 26 at 4pm. The office hours will be held every Thursday through September 23 and are intended for direct recipients of ELC funds. With that being said, again, please feel free to use the chat or the Q&A boxes for questions.

[Q&A Period]

Jason Snow: I want to thank everyone for your attendance, for wonderful questions. I especially want to thank Ruby and her collaboration and partnership in both helping get this award made possible, and then also the ongoing continued support as we continue over the next three years, making sure these funds reach the intended population and serve our public health interest in the confinement facilities. Thank you very much, have a wonderful rest of the day and we'll be in touch soon.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- MMWR – Vol. 70, No. 51-52 [Links, Attachment]
  - The **December 31** edition of CDC's Morbidity and Mortality Weekly Report (MMWR) includes the following COVID-related articles:
    - COVID-19 Vaccine Safety in Children Aged 5–11 Years — United States, November 3–December 19, 2021
    - Interim Estimate of Vaccine Effectiveness of BNT162b2 (Pfizer-BioNTech) Vaccine in Preventing SARS-CoV-2 Infection Among Adolescents Aged 12–17 Years — Arizona, July–December 2021
    - Characteristics and Clinical Outcomes of Children and Adolescents Aged <18 Years Hospitalized with COVID-19 — Six Hospitals, United States, July–August 2021
    - Evaluation of a Test-To-Stay Strategy in Transitional Kindergarten Through Grade 12 Schools — Los Angeles County, California, August 16–October 31, 2021
    - Evaluation of Test-To-Stay Strategy on Secondary and Tertiary Transmission of SARS-CoV-2 in K–12 Schools — Lake County, Illinois, August 9–October 29, 2021
    - Investigation of a SARS-CoV-2 B.1.1.529 (Omicron) Variant Cluster — Nebraska, November–December 2021
- HHS Update: Allocation of bam/ete and REGEN-COV therapeutics [Link, Attachment]
  - Yesterday, **December 29**, the U.S. Department of Health and Human Services (HHS) announced a pause in allocations of bamlanivimab/etesevimab and REGEN-COV COVID-

19 therapeutics to states or territories within regions of the country that have greater than 80% prevalence of the Omicron variant based on CDC NOWCAST data. The purpose of this pause is to ensure effective product is available in most sites.
    - Please see attached for the full update. You may email COVID19Therapeutics@HHS.gov with questions regarding the allocation of bam/ete and REGEN-COV.
- Reminder: CDC All-STLT Update Call Series – Register for 2022 Calls Before 1/3/22 [Link]
    - On **January 3, 2022**, CDC's weekly COVID-19 All-STLT Update call will be moving to a new Zoom link. Before that date, please register here to ensure your access to the 2022 call series. Please note that your unique participant link will be the same for all calls in the series through December 2022; you do not need to register for each individual call. Calls will be held on Mondays from 2:00–2:45 pm ET (unless otherwise notified).
    - Call registrants will also be added to CDC's partner update distribution list. Partner update emails are disseminated every Monday, Wednesday, and Friday afternoon, and are the same updates included below in our "Standing Updates" section.
- Lights, Camera, Action: The Future of Public Health Summit Series – Summit #2 [Link]
    - The CDC Foundation and other public health agencies are hosting a four-part virtual summit to advance recommendations for a modernized U.S. public health system. Registration is now open for the second summit, *Creating an Interoperable and Modern Data and Technology Infrastructure,* occurring on **January 25, 2022 at 11:00 am EST**. Speakers will include CDC's Deputy Director for Public Health Science and Surveillance, Dr. Daniel Jernigan, HHS's National Coordinator for Health Information Technology, Dr. Micky Tripathi and other prominent leaders in the field. Learn more and register for the Summit here.

Standing Updates

- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
    - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

December 31, 2021

COVID-19 Vaccine Safety in Children Aged 5–11 Years — United States, November 3–December 19, 2021

Anne M. Hause, PhD[1]; James Baggs, PhD[1]; Paige Marquez, MSPH[1]; Tanya R. Myers, PhD[1]; Julianne Gee, MPH[1]; John R. Su, MD, PhD[1]; Bicheng Zhang, MS[1]; Deborah Thompson, MD[2]; Tom T. Shimabukuro, MD[1]; David K. Shay, MD[1]

On October 29, 2021, the Food and Drug Administration (FDA) amended the Emergency Use Authorization (EUA) for Pfizer-BioNTech COVID-19 (BNT162b2) mRNA vaccine to expand its use to children aged 5–11 years, administered as 2 doses (10 µg, 0.2mL each) 3 weeks apart (*1*). As of December 19, 2021, only the Pfizer-BioNTech COVID-19 vaccine is authorized for administration to children aged 5–17 years (*2*,*3*). In preauthorization clinical trials, Pfizer-BioNTech COVID-19 vaccine was administered to 3,109 children aged 5–11 years; most adverse events were mild to moderate, and no serious adverse events related to vaccination were reported (*4*). To further characterize safety of the vaccine in children aged 5–11 years, CDC reviewed adverse events after receipt of Pfizer-BioNTech COVID-19 vaccine reported to the Vaccine Adverse Event Reporting System (VAERS), a passive vaccine safety surveillance system co-managed by CDC and FDA, and adverse events and health impact assessments reported to v-safe, a voluntary smartphone-based safety surveillance system for adverse events after COVID-19 vaccination,* during November 3–December 19, 2021. Approximately 8.7 million doses of Pfizer-BioNTech COVID-19 vaccine were administered to children aged 5–11 years† during this period; VAERS received 4,249 reports of adverse events after vaccination with Pfizer-BioNTech COVID-19 vaccine in this age group, 4,149 (97.6%) of which were not serious. Approximately 42,504 children aged 5–11 years were enrolled in v-safe after vaccination with Pfizer-BioNTech COVID-19 vaccine; after dose 2, a total of 17,180 (57.5%) local and 12,223 systemic (40.9%) reactions (including injection-site pain, fatigue, or headache) were reported. The preliminary safety findings are similar to those from preauthorization clinical trials (*4*,*5*). The Advisory Committee on Immunization Practices (ACIP) recommends the Pfizer-BioNTech COVID-19 vaccine for children aged 5–11 years for the prevention of COVID-19 (*6*). Parents and guardians of children aged 5–11 years vaccinated with Pfizer-BioNTech COVID-19 vaccine should be advised that local and systemic reactions are expected after vaccination. Vaccination is the most effective way to prevent COVID-19. CDC and FDA will

continue to monitor vaccine safety and will provide updates as needed to guide COVID-19 vaccination recommendations.

VAERS is a national passive vaccine safety surveillance system, jointly managed by CDC and FDA, that monitors adverse events after vaccination (*7*). VAERS accepts reports from anyone, including health care providers,[§] vaccine manufacturers, and members of the public. Symptoms, signs, and diagnostic findings in VAERS reports are assigned Medical Dictionary for Regulatory Activities (MedDRA) preferred terms by VAERS staff members.[¶] VAERS reports are classified as serious if any of the following are reported: hospitalization, prolongation of hospitalization, life-threatening illness, permanent disability, congenital anomaly or birth defect, or death.[**] Reports of serious adverse events receive follow-up by VAERS staff members to obtain additional information, including medical records. For reports of death, death certificates and autopsy reports are obtained, if available. CDC physicians reviewed all available information for each decedent to form an impression about cause of death. Reports of myocarditis and pericarditis after receipt of COVID-19 vaccine were identified by a search for selected MedDRA preferred terms (*7*); CDC staff members attempted to collect information about clinical course and recovery related to myocarditis and pericarditis from patients and health care providers.

CDC established v-safe,[††] a voluntary smartphone-based active safety surveillance system, specifically to monitor adverse events after COVID-19 vaccination. Parents and guardians can enroll children in v-safe after either the first or second vaccine dose. Text message reminders for online health surveys are sent to parents or guardians to complete for a child.[§§] Health surveys sent in the first week after vaccination included questions about local injection site and systemic reactions (mild, moderate, or severe)[¶¶] and health impacts (i.e., whether the child was unable to perform normal daily activities, missed school, or received care from a medical professional because of new symptoms or conditions). CDC's v-safe call center contacted a parent or guardian when a report indicated that a

[§] Under COVID-19 vaccine EUA requirements, health care providers are required to report certain adverse events after vaccination to VAERS, including death. https://www.cdc.gov/vaccinesafety/ensuringsafety/monitoring/vaers/index.html

[¶] Each VAERS report might be assigned more than one MedDRA preferred term. A MedDRA-coded event does not indicate a medically confirmed diagnosis. https://www.meddra.org/how-to-use/basics/hierarchy

[**] Based on the Code of Federal Regulations Title 21. https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfcfr/cfrsearch.cfm?fr=312.32

[††] https://vsafe.cdc.gov

[§§] Children and adolescents aged ≤15 years must be enrolled by a parent or guardian and cannot self-enroll. Children aged 5–11 years might be enrolled in v-safe if they were vaccinated on or after November 3, 2021. Health check-ins are sent via text messages that link to web-based surveys on days 0–7 after vaccination; then weekly through 6 weeks after vaccination; and then 3, 6, and 12 months after vaccination.

[¶¶] Parents and guardians who participate in v-safe use the following definitions to describe the severity of a child's symptoms: mild (noticeable, but not problematic), moderate (limit normal daily activities), or severe (make daily activities difficult or impossible).

The *MMWR* series of publications is published by the Center for Surveillance, Epidemiology, and Laboratory Services, Centers for Disease Control and Prevention (CDC), U.S. Department of Health and Human Services, Atlanta, GA 30329-4027.

child received medical care for new or worsening symptoms; completion of a VAERS report, if indicated, was encouraged.

VAERS and v-safe data collected during November 3–December 19, 2021 among children aged 5–11 years who received Pfizer-BioNTech COVID-19 vaccine were analyzed and described overall and by sex, age group, and race/ethnicity. Among 5,277 VAERS reports received for children aged 5–11 years who received Pfizer-BioNTech COVID-19 vaccine, 1,028 (19.5%) were excluded from this analysis because vaccination occurred before authorization for use in this age group or date of vaccination was unknown. SAS software (version 9.4; SAS Institute) was used to conduct all analyses. These activities were reviewed by CDC and conducted consistent with applicable federal law and CDC policy.[***]

Review of VAERS Data

During November 3–December 19, 2021, VAERS received and processed 4,249 reports of adverse events (Table 1) for children aged 5–11 years who received Pfizer-BioNTech COVID-19 vaccine[†††]; the median age was 8 years, and 1,896 (44.6%) reports were for males. Most children (4,143; 97.5%) received Pfizer-BioNTech COVID-19 vaccine alone; seasonal influenza vaccine was the most frequently simultaneously administered vaccine (91 [2.1%] children).

Overall, 4,149 (97.6%) VAERS reports were for nonserious events, and 100 (2.4%) were for serious events. The median age of children with reports of nonserious events was 8 years, and 1,835 (44.2%) of these reports were for males. The most commonly reported nonserious events were related to vaccine administration (some without any adverse event), including no adverse event (1,157; 27.9%), product preparation issue (925; 22.3%), and incorrect dose administered (675; 16.3%), (Table 2). The median age of children with reports of serious events was 9 years, and 61 (61.0%) reports were among males. The most commonly reported conditions and diagnostic findings among the 100 reports of serious events were fever (29; 29.0%), vomiting (21; 21.0%), and increased troponin[§§§] (15; 15.0%). Among 12 serious reports of seizure, one child experienced syncope (not seizure) and another child potentially experienced syncope, two children experienced febrile seizure, one child had a history of seizures, two children had a potentially evolving seizure disorder, and five children experienced new-onset seizures. Among 15 preliminary reports of myocarditis identified during the analytic period, 11 were verified (by provider interview or medical record review) and met the case definition for myocarditis[¶¶¶]; of these 11 children, seven recovered, and four were recovering at time of the report. VAERS received two reports of death during the analytic period; both are under review. These deaths occurred in two females, aged 5 and 6 years, both of whom had complicated medical histories and were in fragile health before vaccination. None of the data suggested a causal association between death and vaccination.

Review of v-safe Data

During November 3–December 19, 2021, v-safe enrolled 42,504 children aged 5–11 years who received Pfizer-BioNTech COVID-19 vaccine (Table 3); second dose information was available for 29,899 (70.3%) of these children. During the week after receipt of dose 1, local (23,290; 54.8%) and systemic (14,734; 34.7%) reactions were frequently reported; systemic

Male	44.6	44.2	61.0
Unknown	10.4	10.7	0
Age range, yrs (median)	**5–11 (8)**	**5–11 (8)**	**5–11 (9)**
Ethnicity			
Hispanic or Latino	11.0	10.9	16.0
Non-Hispanic or Latino	40.0	39.7	56.0
Unknown ethnicity	48.9	49.4	28.0
Race			
American Indian or Alaska Native	0.6	0.6	0
Asian	4.0	4.0	7.0
Black	4.1	4.2	2.0
Native Hawaiian or Other Pacific Islander	0.2	0.2	0
White	39.5	39.2	52.0
Multiracial	2.2	2.1	9.0
Other	7.1	7.1	4.0
Unknown race	42.3	42.7	26.0

Abbreviation: VAERS = Vaccine Adverse Event Reporting System.

* VAERS reports are classified as serious if any of the following are reported: hospitalization or prolongation of hospitalization, life-threatening illness, permanent disability, congenital anomaly or birth defect, or death.

§§§ Troponins are proteins found in myocytes (heart muscle cells). Troponin levels typically are measured as part of the evaluation of chest pain or other symptoms of possible myocardial damage.

¶¶¶ Acute myocarditis was defined as presence of signs and symptoms (one or more new or worsening of the following: chest pain/pressure/discomfort, dyspnea/shortness of breath/pain with breathing, palpitations, or syncope; or two or more of the following in children aged ≤11 years: irritability, vomiting, poor feeding, tachypnea, or lethargy); and one or more new finding of elevated troponin, electrocardiogram findings consistent with myocarditis, abnormal cardiac function or wall motion on echocardiogram, cardiac magnetic resonance imaging findings consistent with myocarditis, or histopathologic findings consistent with myocarditis; and no other identifiable cause for these findings.

MS-DOH-21-1816-A-001997

reactions were more frequently reported during the week after dose 2 (12,223; 40.9%) than dose 1. Reactions were reported most frequently on the day after vaccination for both doses. The most frequently reported reactions after either dose were injection site pain, fatigue, and headache. Fever was more frequently reported after dose 2 (4,001; 13.4%) than dose 1 (3,350; 7.9%).

TABLE 2. Most frequent symptoms, signs, diagnostic results, and conditions by MedDRA preferred term* reported to the Vaccine Adverse Event Reporting System among children aged 5–11 years after receipt of Pfizer-BioNTech COVID-19 vaccine (N = 4,249) — United States, November 3–December 19, 2021

Symptom, sign, diagnostic result, or condition (MedDRA PT)	No. reporting	% Reporting
Nonserious reports (n = 4,149)		
No adverse event†	1,157	27.9
Product preparation issue	925	22.3
Incorrect dose administered	675	16.3
Underdose	324	7.8
Vomiting	316	7.6
Fever	291	7.0
Headache	255	6.2
Syncope	255	6.2

Abbreviations: MedDRA PT = Medical Dictionary for Regulatory Activities preferred term; VAERS = Vaccine Adverse Event Reporting System.

* Signs and symptoms in VAERS reports are assigned MedDRA PTs by VAERS staff members. Each VAERS report might be assigned more than one MedDRA PT, which can include normal diagnostic findings. A MedDRA PT does not indicate a medically confirmed diagnosis. Reports of myocarditis and seizure were identified using a combination of MedDRA PTs; in some cases, reports of myocarditis (identified by fulfilling criteria of the CDC working case definition of myocarditis) and seizure did not have the MedDRA PT "myocarditis" or "seizure" assigned to them. https://www.meddra.org/how-to-use/basics/hierarchy

† Reports of no adverse event were accompanied by product preparation issue, incorrect dose administered, or underdose.

§ VAERS reports are classified as serious if any of the following are reported: hospitalization, prolongation of hospitalization, life-threatening illness, permanent disability, congenital anomaly or birth defect, or death; MedDRA PTs are included with serious reports when they occur in association with the criteria for serious classification (i.e., radiologic or laboratory tests that occur during a hospitalization).

Approximately 5.1% of parents reported that their child was unable to perform normal daily activities on the day after receipt of dose 1, and 7.4% after receipt of dose 2. Approximately 1% of parents reported seeking medical care in the week after vaccination; most medical care was received via a clinic appointment (441; 0.6%). Fourteen (0.02%) children reportedly received care at a hospital; information regarding reason for hospitalization was available for five children and included appendicitis (two), vomiting and dehydration (one), respiratory infection (one), and retropharyngeal cellulitis (one). Parents and guardians of all hospitalized children were contacted; two parents completed VAERS reports, and one revealed hospitalization was reported in error.

Discussion

This report provides preliminary safety findings from VAERS and v-safe data collected during the administration of approximately 8 million doses of Pfizer-BioNTech COVID-19 vaccine to children aged 5–11 years. The findings summarized in this report are similar to the safety data from preauthorization trials for Pfizer-BioNTech COVID-19 vaccine administered to

TABLE 3. Reactions reported for children aged 5–11 years (N = 42,504) who completed at least one v-safe health check-in survey on days 0–7 after receiving Pfizer-BioNTech COVID-19 vaccine — United States, November 3–December 19, 2021

children aged 5–11 years (*4*,*5*). Trial participants who received Pfizer-BioNTech COVID-19 vaccine frequently reported local (86.2%) and systemic (66.6%) reactions that were mostly mild (i.e., did not interfere with normal daily activities) or moderate (some interference with normal daily activities); no serious adverse events judged to be related to vaccination were reported (*3*).

Among VAERS reports for children aged 5–11 years who received Pfizer-BioNTech COVID-19 vaccine, approximately 97% were nonserious. The most common adverse events reported to VAERS in the age group were related to administration error. This age group is the first to receive a smaller dosage of mRNA (10 μg) than that recommended for persons aged ≥12 years (30 μg), and administration errors are not unexpected. Most reports of administration errors often mentioned that no adverse event was associated with receipt of an incorrect dose.

Myocarditis is a rare and serious adverse event that has been associated with mRNA-based COVID-19 vaccines; reporting rates for vaccine-associated myocarditis appears highest among males aged 12–29 years (*8*). To date, myocarditis among children aged 5–11 years appears rare; 11 verified VAERS reports have been received after administration of approximately eight million vaccine doses, and, in an active vaccine safety surveillance system, no chart-confirmed reports of myocarditis were observed during the 1–21 days or 1–42 days after 333,000 vaccine doses were administered to children of the same age (*6*) These cases appear consistent with other reports of myocarditis after mRNA COVID-19 vaccination regarding time to symptom onset and a mild clinical course (*9*). Two deaths after Pfizer-BioNTech COVID-19 vaccine were reported for children with multiple chronic medical conditions; on initial review, no data were found that would suggest a causal association between death and vaccination.

Local (57.5%) and systemic (40.9%) reactions after receipt of dose 2 of Pfizer-BioNTech COVID-19 vaccination among v-safe registrants aged 5–11 years were less frequently reported than reactions reported among children and adolescents aged 12–15 years (local 62.4%; systemic, 63.4%) (*9*). Fourteen v-safe registrants aged 5–11 years were reported to have been hospitalized after vaccination. V-safe does not directly record diagnoses associated with hospitalization; however, parents and guardians can include supplemental text for each health check-in. Whether hospitalization was the result of vaccination could not be determined; however, all parents and guardians who reported a child's hospitalization were contacted and encouraged to complete a VAERS report. Two parents completed a VAERS report on behalf of a child who was reported to v-safe to have been hospitalized.

Summary

What is already known about this topic?

In preauthorization trials for Pfizer-BioNTech (BNT162b2) COVID-19 vaccine, vaccinated children aged 5–11 years reported mild to moderately severe local and systemic reactions; no serious vaccination-related events were noted.

What is added by this report?

After authorization of Pfizer-BioNTech COVID-19 vaccine for children aged 5–11 years during October 2021, and administration of approximately 8 million doses, local and systemic reactions after vaccination were commonly reported to VAERS and v-safe for vaccinated children aged 5–11 years. Serious adverse events were rarely reported.

What are the implications for public health practice??

Parents and guardians of children aged 5–11 years should be advised that local and systemic reactions are expected after vaccination with Pfizer-BioNTech COVID-19 vaccine and are more common after the second dose.

The findings in this report are subject to at least four limitations. First, VAERS is a passive surveillance reporting system and is subject to reporting biases and underreporting, especially of nonserious events (*8*). Second, data on race/ethnicity were not provided in >40% of VAERS reports. Third, v-safe is a voluntary program; as a result, v-safe data might not be representative of the vaccinated population. Finally, these data are limited by the short surveillance period and might change as safety monitoring continues and more doses are administered to children aged 5–11 years.

Vaccination is the most effective way to prevent COVID-19 infection. ACIP recommends the Pfizer-BioNTech COVID-19 vaccine for children aged 5–11 years for the prevention of COVID-19 (*10*). Preliminary safety findings are similar to those described in the clinical trials. Parents and guardians of children aged 5–11 years vaccinated with Pfizer-BioNTech COVID-19 vaccine should be advised that local and systemic reactions are expected after vaccination. CDC and FDA will continue to monitor vaccine safety and will provide updates as needed to guide COVID-19 vaccination recommendations.

The BNT162b2 (Pfizer-BioNTech) mRNA COVID-19 vaccine has demonstrated high efficacy in preventing infection with SARS-CoV-2 (the virus that causes COVID-19) in randomized placebo-controlled Phase III trials in persons aged 12–17 years (referred to as adolescents in this report) (*1*); however, data on real-word vaccine effectiveness (VE) among adolescents are limited (*1–3*). As of December 2021, the Pfizer-BioNTech vaccine is approved by the Food and Drug Administration (FDA) for adolescents aged 16–17 years and under FDA emergency use authorization for those aged 12–15 years. In a prospective cohort in Arizona, 243 adolescents aged 12–17 years were tested for SARS-CoV-2 by reverse transcription–polymerase chain reaction (RT-PCR) each week, irrespective of symptoms, and upon onset of COVID-19–like illness during July 25–December 4, 2021; the SARS-CoV-2 B.1.617.2 (Delta) variant was the predominant strain during this study period. During the study, 190 adolescents contributed fully vaccinated person-time (≥14 days after receiving 2 doses of Pfizer-BioNTech vaccine), 30 contributed partially vaccinated person-time (receipt of 1 dose or receipt of 2 doses but with the second dose completed <14 days earlier), and 66 contributed unvaccinated person-time. Using the Cox proportional-hazards model, the estimated VE of full Pfizer-BioNTech vaccination for preventing SARS-CoV-2 infection was 92% (95% CI = 79%–97%), adjusted for sociodemographic characteristics, health information, frequency of social contact, mask use, location, and local virus circulation. These findings from a real-world setting indicate that 2 doses of Pfizer-BioNTech vaccine are highly effective in preventing SARS-CoV-2 infection among Arizona adolescents. CDC recommends COVID-19 vaccination for all eligible persons in the United States, including persons aged 12–17 years.*

The PROTECT† study is a prospective cohort of persons aged 4 months–17 years initiated in Arizona in July 2021. The study seeks to understand the risk for COVID-19 and how well COVID-19 vaccines protect children and adolescents from SARS-CoV-2 infection and illness. PROTECT expanded to Florida, Texas, and Utah in late September 2021, and those sites will be included in future analyses. PROTECT is an ancillary study of the HEROES-RECOVER cohorts,§ which previously reported VE of COVID-19 vaccines among working adults aged 18–85 years using similar methods (*4*). PROTECT participants in Arizona were recruited from families of adults participating in the HEROES study and the general public. Upon enrollment, participants responded to electronic surveys collecting demographic, health and vaccination history, and prior SARS-CoV-2 infection information. Participants submitted self-collected (or parent-/guardian-collected) mid-turbinate nasal swabs weekly, irrespective of COVID-19–like illness symptoms, and collected an additional swab at the onset of any COVID-19–like illness. Self-reported signs and symptoms of COVID-19–like illness (fever, chills, cough, shortness of breath, sore throat, diarrhea, muscle or body aches, change in smell or taste, or loss of appetite or poor feeding) that occurred in the preceding 7 days were self-reported on the weekly nasal swab envelopes. Specimens were shipped on cold packs and tested by RT-PCR assay for SARS-CoV-2 at Marshfield Clinic Laboratory (Marshfield, Wisconsin). Receipt of COVID-19 vaccines was documented by self-report in electronic surveys and direct upload of vaccine card images by participants' parents or guardians. The number of hours and percentage of time participants wore masks in school and in the community were also collected via self-reported electronic surveys upon enrollment and each subsequent month.

The primary outcome measure was time to RT-PCR–confirmed SARS-CoV-2 infection in vaccinated participants compared with that in unvaccinated participants. VE was calculated using the Anderson-Gill extension of the Cox proportional-hazards models, in which unvaccinated person-time included days before receiving the first dose of a COVID-19

† Pediatric Research Observing Trends and Exposures in COVID-19 Timelines (PROTECT).

§ Arizona Healthcare, Emergency Response and Other Essential Workers Surveillance Study (HEROES) and Research on the Epidemiology of SARS-CoV-2 in Essential Response Personnel (RECOVER) cohorts.

MS-DOH-21-1816-A-002001

vaccine, and fully vaccinated person-time included number of days following 14 days after receipt of the second of 2 Pfizer-BioNTech vaccine doses. For participants infected with SARS-CoV-2, the event date for this analysis was the earlier of the collection date of the first specimen to test positive or the symptom onset date. Unadjusted VE was calculated as 100% x (1 – hazard ratio for SARS-CoV-2 infection in vaccinated versus unvaccinated participants). An adjusted model used an inverse probability of treatment weighting approach (*5*) with individual propensities to be vaccinated during each week based on sociodemographic characteristics (age, sex, race/ethnicity, and household size); health information (chronic conditions and daily medication use); frequency of close social contact (school and community); percentage of time wearing masks (school and community); and local virus circulation (daily percentage of all SARS-CoV-2 tests performed in the local county returning a positive result). These predicted propensities were used to calculate stabilized weights, which were incorporated into a Cox proportional-hazards model. Robust SEs were used to account for the clustering of participants within the same household and correlation by stabilized weights. All analyses were conducted using SAS software (version 9.4; SAS Institute) or R software (version 4.1.2; R Foundation for Statistical Computing). This activity was approved by University of Arizona Institutional Review Board on which CDC relied. The study was conducted consistent with applicable federal law and CDC policy.¶

Among 1,478 participants aged 4 months–17 years in the full Arizona PROTECT cohort, 280 (18.9%) were aged 12–17 years; 32 (11.4%) of these participants were excluded based on a documented RT-PCR–positive SARS-CoV-2 test result before enrollment, three were excluded because of failure to complete weekly nasal swabs, one was excluded because vaccination information was incomplete, and one was excluded because the participant had received the mRNA-1273 (Moderna) COVID-19 vaccine, leaving 243 participants (86.8% of participants aged 12–17 years) in the analytic sample.

Approximately one half (51.4%) were male, 65.8% were from Tucson, most were aged 12–15 years (74.5%), White (87.7%), non-Hispanic (74.5%), and had private insurance (85.2%) (Table 1). Participants reported attending in-person school a mean of 28.2 (SE = 1.0) hours per week. They reported wearing a mask in school 73.3% (SE = 2.4) of the time; the SE, in part, reflects the variability in mask mandates across the state (*6*). Participants who received a positive SARS-CoV-2 test result during the study reported a lower percentage of time masked in school (48.6%, SE = 10.0) compared with those who did not receive a positive test result (75.7%, SE = 2.3) (p = 0.031). Participants also reported using masks in the community a mean of 58.5% (SE = 2.6) of the time overall, with participants who received positive SARS-CoV-2 test results reporting a lower mean percentage of community masked time (29.3%; SE = 9.0) compared with those who received negative test results (61.3%; SE = 2.7) (p = 0.003).

During the study period, 66 participants contributed 4,288 unvaccinated person-days, 30 contributed 909 partially vaccinated person-days, and 190 contributed 21,693 fully vaccinated person-days (Table 2). Most (n = 171, 70.3%) vaccinated participants entered the study fully vaccinated. The median number of fully vaccinated person-days during the analysis period was 119 (IQR = 105–133 days).

Twenty-one persons (8.6%) received positive RT-PCR SARS-CoV-2 test results (Table 1). RT-PCR–confirmed infection was more prevalent among residents of areas other than Tucson or Phoenix (p = 0.003). The majority (n = 18, 85.7%) of participants with RT-PCR–confirmed infection reported COVID-19–like illness. The remaining three participants reported being asymptomatic. Two participants with RT-PCR–confirmed infections, both unvaccinated and from the same household, sought outpatient medical care for their illness.

During the 4,288 unvaccinated person-days, 16 RT-PCR–confirmed infections were identified (incidence rate = 3.73 per 1,000 person-days) (Table 2). During the 909 person-days <14 days after receipt of the second vaccine dose, when persons were considered partially vaccinated, no RT-PCR–confirmed infections were identified. Five RT-PCR–confirmed infections occurred during 21,693 fully vaccinated person-days (incidence rate = 0.23 per 1,000 person-days). Estimated unadjusted VE of full vaccination for preventing SARS-CoV-2 infection was 94% (95% CI = 83%–98%). Estimated adjusted VE of full vaccination for preventing SARS-CoV-2 infection was 92% (95% CI = 79%–97%).

Discussion

Analysis of a prospective Arizona cohort of adolescents found adjusted VE for full vaccination with 2 doses of Pfizer-BioNTech vaccine to be 92% against RT-PCR–confirmed SARS-CoV-2 infection, indicating that the Pfizer-BioNTech COVID-19 vaccine is highly effective in real-world conditions among adolescents aged 12–17 years.

These findings are consistent with those from previous Phase III trials (*1*,*7*) and recent observational studies of mRNA VE against severe COVID-19 in adolescents and young adults (*3*,*8*). The scientific rigor of these findings is enhanced by the study's prospective design and the participants' weekly specimen collections. The observation period for this analysis coincided with the period of Delta variant predominance in the

¶45 C.F.R. part 46; 21 C.F.R. part 56; 42 U.S.C. Sect. 241(d), 5 U.S.C. Sect. 552a, 44 U.S.C. Sect. 3501 et seq.

MS-DOH-21-1816-A-002002

United States and with return to in-person K–12 instruction in Arizona schools, with potentially higher rates of exposure.

The findings in this report are subject to at least five limitations. First, VE point estimates should be interpreted with caution given the moderately wide CIs, attributable in part to the limited number of unvaccinated person-days relative to fully vaccinated person-days, and a small overall sample size. Second, although several potential confounders were controlled for, including differences in mask use between vaccinated and unvaccinated participants, residual and unmeasured confounding might have occurred. Third, self-collection of specimens and use of nasal rather than nasopharyngeal swabs could reduce sensitivity of virus detection by RT-PCR but might have increased participation, because studies indicate that nasal swabs are more acceptable to participants (*9*); if the difference in sensitivity of virus detection between the two methods disproportionately affected those who received the vaccine, VE would be overestimated. Fourth, if vaccination attenuates viral RNA shedding among children, as has been noted in some studies of adults (*4*), this effect would also result in overestimation of VE by reducing RT-PCR detection among infected but vaccinated participants. Finally, the study

Abbreviations: Col = column; PROTECT = Pediatric Research Observing Trends and Exposures in COVID-19 Timelines.

* P-values comparing the percentage of persons with SARS-CoV-2 infections to those not infected by sociodemographic and health categories and comparing the percentage of vaccinated persons to those not vaccinated by these categories, calculated using Pearson's chi-square test (cells with ≥5 observations) or Fisher's exact test (cells with <5 observations). P-values for continuous variables calculated using the Mann-Whitney test.

† All participants in the "Other races" category were collapsed into a single group because of small numbers.

§ Number and percentage of participants who completed weekly nasal swab throughout the analysis period.

¶ Chronic conditions included asthma or chronic lung disease, cancer, diabetes, heart disease, hypertension, immunosuppression or autoimmune disorder, kidney disease, liver disease, neurologic or neuromuscular disorder, or other chronic conditions.

MS-DOH-21-1816-A-002003

might not be generalizable to other populations. The study was restricted to adolescents in Arizona and might not be representative of the racial or ethnic distribution in Arizona nor the United States. In addition, participants reported very few chronic conditions and low rates of obesity; previous studies have indicated that VE has not varied by chronic conditions except for among immunocompromised adults (*10*). The study was also restricted to persons aged 12–17 years; it is not known whether these findings can be generalized to children aged 5–11 years, who are now eligible to receive the Pfizer-BioNTech vaccine under an emergency use authorization.

The VE estimates described in this report for the Pfizer-BioNTech vaccine in real-world conditions during the period of Delta variant predominance corroborate and expand upon the VE estimates from other recent studies in adolescents (*1*,*7*) and reinforce previous findings that current vaccination efforts are resulting in substantial preventive benefits among adolescents aged 12–17 years. CDC recommends COVID-19 vaccination for all eligible persons in the United States, including adolescents aged 12–17 years.

Summary

What is already known about this topic?

The Pfizer-BioNTech COVID-19 vaccine has been shown to be effective in preventing SARS-CoV-2 infection in adolescents in randomized placebo-controlled Phase III trials.

What is added by this report?

A prospective cohort of 243 adolescents aged 12–17 years in Arizona completed weekly SARS-CoV-2 testing by nasal swab for 19 consecutive weeks. Under real-world conditions, vaccine effectiveness of full immunization (completion of the second in a 2-dose series ≥14 days earlier) was 92% against SARS-CoV-2 infections irrespective of symptom status.

What are the implications for public health practice?

In real-world conditions among adolescents aged 12–17 years, the Pfizer-BioNTech vaccine was highly effective in preventing SARS-CoV-2 infection.

TABLE 2. Contributing participants, total person-days, number of RT-PCR–confirmed SARS-CoV-2 infections by vaccination status, and estimated Pfizer-BioNTech COVID-19 vaccine effectiveness for full vaccination in preventing infection among vaccine-eligible adolescents aged 12–17 years (N = 243) — Arizona, July–December 2021

Pfizer COVID-19 vaccination status	No. of contributing participants*	Total person-days	No. of days, median (IQR)	No. of SARS-CoV-2 infections	VE, % (95% CI)	
					Unadjusted	Adjusted†,§
Unvaccinated	66	4,288	62 (23–98)	16	—	—
Partially vaccinated (≥14 days after dose 1 to day 13 after dose 2)	30	909	21 (20–28)	0	—	—
Fully vaccinated (≥14 days after dose 2)	190	21,693	119 (105–133)	5	94 (83–98)	92 (79–97)

Abbreviations: RT-PCR = reverse transcription–polymerase chain reaction; SMD = standardized mean difference; VE = vaccine effectiveness.

* Contributing participants in vaccination categories did not equal the number of participants in the study because participants could contribute to more than one vaccination category since vaccination status varies by time.

† Adjusted VE is inversely weighted for propensity to be vaccinated; all covariates met balance criteria of SMD<0.2 after weighting except community mask use and local virus circulation (SMD = 0.228 and 0.288, respectively), but community mask use was only found to change VE estimate by ≥5% when added to the model and was therefore included as a covariate in the Cox regression model for VE.

§ Five participants missing community mask use were excluded from analysis; this exclusion did not affect the VE estimate.

Siegel, MD[1,*]

During June 2021, the highly transmissible[†] B.1.617.2 (Delta) variant of SARS-CoV-2, the virus that causes COVID-19, became the predominant circulating strain in the United States. U.S. pediatric COVID-19–related hospitalizations increased during July–August 2021 following emergence of the Delta variant and peaked in September 2021.[§] As of May 12, 2021, CDC recommended COVID-19 vaccinations for persons aged ≥12 years,[¶] and on November 2, 2021, COVID-19 vaccinations were recommended for persons aged 5–11 years.[**] To date, clinical signs and symptoms, illness course, and factors contributing to hospitalizations during the period of Delta predominance have not been well described in pediatric patients. CDC partnered with six children's hospitals to review medical record data for patients aged <18 years with COVID-19–related hospitalizations during July–August 2021.[††] Among 915 patients identified, 713 (77.9%) were hospitalized for COVID-19 (acute COVID-19 as the primary or contributing reason for hospitalization), 177 (19.3%) had incidental positive SARS-CoV-2 test results (asymptomatic or mild infection unrelated to the reason for hospitalization), and 25 (2.7%) had multisystem inflammatory syndrome in children (MIS-C), a rare but serious inflammatory condition associated with COVID-19.[§§] Among the 713 patients hospitalized for COVID-19, 24.7% were aged <1 year, 17.1% were aged 1–4 years, 20.1% were aged 5–11 years, and 38.1% were aged 12–17 years. Approximately two thirds of patients (67.5%) had one or more underlying medical conditions, with obesity being the most common (32.4%); among patients aged 12–17 years, 61.4% had obesity. Among patients hospitalized for COVID-19, 15.8% had a viral coinfection[¶¶] (66.4% of whom had respiratory syncytial virus [RSV] infection). Approximately one third (33.9%) of patients aged <5 years hospitalized for COVID-19 had a viral coinfection. Among 272 vaccine-eligible (aged 12–17 years) patients hospitalized for COVID-19, one (0.4%) was fully vaccinated.[***] Approximately one half (54.0%) of patients hospitalized for COVID-19 received oxygen support, 29.5% were admitted to the intensive care unit (ICU), and 1.5% died; of those requiring respiratory support, 14.5% required invasive mechanical ventilation (IMV). Among pediatric patients with COVID-19–related hospitalizations, many had severe illness and viral coinfections, and few vaccine-eligible patients hospitalized for COVID-19 were vaccinated, highlighting the importance of vaccination for those aged ≥5 years and other prevention strategies to protect children and adolescents from COVID-19, particularly those with underlying medical conditions.

†† COVID-19 was confirmed with laboratory detection of SARS-CoV-2 by reverse transcription–polymerase chain reaction or antigen test.

§§ Patients with MIS-C as the reason for hospitalization included patients who met the clinical case definition for MIS-C (clinically severe illness requiring hospitalization in a person aged <21 years with fever, laboratory evidence of inflammation, multisystem [≥2] organ involvement and no alternative plausible diagnosis, and evidence of current or recent SARS-CoV-2 infection by reverse transcription polymerase chain reaction, serology or antigen test, or COVID-19 exposure within the 4 weeks preceding symptom onset [https://emergency.cdc.gov/han/2020/han00432.asp]) and were hospitalized for diagnosis and management of MIS-C, based on chart review.

¶¶ Patients were considered to have a viral coinfection if they had ≥1 of the following infections: type A influenza, type B influenza, unspecified influenza, coronavirus 229e, coronavirus hku1, coronavirus nl63, coronavirus 0c43, respiratory syncytial virus, adenovirus, parainfluenza type 1, parainfluenza type 2, parainfluenza type 3, parainfluenza type 4, human metapneumovirus, rhinovirus, enterovirus, or other viral coinfection.

*** Fully vaccinated was defined as having received 2 doses of an mRNA-based COVID-19 vaccine ≥14 days before hospital admission date. Partially vaccinated was defined as having received only 1 dose of an mRNA-based COVID-19 vaccine ≥14 days before hospitalization. All vaccinated patients in this study received the Pfizer-BioNTech (BNT162b2) vaccine.

MS-DOH-21-1816-A-002006

Data were collected from six U.S. children's hospitals located in areas with high COVID-19 incidence during July–August 2021 (Arkansas, District of Columbia, Florida, Illinois, Louisiana, and Texas).††† Data from hospitalized patients aged <18 years with COVID-19 or SARS-CoV-2 infection§§§ were abstracted from electronic medical records using REDCap software (version 11.1.8; Vanderbilt University). Patients were categorized¶¶¶ by reason for hospitalization: 1) acute COVID-19, 2) incidental positive SARS-CoV-2 test result, or 3) MIS-C. Patient demographic characteristics, medical history, coinfections, and disease severity, including need for and duration of respiratory support, ICU admission, IMV, extracorporeal membrane oxygenation (ECMO),**** and deaths were abstracted from the medical record. Among patients hospitalized for COVID-19, presence of underlying medical conditions (including obesity),†††† viral coinfection, and illness course were described by age group. Pearson's chi-square and Kruskal-Wallis tests were used to compare categorical and continuous variables, respectively; p-values <0.05 were

††† A convenience sample of six hospitals was selected among members of the Children's Hospital Association. All hospitals were in jurisdictions with a high level of COVID-19 community transmission during July–August 2021; these jurisdictions were not represented by the COVID-NET surveillance system. https://www.cdc.gov/coronavirus/2019-ncov/covid-data/covid-net/purpose-methods.html

§§§ COVID-19 diagnosis indicated in medical record or based on positive SARS-CoV-2 test result (antigen or polymerase chain reaction/nucleic acid amplification test, or antibody test among patients with a diagnosis of MIS-C).

¶¶¶ Abstractors selected the category that best fit the overall reason for hospitalization, with adjudication by project leaders, and through audits of 5% of all charts.

**** ECMO is a form of advanced life support used in patients with medically refractory respiratory or cardiac failure.

†††† For children aged ≥2 years, height and weight were used to calculate body mass index (BMI) (kg/m^2). BMI percentiles were calculated using BMI, age, and sex. Children with BMI percentiles ≥95% were considered to have obesity (https://www.cdc.gov/obesity/childhood/defining.html) and those with BMI ≥120% of the 95th percentile were considered to have severe obesity. BMI data extracted from charts was used if height or weight was missing. If BMI was missing or unable to be calculated, a diagnosis of obesity recorded in charts was used and severity of obesity was unable to be assessed. Obesity was not assessed for children aged <2 years.

TABLE 2. (*Continued*) Hospitalization and illness course among children and adolescents aged <18 years hospitalized for COVID-19,* by age group — six hospitals,† United States, July–August 2021

Abbreviations: BiPAP = bilevel positive airway pressure; BMI = body mass index; CPAP = continuous positive airway pressure; ECMO = extracorporeal membrane oxygenation; ICU = intensive care unit; IMV = invasive mechanical ventilation; RAD = reactive airway disease; RSV = respiratory syncytial virus.

* Patients hospitalized for COVID-19 included patients with acute COVID-19 as the primary reason for hospitalization or with acute COVID-19 as a secondary or contributing reason for hospitalization, based on chart review.

† The six children's hospitals were in Arkansas, District of Columbia, Florida, Illinois, Louisiana, and Texas.

§ Clinical characteristics and outcomes were compared among groups using Pearson's chi-square test for categorical variables and a Kruskal-Wallis test for nonnormally distributed variables.

¶ Metabolic and endocrine conditions included dyslipidemia, obesity, thyroid disorder, type 1 diabetes, type 2 diabetes, and other endocrine disorders.

** For children aged ≥2 years, height and weight were used to calculate BMI (kg/m^2). BMI percentiles were calculated using BMI, age, and sex. Those children with BMI percentiles ≥95th percentile were considered to have obesity and those with BMI ≥120% of the 95th percentile were considered to have severe obesity. BMI data extracted from charts were used if height or weight was missing. If BMI was missing or unable to be calculated, a diagnosis of obesity recorded in charts was used and severity of obesity was unable to be assessed. Obesity was not assessed for children aged <2 years.

†† Neurologic and developmental conditions included attention deficit hyperactivity disorder, autism spectrum disorder, cerebral palsy, cognitive disfunction, muscular dystrophy, neural tube defect or spina bifida, neurologic or neurodevelopmental disorder, neuropathy, plegias or paralysis, preterm birth (for children aged <2 years only), seizure disorder, and wheelchair/walker-dependence or bed-bound status.

§§ Respiratory conditions included active tuberculosis, asthma or reactive airway disease, chronic hypoxemic respiratory failure with oxygen or ventilator dependence, cystic fibrosis, current smoking or e-cigarette use, tracheostomy dependence, and other chronic lung diseases.

¶¶ Gastrointestinal or hepatic conditions included Crohn's disease, feeding tube dependence, liver disease, malnutrition, ulcerative colitis, and other gastrointestinal disorders.

*** Psychiatric conditions included anxiety, borderline personality disorder, depression, substance use disorder, and other psychiatric diagnoses.

††† Patients were considered to have a viral coinfection if they had at least one of the following infections: type A influenza, type B influenza, unspecified influenza, coronavirus 229e, coronavirus hku1, coronavirus nl63, coronavirus 0c43, respiratory syncytial virus, adenovirus, parainfluenza type 1, parainfluenza type 2, parainfluenza type 3, parainfluenza type 4, human metapneumovirus, rhinovirus enterovirus, or other viral coinfection.

were non-Hispanic Black persons or African American persons (Black), and 211 (29.6%) were Hispanic persons.

Among the 713 patients hospitalized for COVID-19, 32.5%, 51.3%, and 16.1% had zero, one or two, and three or more underlying medical conditions, respectively (Table 2). The most common conditions were obesity (32.4%), asthma or reactive airway disease (16.0%), and feeding tube dependence (8.3%). Among patients aged 12–17 years, 61.4% had obesity (60.5% of whom had severe obesity). Among patients aged 5–11 years, 33.6% had obesity (60.4% of whom had severe obesity). Among patients hospitalized for COVID-19, 210 (29.5%) had ICU admissions, eight (1.1%) received ECMO, and 11 (1.5%) died. Of the 385 (54.0%) patients hospitalized for COVID-19 who received oxygen support, high-flow nasal cannula was the most common highest level of support (142; 36.9%); 56 (14.5%) patients received IMV. Across all age groups, the median hospital stay was 3 days, and the median IMV duration was 7 days. Patients aged 12–17 years had the longest median hospitalizations (4 days) and IMV requirement (9.5 days). Viral coinfection was common among patients aged <1 year (32.4%) and 1–4 years (36.1%); overall, approximately two thirds of viral coinfections were with RSV (Table 2).

Among 272 vaccine-eligible patients hospitalized for COVID-19, one (0.4%) was fully vaccinated and 12 (4.4%) were partially vaccinated with an mRNA COVID-19 vaccine at the time of hospitalization (Table 1).

A higher percentage of patients hospitalized for COVID-19 with any underlying condition were admitted to the ICU (34.7%) compared with those without an underlying condition (18.5%) (p<0.001) (Table 3). The duration of hospitalization was longer for patients with obesity (median = 4 days [IQR = 2.0–7.5 days]) than that for those without obesity (median = 2 days [IQR = 1.0–5.0 days]) (p<0.001). A higher proportion of patients with obesity were admitted to the ICU (41.1%) than were those without obesity (23.9%) (p<0.001). A higher proportion of patients with viral coinfection required oxygen support (69.0%) compared with those without viral coinfection (51.2%) (p<0.001).

Discussion

In this study of six U.S. hospitals during July–August, 2021, approximately three quarters of pediatric patients with COVID-19–related hospitalizations were hospitalized for COVID-19. The majority of those hospitalized for COVID-19 were Black or Hispanic and were aged <5 or 12–17 years. Approximately one third of patients aged <1 and 1–4 years had a viral coinfection, approximately one third of patients aged 5–11 years and approximately two thirds of patients aged 12–17 years had obesity. Less than 1% of vaccine-eligible patients were fully vaccinated against COVID-19.

Five of the six hospitals had policies to test all pediatric patients for SARS-CoV-2 upon admission during the study period, allowing for detection of incidental positive SARS-CoV-2 test results. However, the proportion of such patients was smaller in this study compared with that in a previous report (*1*). Patients aged 0–4 and 12–17 years accounted for 79% of COVID-19–related hospitalizations in this study, which is consistent with data from other hospitals and communities (*2*). Among hospitalized children aged <5 years, most were aged <1 year, which might reflect clinical practice differences, because infants might be more likely to be hospitalized with milder disease than older children (*3*). Most patients were

Abbreviations: BIPAP = bilevel positive airway pressure; BMI = body mass index; CPAP = continuous positive airway pressure; ECMO = extracorporeal membrane oxygenation; ICU = intensive care unit; IMV = invasive mechanical ventilation; RSV = respiratory syncytial virus.

* Patients hospitalized for COVID-19 included patients with acute COVID-19 as the primary reason for hospitalization or with acute COVID-19 as a secondary or contributing reason for hospitalization, based on chart review.

† The six children's hospitals were in Arkansas, District of Columbia, Florida, Illinois, Louisiana, and Texas.

§ For children aged ≥2 years, height and weight were used to calculate BMI (kg/m^2). BMI percentiles were calculated using BMI, age, and sex. Those children with BMI percentiles ≥95th percentile were considered to have obesity, and those with BMI ≥120% of the 95th percentile were considered to have severe obesity. BMI data extracted from charts were used if height or weight was missing. If BMI was missing or unable to be calculated, a diagnosis of obesity recorded in charts was used and severity of obesity was unable to be assessed. Obesity was not assessed for children aged <2 years.

¶ Clinical characteristics and outcomes were compared among groups using Pearson's chi-square test for categorical variables and a Kruskal-Wallis test for nonnormally distributed variables.

** Patients were considered to have a viral coinfection if they had ≥1 of the following infections: type A influenza, type B influenza, unspecified influenza, coronavirus 229e, coronavirus hku1, coronavirus nl63, coronavirus 0c43, respiratory syncytial virus, adenovirus, parainfluenza type 1, parainfluenza type 2, parainfluenza type 3, parainfluenza type 4, human metapneumovirus, rhinovirus, enterovirus, or other viral coinfection.

Black or Hispanic in this study; an earlier study demonstrated higher hospitalization rates among Black or Hispanic children compared with White children (*1*).

Approximately two thirds of patients hospitalized for COVID-19, including 83% and 88% of patients aged 5–11 and 12–17 years, respectively, had one or more underlying medical conditions. Approximately two thirds of patients hospitalized for COVID-19 aged 12–17 years had obesity. Compared with patients without obesity, those with obesity required higher levels and longer duration of care. These findings are consistent with previous reports (*4*) and highlight the importance of obesity and other medical conditions as risk factors for severe COVID-19 in children and adolescents.

The proportions of patients admitted to ICU and who required IMV are similar to those in prior reports, which predominantly included hospitalized pediatric COVID-19 patients before Delta variant predominance (*2*,*5*). Adolescents were more likely to require ICU admission and oxygen support compared with other age groups and required the longest median duration of IMV. The median duration of IMV overall (7 days) is consistent with previous reports (*6*,*7*). Approximately one half of patients aged 1–4 years required

MS-DOH-21-1816-A-002010

Summary

What is already known about this topic?

Pediatric COVID-19–related hospitalization rates increased when the highly transmissible SARS-CoV-2 B.1.617.2 (Delta) variant became the predominant circulating strain.

What is added by this report?

Among children and adolescents with SARS-CoV-2 infection admitted to six hospitals during July–August 2021, 77.9% were hospitalized for acute COVID-19. Among these patients, approximately one third aged <5 years had a viral coinfection (approximately two thirds of which were respiratory syncytial virus) and approximately two thirds of those aged 12–17 years had obesity; only 0.4% of age-eligible patients were fully vaccinated.

What are the implications for public health practice?

COVID-19 vaccination and other prevention strategies are important to protect children from COVID-19, particularly children with obesity and other underlying health conditions.

oxygen support, which might be related to the high proportion with viral coinfection. This study occurred during July–August 2021, the first period during the COVID-19 pandemic with high circulation of RSV[¶¶¶¶] and other respiratory viruses. Compared with prior studies (*2*,*5*), this study found a high proportion of patients had high-flow nasal cannula as the highest level of respiratory support (37%), which might reflect a change in practice to avoid intubation or the high proportion of viral coinfections, including RSV.

On November 2, 2021, CDC recommended COVID-19 vaccinations for children aged 5–11 years (*8*). As of July 31, 2021, 29% of U.S. persons aged 12–17 years were fully vaccinated against COVID-19.[*****] In this study, only 0.4% of vaccine-eligible adolescents hospitalized for COVID-19 were fully vaccinated. Hospitalization rates have been shown to be 10 times higher among unvaccinated adolescents compared with fully vaccinated adolescents (*2*). Similarly, this study demonstrates that unvaccinated children hospitalized for COVID-19 could experience severe disease and reinforces the importance of vaccination of all eligible children to provide individual protection and to protect those who are not yet eligible to be vaccinated.

The findings in this report are subject to at least five limitations. First, the data came from only six hospitals, five of which are in the southern U.S. region. The proportion of adolescents with obesity in the southern United States is higher than in other regions,[†††††] which might explain the high rates of obesity described in this report. Therefore, findings might not be generalizable to other areas. Second, findings might reflect differences in practices by hospitals or changes in practice over time and might not reflect differences in severity of COVID-19 related to the Delta variant. Third, incomplete or missing data in medical records might lead to underreporting and underestimation of details such as COVID-19 vaccination frequencies. Fourth, at the time of hospitalization, persons aged 12–15 years had only been vaccine-eligible for 2–3 months (*9*), possibly contributing to the low vaccination rates observed. Finally, hospitals identified patients for review based on positive polymerase chain reaction and antigen SARS-CoV-2 test results and hospitalization during the study period. Therefore, proportions of patients with MIS-C are likely underestimated.

Among pediatric patients with COVID-19–related hospitalizations, many had severe illness and viral coinfections, and few vaccine-eligible patients hospitalized for COVID-19 were vaccinated. These data highlight the importance of COVID-19 vaccination for those aged ≥5 years and other prevention strategies to protect children and adolescents from COVID-19, particularly those with obesity and other underlying health conditions. Further research and surveillance for viral coinfections with SARS-CoV-2 in pediatric patients can inform public health and capacity planning (*10*).

MS-DOH-21-1816-A-002012

Evaluation of a Test to Stay Strategy in Transitional Kindergarten Through Grade 12 Schools — Los Angeles County, California, August 16–October 31, 2021

Kimberly Harris-McCoy, MSPH[1]; Veronica C. Lee, PhD[1]; Cortney Munna[1]; Andrea A. Kim PhD[1]

On December 17, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

On July 12, 2021, the California Department of Public Health updated COVID-19 school guidance, allowing a Test to Stay (TTS) strategy to increase access to in-person learning* (*1*). The TTS strategy enabled unvaccinated students, exposed in school to a person infected with SARS-CoV-2 (the virus that causes COVID-19), to remain in school while under quarantine, if both the infected person and the exposed person wore masks correctly and consistently throughout the exposure. To stay in school during the quarantine period, the exposed student must remain asymptomatic, wear a mask at school, and undergo twice weekly testing for SARS-CoV-2. To date, few studies have evaluated the impact of TTS on transmission (*2*–*4*). This study evaluated a TTS strategy implemented by Los Angeles County Department of Public Health (LAC DPH). During September 20–October 31, 2021, among 78 school districts, one half permitted TTS; in total, 432 (21%) of 2,067 schools adopted TTS. TTS schools did not experience increases in COVID-19 incidence among students after TTS implementation, and in 20 identified outbreaks in TTS schools,† no tertiary transmission was identified. The ratio of student COVID-19 incidence in TTS districts to that in non-TTS districts was similar before and after TTS adoption (rate ratio = 0.5). Non-TTS schools lost an estimated 92,455 in-person school days during September 20–October 31 while students were in quarantine, compared with no lost days among quarantined students in TTS schools. Non-TTS schools cited resource-related reasons for not adopting TTS; 75% of these schools were in LAC's most disadvantaged neighborhoods. Preliminary data from LAC suggest that a school-based TTS strategy does not increase school transmission of SARS-CoV-2, and might greatly reduce loss of in-person school days; however, TTS might have barriers to implementation and require resources that are not available for some schools. Continued efforts to simplify school quarantine strategies might help to ensure that all students have access to safe in-person education. Although vaccination remains the leading public health recommendation to protect against COVID-19 for persons aged ≥5 years, schools might consider TTS as an option for allowing students with a school exposure who are not fully vaccinated to remain in the classroom as an alternative to home quarantine.

LAC has 78 public school districts with 2,067 schools for students in transitional kindergarten through grade 12.§ Schools require indoor masking, physical distancing where feasible, vaccination, isolation of persons with confirmed cases, contact tracing, quarantining of close contacts, and SARS-CoV-2 testing (*5*). School SARS-CoV-2 testing strategies include weekly testing of asymptomatic, unexposed persons and response testing of persons with symptoms or exposures using SARS-CoV-2 nucleic acid amplification tests or antigen tests. LAC DPH is notified of school COVID-19 cases and close contacts of persons who received positive test results via a secure line list or online survey using REDCap (version 10.3.3; Vanderbilt University).

LAC DPH allowed schools to adopt a TTS strategy starting on September 20, 2021. For asymptomatic, unvaccinated students under quarantine orders,¶ TTS was permitted during the quarantine period if the exposure occurred in school and the exposed student and infected person both wore masks correctly and consistently during the exposure. During TTS, contacts could continue in-person academic activities during regular school hours if they remained asymptomatic, wore a mask while at school (indoors, outdoors, and on school buses), received testing twice weekly by a certified testing program or health care provider,** and agreed to quarantine at home

* California Department of Public Health's Test to Stay strategy in k–12 schools is described in section 8 of the COVID-19 Public Health Guidance for K–12 Schools in California, 2021–22 School Year. https://www.cdph.ca.gov/Programs/CID/DCDC/Pages/COVID-19/K-12-Guidance-2021-22-School-Year.aspx

† A school outbreak was defined as three or more epidemiologically linked COVID-19 school-associated cases within 14 days. Outbreaks that occurred after September 20, 2021, were reviewed. Because students participating in TTS were permitted to continue in-person academic activities in school only while under quarantine, outbreak data review was limited to outbreaks that occurred in an academic setting at school (e.g., classroom outbreak). Outbreaks in youth sports settings were excluded.

§ Los Angeles County Public School Districts do not include independent, independent charter, regional occupational programs, or Los Angeles County Special Education. Transitional kindergarten is a public school program serving to bridge preschool and kindergarten.

¶ Fully vaccinated persons with school exposures are exempt from quarantine but are recommended to test 5–7 days after their last exposure date. A person is considered fully vaccinated 2 weeks after receiving 1) the Janssen (Johnson & Johnson) COVID-19 vaccine; 2) the second dose of a Pfizer or Moderna mRNA COVID-19 vaccine; or 3) completing the series of a COVID-19 vaccine that is listed for emergency use by the World Health Organization.

** For school-based TTS, the California Department of Public Health recommends the same testing cadence as in standard quarantine: testing immediately after notification of the exposure and subsequent testing on or after day 5 following the date of last exposure.

MS-DOH-21-1816-A-002013

when not at school. Contacts could not participate in extracurricular activities or before- or after-school care during the quarantine period.

School COVID-19 cases were defined as a laboratory-confirmed SARS-CoV-2 infection in a person who was at school anytime during the 14 days before their episode date (symptom onset date or the positive SARS-CoV-2 test result date, whichever was earlier). School cases were verified with test results reported by laboratories or health care providers to the LAC DPH Integrated Reporting and Investigation Surveillance System (IRIS). Cases among students with episode dates during August 16–October 31 and school exposures of student close contacts during August 17–October 31 were used to calculate secondary infection risk (number of quarantined contacts with a COVID-19 diagnosis 1–14 days after exposure divided by the total number of quarantined contacts).[††] COVID-19 student case rates were calculated as the average daily number of student cases during a 7-day period divided by the number of enrolled students.[§§] COVID-19 student rates are presented with 95% CIs; rates with non-overlapping CIs were considered to be significantly different. COVID-19 student rate ratios were calculated by dividing COVID-19 student case rates in TTS schools by those in non-TTS schools.

School district administrators were interviewed during November 3–16, 2021, to determine whether the district adopted TTS and to assess implementation challenges and reasons for not implementing TTS. TTS districts might have permitted TTS only for certain school levels; therefore, schools were subsequently categorized as having adopted versus not adopted TTS. School outbreak data were reviewed for evidence of tertiary transmission within TTS schools. Tertiary transmission was defined as likely SARS-CoV-2 transmission to a student, from a student participating in TTS who received a positive SARS-CoV-2 test result during the TTS period (i.e., a student with a secondary case). Schools were grouped into quartiles of disadvantage based on the California Healthy Places Index (HPI)[¶¶] (*6*). Zip codes falling within the lowest HPI quartile represented the most disadvantaged neighborhoods. Among non-TTS schools, estimation of lost in-person school days assumed 5 missed school days for each 7-day student quarantine.[***] This analysis was restricted to public school districts; Pasadena Unified School District (USD), Long Beach USD, and non-residents of LAC were excluded.[†††] SAS statistical software (version 9.4; SAS Institute) was used for all analyses. This public health surveillance activity was reviewed and approved by LAC DPH.

An estimated 1,292,067 LAC public school students returned to school for the 2021–22 academic year, which commenced on August 16, 2021, for most LAC public schools. During August 16–October 31, an average of 462,189 student and staff member SARS-CoV-2 tests were conducted each week in all schools. During the week of August 16, 0.6% of test results were positive, but this percentage declined to 0.2% by October 31 (Figure 1). Among all schools, 12,919 student COVID-19 cases (1% of the student population) and 57,513 student contacts (4% of the student population) were reported during the 10-week observation period; case numbers peaked at 2,270 during the week of August 16, and the number of contacts peaked at 8,589 during the week of August 23.

During September 20–October 31, among 78 school districts, 39 (50%) permitted TTS; within these districts, 94% of schools (432 of 452) adopted TTS (Table). These TTS schools constitute 21% of LAC public schools. LAC's largest school district, which accounts for one third of public school students, did not adopt TTS. Overall, within the 1,635 non-TTS schools, 4,322 COVID-19 cases occurred among 967,188 enrolled students (4.7 cases per 1,000 students); among 18,729 student close contacts, the secondary infection risk was 1.3%. Non-TTS districts lost an estimated 92,455 in-person school days during September 20–October 31 while students were in quarantine. Within the 432 TTS schools, among 324,879 enrolled students, 812 COVID-19 cases occurred (2.5 cases per 1,000 students); among 7,511 student close contacts, the secondary infection risk was 0.7%. As a result of the TTS protocol, no in-person school days were lost among quarantined students participating in TTS. Among 20 school outbreaks that occurred in TTS schools after TTS implementation, three outbreaks included four TTS students who were secondarily infected; contact tracing confirmed seven contacts of these patients and identified no tertiary transmission.

[††] Contacts who had a positive SARS-CoV-2 test result 1–14 days after exposure reported in IRIS but not identified by schools were also classified as having secondary infections. In order to correct surveillance data reporting ambiguities, contacts with a positive SARS-CoV-2 test result date the same as the quarantine start date were not considered to have secondary infections.

[§§] School district student enrollment was reported by the California Department of Education for the 2020–21 school year.

[¶¶] California HPI classifies California zip codes into quartiles based on a composite score of disadvantages. Indicators that determine the HPI score include economic, education, transportation, social, neighborhood, housing, clean environment, and health care access. Zip codes falling within the lowest HPI quartile in LAC represent the most disadvantaged neighborhoods.

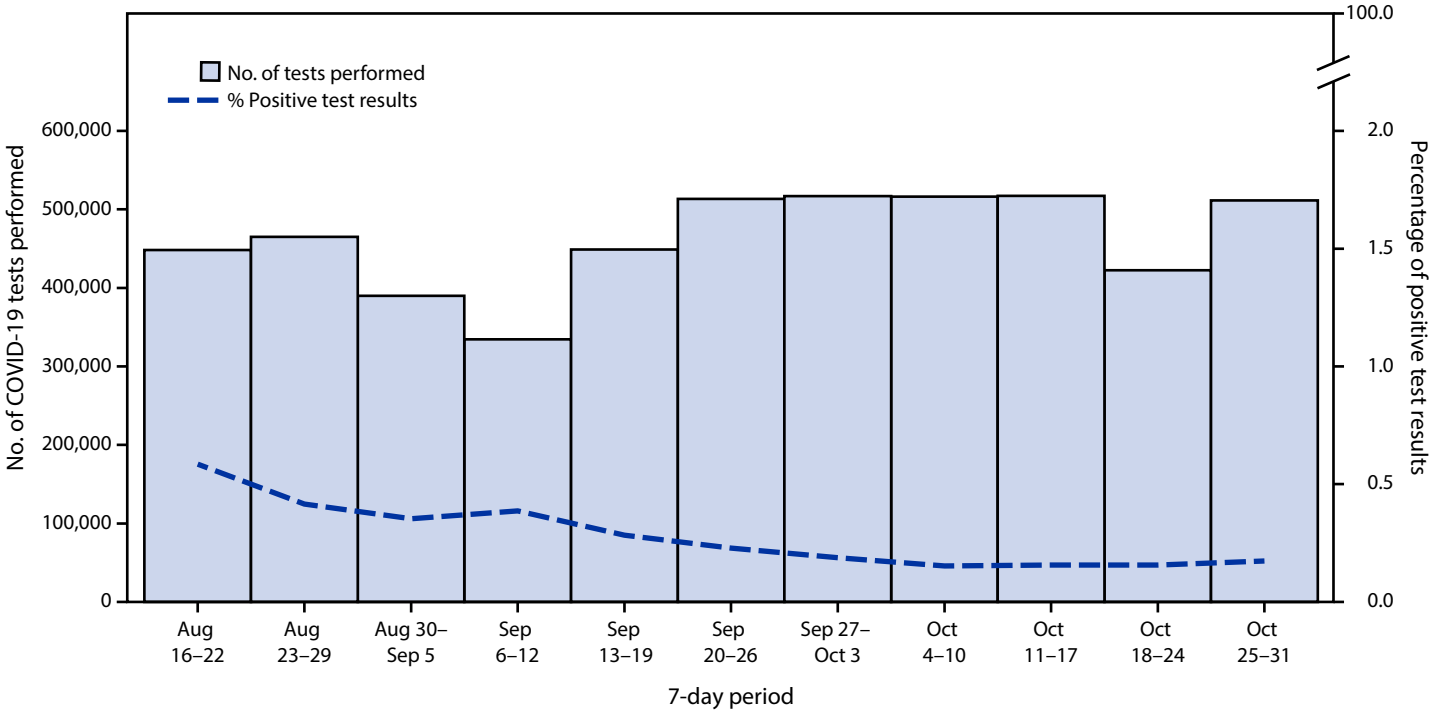
[***] Number of lost school days assumed that the quarantined students were under a 7-day quarantine period, and the student might be released from quarantine after day 7 from the last date of exposure, if the student remained without symptoms and had a negative SARS-CoV-2 viral diagnostic test result from a specimen collected on or after day 5 from the last date of exposure. It is assumed that every 7-day student quarantine resulted in 5 days of missed in-person school days. This represents the lower bound of missed in-person school days because quarantined persons without symptoms and a SARS-CoV-2 viral diagnostic test during quarantine were subject to a 10-day quarantine period.

[†††] The cities of Long Beach and Pasadena have their own health departments, separate from LAC DPH, and were therefore not included in the analysis.

MS-DOH-21-1816-A-002014

Before TTS adoption (August 16–September 19, 2021), average daily student COVID-19 incidence was lower in TTS districts (10 per 100,000 students; 95% CI = 7–13) than in non-TTS districts (20 per 100,000 students; 95% CI = 18–23) (Figure 2). After TTS adoption, average student daily case rates declined in all districts but remained lower on average in TTS districts (6 per 100,000 students; 95% CI = 3–9) compared with non-TTS districts (11 per 100,000 students; 95% CI = 9–13). The ratio of student COVID-19 incidence in TTS districts to that in non-TTS districts was similar before and after TTS adoption (rate ratio = 0.5). (Figure 2).

FIGURE 1. Number of SARS-CoV-2 tests performed and percentage of positive test results* in transitional kindergarten through grade 12 public school districts — Los Angeles County, California, August 16–October 31, 2021



* Weekly data might have included repeat tests for an individual person.

TABLE. Characteristics of transitional kindergarten through grade 12 public schools, by school Test to Stay status — Los Angeles County, California, September 20–October 31, 2021

Characteristic	Did not implement TTS	Implemented TTS
Schools	**(n = 1,635)**	**(n = 432)**
No. of enrolled students*	967,188†	324,879
Student COVID-19 cases, total	**4,322**	**812**
Elementary school, no. (% of total)	2,403 (56)	341 (42)
Middle school, no. (% of total)	956 (22)	159 (20)
High school, no. (% of total)	963 (22)	312 (38)
Student close contacts of COVID-19 cases,§ total	**18,729**	**7,511**
Elementary school, no. (% of total)	9,177 (49)	2,253 (30)
Middle school, no. (% of total)	4,870 (26)	1,878 (25)
High school, no. (% of total)	4,682 (25)	3,380 (45)
Student secondary infection risk¶	1.3	0.7
Percentage of schools in the most disadvantaged neighborhoods**	74	26

Abbreviations: HPI = Healthy Places Index; LAC = Los Angeles County; TTS = Test to Stay.

* District student enrollment reported by the California Department of Education as of the 2020–21 school year.

† LAC's largest school district, which accounts for one third of public-school students, did not adopt TTS.

§ Student contacts with unknown school level and age were excluded.

¶ Secondary infection risk was defined as the number of quarantined contacts who received a positive SARS-CoV-2 test result 1–14 days after exposure divided by the total number of quarantined contacts. Limited to student school contacts.

** Based on the California HPI, which classifies California zip codes into quartiles based on a composite score of disadvantages. Indicators that determine the HPI score include economic, education, transportation, social, neighborhood, housing, clean environment, and healthcare access. Zip codes falling within the lowest HPI quartile in LAC represent the most disadvantaged neighborhoods. HPI data were missing for 16 non-TTS schools and 22 TTS schools.

MS-DOH-21-1816-A-002015

Among the schools that implemented TTS, 107 of 410 (26%) were categorized as most disadvantaged compared with 1,192 of 1,619 (74%) non-TTS schools.[§§§] Challenges cited to TTS implementation were limited staffing and systems to monitor mask use, testing, and lack of family support (Supplementary Table, https://stacks.cdc.gov/view/cdc/112641). Non-TTS districts reported similar resource barriers.

Discussion

Among LAC schools that implemented TTS during September 20–October 31, 2021, COVID-19 incidence did not increase, and tertiary transmission was not identified in school outbreaks after TTS implementation. Non-TTS districts lost substantial in-person school days. Taken together, these findings reinforce the usefulness of TTS for helping to maintain in-person learning in schools.

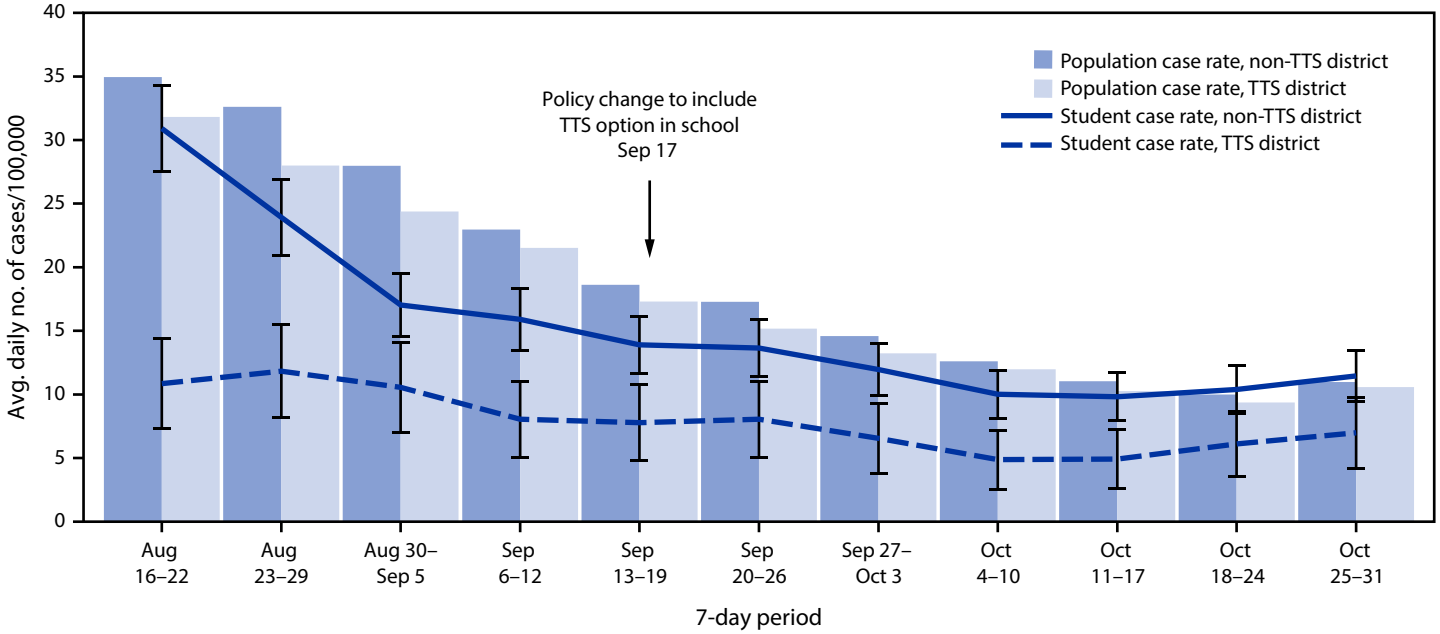
Only one in five public schools in LAC adopted TTS, and non-TTS schools cited resource-related reasons for opting out of TTS. Inability to implement TTS might exacerbate health and educational disparities between TTS and non-TTS schools. Operationalizing TTS requires staffing resources and systems for monitoring eligibility for and compliance to TTS that might not currently be available in schools in disadvantaged communities, including most LAC non-TTS schools. Moreover, because TTS is currently permitted for quarantined students only during regular school hours, families who rely on before- and after-school programs might opt for home quarantine.

The findings in this report are subject to at least three limitations. First, monitoring systems were not established to assess compliance with TTS requirements or designed to evaluate school transmission before and after TTS adoption. Second, this analysis relied on the existing school case reporting system to characterize school transmission after TTS adoption. Because TTS schools were not required to inform LAC DPH about which students participated in TTS, tertiary transmission from a student participating in TTS could not be determined in non-outbreak settings. Finally, rates were unadjusted and did not control for confounders. However, non-TTS schools were disproportionately located in the most disadvantaged neighborhoods, where population case rates tend to be highest (*7*); this might explain the difference in student case rates in TTS and non-TTS schools.

Preliminary data from LAC suggest that a school-based TTS strategy in a large and diverse county did not increase school transmission risk and might greatly reduce loss of in-person school days. Thus, schools might consider TTS as an option for keeping quarantined students in school to continue in-person learning. However, the resources and operational complexities required to implement school-based TTS might present

[§§§] HPI data were missing for 16 (1%) of 1,635 non-TTS schools and 22 (5%) of 432 TTS schools.

FIGURE 2. Student and population COVID-19 case rates,* by school district Test to Stay status — Los Angeles County, California, August 16–October 31, 2021



Abbreviation: TTS = Test to Stay.

* SARS-CoV-2 student case rates were calculated as the average daily number of student cases reported to Los Angeles County Department of Public Health during a 7-day period divided by the number of enrolled students at the school district level. SARS-CoV-2 population case rates were calculated as the average daily number of community cases reported to Los Angeles County Department of Public Health during a 7-day period divided by the population of county residents at the school district level. Standard error bars shown for student case rates.

MS-DOH-21-1816-A-002016

Summary

What is already known about this topic?

Los Angeles County Department of Public Health permits Test to Stay (TTS) as a COVID-19 quarantine strategy that allows students with school exposures to remain in school if both infected and exposed persons wore masks.

What is added by this report?

One in five LAC public schools adopted TTS. In TTS schools, student case rates did not increase, and tertiary transmission was not identified. A higher percentage of disadvantaged schools did not implement TTS.

What are the implications for public health practice?

TTS does not appear to increase transmission risk in public schools and might greatly reduce loss of in-person school days. Implementation requires resources that might be currently unavailable for some schools. Vaccination remains the leading recommendation to protect against COVID-19; TTS allows students with a school exposure to remain in the classroom as an alternative to home quarantine.

barriers, particularly for disadvantaged schools. Efforts to better understand barriers and simplify school quarantine strategies might help ensure that all students have access to safe in-person education. Although vaccination remains the leading public health recommendation to protect against COVID-19 for those aged ≥5 years, schools might consider TTS as an option for allowing close contacts who are not fully vaccinated to remain in the classroom as an alternative to home quarantine.

Evaluation of Test to Stay Strategy on Secondary and Tertiary Transmission of SARS-CoV-2 in K–12 Schools — Lake County, Illinois, August 9–October 29, 2021

Natsumi Nemoto, MPH[1]; Soneet Dhillon, MS[2]; Steven Fink, MA[3]; Emily J. Holman, MSc[3]; Amyanne Keswani Cope, MS[1]; Thu-Ha Dinh MD[3]; Juliana Meadows, PhD[3]; Dina Taryal, MD[4]; Funmilayo Akindileni, MD[1]; Megan Franck, MPH[4]; Emily Gelber, MSW[4]; Lea Bacci[4]; Sana Ahmed, MD[4]; Ebony S. Thomas, MPH[3]; John C. Neatherlin, MPH[3]

On December 17, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

The COVID-19 pandemic has resulted in school closures and reduction of in-person learning (*1*). In August 2021, the Lake County Health Department (LCHD) in Illinois introduced a Test to Stay (TTS) strategy, whereby unvaccinated students, teachers, and staff members with certain school-related COVID-19 exposures could remain in school and participate in school-related extracurricular activities. Eligibility to participate in TTS required the following conditions to be met: 1) the exposure occurred while both the person with COVID-19 (index patient) and the close contact were masked; 2) the close contact remained asymptomatic, practiced consistent mask wearing, and maintained physical distancing; and 3) the close contact underwent testing for SARS-CoV-2 (the virus that causes COVID-19) on days 1, 3, 5, and 7 after exposure to the index patient. LCHD permitted kindergarten through grade 12 (K–12) schools in Lake County to implement TTS; 90 schools, representing 31 school districts in Lake County, implemented TTS during August 9–October 29, 2021. During the implementation period, 258 COVID-19 cases were reported. Among 1,035 students and staff members enrolled in TTS, the secondary attack risk (number of close contacts who received a positive SARS-CoV-2 test result within 14 days after exposure to an index patient, divided by total number of close contacts) was 1.5% (16 of 1,035). Among the 16 secondary cases identified, all were in students, and none appeared to transmit SARS-CoV-2 to other school-based contacts. However, nine tertiary cases were identified among household contacts of the 16 secondary cases, and four of the nine were fully vaccinated. Assuming a maximum of 8 missed school days for every 10-day quarantine period, up to 8,152 in-person learning days were saved among TTS participants. Implementation of TTS with other concurrent prevention strategies, including masking and physical distancing, limited further spread of SARS-CoV-2 within K–12 schools and allowed students to safely sustain in-person learning. Although vaccination remains the leading public health recommendation to protect against COVID-19 for those aged ≥5 years, schools might consider TTS as an option for allowing close contacts who are not fully vaccinated to remain in the classroom as an alternative to home quarantine.

In fall 2021, LCHD encouraged eligible schools in Lake County, Illinois, to implement TTS. School eligibility criteria included 1) ability to report test results, including index patients and school-based close contacts, to Illinois Department of Public Health (IDPH) and LCHD within 24 hours and 2) school staff members' availability for interviews to provide details regarding school-related exposures. School-based close contacts of persons with COVID-19 were eligible to participate in TTS if both the person with COVID-19 (i.e., index patient) and the contact were masked during the exposure, and the exposure occurred at school or while participating in school-related extracurricular activities. Contacts who met eligibility criteria could participate in TTS if they remained asymptomatic, practiced consistent mask wearing, maintained physical distancing, obtained parental consent, and underwent SARS-CoV-2 testing at school or off campus* on days 1, 3, 5, and 7 after exposure. Asymptomatic TTS participants who received negative SARS-CoV-2 test results and adhered to TTS requirements, including mandatory masking, could ride the school bus and attend in-person learning and school-based extracurricular activities, including sports. TTS participants were required to quarantine at home for 14 days while not attending school or participating in school-based activities. Close contacts were defined as persons who were within 3 feet (0.9 meters) of a COVID-19 patient for ≥15 cumulative minutes over a 24-hour period.† Close contacts who had unmasked exposures within 6 feet (1.8 meters) of a COVID-19 patient were not eligible for TTS and quarantined at home. Persons who were fully vaccinated or who received

* Schools were provided flexibility to recommend that close contacts get off-campus nucleic acid amplification testing or antigen testing through pharmacies, clinics, or community-based testing sites during extended holidays when an interruption in the testing cadence was anticipated or if the school experienced a shortage of testing resources. In addition, some schools might have contracted private laboratories to assist in their testing program.

† Contacts with exposure to COVID-19 outside of school in the 14 days before the school-based exposure were not eligible to participate in TTS. Staff member close contacts were defined as those within 6 ft of a patient with COVID-19 for ≥15 cumulative minutes over a 24-hour period. Before October 18, 2021, a close contact on school transportation was defined by IDPH as being within 6 ft for ≥15 minutes over a 24-hour period. After October 18, 2021, the definition changed to <3 ft for ≥15 minutes over a 24 hour-period and those within 3–6 ft were no longer considered close contacts if both the confirmed patient and the close contact were masked and windows were opened or HEPA air filter was used.

MS-DOH-21-1816-A-002018

a COVID-19 diagnosis in the 90 days before exposure were not required to quarantine and were not eligible to participate in TTS.

Schools reported COVID-19 case and close contact information to LCHD via REDCap (version 11.2.6; Vanderbilt University). LCHD staff members called parents of close contacts to identify additional exposures outside of school. Data were supplemented with information from the Salesforce case investigation and contact tracing management system, Illinois' National Electronic Disease Surveillance System (I-NEDSS), and the Illinois state vaccination registry. Among TTS participants, secondary cases were defined as contacts who received a positive SARS-CoV-2 test result by a contact within 14 days after exposure to an index patient. Secondary attack risk of TTS participants was defined as number of close contacts who received a positive SARS-CoV-2 test result within 14 days after exposure divided by total number of close contacts. Estimated in-person learning days saved from TTS was calculated assuming a maximum of 8 missed school days for every 10-day quarantine. All analyses were performed using SAS software (version 9.4; SAS Institute). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[§]

During August 9–October 29, 2021, 90 Lake County schools implemented TTS, representing 53.7% (6,267) of staff members and 53.4% (65,384) of public school students in Lake County (*2*). During this period, 258 index COVID-19 patients and 1,664 close contacts were reported. Among 1,068 close contacts eligible for TTS, 1,035 (96.9%) participated (Figure). Among TTS participants, 16 secondary cases were identified, all of whom were in students (Table 1); no secondary cases were identified among staff members. Eleven of the 16 secondary cases occurred among males, and nearly all cases were in non-Hispanic White students. The overall secondary attack risk was 1.5% (16 of 1,035).

The 16 students with secondary cases received their positive test results on days 1 (three students), 2 (two), 3 (two), 4 (two), 5 (four), 6 (one), and 10 (two). Testing after day 7 occurred for those who missed the last day of TTS testing because of school holidays or weekends. Seven of the 16 students with secondary cases were symptomatic on the date of their positive test result, three developed symptoms after receiving a positive test result, and six remained asymptomatic. Based on investigation interviews, the most common likely locations[¶] of COVID-19 exposure among TTS participants were school buses (56.3%), classrooms (32.4%), and school-sanctioned sports (7.4%); among these locations, the secondary attack risks were 1.5%, 0.6%, and 6.5%, respectively (Table 2).

* This group represents secondary cases.

Secondary transmission was lowest in elementary schools (1.1%), followed by middle schools (1.3%) and high schools (4.9%).

Assuming a maximum of 8 missed school days for every 10-day quarantine, TTS preserved up to 8,152 in-person learning days for TTS close contacts. None of the 16 secondary cases appeared to transmit SARS-CoV-2 to other school-based contacts. However, nine tertiary cases in five households were identified among household contacts of the 16 secondary cases; four of the nine were fully vaccinated (Figure).

Discussion

Implementation of a TTS strategy with multiple prevention components, including masking and physical distancing, resulted in low secondary transmission of SARS-CoV-2 in K–12 schools in Lake County, Illinois. These findings highlight the usefulness of TTS to limit school-based transmission and sustain in-person learning (*1*,*3*,*4*). Previous research suggests that limited in-person instruction during the pandemic might have had a negative effect on learning and well-being among children (*5*).

Secondary transmission risk to students exposed during school-sanctioned sports was higher than that associated with classroom or school bus exposures. This is consistent with studies showing high transmission among sports participants (*6*,*7*). Also consistent with previous research (*8*), this study found that household contacts of persons exposed at school continue to be at risk for infection; among household contacts of the 16 secondary patients, nine tertiary cases were identified, four in fully vaccinated persons. Schools can help inform parents

† Classroom exposures include academic classes, indoor recess, physical education class, and staff meetings.
§ Extracurricular activities include drama club and band.

Summary

What is already known about this topic?

COVID-19 transmission within K–12 schools can remain low with implementation of multiple, concurrent prevention strategies.

What is added by this report?

During fall 2021, 90 Lake County, Illinois, schools implemented Test to Stay (TTS), permitting eligible close contacts with masked COVID-19 exposures to remain in school. Secondary transmission among TTS participants was 1.5%; no tertiary transmission was observed among school-based contacts; however, tertiary cases were identified among household contacts. Implementation of TTS preserved up to 8,152 in-person learning days.

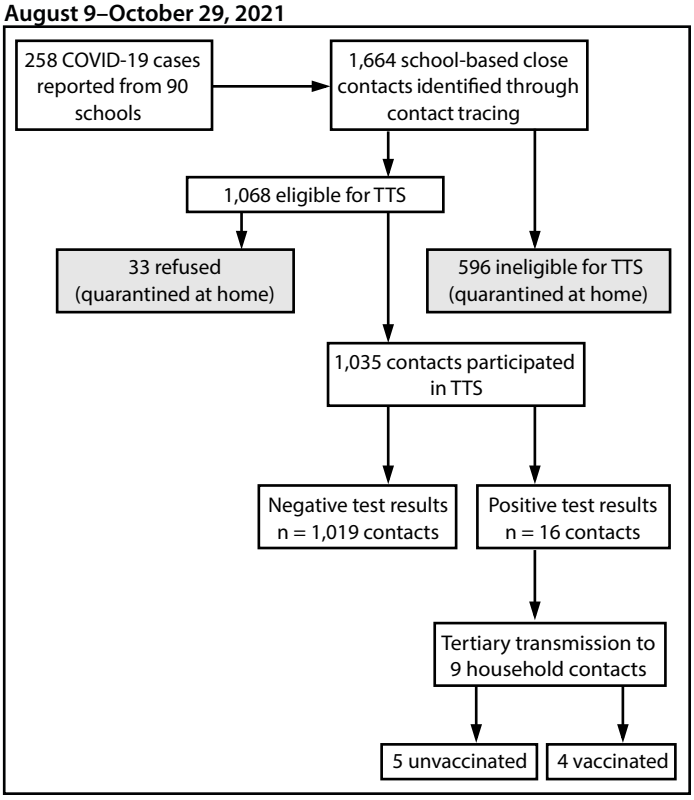
What are the implications for public health practice?

Although vaccination remains the leading recommendation to protect against COVID-19, TTS allows close contacts to remain in the classroom as an alternative to home quarantine.

and guardians about the benefits of COVID-19 prevention strategies, including vaccination.

Although TTS can help limit in-school transmission of SARS-CoV-2, it is a resource-intensive strategy that might be difficult to implement because of increased administrative demands on staff members, requirements for robust contact identification and tracing, and testing availability. Low-resource schools might lack space for physical distancing during lunch, resulting in unmasked exposures within 6 feet, which would disqualify students from TTS eligibility, necessitating home quarantine. Among the 90 TTS schools in this study, 25.6% participated in a subsidized lunch program, compared with 38.1% of schools that did not implement TTS (*9*). Some

FIGURE. Identification of students and staff members who received a positive SARS-CoV-2 test result, school-based close contacts,* and SARS-CoV-2 test results among close contacts — Lake County, Illinois, August 9–October 29, 2021



Abbreviation: TTS = Test to Stay program.
* Ineligibility for TTS includes unmasked exposures within 6 feet of a person with a case of COVID-19 and exposure to a person with a case of COVID-19 outside of school or school-related activities.

schools reported a shortage of testing supplies, requiring TTS participants to access off-site testing, which might have presented a barrier in low-resource school settings. State and local public health and education agencies should strive to ensure that schools in low-resource areas have equitable access to staffing and testing supplies to implement TTS.

The findings in this report are subject to at least seven limitations. First, inequity in school districts' staffing and testing resources might have introduced selection bias because only schools with sufficient resources offered TTS. High-resource schools might have more staffing capacity and physical spacing to apply prevention strategies (e.g., distancing students), which might have resulted in low transmission levels that are not generalizable to low-resource schools. Second, data might not be generalizable to areas with higher COVID-19 incidences and lower vaccination rates; COVID-19 incidence (7-day rolling average number of cases per 100,000 persons) in Lake County ranged from 59.7 to 217.1 over the evaluation period, with 53.5% of the total population vaccinated (*10*). Third, 33% of parents did not respond to LCHD calls or might have chosen not to disclose exposures occurring outside school, resulting in students at high risk being incorrectly enrolled

MS-DOH-21-1816-A-002020

in TTS. This would likely have resulted in an overestimation of secondary transmission among TTS participants. Fourth, testing days often deviated from testing cadence because school testing was not conducted on weekends. This deviation might have resulted in a delay of case and close contact identification. Fifth, teachers and staff members had much lower participation rates than did students in this evaluation because of high vaccination rates, low number of exposures meeting close contact definition, and lack of awareness in some schools that adults could participate in TTS. Sixth, households representing three secondary cases were unresponsive to attempted interviews to ascertain tertiary transmission, resulting in incomplete investigations. Finally, this analysis assumes that secondary attack risk represents direct transmission from contacts to cases. Given the unknown exposures and overlapping incubation and infectious periods that occur, distinct generations of transmission might be difficult to ascertain.

Implementation of TTS in coordination with other concurrent prevention strategies, including masking and physical distancing, allowed transmission of SARS-CoV-2 to remain low among K–12 schools in Lake County, Illinois, and saved up to 8,152 in-person learning days. Although vaccination remains the leading public health recommendation to protect against COVID-19 for those aged ≥5 years, schools might consider TTS as an option for allowing close contacts who are not fully vaccinated to remain in the classroom as an alternative to home quarantine.

MS-DOH-21-1816-A-002021

Investigation of a SARS-CoV-2 B.1.1.529 (Omicron) Variant Cluster — Nebraska, November–December 2021

Lauren Jansen, MD[1,2]; Bryan Tegomoh, MD[1,3]; Kate Lange[4]; Kimberly Showalter[4]; Jon Figliomeni, MHA[1]; Baha Abdalhamid, MD, PhD[5]; Peter C. Iwen, PhD[5]; Joseph Fauver, PhD[6]; Bryan Buss, DVM[1,7]; Matthew Donahue, MD[1]

On December 28, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

The B.1.1.529 (Omicron) variant of SARS-CoV-2 (the virus that causes COVID-19) was first detected in specimens collected on November 11, 2021, in Botswana and on November 14 in South Africa;* the first confirmed case of Omicron in the United States was identified in California on December 1, 2021 (*1*). On November 29, the Nebraska Department of Health and Human Services was notified of six probable cases† of COVID-19 in one household, including one case in a man aged 48 years (the index patient) who had recently returned from Nigeria. Given the patient's travel history, Omicron infection was suspected. Specimens from all six persons in the household tested positive for SARS-CoV-2 by reverse transcription–polymerase chain reaction (RT-PCR) testing on December 1, and the following day genomic sequencing by the Nebraska Public Health Laboratory identified an identical Omicron genotype from each specimen (Figure). Phylogenetic analysis was conducted to determine if this cluster represented an independent introduction of Omicron into the United States, and a detailed epidemiologic investigation was conducted. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.§

The index patient, who was unvaccinated, had a history of domestically acquired symptomatic SARS-CoV-2 infection confirmed by RT-PCR a year prior in November 2020. He reported unmasked close contact¶ with a masked, coughing person on November 20, 2021, during an international conference in Nigeria, which included attendees from multiple African countries. Before his return trip to the United States, he completed required pretravel testing with receipt of a negative antigen test result on November 21. Upon his return on November 23, while still asymptomatic, he had unmasked close contact with five household contacts. One household contact was fully vaccinated** (second Pfizer-BioNTech vaccine dose received in August 2021) and had previous symptomatic COVID-19 (RT-PCR confirmed in November 2020), three were unvaccinated and had previous symptomatic COVID-19 (RT-PCR confirmed in November 2020), and one was unvaccinated and had mild upper respiratory symptoms in November 2020, just before illness onset in the other household members, but received a negative SARS-CoV-2 RT-PCR test result at that time. No household members reported underlying medical conditions or immunocompromising conditions known to increase the risk for severe COVID-19 or diminish response to vaccination.††

On November 24, 2021, the index patient experienced symptoms consistent with COVID-19§§ and initially received a positive SARS-CoV-2 antigen test result from a local medical center on November 26. All six household members (median age = 18.5 years; range = 11–48 years) experienced symptom onset during November 24–26; median interval between earliest possible exposure to the index patient and symptom onset was 73 hours (range = 33–75 hours). The index patient and the four household contacts with previous confirmed infections described the symptoms and severity of their recent COVID-19 infection as being similar to or milder than those during their first infection. The five reinfected patients experienced fewer current symptoms, including loss of taste (none), loss of smell (none), and subjective fever (two), compared with symptoms reported during their first infections (four, four, and four, respectively). The unvaccinated patient without a previous COVID-19 diagnosis experienced cough, joint pain, congestion, fever, and chills. None required hospitalization for either their first or second infections. Twelve close community contacts of the family were identified. Four consented to testing for SARS-CoV-2 (median of 10.5 days postexposure; range = 10–11 days); specimens from these four close contacts tested negative.

Epidemiologic and clinical features of Omicron infection are still being described. Observations from this investigation, which included one patient who experienced reinfection¶¶ after having been fully vaccinated, four patients who experienced reinfection,

MS-DOH-21-1816-A-002023

and one who experienced their first infection, suggest a shorter incubation period and a clinical syndrome similar to or milder than that associated with previously described variants in persons who have been vaccinated or previously infected, and add to existing evidence suggesting an increased potential for reinfection.*** Whereas the median SARS-CoV-2 incubation period has been described as ≥5 days (*2*,*3*), and closer to 4 days for the SARS-CoV-2 B.1.617.2 (Delta) variant,††† the median incubation period§§§ observed in this cluster was approximately 3 days. Although few clinical descriptions of Omicron infections are available, mild illness among vaccinated patients has been reported (*4*). It is unknown whether the mild clinical syndromes or differing symptom descriptions are a result of existing immunity or altered clinical features associated with Omicron infection. The five reinfections, including one after full vaccination, might be explained by waning immunity, the potential for partial immune evasion by Omicron, or both. Conclusions drawn from these observations are limited by small sample size. More data will be needed to fully understand the epidemiology of the Omicron variant.

Travel history of the index patient and phylogenetic analysis of the secondary cases indicate an international introduction of the Omicron variant, consistent with other early cases identified in the United States (*1*). The recent emergence of Omicron, which is now projected to be the dominant variant in the United States,¶¶¶ reinforces the importance of vaccination, in coordination with other prevention strategies (e.g., masking and physical distancing), to protect people from COVID-19, slow transmission, and reduce the likelihood of new variants emerging. In addition, the rapid identification and epidemiologic characterization of this cluster underscore the importance of robust and timely genomic surveillance to detect and respond to emerging SARS-CoV-2 variants of concern.

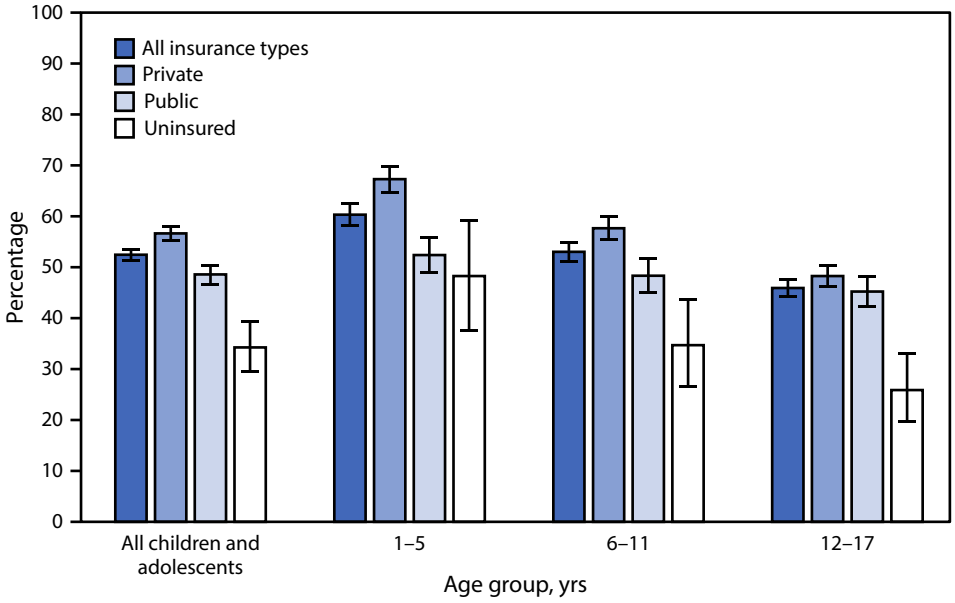
QuickStats

FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Percentage* of Children and Adolescents Aged 1–17 Years Who Received an Influenza Vaccine Within the Past 12 Months,† by Health Insurance Coverage§ and Age Group — National Health Interview Survey, United States, 2019–2020¶



* With 95% CIs indicated with error bars.

† Based on an affirmative response to the question, "There are two types of flu vaccinations. One is a shot and the other is a spray, mist, or drop in the nose. During the past 12 months, have you had a flu vaccination?" Annual calendar-year estimates of vaccinations are presented, which might differ from seasonal influenza vaccination totals that reflect vaccinations obtained during the influenza season.

§ Health insurance coverage is based on the status at the time of interview. Private insurance includes plans obtained through an employer, purchased directly, and received through local and community programs. Public insurance includes persons without private insurance who reported Medicaid, Children's Health Insurance Program, or other state-sponsored health plans. In addition to those without coverage, uninsured includes a very small percentage of children and adolescents who only have Indian Health Service coverage or a private plan that paid for only one type of service.

¶ Estimates are based on household interviews of a sample of the civilian, noninstitutionalized U.S. population.

Throughout calendar years 2019–2020, 52.4% of children and adolescents aged 1–17 years received an influenza vaccine within the previous 12 months. The percentage was highest in children and adolescents with private insurance (56.6%), followed by those with public insurance (48.6%), and lowest in the uninsured (34.2%). This pattern was seen in each age group. The percentage of children and adolescents who received an influenza vaccine decreased with increasing age from 60.3% in children aged 1–5 years, to 53.0% in those aged 6–11 years, to 45.9% in adolescents aged 12–17 years. The decrease with age group was seen for each insurance type. Privately insured children aged 1–5 years had the highest rate of influenza vaccination, and uninsured adolescents aged 12–17 years had the lowest rate.

Subject: UPDATE – HHS Allocation of bam/ete and REGEN-COV therapeutics

Dear State and Territorial Health Officials,

The U.S. Department of Health and Human Services (HHS) continues to assess the COVID-19 environment to further inform the allocation and distribution of COVID-19 therapeutics.

Based on recent data and assessment, HHS will pause allocations of bamlanivimab/etesevimab and REGEN-COV COVID-19 therapeutics to states or territories within regions of the country that have greater than 80% prevalence of the Omicron variant based on CDC NOWCAST data. These two products are not expected to be effective in patients infected with the Omicron variant, and other therapeutic options are available. The purpose of this pause is to ensure effective product is available in most sites. In regions that have less than 80% prevalence of the Omicron variant, states and territories will continue to receive allocations of the two products to use as clinically appropriate.

If monoclonal antibody treatment sites are able to utilize testing to distinguish between variants (i.e., infections caused by Omicron vs. Delta) and can subsequently treat those individuals within the appropriate treatment window, even in regions that have greater than 80% Omicron variant, states and territories will be able to continue requesting bam/ete and REGEN-COV provided by HHS. Sites that have the test and treat capability and wish to continue receiving bam/ete and REGEN-COV products should submit requests through their state or territorial health department. Health departments can then make the requests directly through their ASPR Regional Emergency Coordinator.

We encourage you to review the updated Food and Drug Administration (FDA) Health Care Provider Fact Sheets for bam/ete and REGEN-COV as they contain specific information regarding expected activity against the Omicron variant. Additionally, health departments and healthcare providers should continue to assess local data and review current National Institutes of Health (NIH) guidelines to help inform treatment decisions.

Thank you for your continued focus and efforts throughout the pandemic. Please contact your ASPR Regional Emergency Coordinator or email us at COVID19Therapeutics@HHS.gov with questions regarding the allocation of bam/ete and REGEN-COV.

Regards,
The Federal COVID-19 Response Team

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC Partner Alert: N95 Effectiveness as Source Control [Attachments]
  - Today, **Tuesday, January 11**, CDC issued a partner update (attached) in response to numerous questions about N95 mask effectiveness as source control. The update shared two peer reviewed publications from National Institute for Occupational Safety and Health (NIOSH) researchers (both attached) on N95 mask effectiveness, including findings that a N95 respirator was 99% effective at blocking cough aerosols.
- HHS Update: COVID-19 Allocation Projections for January [Attachments]
  - On **Friday, January 7**, the U.S. Department of Health and Human Services (HHS) issued an update with a projected calendar of allocation amounts and cadence of COVID-19 therapeutics for the remainder of January (attached). Questions may be directed to us COVID19Therapetuics@hhs.gov.
- Partner Alert: CDC Expands Booster Shot Eligibility [Attachment, Link]
  - On **Saturday, January 6**, CDC issued a partner alert (attached) adjusting its recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months. CDC has extended this recommendation to recipients of a Moderna primary series. This means that people 12 years of age and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.

- CDC COCA Call: What Clinicians Need to Know About the New Oral Antiviral Medications for COVID-19 [Links]
    - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **tomorrow, Wednesday, January 12 at 2:00 pm EST** to discuss the recent emergency use authorizations (EUAs) for new oral antiviral medications intended to decrease hospitalizations, as well as prevent severe COVID-19 and death Call information is below:
        - Weblink: https://www.zoomgov.com/j/1612974214?pwd=VitYMEorako1YWhCaXpnaWdsc2Ixdz09
          Telephone: (660) 254-5252 or (646) 828-7666 or (669) 216-1590 or (551) 285-1373
          Webinar ID: 161 297 4214
          Passcode: 180866
          Post-Event Recording:
          https://emergency.cdc.gov/coca/calls/2021/callinfo_011222.asp
- Reminder: CDC Preventive Medicine Grand Rounds: "The Public Health System of the Future – Moving Ahead in Partnership with Health Care & Other Sectors" [Link]
    - CDC will host its monthly Preventive Medicine Grand Rounds **tomorrow, Wednesday, January 12** at **1:30 pm EST**. The session will focus on the public health system of the future and the speaker is John Auerbach, Director of Intergovernmental and Strategic Affairs for CDC. Continuing education (CE) is available at no cost. Registration information is available here.

Standing Updates

- CDC Partner Update – January 10 [Attachment]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – January 10 [Link]
    - Please click here for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am ET**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]

- CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

CDC Resources

New & Updated

- CDC Recommends Moderna Booster at 5 Months: On January 4th, CDC made this recommendation for recipients of a Pfizer-BioNTech primary series. After FDA action on January 7th, we're extending this recommendation to recipients of a Moderna primary series. This means that people who initially received an mRNA vaccine series——two doses of Moderna or Pfizer-BioNTech —can now receive an mRNA booster shot 5 months after completing their initial series.
- Guidance for COVID-19 Prevention in K-12 Schools was recently updated to reflect new recommendations for isolation for people with COVID-19 and recommendations for people who have come into close contact with a person with COVID-19.
- CDC Expands Booster Shot Eligibility and Strengthens Recommendations for 12-17 Year Olds: CDC now recommends that adolescents age 12 to 17 years old should receive a booster shot 5 months after their initial Pfizer-BioNTech vaccination series.
- CDC Recommends Pfizer Booster at 5 Months, Additional Primary Dose for Certain Immunocompromised Children: On January 4th, CDC updated its recommendation for when many people can receive a booster shot, shortening the interval from 6 months to 5 months for people who received the Pfizer-BioNTech COVID-19 Vaccine.
- Stay Up to Date with Your Vaccines: To align with standard language CDC uses about other vaccinations, CDC is now using the phrase "up to date" when talking about COVID-19 vaccination. CDC recommends that individuals stay "up to date" by receiving any additional doses they are eligible for, according to CDC's recommendations, to ensure they have optimal protection against COVID-19. The technical definition of "fully vaccinated"—two doses of an mRNA vaccine or one dose of the J&J vaccine—has not changed.
- What We Know About Quarantine and Isolation provides information on why CDC shortened quarantine and isolation guidance for the general population.

Subject: HHS Update: COVID-19 allocation projections for January

Dear State and Territorial Health Officials,

Thank you for your continued partnership in this all-of-America approach to fighting the COVID-19 pandemic. It remains our goal to facilitate a fair and equitable process in the allocation of COVID-19 therapeutics, and we certainly couldn't do this without you. We know that providing a longer look ahead for expected allocation amounts will help further support your jurisdictional planning. As such, attached is a projected calendar of allocation amounts and cadence for the remainder of January. Of course, the COVID-19 environment is very dynamic; so, these projections could change based on daily analysis of related data.

Additionally, we wanted to provide you with an update regarding Gilead's product - VEKLURY(tm) (remdesivir), which is not allocated by the federal government but is available commercially. Following the recent statement from the National Institutes of Health (NIH) COVID-19 Treatment Guidelines Panel regarding therapies for the COVID-19 Omicron variant, CMS created HCPCS code J0248 for the VEKLURY(tm) (remdesivir) antiviral medication when administered in an outpatient setting. This code is available for use by all payers and is effective for dates of service on or after December 23, 2021:

* Long descriptor: Injection, remdesivir, 1 mg
* Short descriptor: Inj, remdesivir, 1 mg

Medicare Administrative Contractors (MACs) determine Medicare coverage when there is no national coverage determination, including in cases when providers use FDA-approved drugs for indications other than what is on the approved label. The MACs consider the major drug compendia, authoritative medical literature and accepted standards of medical practice to determine medical necessity when considering coverage. Therefore, the MACs will determine Medicare coverage for HCPCS code J0248 for VEKLURY(tm) (remdesivir) administered in an outpatient setting.

Thank you, again, and please contact us at COVID19Therapetuics@hhs.gov with any questions.

Regards,
HHS - Coordination Operations and Response Element (H-CORE)
Office of the Assistant Secretary for Preparedness and Response
U.S. Department of Health and Human Services

ABSTRACT

Universal mask wearing is recommended to help control the spread of COVID-19. Masks reduce the expulsion of aerosols of respiratory fluids into the environment (called source control) and offer some protection to the wearer. Masks are often characterized using filtration efficiency, airflow resistance, and manikin or human fit factors, which are standard metrics used for personal protective devices. However, none of these metrics are direct measurements of how effectively a mask blocks coughed and exhaled aerosols. We studied the source control performance of 15 cloth masks (face masks, neck gaiters, and bandanas), two medical masks, and two N95 filtering facepiece respirators by measuring their ability to block aerosols $\leq$7 µm expelled during simulated coughing and exhalation (called source control collection efficiency). These measurements were compared with filtration efficiencies, airflow resistances, and fit factors measured on manikin headforms and humans. Collection efficiencies for the cloth masks ranged from 17% to 71% for coughing and 35% to 66% for exhalation. Filtration efficiencies for the cloth masks ranged from 1.4% to 98%, while the fit factors were 1.3 to 7.4 on headforms and 1.0 to 4.0 on human subjects. The Spearman's rank correlation coefficients between the source control collection efficiencies and the standard metrics ranged from 0.03 to 0.68 and were significant in all but two cases. However, none of the standard metrics were strongly correlated with source control performance. A better understanding of the relationships between source control collection efficiency, filtration efficiency, airflow resistance, and fit factor is needed.

ARTICLE HISTORY

Accepted 11 May 2021

EDITOR
Yannis Drossinos

Introduction

Humans infected with SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can produce droplets and aerosols of respiratory fluids containing the virus when they cough, breathe, talk, sing and sneeze (Anderson et al. 2020; CDC 2020b; Hamner et al. 2020; Ma et al. 2020; Morawska and Milton 2020). To reduce the transmission of SARS-CoV-2, public health agencies have recommended that the general public wear cloth masks (CDC 2020c, 2020d, 2021; Edelstein and Ramakrishnan 2020; WHO 2020). The primary purpose of masks (which in this article includes face masks, neck gaiters, bandanas and other face coverings) is to block the expulsion of infectious droplets and aerosols from the wearer into the environment (called source control) and thereby reduce the exposure of other people to the virus (CDC 2020a). Laboratory studies using manikins and human subjects have shown that cloth face masks can partially block respiratory aerosols produced during coughing, breathing and talking (Asadi et al. 2020; Davies et al. 2013; Lindsley et al. 2021; Pan et al.

This work was authored as part of the Contributor's official duties as an Employee of the United States Government and is therefore a work of the United States Government. In accordance with 17 USC. 105, no copyright protection is available for such works under US Law.
This is an Open Access article distributed under the terms of the Creative Commons Attribution-NonCommercial-NoDerivatives License (http://creativecommons.org/licenses/by-nc-nd/4.0/), which permits non-commercial re-use, distribution, and reproduction in any medium, provided the original work is properly cited, and is not altered, transformed, or built upon in any way.

2021). Wearing medical face masks (i.e., "surgical masks" as defined by the U.S. Food and Drug Administration [FDA 2004]) reduces the dispersion of potentially infectious aerosols from patients with respiratory infections (Leung et al. 2020; Milton et al. 2013). Masks may also provide some personal protection to the wearer by reducing their exposure to infectious droplets and aerosols produced by others, although they are not as effective as a respiratory protective device such as a NIOSH-approved N95 filtering facepiece respirator (N95 respirator) (CDC 2020a; Lawrence et al. 2006; Oberg and Brosseau 2008; Pan et al. 2021). Several community level studies have shown that universal masking helps reduce the spread of COVID-19 (CDC 2020a). For example, a comparison of counties in the US state of Kansas found that mask mandates were associated with lower incidence rates of COVID-19 (Van Dyke et al. 2020). A study of 10 US states found that statewide mask mandates were associated with a decline in weekly COVID-19–associated hospitalization growth compared to states without such mandates (Joo et al. 2021).

In response to the need for source control devices for the general public, manufacturers worldwide have produced a broad array of masks. Unfortunately, because of the many different designs and construction materials, it is not possible to predict how well a particular mask will perform as a source control device without testing, which is rarely done for non-medical masks not intended for occupational use. Although general guidelines have been developed (CDC 2020d), it is very difficult for public health organizations, governments, medical facilities, and the general public to know which of the available devices are most effective.

Test methods and performance standards do exist for regulated medical face masks and respiratory protective devices (Rengasamy et al. 2017). In the United States, respiratory protective devices, which are devices such as N95 filtering facepiece respirators that are intended to protect the wearer from airborne particles, must be approved by the National Institute for Occupational Safety and Health (NIOSH) under 42 Code of Federal Regulations (CFR) Part 84 (NIOSH 1995). The approval process includes testing the filtration efficiency for the most-penetrating aerosol particle size and measuring the airflow resistance of the device (NIOSH 2019). Medical face masks that are not intended to be used as respiratory protective devices are cleared by the Food and Drug Administration (FDA), which reviews manufacturer-supplied information on filtration efficiency, airflow resistance, resistance to fluid penetration and flammability (FDA 2004). The FDA recommends that manufacturers use the ASTM standards F2299 for measuring particle filtration efficiency through the mask material using latex microspheres (ASTM 2003), and the F2101 Standard test method of evaluating the bacterial filtration efficiency (BFE) of medical face mask materials, using a biological aerosol of *Staphylococcus aureus* (ASTM 2019). Bacterial filtration efficiency can also be measured with the modified Greene and Vesley method using human test subjects (Greene and Vesley 1962; Quesnel 1975).

In addition to filtration performance, how well a respiratory protective device protects the wearer depends upon how well the device fits the face and whether the seal between the face and the device has gaps or leaks (Lawrence et al. 2006). ASTM Standard F3407-20 outlines procedures for testing respirators using a bivariate panel of human test subjects with different facial dimensions (ASTM 2020). The NIOSH approval test for respirators measures the filtration properties but does not include tests of how well the device fits faces of different shapes, although this has been proposed. Consequently, in the United States, when a worker is required to wear a respirator, the Occupational Safety and Health Administration (OSHA) requires that a respirator fit test be performed annually for each worker to determine how well the respirator protects the worker (OSHA 2020). Quantitative fit tests measure the aerosol particle concentration inside and outside the respirator during a series of exercises, and this information is used to calculate the fit factor (outside concentration/inside concentration) (Janssen and McKay 2017). The minimum acceptable fit factor for a respirator depends upon the exposure level and potential health consequences of the hazards to which the worker may be exposed (OSHA 2020).

The existing test methods for respirators and medical face masks provide a possible basis for developing standards for non-medical masks used as source control devices. The American Association of Textile Chemists and Colorists (AATCC) published guidelines for cloth face coverings that include the use of ASTM F2299 and other national and international performance standards (AATCC 2020). Leith, L'Orange, and Volckens (2021) proposed an estimated mask protection factor that is calculated based on tests of filtration efficiency and fit and on estimates of the average time spent speaking, inhaling, and exhaling. ASTM International has released a standard for testing barrier face coverings that includes tests of filtration efficiency and airflow resistance, and an assessment of leakage, which are standard metrics that are commonly used to test personal protective devices (ASTM 2021). The use of these standard performance metrics has many advantages, most notably that the equipment and procedures needed to conduct the tests are widely available. However, none of these metrics are

Table 1. Performance metrics used in this study. Outward mask airflow is in the direction of exhalation. Inward airflow is in the direction of inhalation.

Performance metric	**Parameter measured**	Mask airflow direction	Measurement instrument	**Measurement method**	Particle size	**Instrument airflow rate (liters/minute)**
Cough aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Outward	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Exhaled aerosol collection efficiency	Aerosol mass escaping beyond mask into collection chamber	Cyclical	Andersen impactor	Fluorescence of aerosol on impactor stages	0.1 to 7 μm	28.3
Filtration efficiency	Aerosol mass concentration upstream & downstream of mask	Inward	TSI 8130 A	Photometer	75 nm count median diameter (GSD 1.86)	85
Airflow resistance	Pressure required for 85 lpm flow	Inward	TSI 8130 A	Manometer	n/a	85
Manikin fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode)	0.35
Human fit factor	Aerosol particle count inside & outside mask	Cyclical	TSI PortaCount	Size classifier & condensation particle counter	55 nm (N95 mode) 0.02–1.0 μm (Class 100 mode)	0.35

direct measurements of the ability of a mask to block aerosols expelled during coughing and exhalation. To assist in the further development of these types of standards and guidelines, the relationship between the efficacy of masks as source control devices and their performance using standard metrics needs to be better understood. For example, it is possible to measure the filtration efficiency of the mask material, but it is not clear how that filtration efficiency translates to source control efficacy or what minimum performance level should be required.

The purpose of this study was to compare the performance of a variety of N95 respirators, medical masks, and cloth masks as source control devices with their filtration efficiencies, airflow resistances, fit factors measured using manikin headforms, and fit factors measured on humans. The results of these experiments will assist in the development of appropriate test methods and standardized performance metrics to evaluate the efficacy of cloth masks as source control devices for respiratory aerosols.

Materials and methods

Experimental design

A source control measurement system was used to assess the efficacy of N95 respirators, medical masks, and cloth masks as source control devices. The source control performance was determined by measuring the source control collection efficiency of the mask, which is the fraction of the mass of the coughed or exhaled test aerosol particles that were blocked by the mask from reaching the collection chamber. The filtration efficiencies and airflow resistance of the construction materials were measured using a modified version of the test method used for respirator approvals. Fit tests were performed both on a manikin headform with pliable skin and with human test subjects. The source control collection efficiencies were then compared with the fit factors, filtration efficiencies and airflow resistances measured on the same devices. A summary of the performance metrics used in the study is shown in Table 1.

Respiratory aerosol source control measurement system

The efficacy of respirators, medical masks, and cloth masks as source control devices for aerosols produced during coughing and exhalation was determined using a respiratory aerosol source control measurement system described previously (Lindsley et al. 2021). The system includes a coughing and breathing aerosol simulator, a manikin headform, an 136 L aerosol collection chamber, and a cascade impactor (Figure 1). The manikin headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each source control device would fit a human face (Bergman et al. 2014).

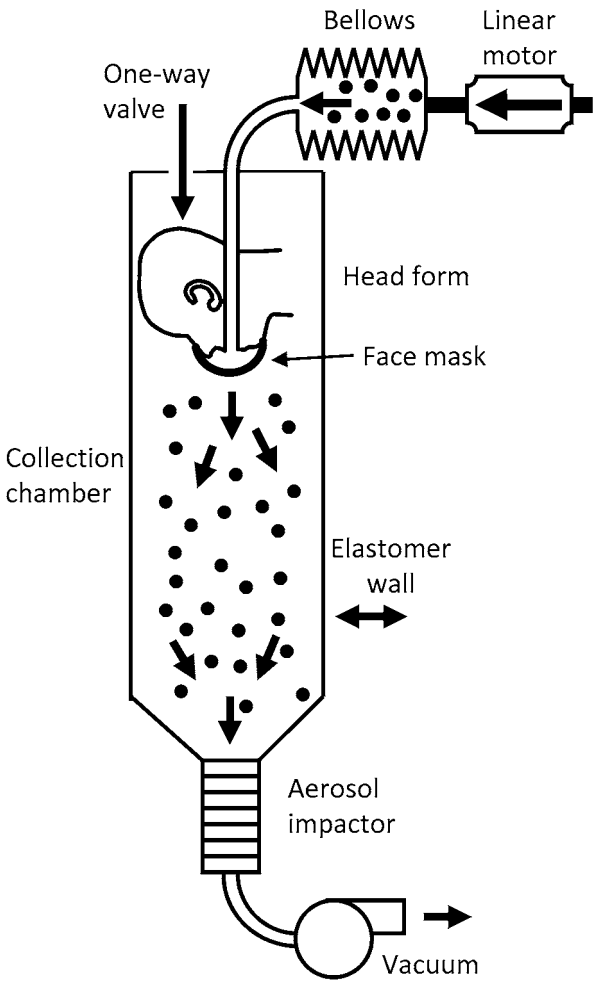

Figure 1. Source control measurement system. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated coughing and breathing, a pliable skin headform on which the source control device is placed, a 136 liter collection chamber into which the aerosol is coughed or exhaled, and a cascade impactor to separate the aerosol particles by size and collect them. The system is oriented vertically as shown to minimize the loss of aerosol particles due to settling before collection. The system is described in more detail in Lindsley et al. (2021).

The test aerosol was produced using a solution of 14% potassium chloride (KCl) and 0.4% sodium fluorescein in a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2). The aerosol passed through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), mixed with dry filtered air flowing at 10 L/min for the cough tests and 15 L/min for the breathing tests, and neutralized using a bipolar ionizer (Model HPX-1, Electrostatics). An elastomeric bellows driven by a computer-controlled linear motor produced the coughing or breathing airflow.

For cough tests, the test aerosol was loaded into the elastomeric bellows and then coughed out using a single cough with a volume of 4.2 L and a peak flow rate of 11 L/s (Lindsley et al. 2013). An Andersen cascade impactor (Model TE-10-830, Tisch Environmental) collected all aerosol particles that traveled through or around the device for 20 min after each cough. For breathing tests, the system used a ventilation rate of 15 L/min with a breathing rate of 12 breathes/min and a tidal volume of 1.25 liters, which corresponds to the ISO standard for a female performing light work (ISO 2015). The test aerosol was only generated for the first 30 s of breathing to avoid overloading the impactor. The breathing continued for 20 min total. The impactor collected the aerosol particles in the chamber during the 20-minute breathing period followed by an additional five minutes of collection after the breathing had stopped.

The impactor operated at a flow rate of 28.3 liters/minute and had six collection stages and a filter that separated the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm; 4.7–7.0 µm; and >7 µm. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). Because the amount of aerosol in the largest size fraction was small (<0.7% of total aerosol mass) and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction were not included in the analysis. After aerosol collection was completed, the aerosol particles were eluted from the impactor plates using a 0.1 M Tris solution and the fluorescence of the solution was read using a spectrofluorometer (SpectraMax M4, Molecular Devices).

To control for variations in the amount of aerosol in each experiment, a sample of each test aerosol was collected from the bellows prior to coughing or breathing using a 47 mm 5 µm PVC filter. The aerosol was eluted from the filter using 0.1 M Tris. An adjustment factor for the experiment (A) was calculated as:

$$A = \frac{Mass\ of\ aerosol\ on\ filter}{Mean\ (mass\ of\ aerosol\ on\ filter\ for\ all\ control\ experiments)} \quad (1)$$

The adjusted mass of aerosol on each impactor stage for the experiment was then calculated as:

$$M_{stage,\ adjusted} = \frac{M_{stage,\ unadjusted}}{A} \quad (2)$$

The adjusted masses were used for all subsequent calculations. The adjusted aerosol masses collected by the cascade impactor during the experiments are

Table 2. Source control devices used in experiments.

Type	Manufacturer	Product	Fastener	Material
Medical masks & respirators	3M	Model 1860 N95 respirator and surgical mask (TC-84A-0006)	Two elastic straps around head	Polypropylene and polyethylene composition
	BYD	N95 filtering facepiece respirator (TC-84A-9221)	Two elastic straps around head	IL and OL: Polypropylene spun-bound nonwoven fabric. ML: Polypropylene melt-blown nonwoven + hot air cotton
	3M	Model 1818 surgical mask	Two ties behind head	Poly(ethylene terephthalate) and polypropylene

In this article, the reusable cloth face masks, neck gaiters and bandanas are referred to collectively as "cloth masks". IL is inner layer, ML is middle layer, and OL is outer layer. Photographs are shown in Figures S3–S5 (SI).

shown in Tables S1 and S2 in the supplemental information (SI).

The source control performance, or source control collection efficiency, of a face covering is defined as the fraction of the mass of the respiratory aerosol that is blocked from entering the environment around the wearer. For example, if 80% of the mass of the aerosol from a cough is blocked by a face mask and 20% of the aerosol mass is able to flow through or around the mask into the air around the wearer, then the mask is said to have a collection efficiency of 80%. The performance of each source control device was evaluated by calculating the collection efficiency as:

$$Collection\ efficiency = 1 - \frac{M_{mask}}{M_{control}} \qquad (3)$$

where:

M_{mask} = adjusted total mass of the aerosol particles that passed through or around the source control device and was collected by the impactor.

$M_{control}$ = adjusted total mass of the aerosol particles collected by the impactor while not wearing a source control device.

Note that the collection efficiency is based on the mass of the aerosol rather than a measure such as particle counts. Also, the aerosol is flowing from the inside of the mask toward the outside; that is, in our test system the aerosol flows in the same direction as it would flow during a cough or exhalation by a person wearing the mask.

Respirators, medical masks, and cloth masks

In our study, the term "cloth mask" refers to a cloth face mask, neck gaiter or bandana constructed from textiles or fabrics (both natural and synthetic) that is not a surgical mask or N95 respirator and is not intended for use as personal protective equipment. The term "medical masks" in this article refers to non-woven disposable masks that are held on the face with elastic ear loops. These masks are loose-fitting and are not expected to provide the wearer with as reliable a level of protection against airborne or aerosolized particles as N95 respirators regulated by NIOSH. Commercial manufacturers often refer to

masks held on by ear loops as procedure masks and masks that tie behind the head as surgical masks. However, the U.S. Food and Drug Administration uses the term "surgical mask" to describe commercially produced masks regulated by the under 21 CFR 878.4040 for performing medical procedures (FDA 2004). The FDA definition applies to all masks that cover the user's nose and mouth and provides a physical barrier to fluids and particulate materials, and includes masks that are labeled as surgical, laser, isolation, dental or medical procedure masks with or without a face shield.

Nineteen commercially available N95 respirators, medical masks, and cloth masks were selected to provide a broad cross-section of the different types of source control devices that are available (Table 2). For the source control tests, each device was placed on the headform as it would normally be worn by a person. Three of the neck gaiters were tested both as a single layer of fabric and folded over to provide two layers of fabric. Before the source control test, the manikin fit factor (Janssen and McKay 2017) was measured by performing a respirator fit test (Bergman et al. 2015) for each device using a PortaCount® Pro + respirator fit tester (Model 8038, TSI, Shoreview, MN) in N95 mode with the system breathing at 36 L/min but not producing an aerosol. Each device was used for two consecutive tests. Photographs of the source control devices on the headform are shown in the SI (SI; Figures S1–S3).

Filtration efficiency and airflow resistance measurements

The filtration efficiency of the face covering is the fraction of the test aerosol that is collected as the aerosol passes through the mask material. For example, if 70% of the test aerosol is collected by the mask material and 30% of the aerosol passes through it, then the filtration efficiency is 70%. Note that the filtration efficiency tests are performed by fastening the mask to a holder so that all the aerosol flows through the mask material, and none can escape through face seal leaks. Thus, the filtration efficiency is a property of the mask material.

The filtration efficiency and airflow resistance of the construction materials were measured using automated filter testers (Models 8130 and 8130 A, TSI). Material samples were secured to a test plate using beeswax as shown in Figure S4 in the SI. Measurements were made using a modified version of the NIOSH standard testing procedure (STP) (NIOSH 2019). Under the modified STP, samples were tested at ambient temperature and humidity but were not subjected to conditioning at 38°C and 85% relative humidity for 25 h, and sample testing was limited to 10 min. The device to be tested was oriented in the filter tester so that the air and aerosol flowed from the exterior of the device toward the interior (that is, as if the wearer were inhaling, which is the same direction as when testing a respirator as a personal protective device). The challenge aerosol was generated using a 2% sodium chloride (NaCl) solution in distilled water, conditioned to 25 °C and 30% relative humidity and neutralized to the Boltzmann equilibrium state. The challenge aerosol had a count median diameter of 75 nm ± 20 nm, a mass mean diameter of 260 nm and a geometric standard deviation (GSD) $\leq$ 1.86 (TSI 8130 A specifications). The automated filter tester compares particle mass concentration readings from upstream and downstream light-scattering laser photometers to calculate the material filtration efficiency. An electronic pressure transducer measures the pressure difference across the material sample to indicate airflow resistance. Tests were performed with an airflow of 85 L/minute.

Fit tests on human subjects

A convenience sample of eleven subjects (six males and five females) participated in fit testing. Subjects complied with CDC/NIOSH guidelines for facial hair styles intended for workers who wear tight-fitting respirators (CDC 2017). Fit testing was performed with a PortaCount® fit tester (model 8038, TSI) using OSHA's modified ambient aerosol condensation nuclei counter (CNC) protocol for filtering facepiece respirators (OSHA 2019). Because only fit factors were measured and no identifiable private information was collected, the West Virginia University Office of Human Research Protections determined that Institutional Review Board approval was not required. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy (see e.g., 45 C.F.R. part 46; 21 C.F.R. part 56; 42 U.S.C. §241(d), 5 U.S.C. §552a, 44 U.S.C. §3501 et seq.). All measurements were performed in a room with volume of 43.4 m^3 (1531 ft^3) at 19 °C (67 °F).

An NaCl aerosol generator (Model 8026, TI) was used to supplement the naturally occurring particles in the air. The particle generator was placed 10 feet away from all sampling apparatus and fit testing equipment. The generator was turned on ten minutes prior to testing to seed aerosols and turned off while

a triplicate series of fit tests were performed (around 7 min). As the aerosol concentration in the room had started to slightly decline at this point, the generator was turned on between tests (around 7 min) and then turned off during subsequent tests. This process was repeated until testing for the day was completed.

To verify that suitable aerosol concentrations were present during testing, particle concentrations were measured with a condensation particle counter (CPC Model 3775, TSI) for 25 min beginning at 2 min prior to the nebulizer being initially turned on. Particle size distributions were measured for 20 min with a scanning mobility particle sizer (SMPS Model 3938, TSI) and an electrical low-pressure impactor (ELPI+, Dakati). Information on the aerosol particle size distribution and concentration are shown in the SI (Figures S5 and S6).

Each source control device was tested by three subjects; for each subject three replicate measurements were made using each of the two protocols described below. One individual administered all fit tests. Subjects were instructed in the proper donning of medical masks and respirators, and they were asked to don cloth masks in the manner that they ordinarily don similar coverings for public use. If a cloth mask was too large, it was modified using materials that would be accessible to most lay individuals: tape was used to shorten mask ear loops or head straps, and a binder clip was used to decrease the circumference of neck gaiters. These adjustments were made so that the covering was held flush to the face, but the materials were not under tension.

Two particle measurement protocols were performed on all source control devices: the PortaCount® N95 Companion protocol (referred to here as N95 mode), which counts negatively charged particles 40–70 nm (mean 55 nm) in diameter; and the PortaCount® standard protocol (referred to here as Class 100 mode), which counts all particles from 0.02–1.0 µm (TSI 2010). The "Class 100 mode" is also called "N99 mode". For both modes, the fit factor (FF) was calculated by the PortaCount® software as (Janssen and McKay 2017; TSI 2015):

$$FF = \frac{C_B + C_A}{2C_R} \quad (4)$$

where:

C_B = ambient particle concentration measured before the particle concentration is measured inside the respirator.

C_A = ambient particle concentration measured after the particle concentration is measured inside the respirator.

C_R = particle concentration measured inside the respirator.

Note that the TSI PortaCount instrument used in our experiments measures the aerosol concentration based on the number of aerosol particles rather than the particle mass.

Data analysis

The source control results were compared with the filtration efficiencies, airflow resistances, and fit factor measurements by calculating the Spearman's rank correlation coefficients (ρ) between the metrics. Fit factors were transformed into fit efficiencies (= 1-1/fit factor) to allow for a direct comparison with the other parameters. For example, a fit factor of 5 corresponds to a fit efficiency of 80%, indicating that the mask blocked 80% of the ambient aerosol from being inhaled by the wearer. Because the replicate numbers were different for the different performance metrics, the correlations were calculated based on the mean results for each device. When analyzing the human fit factor results, we did not attempt to account for differences among test subjects. The p-value was calculated based on ρ and the number of types of devices that were tested (22 for all source control devices and 18 for the cloth masks alone, with the 1-layer and 2-layer gaiter tests counted separately). Correlations were considered significant if $p \leq 0.05$.

Results

Efficacy of N95 respirators, medical masks, and cloth masks as source control devices for respiratory aerosols

Twenty-six cough experiments were performed without a source control device to measure the cough aerosol output from the source control measurement system. The cough aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 525 µg (standard deviation [SD] 65; Figure 2 and SI Figure S7). Thirty-five breathing aerosol experiments were performed without a source control device to measure the exhaled aerosol output. The exhaled aerosol had a geometric mean aerodynamic diameter of 1.3 µm with a GSD of 2.3 and a mean mass of 495 µg (SD 68; Figure 2 and SI Figure S8). The experiments without source control devices were used as control experiments when evaluating performance of the devices.

The collection efficiencies of the 19 source control devices are shown in Figure 3 and Table 3. The mean

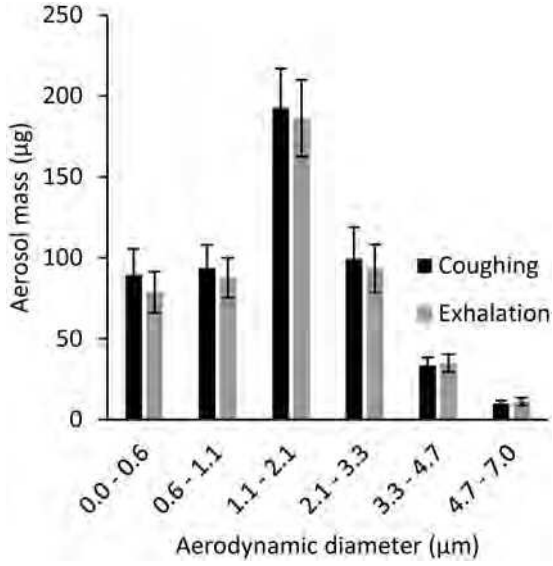

Figure 2. Mass of aerosol expelled by the source control measurement system during coughs and exhalations. The size bins correspond to the stages of the Andersen impactor. The size distribution is shown in units of µg/µm in Figures S7 and S8 in the SI.

collection efficiencies of the N95 respirators and the surgical mask ranged from 83% to 99% for aerosol particles during coughing and exhalation. For the procedure and cloth masks, the mean collection efficiencies ranged from 35% to 71% for coughing (except for the bandana at 17%) and 35% to 66% for exhalation. The collection efficiencies for the coughing and breathing source control experiments were correlated, with a Spearman's correlation coefficient (ρ) of 0.76 ($p < 0.001$; Table 4) when considering all the devices and 0.67 ($p = 0.003$; Table 4) when considering only the cloth face masks, gaiters and bandanas. The amounts of aerosol collected on each stage of the impactor are shown in Tables S1 and S2 in the SI.

Filtration efficiencies and inhalation airflow resistance

The mean material filtration efficiencies were >99% for the respirators, 80% to 93% for the medical masks, and 1.4% to 36% for the cloth face masks, neck gaiters, and bandanas, except for the Besungo sports mask at 98% (Figure 4 and Table 3). The inhalation

Exhaled aerosol collection efficiency	Filtration efficiency of material	0.60	0.004	0.54	0.023
	Airflow resistance of material	0.51	0.016	0.58	0.012
	Human subject fit (N95 mode)	0.60	0.003	0.51	0.024
	Human subject fit (Class 100 mode)	0.71	<0.001	0.63	0.003
	Manikin fit before breathing	0.72	<0.001	0.68	0.002
Manikin fit before coughing	Manikin fit before breathing	0.61	0.003	0.38	0.112
Filtration efficiency of material	Airflow resistance of material	0.78	<0.001	0.78	<0.001

Each Spearman's rank coefficient (ρ) was calculated based on data from 22 experiments for all source control devices and 18 experiments for cloth masks (cloth face masks, gaiters, and bandanas). A correlogram of the ρ values in shown in Figure S9 in the SI.

airflow resistances were from 5.2 to 154 Pa (Table 3). When comparing the data for all devices, the filtration efficiencies were correlated with cough aerosol collection efficiency ($\rho = 0.69$, $p = 0.001$) and exhaled aerosol collection efficiency ($\rho = 0.60$, $p = 0.004$; Table 4). For the group of cloth masks, the correlations were not as strong; the cough aerosol collection efficiency and filtration efficiency had an ρ of 0.51 ($p = 0.032$) while the exhaled aerosol collection efficiency and filtration efficiency had an ρ of 0.54 ($p = 0.023$; Table 4). The airflow resistance did not correlate as well as the filtration efficiency when all devices were considered ($\rho = 0.55$ and $p = 0.009$ for coughing; $\rho = 0.51$ and $p = 0.016$ for exhalation). However, when examining the cloth masks alone, the airflow resistance was slightly better correlated than filtration efficiency ($\rho = 0.54$ and $p = 0.020$ for coughing; $\rho = 0.58$ and $p = 0.012$ for exhalation).

Human fit tests

The fit factors measured on the human test subjects are shown in Table 3 and Figure 5. The mean fit factors for the two N95 respirators were 148 and 164

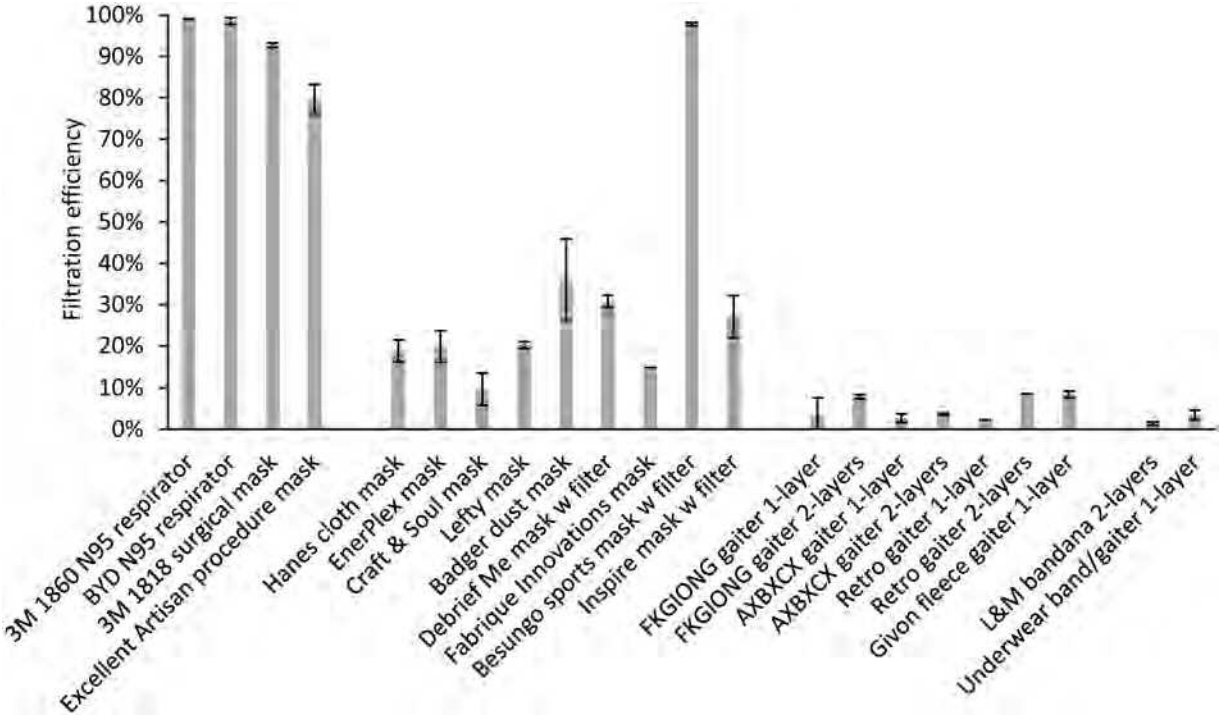

Figure 4. Filtration efficiencies for the source control devices used in the study. Three samples of each device were tested, except for the 3 M 1860 N95 respirator and Hanes cloth mask (10 samples each) and the Fabrique Innovations mask, Retro gaiter 1-layer, and Retro gaiter 2-layers (one sample each). Error bars show the standard deviation.

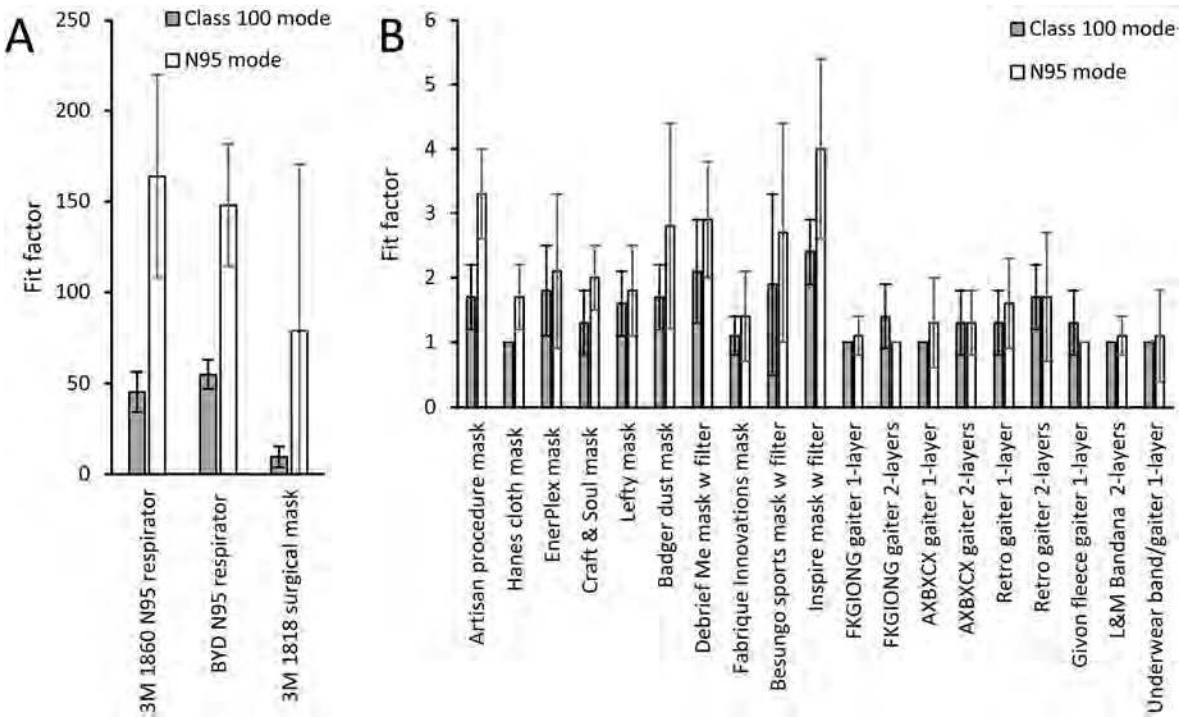

Figure 5. Fit factors measured with human subjects for (a) N95 respirators and surgical mask and (b) procedure mask, cloth face masks, gaiters and bandanas. The plot shows the means and standard deviations. Results for all human fit tests are given in Table S3 in the SI.

when using the N95 mode on the fit tester and 55 and 45 with the Class 100 mode. The surgical mask provided a mean N95 mode fit factor of 79 and a much lower mean fit factor of 9.6 in Class 100 mode. The mean N95 mode fit factor of the reusable cloth face masks ranged from 1.4 to 4.0, and the all sizes

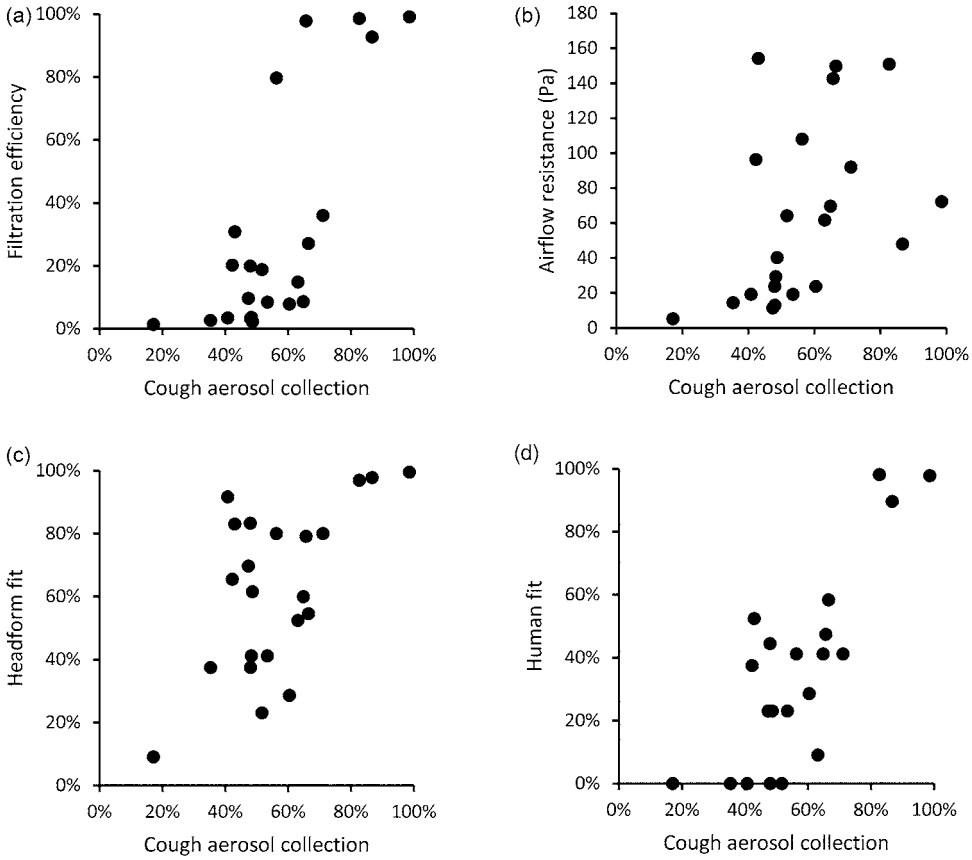

Figure 6. Comparison of collection efficiencies for aerosols from coughs to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot corresponds to the mean result for one type of source control device.

mode mean fit factors ranged from 1.0 to 2.4. Neck gaiters and bandanas demonstrated N95 mode fit factors ranging from 1.0 to 1.7 and all particle size mode mean fit factors from 1.0 to 1.7. The performance of cloth masks sometimes varied considerably when worn by different subjects. The fit test results for individual subjects are shown in Table S3 in the SI.

The cough and exhalation aerosol collection efficiencies for all devices were well correlated with the fit factors when measured using the Class 100 mode ($\rho = 0.68$ and $p < 0.001$ for coughing, $\rho = 0.71$ and $p < 0.001$ for exhalation, Table 4). When looking at the results for the cloth masks, gaiters, and bandanas in the all sizes mode, the correlations were not as strong, with $\rho = 0.48$ for coughing ($p = 0.035$), and $\rho = 0.63$ for exhalation ($p = 0.003$; Table 4). In all cases, the correlation coefficients were higher when the fit tester was in the Class 100 mode than when the tester was in N95 mode.

Manikin fit tests

The manikin fit factor measurements found using the source control measurement system before the cough tests were 25 to 198 for the N95 respirators and the surgical mask and 1.3 to 7.4 for the procedure mask and cloth masks (Table 3). Before the breathing tests, the manikin fit factors were 28 to 133 for the N95 respirators and the surgical mask and 1.4 to 6.1 for the procedure mask and cloth masks. The cough aerosol collection efficiencies and the pre-cough manikin fit factors were not significantly correlated, with a ρ of 0.39 ($p = 0.076$) for all devices (Table 4 and Figure 6) and a ρ of only 0.03 ($p = 0.890$) for the cloth masks (Table 4). The correlation was better between the exhaled aerosol collection efficiency and pre-breathing manikin fit factors, with a ρ of 0.72 ($p < 0.001$) for all devices (Table 4 and Figure 7) and 0.68 ($p = 0.002$) for the cloth masks (Table 4).

Discussion

The COVID-19 pandemic has resulted in considerable interest in the performance characteristics of masks and respirators as a means of reducing the person-to-person transmission of SARS-CoV-2. Some studies have looked at the emission of particles from human volunteers wearing different face coverings, which has

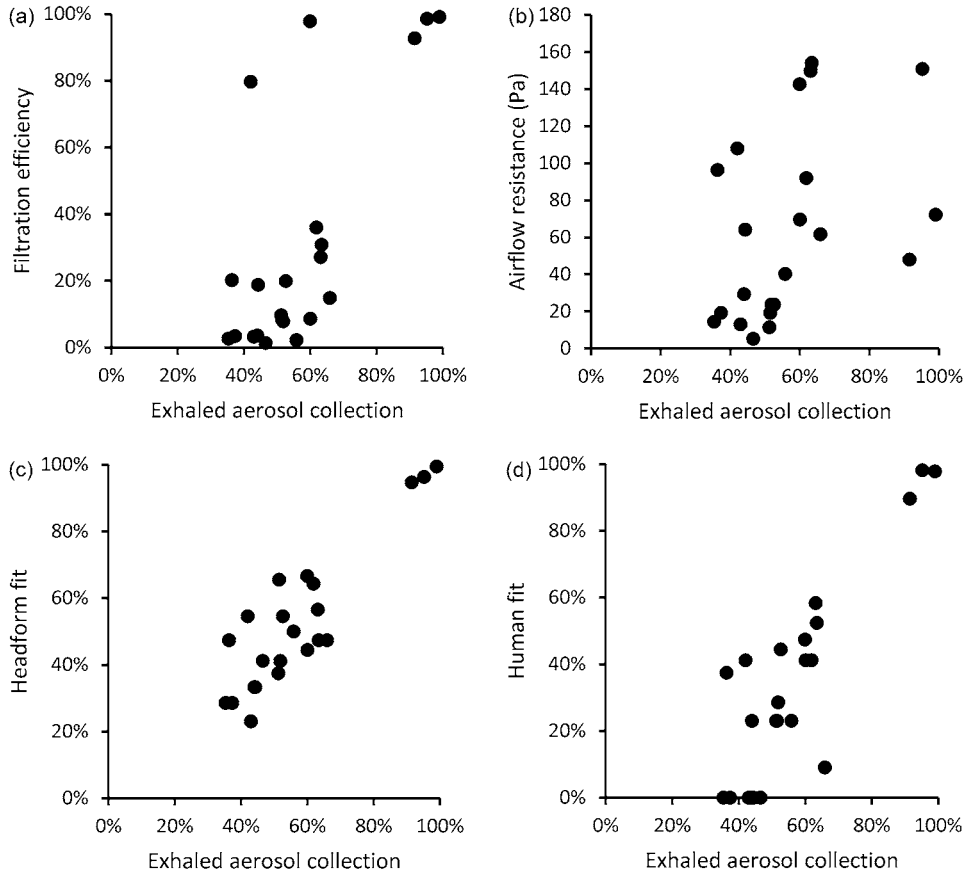

Figure 7. Comparison of collection efficiencies for exhaled aerosols from simulated breathing to (a) filtration efficiency of construction material; (b) airflow resistance; (c) fit on manikin headform (using N95 mode); and (d) fit on human test subjects (using Class 100 mode). Each dot shows the mean result for one type of source control device.

the advantage of directly examining the expulsion of aerosols into the environment by people (Asadi et al. 2020; Davies et al. 2013; Leung et al. 2020; Li, Niu, and Zhu 2021). However, the collection and measurement of human-generated respiratory aerosols is challenging and can be hazardous when the subject has a contagious respiratory infection. In addition, the amount and size distribution of aerosol particles produced by people during coughing, breathing and other respiratory activities varies tremendously from person to person and even for a particular person over time, which makes it difficult to compare results (Asadi et al. 2019; Fennelly 2020; Gralton et al. 2011; Lindsley et al. 2012). Consequently, lab-based surrogate techniques are more frequently used to study source control devices. The most commonly reported methods have been tests of filtration efficiencies and fit factors (Clapp et al. 2021; Guha et al. 2021; Konda et al. 2020; Wang et al. 2020; Zhao et al. 2020). Other studies have used manikins in a chamber or room to assess the efficacy of medical masks and cloth masks both as source control devices and as personal protective equipment (Pan et al. 2021; Patel et al. 2016; Rothamer et al. 2021). Experimental data have also been used to develop computational fluid dynamics models of medical and cloth masks performance (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020). These studies have provided valuable information about the properties of masks and respirators. However, it is unclear how the various metrics used in these studies are related to source control performance.

The source control measurement system used in this study allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough and exhaled breath aerosol particles into the environment (Lindsley et al. 2021). However, the system is complex and requires expertise to operate, and it is neither commercially sold nor easily constructed. In contrast, filtration measurement systems and respirator fit testers are widely available. If a methodology could be developed to gauge source control performance using existing commercially available equipment, it could be rapidly expanded and adopted by manufacturers and public health entities.

The filtration efficiency of a mask or respirator is a measurement of the ability of the mask material to remove aerosol particles from an airstream traveling through the fabric. Filtration efficiency tests typically use aerosol particles at or near the most-penetrating aerosol particle size, which is around 300 nm for an uncharged filter at low air velocities but shifts to smaller sizes at higher velocities and when the filter and particles are electrostatically charged (Martin and Moyer 2000; Rengasamy, BerryAnn, and Szalajda 2013; Rengasamy et al. 2017). The mechanisms by which filters collect aerosol particles are strongly dependent upon the size of the particles; for example, large particles are more likely to be collected by impaction or interception while small particles are more likely to be collected by diffusion (Lindsley 2016). Although the SARS-CoV-2 virus is about 100 nm in diameter, contagious humans do not shed bare viral particles. Instead, they expel aerosols and droplets of respiratory fluids that contain respiratory virus, and the size of these virus-laden aerosols and droplets can range from hundreds of nanometers to visible droplets of 1 mm or more (Fennelly 2020; Gralton et al. 2011). Thus, the collection efficiencies for 100-300 nm particles may not predict the performance for larger particles (Drewnick et al. 2021). In our experiments, the coughing and exhalation source control collection efficiencies increased as the particle size increased (Tables S1 and S2 in the SI) and in most cases were higher than the filtration efficiencies, likely because our coughing and exhalation test aerosols were much larger than the 75 nm aerosol used for filtration tests.

The fit factor is normally used to determine how well a respiratory protective device fits the wearer by measuring the degree to which aerosol particles can enter through gaps between the wearer's face and the respirator (face seal leaks). It is determined by placing the device on a person or on a manikin headform and measuring the ratio of the aerosol concentration outside the respirator to the aerosol concentration inside the respirator (Janssen and McKay 2017). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the respirator. Fit factor measurements are not intended to test the filtration efficiency of the device itself. In fact, the calculation of the fit factor for a respirator assumes that any ambient aerosol particles passing through respirator material are filtered out and that any particles detected inside the respirator are due to face seal leaks, not penetration of particles through the filter material (Halvorsen 1998). For example, a fit factor of 10 is interpreted as indicating that 90% of the air inside the respirator has passed through the respirator filtration media (with aerosol particles being completely removed) and that 10% of the air bypassed the media and entered through face seal leaks.

For high efficiency filters such as P100 respirator filters, which filter out 99.97% of airborne particles, a respirator fit test is performed by measuring the concentrations of aerosol particles of all sizes inside and outside the respirator (referred to here as Class 100 mode). However, N95 respirators can allow up to 5% of aerosol particles of the most penetrating size to pass through the filtration media. These particles would reduce the apparent fit factor if they were included in the calculation. Thus, when fit testing N95 respirators, the respirator fit tester used in our experiments has a size classifier to count only negatively charged aerosol particles near 55 nm in size (referred to here as N95 mode). For an N95 respirator, these charged 55 nm particles are almost entirely filtered out by the filtration media, and thus any particles detected inside the respirator can then be assumed to have entered through face seal leaks and not through the respirator (Halvorsen 1998; Han and Prell 2010).

It is important to note, however, that this assumption is not correct when using the fit tester with cloth masks. As can be seen in Table 3, the filtration efficiencies of most cloth masks are much lower than those of respirators, and ambient particles therefore can penetrate more easily through the cloth material. Thus, the fit factor for a cloth mask is not a true measurement of face seal leakage alone; instead, it represents a combination of face seal leakage and particle penetration through the mask material.

Our findings suggest that the results from filtration efficiency, airflow resistance and fit factor tests are correlated with measurements made using our source control measurement system. For the cloth masks, all but two of the standard performance metrics were significantly correlated with the cough and exhaled aerosol collection efficiencies, which suggests that these other measures could be useful as part of a method for testing the performance of cloth masks. However, none of the standard metrics were strong predictors of source control performance, and no metric was clearly superior to the others.

The limited correlations between the different test methods in our study likely have several explanations. First, filtration efficiency and airflow resistance measurements do not account for how well the devices fit the wearer or for face seal leaks around the edges of

the device. Thus, for example, the Artisan procedure mask had an 80% filtration efficiency but a 56% collection efficiency for cough aerosols and a 42% collection efficiency for exhaled aerosols. The most likely explanation is that this mask's material is an efficient filter but that aerosol particles were able to travel around the mask through face seal leaks because the Artisan mask fits loosely on the headform. On the other hand, the Hanes Defender cloth mask had only a 19% filtration efficiency but had similar aerosol collection efficiencies of 52% for coughs and 44% for exhalations. In this case, the cloth mask was not an effective filter for the 75 nm aerosol used in filtration testing, but the Hanes mask fit the manikin headform more tightly. Thus, much of the aerosol then flowed through the mask rather than around it during coughing and breathing tests and the larger aerosol particles that were used in the coughing and breathing tests were filtered out more effectively than the 75 nm particles used in filtration testing. The results presented here are consistent with a previous study by our group in which knotting the Artisan procedure mask to improve the fit increased the cough aerosol collection efficiency to 77%, while wearing a Hanes Defender cloth mask on top of an Artisan procedure mask increased the cough collection efficiency to 85% (Brooks et al. 2021). Together, these results also support the recommendation by Gandhi and Marr that members of the public wear a high-quality mask that fits tightly or wear a tight-fitting cloth mask over a surgical mask in order to reduce face seal leaks and improve the source control performance and protection offered by the masks (Gandhi and Marr 2021).

Fit tests are designed to measure the effects of face seal leaks but have their own limitations when applied to cloth masks. As noted above, fit factor measurements for cloth masks reflect some combination of particle penetration through the media and face seal leakage which will likely vary from mask to mask. Thus, it is neither clear how to interpret fit factor measurements for cloth masks nor is it clear how this relates to the effectiveness of the mask as a source control device. In addition, fit test results can vary greatly from person to person and even somewhat for the same person during repeated tests (Lawrence et al. 2006). Similarly, a comparison of fit tests between humans and a pliable skin manikin headform found significant differences (Bergman et al. 2015). Much of this discrepancy is likely due to facial variations and differences in how the mask is placed on the person or manikin headform. It is possible to shift, stretch, tighten, loosen, or adjust the masks in many ways,

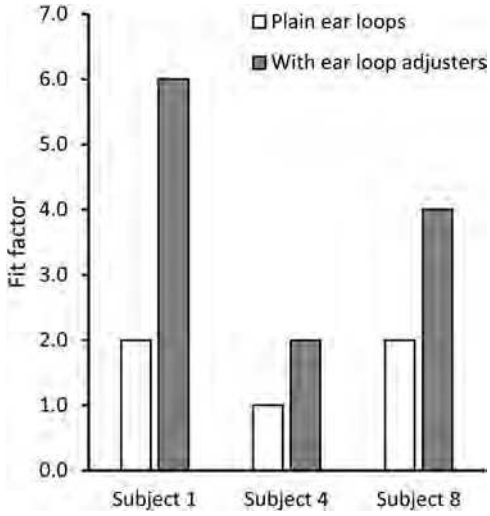

Figure 8. Effect on mask fit factor of adding ear loop adjusters to tighten the mask fit. Subjects were wearing the Excellent Artisan procedure mask. Tests were conducted with the fit tester in Class 100 mode. Each bar is the mean of three trials. All standard deviations were zero.

and small differences in how the mask is worn may have substantial effects on the fit test results. For example, in tests with three subjects using the Artisan procedure mask, we found that tightening the mask against the face by using silicone ear loop adjusters increased the mean fit factor from 1.7 to 4.0 (Figure 8). In experiments with cloth masks, the ρ value for the manikin headform fit tests done before coughing experiments compared with tests done before exhalation experiments was only 0.38, suggesting that differences were occurring even when the same model of mask was being placed on the same headform.

Finally, our study has several limitations. The source control measurement system produced a test aerosol with particles $\leq$7 µm in diameter, which is the size range of aerosol particles most likely to remain airborne and most difficult to block with source control devices. However, humans expel aerosol particles in a much broader range of sizes, particularly when coughing. We used a single cough flowrate profile and a single breathing ventilation rate for our studies; these parameters can vary greatly from person to person under different physiological conditions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We used representative examples of different types of source control devices, but many such devices are available with a wide range of shapes and compositions, which would be expected to affect their individual performance. As shown in Table 1, the instrumentation used for the

different performance metrics are based on different operating principles and thus caution should be used when comparing results; for example, the collection efficiency results from the impactors are based on aerosol mass, while the fit factor results from the PortaCount are based on particle counts. Lastly, because of the need to rapidly produce results in response to the COVID-19 pandemic, we only tested 2-3 samples of each source control device (each sample was used in two consecutive tests). By comparison, for example, the NIOSH procedure for evaluating N95 respirators calls for 20 samples to be tested (NIOSH 2019).

Current evidence indicates that masks like those tested in our experiments can substantially decrease the amount of respiratory aerosols released by the wearer, and also help reduce what the wearer breathes in (CDC 2020a). Both effects vary depending upon the material and construction of the mask, as well as how it is worn. In addition to consistent and correct mask use when in the company of others, other measures such as physical separation are important, particularly during brief exposures. In a room where someone sneezes, being six feet or further away is better than being closer. However, with prolonged exposure in the same space for more than a few minutes, the benefit of distance fades as exhaled respiratory aerosols drift, mix, and accumulate in the enclosed air space. Optimizing ventilation, air filtration, and the introduction of fresh air can help counter this effect, but at every distance, correct mask use reduces the risk for everyone.

Conclusions

The ongoing COVID-19 pandemic has created an urgent need for simple methods to evaluate cloth masks as respiratory aerosol source control devices and to produce meaningful performance metrics that can be used to determine the effectiveness of different materials and designs. Our results suggest that test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements on manikin headforms or human subjects have potential as ways to estimate the performance of masks as source control devices for respiratory aerosols. However, more research and improvements in the test methodologies are needed before such methods can be reliably implemented. Until the factors controlling the performance of source control devices are better understood and better testing methodologies are developed, results from test methods such as filtration efficiency testing, airflow resistance testing, and fit factor measurements should be interpreted cautiously when used to evaluate source control devices for respiratory aerosols.

Efficacy of face masks, neck gaiters and face shields for reducing the expulsion of simulated cough-generated aerosols

William G. Lindsley, Francoise M. Blachere, Brandon F. Law, Donald H. Beezhold, and John D. Noti

Health Effects Laboratory Division, National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Morgantown, West Virginia, USA

ABSTRACT

Face masks are recommended to reduce community transmission of SARS-CoV-2. One of the primary benefits of face masks and other coverings is as source control devices to reduce the expulsion of respiratory aerosols during coughing, breathing, and speaking. Face shields and neck gaiters have been proposed as an alternative to face masks, but information about face shields and neck gaiters as source control devices is limited. We used a cough aerosol simulator with a pliable skin headform to propel small aerosol particles (0 to 7 μm) into different face coverings. An N95 respirator blocked 99% (standard deviation (SD) 0.3%) of the cough aerosol, a medical grade procedure mask blocked 59% (SD 6.9%), a 3-ply cotton cloth face mask blocked 51% (SD 7.7%), and a polyester neck gaiter blocked 47% (SD 7.5%) as a single layer and 60% (SD 7.2%) when folded into a double layer. In contrast, the face shield blocked 2% (SD 15.3%) of the cough aerosol. Our results suggest that face masks and neck gaiters are preferable to face shields as source control devices for cough aerosols.

Introduction

SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), can be transmitted from person-to-person by large respiratory aerosols (airborne liquid droplets and dried particles greater than about 10 μm in diameter) produced by people who are infectious while they are talking, singing, coughing, breathing or sneezing (CDC 2020a; Hamner et al. 2020). Smaller aerosols also are emitted by people during these activities, suggesting that short-range airborne transmission of SARS-CoV-2 might be possible under some circumstances (Anderson et al. 2020; CDC 2020a; Fennelly 2020; Ma et al. 2020; Morawska and Milton 2020).

To interrupt this potential transmission route, the Centers for Disease Control and Prevention (CDC), the World Health Organization (WHO), and other public health organizations recommend the wearing of face masks or other face coverings by the general public during the ongoing COVID-19 pandemic (CDC 2020b, 2020c; Edelstein and Ramakrishnan 2020; WHO 2020). One of the primary benefits of face coverings is to act as source control devices to reduce the expulsion of aerosols containing the virus from people who are infectious during coughing, breathing, and speaking. Source control devices are intended to protect other people from infectious aerosols emitted by the wearer, as compared with personal protective equipment such as N95 respirators which are primarily intended to protect the wearer. A face covering can provide source control in two ways (Diaz and Smaldone 2010). First, and most importantly, the covering may collect aerosol particles by filtration, impaction, or other mechanisms, and thus prevent infectious aerosols from entering the environment. Second, the face covering may change the direction of travel and the velocity of the aerosol stream and thus possibly divert the aerosol away from a potential recipient. However, deflection is more uncertain as a source control mechanism. For example, if large aerosols are deflected downward, they may settle to the floor or otherwise be unable to reach the breathing zones of other people. However, since exhaled breath is often warmer than the surrounding air, this

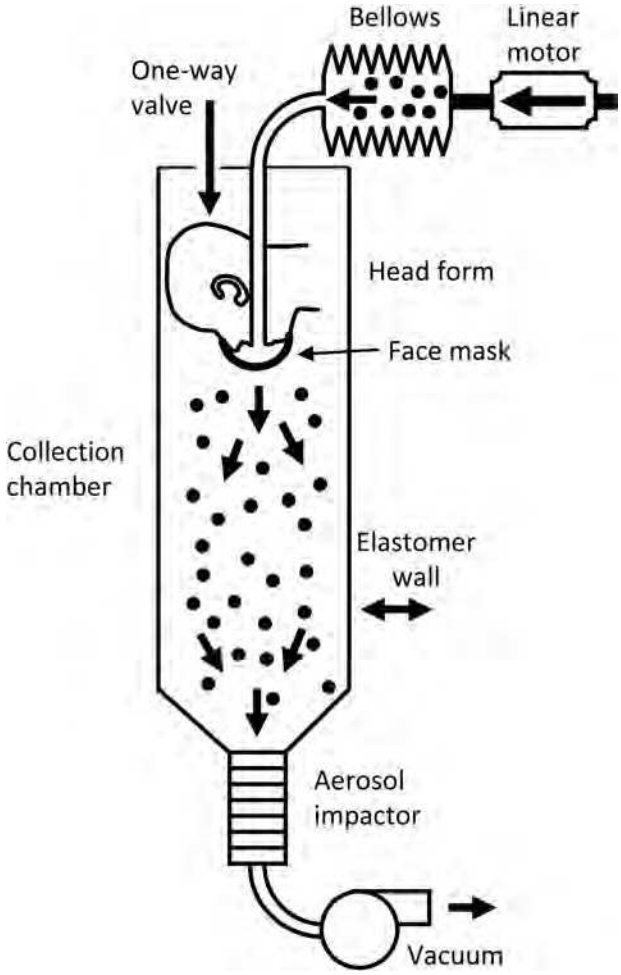

Figure 1. Cough aerosol simulator system for source control measurements. The system consists of an aerosol generation system, a bellows and linear motor to produce the simulated cough, a pliable skin head form on which the face mask, neck gaiter or face shield is placed, a 105 liter collection chamber into which the aerosol is coughed, and an Andersen impactor to separate the aerosol particles by size and collect them. More information about the cough aerosol simulator is provided in the SI.

downward deflection may be counteracted by the buoyancy of the breath for smaller aerosols. In addition, if the respiratory aerosols are deflected sideways, they may be diverted away from a person directly in front of the wearer but toward someone to the side or behind the wearer.

Studies using manikins (Lai, Poon, and Cheung 2012; Patel et al. 2016) and patients with respiratory infections (Leung et al. 2020; Milton et al. 2013) have shown that wearing medical face masks can reduce the dispersion of potentially infectious aerosols from patients. Two studies in which face masks were required for visitors and healthcare workers interacting with patients in bone marrow transplant centers found a reduction in respiratory viral infections among patients (Sokol et al. 2016; Sung et al. 2016). Studies of cloth face masks have suggested that they also can be effective at reducing the release of respiratory aerosols into the environment (Asadi et al. 2020; Davies et al. 2013; Konda et al. 2020). Several computational fluid dynamics studies have examined the generation and expulsion of respiratory aerosols and have provided important insights into the ability of face coverings to reduce the dispersion of large and small aerosols from the wearer (Dbouk and Drikakis 2020; Mittal, Ni, and Seo 2020).

Unfortunately, the use of face masks and other face coverings by the general public can present challenges. People often dislike wearing masks, and compliance can be low and inconsistent (Longtin et al. 2009). Mask wearers may repeatedly don, doff and adjust face masks, which can contaminate the hands and potentially lead to disease transmission, especially when the masks are reused (Brady et al. 2017; Casanova et al. 2008). For cloth masks, the filtration efficiency and air flow resistance of different textiles varies widely (Konda et al. 2020; Teesing et al. 2020; Wilson et al. 2020). Alternative face coverings such as neck gaiters (an elastic fabric tube that fits snugly around the head and neck) are commonly used, but information about their performance as source control devices is limited. Factors such as how well the mask fits the face and the coverage provided by a mask can have a substantial impact on the effectiveness of face masks (Davies et al. 2013; Lawrence et al. 2006). Comparisons of face coverings have found substantial differences in the ability of different types of these devices to reduce the release of respiratory aerosols (Asadi et al. 2020; Davies et al. 2013).

An opinion article in JAMA proposed that face shields would be more effective than face masks at reducing community disease transmission, in large part because the authors felt that face shields were more comfortable and thus that they were more likely to be widely adopted by the public (Perencevich, Diekema, and Edmond 2020). A previous study by our group of face shields used as personal protective devices showed that face shields protect the wearer from large cough aerosols directed at the face but are much less effective against smaller aerosols which were able to flow around the edges of the shield and be inhaled (Lindsley et al. 2014). However, very little work has been done examining face shields as source control devices. Two qualitative flow visualization studies of face shields and masks found that, although face shields deflected the air flow from the mouth, they did not stop aerosol particles from traveling around the face shield and entering the environment

(Verma, Dhanak, and Frankenfield 2020; Viola et al. 2020). Beyond these studies, quantitative data on the efficacy of face shields for source control are lacking.

The objective of our study was to conduct a quantitative comparison of the efficacy of an N95 respirator, a medical procedure mask, a commercial 3-ply cloth face mask, a single and double layer fabric neck gaiter, and a commercial disposable face shield as source control devices to reduce the expulsion of small cough-generated aerosol particles into the environment. Our results provide more information about the effectiveness of different types of source control devices and will help the public health community make recommendations about the best ways to use these devices to help reduce the spread of COVID-19.

Materials and methods

Experimental design

In our experiments, a cough aerosol simulator propelled a test aerosol through a headform into a collection chamber (Figure 1), and the amount of aerosol in the collection chamber was measured in each of six size fractions. The collection efficiency of each face mask, neck gaiter, or face shield was determined by comparing the amount of aerosol that was collected from the chamber with and without the device. Our test method was similar to the modified Greene and Vesley method used to test medical masks (Quesnel 1975), with the human test subject replaced by the cough aerosol simulator.

Cough aerosol simulator

The cough aerosol simulator is a modified version of the NIOSH cough aerosol simulator described previously (Lindsley et al. 2019; Lindsley et al. 2014; Lindsley et al. 2013). The experimental cough aerosol was generated by nebulizing a solution of 14% KCl and 0.4% sodium fluorescein using a single-jet Collison nebulizer (BGI, Butler, NJ, USA) at 103 kPa (15 lbs./in^2), passing the aerosol through a diffusion drier (Model 3062, TSI, Shoreview, MN, USA), and mixing it with 10 L/min of dry filtered air. The test aerosol was loaded into an elastomeric bellows, and the cough airflow was produced by a computer-controlled linear motor that compresses the bellows. The cough aerosol was expelled through the mouth of a headform into a collection chamber. The headform used in the study has pliable skin that mimics the elastic properties of human skin in order to create a realistic simulation of how each face covering or shield would fit a human face (Bergman et al. 2014).

Source control devices

The source control devices tested were an N95 medical respirator (3 M model 1860), a medical grade (ASTM Level 3) procedure mask with ear loops (Kimberly Clark model 47107), a cloth face mask with 3 layers of cotton fabric and ear loops (Hanes Defender), a fabric neck gaiter (FKGIONG Sun UV Protection Neck Gaiter, 95% polyester, 5% Spandex) and a disposable face shield (Fisher Scientific # 19-181-600 A). The neck gaiter was tested both as a single layer of fabric and doubled over to provide two layers of fabric. The masks and respirator were not equipped with exhalation valves. The face shield was 25 cm tall and extended from the forehead of the headform to 3 cm below the chin and around the side to 3 cm before the front of the ear. Photographs of the source control devices on the headform are shown in the online supplementary information (SI).

Mask fit test

For the experiments, either no device, a face mask, a neck gaiter, or a face shield were placed on the head form. Each device was used for two consecutive tests. For face masks and gaiters, a respirator fit test was performed using a PortaCount (TSI). The fit factor is a measure of the protection against airborne particles that is provided by a respiratory protective device. It is defined as the ratio of the aerosol concentration outside the respiratory protective device to the aerosol concentration inside the device (i.e., the aerosol concentration that is inhaled by the wearer). For example, a fit factor of 10 means that the ambient aerosol concentration is 10 times higher than the concentration inside the mask, and that the mask is therefore filtering out 90% of the ambient aerosol.

Aerosol collection and analysis

After placing the device on the headform and performing the fit test, the system was sealed. The test aerosol was then generated and propelled with a simulated cough through the headform and into the collection chamber. The Andersen impactor at the bottom of the collection chamber collected the aerosol particles that traveled through or around the device for 20 min after each cough. The Andersen impactor operates at a flow rate of 28.3 liters/minute and has six collection stages and a filter that separate the aerosol particles into seven size fractions based on the aerodynamic diameter of the particles: <0.6 µm; 0.6–1.1 µm; 1.1–2.1 µm; 2.1–3.3 µm; 3.3–4.7 µm;

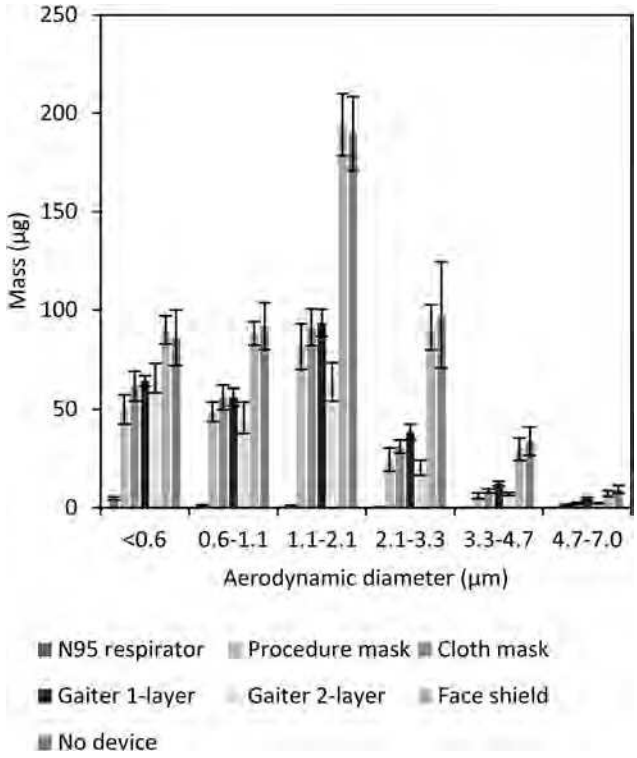

Figure 2. Mass of aerosol collected in each size fraction. The graph shows the amount of simulated respiratory aerosol that was collected from the collection chamber in each aerosol particle size fraction after a single simulated cough. The bars show the mean and standard deviation. A larger color version of this figure is shown in the SI.

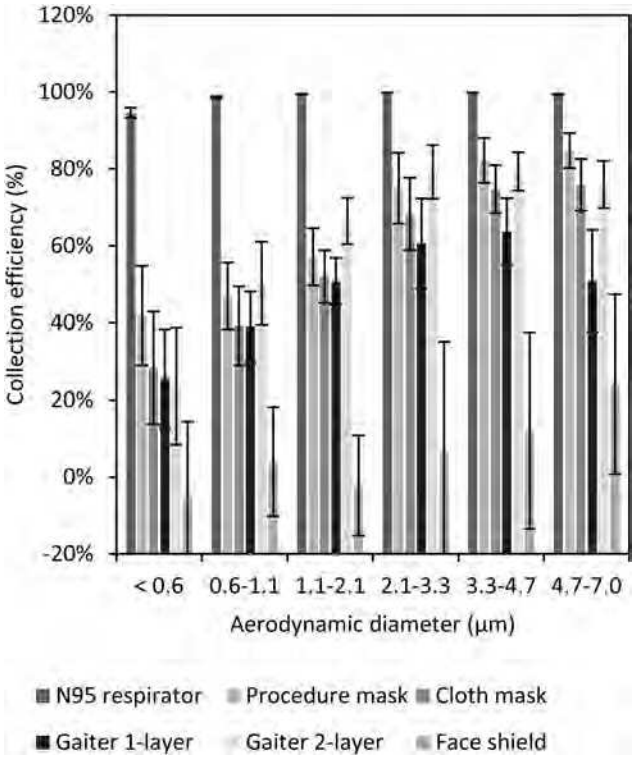

Figure 3. Collection efficiency of face masks, neck gaiter and face shield. The collection efficiency is the percentage of aerosol particles that were blocked by the face mask, neck gaiter or face shield compared with experiments without a device. The plot shows the means and standard deviations of the collection efficiency in each size fraction. A larger version of this figure is shown in color in the SI.

4.7–7.0 µm; and >7 µm. Because the amount of aerosol in the largest size fraction was small and because of possible losses due to settling of the large aerosol particles, data for the largest size fraction was not included in the analysis. The impactor collection plates were coated with a solution of glycerol and Brij 35 to prevent particles from bouncing off the plates during collection (Mitchell 2003). After aerosol collection was completed, the impactor plates were rinsed with 0.1 M Tris solution and the fluorescence of the solution was measured using a fluorometer (SpectraMax M4, Molecular Devices). The complete experimental protocol is given in the SI.

Statistical analysis

The performance of each device was evaluated by comparing the total mass of the aerosol particles from a single cough that passed through or around the device and was collected by the Andersen impactor. The results were evaluated using a one-way ANOVA and multiple comparisons among the different devices and the control experiments without a device were conducted using a Tukey-Kramer test. To control for variations in the amount of aerosol in each cough, a sample of each cough aerosol was collected from the bellows prior to coughing and used to normalize the aerosol mass collection results for each experiment.

Results

The cough aerosol simulator provides a cough with a controlled cough airflow rate containing a test aerosol with a consistent aerosol size distribution. The simulator allows for a direct quantitative comparison of the ability of different types of source control devices to block the expulsion of simulated cough aerosol particles of different sizes into the environment. The flow rate of the simulated cough used in our experiments was based on cough flow profiles recorded from influenza patients and had a volume of 4.2 L with a peak flow rate of 11 L/s (Lindsley et al. 2013). The cough aerosol collected from the control experiments without a face covering had a mass median aerodynamic diameter of 1.3 µm, a geometric standard deviation of 2.3 and a total aerosol mass of 505 µg (standard deviation 69).

For our study, we tested the collection efficiencies (that is, the fraction of the cough aerosol that was

Table 1. Total mass of aerosol expelled into collection chamber and device collection efficiencies.

Device tested	Number of experiments	Fit factor	Aerosol mass (μg)	Collection efficiency
No device	12	n/a	512 (64)	n/a
Procedure mask	6	2.9 (0.5)	212 (23)	58.5% (6.9%)
Cloth mask	6	1.3 (0.1)	251 (23)	50.9% (7.7%)
Neck gaiter (single layer)	6	1.7 (0.5)	270 (18)	47.2% (7.5%)
Neck gaiter (double layer)	6	1.9 (0.4)	206 (26)	59.8% (7.2%)
Face shield	6	n/a	502 (46)	1.8% (15.3%)
N95 respirator	6	198 (3.5)	7.2 (1.2)	98.6% (0.3%)

Note: The fit factor, aerosol mass, and collection efficiency are given as mean (standard deviation).

blocked) of a medical grade procedure mask, a cotton cloth face mask, a polyester neck gaiter, an N95 medical respirator and a disposable face shield. These source control devices were chosen to provide representative samples of the different types of face coverings and face shields that are in common use during the pandemic. Neck gaiters are typically worn either as a single layer of fabric over the mouth and nose or doubled over to provide two layers of fabric; for our experiments, we tested both configurations. The quantity of aerosol particles in six size fractions that were able to travel through or around each source control device are shown in Figure 2. The collection efficiencies of the devices are shown as a function of aerosol size in Figure 3. All the devices showed increased collection efficiencies as the aerosol size increased.

On average, the N95 respirator blocked 99% of the total mass of test aerosol from being released into the environment, while the medical procedure mask blocked 59%, the cloth face mask blocked 51%, the single-layer gaiter blocked 47%, the double-layer gaiter blocked 60%, and the face shield blocked 2% of the total aerosol (Table 1). The N95 respirator, procedure mask, cloth mask, and the single-layer and double-layer gaiters all significantly reduced the aerosol emitted into the environment compared with no device ($P < 0.0001$ for each), but the face shield did not ($P = 0.9993$). The collection efficiencies of the procedure mask, cloth mask, and the single and double-layer gaiters did not differ significantly from each other, but all blocked cough aerosols significantly better than did the face shield ($P < 0.0001$). The N95 respirator outperformed all the other devices ($P < 0.0001$) (Table 2).

Discussion

Humans continuously emit aerosols of respiratory fluids as they breathe, talk, cough, sneeze, sing, or carry out other respiratory activities. These respiratory aerosols can have a very broad size range, from tens of nanometers in diameter to visible droplets of a millimeter or more (Bourouiba, Dehandschoewercker, and Bush 2014; Fennelly 2020; Gralton et al. 2011; Morawska et al. 2009). Airborne particles larger than 100 μm are ballistic; that is, they are affected primarily by gravity and fall quickly to the ground. Respiratory aerosol particles in this size range tend to deposit within a few meters of the source (Prather et al. 2020). As the aerosol particle diameter decreases from 100 μm, a gradual transition occurs where the settling velocity rapidly decreases and the particles remain airborne for longer times. For example, a 100 μm aerosol particle takes 4 s to fall 1 m in still air, while a 10 μm aerosol particle takes 5.4 min and a 1 μm aerosol particle takes 8 h to settle the same distance (Hinds 1999). Air currents such as plumes of warm air rising from the body can lift these particles and extend the time for which they stay in the air. Thus, small aerosol particles can remain airborne for minutes to hours and can accumulate over time in environments with poor ventilation (Bahl et al. 2020). Small aerosol particles also are easier to inhale and can travel more deeply into the lungs (Vincent 2005).

The amount and sizes of aerosol particles containing SARS-CoV-2 that are expelled by people who are infected are not yet known. Two studies of aerosol samples collected in patient rooms found infectious (replication-competent) SARS-CoV-2 in aerosol particles <4 μm in diameter (Santarpia et al. 2020a) and <10 μm in diameter (Lednicky et al. 2020). Other studies have reported SARS-CoV-2 RNA in exhaled breath from infected patients (Ma et al. 2020), aerosol samples from biocontainment and quarantine units housing SARS-CoV-2 infected persons (Santarpia et al. 2020b), and in aerosol samples at multiple locations throughout two hospitals in Wuhan, China during a COVID-19 outbreak (Liu et al. 2020). The presence of small aerosol particles containing

infectious SARS-CoV-2 detected in these studies suggests that in addition to large aerosols, these small aerosols might play a role in SARS-CoV-2 transmission (Anderson et al. 2020; Bahl et al. 2020; Ma et al. 2020; Morawska and Milton 2020).

Source control devices like face coverings and face shields collect respiratory particles larger than 0.3 μm primarily by impaction and interception of the aerosol particles against the fibers or solid surfaces of the device. As noted earlier, source control devices may also deflect aerosols, but this mechanism can be problematic as a means of source control because the infectious aerosol is not prevented from entering the surrounding environment; it is merely sent in a different direction which may or may not be protective depending upon local airflows and the locations of other people. Our experimental system measures particle collection only; any particles that are deflected but not collected by the face covering are still collected by the Andersen impactor. Thus, we are able to measure the particle collection efficiency of the face coverings without the potentially confounding variable of particle deflection. On the other hand, this does means that any potential benefits from, for example, deflecting large aerosol particles toward the ground were not measured by our system.

Small aerosols require much higher air velocities to deposit by impaction than do larger aerosols, and thus are more difficult to block with source control devices (Hinds 1999; Lindsley 2016). Consequently, small aerosols present the most challenging scenario for testing source control devices since devices that block small aerosol particles would be expected to block larger ones as well. Our results show that face masks and neck gaiters can significantly reduce the expulsion of small respiratory aerosol particles during coughing. This suggests that various types of face coverings can make an important contribution to reducing the quantity of aerosol particles containing SARS-CoV-2 released into the environment by people who are infected. N95 respirators, which are worn for personal protection by healthcare workers and others at highest risk of exposure, are also very effective source control devices. In contrast, the face shield blocked very little of the cough aerosol, indicating that face shields are not effective as source control devices for small respiratory aerosols.

The collection efficiencies of all the devices tested increased as the aerosol particle size increased, and this trend would be expected to continue for larger aerosol particles than were tested here. For example, the collection efficiency of the cloth face mask was 28% for the <0.6 μm particles and increased to 76% for the 4.7 to 7 μm particles. Similarly, the double-layer gaiter blocked 24% of the <0.6 μm particles and 76% of the 4.7 to 7 μm particles. These results suggest that cloth face coverings would be effective as source control devices against the large respiratory aerosols that are thought to play an important role in SARS-CoV-2 transmission.

Our study has several limitations. We used a single cough volume, air flow profile, and aerosol size distribution for our studies; these parameters can vary greatly from person to person. We examined the

performance of these devices during simulated coughing but not breathing or speaking, which have different air flow rates and aerosol size distributions. Some internal losses of the test aerosol particles likely occurred due to settling or impaction on the surfaces of the collection chamber, which may affect the estimates of the collection efficiencies. We only used a single representative example of each type of device. The shape and composition of face coverings vary widely, and this would be expected to affect the performance of individual devices. Some face masks have exhalation valves or vents which could reduce their efficacy as source control devices. The fit of a particular mask to an individual wearer and compliance in wearing the mask correctly (i.e., over the nose and mouth) also are important factors in how well the mask performs as a source control device. Because we used a < 0.6 to 7 µm test aerosol, our results do not indicate if face shields would be more effective as source control devices for large droplets. The face shield that we tested has a widely used design, but alternative designs are being marketed that provide greater facial coverage and, in some cases, include fabric skirts between the shield and the face. These alternative face shield designs might perform better as source control devices.

Previous studies have shown that face shields provide eye and facial protection to the wearer from droplets and splashes (Lindsley et al. 2014; Roberge 2016). When a face shield is worn in addition to a face mask, the face shield can also help reduce surface contamination of the mask by large aerosols and reduce the likelihood of hand contamination when the mask is removed or inadvertently touched (Lindsley et al. 2014). Our previous study showed that face shields provide some benefits as personal protective equipment when face masks cannot be worn (Lindsley et al. 2014), but as with all personal protection and source control devices, their limitations must be respected. Our results suggest that face masks and neck gaiters are more effective than face shields as source control devices to reduce the expulsion of respiratory aerosols into the environment as a public health measure to reduce the community transmission of SARS-CoV-2.

Acknowledgments

We would like to thank NIOSH machinist Bryan Williamson for manufacturing the parts for the cough simulator. We also would like to thank the NIOSH Morgantown maintenance, security, warehouse and housekeeping departments for their assistance and dedication during the ongoing pandemic. The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the National Institute for Occupational Safety and Health (NIOSH), US Centers for Disease Control and Prevention (CDC). Subject: N95 effectiveness as source control

Dear Partners,

We have had a number of questions from you and others about N95 effectiveness as source control and wanted to share some information back with you.

National Institute for Occupational Safety and Health (NIOSH) researchers have evaluated N95s as source control in two different peer reviewed publications. In the first paper (Lindsley et al. 2021a- attached), NIOSH researchers found that a N95 respirator (3M model 1860) was 99% effective at blocking cough aerosols. In a second paper (Lindsley et al. 2021b- attached), NIOSH researchers found that one N95 respirator (3M 1860 N95) was 99% effective at blocking coughed and exhaled aerosols, and a second N95 Respirator (BYD) was 83% effective at blocking cough aerosols and 95% effective at blocking exhaled aerosols.

Subject: PARTNER ALERT: CDC Expands Booster Shot Eligibility

Dear Partners –

Yesterday, CDC adjusted our recommendation for when people can receive a booster shot, shortening the interval from 6 months to 5 months.

Earlier this week CDC made this recommendation for recipients of a Pfizer-BioNTech primary seriesand, after FDA action this morning, we're extending this recommendation to recipients of a Moderna primary series. This means that people 12 and older who initially received an mRNA vaccine series – two doses of Moderna or Pfizer-BioNTech – can now receive an mRNA booster shot 5 months after completing their initial series.

Recently CDC strengthened our COVID-19 vaccination recommendations for children, now recommending that:

- Moderately to severely immunocompromised children ages 5–11 years receive an additional primary dose of Pfizer-BioNTech to ensure optimal protection from the vaccine.
- Children and teens ages 12–17 years should receive a booster shot.

Thank you,

Vaccine Task Force

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of recent Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

- White House National Strategy for the COVID-19 Response and Pandemic Preparedness and Executive Order on a Data-Driven Response [Attachment, Link]
  - Yesterday, the White House released its National Strategy for the COVID-19 Response and Pandemic Preparedness, providing a roadmap to guide America out of the worst public health crisis in a century. An executive summary of the new National Strategy is attached, while the complete plan is linked above. A fact sheet summarizing the new National Strategy to quickly contain the COVID-19 crisis has also been released. [Link]
  - The White House also issued an executive order yesterday to ensure a "Data-Driven Response to COVID-19 and Future High-Consequence Public Health Threats." [Link]
  - White House activities – Thursday, January 21, 2021 [Link] and Friday, January 22, 2021 [Link]
- MMWR Early Release: "Allergic Reactions Including Anaphylaxis After Receipt of the First Dose of Moderna COVID-19 Vaccine — United States, December 21, 2020–January 10, 2021" [Attachment, Link]
  - From the summary: *"During December 21, 2020–January 10, 2021, monitoring by the Vaccine Adverse Event Reporting System detected 10 cases of anaphylaxis after administration of a reported 4,041,396 first doses of Moderna COVID-19 vaccine (2.5 cases per million doses administered). In nine cases, onset occurred within 15 minutes of vaccination. No anaphylaxis-related deaths were reported."*
- Reminder: CSTE Webinar: COVID-19 during Pregnancy [Link]

- CSTE will host its next COVID-19 Response Membership Webinar, "COVID-19 during Pregnancy," **Friday, January 29, 2021** at **3:00 pm EST**. CDC will present the current evidence on COVID-19 in pregnant women and their babies and provide an overview of current surveillance efforts, including successes and challenges. Massachusetts will provide a state perspective on efforts to improve identification of SARS-CoV-2 infection during pregnancy through data linkages to existing data sources.
- Call capacity is limited to 1,000 participants, and is first-come, first-served. Call information is below:
    - Weblink: https://webinar.ringcentral.com/j/1487195918

- Reminder: CDC Partner Update Call: Engaging Faith Leaders to Advance Effective COVID-19 Response: Lessons Learned through Global-Domestic Collaborations [Link]
    - CDC will host a webinar **Monday, January 25, 2021** at **3:00 pm EST**. During the call, Dr. Cliff McDonald will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Dr. Jay Butler will give a brief status report on the pandemic and an overview of prevention with a specific emphasis on opportunities for faith-based organizations. Dr. Susan Hillis will describe successes from other countries through shared collaborative leadership between faith and government partners. Ms. Lauren Erickson-Mamane will also discuss COVID-19 resources developed for Global Faith Leaders by the International Task Force.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 1/25" in the subject line. The call will be recorded and posted to CDC's website here.
- Reminder: COCA Call: Treating Long COVID: Clinician Experience with Post-Acute COVID-19 Care [Attachment]
    - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **Thursday, January 28, 2021** at **2:00 pm EST**. During this call, presenters will share their firsthand experiences with treating long COVID, focusing on the pulmonary, neurologic, and psychological aspects. They will also describe their experiences with establishing clinics that provide care for patients with these long-term effects.

Subject: CDC COCA Call: Treating Long COVID: Clinician Experience with Post-Acute COVID-19 Care

Treating Long COVID: Clinician Experience with Post-Acute COVID-19 Care

Overview

For some people, the effects of COVID-19 can last well beyond the immediate illness. Patients and clinicians across the United States are reporting long-term effects of COVID-19, commonly referred to as long COVID. Symptoms may include cognitive difficulties, fatigue, and shortness of breath. In some patients, critical illness from COVID-19 may be the cause of persistent symptoms, but many patients with long-term effects had mild or asymptomatic acute COVID-19 infection. During this COCA Call, presenters will share their firsthand experiences with treating long COVID, focusing on the pulmonary, neurologic, and psychological aspects. They will also describe their experiences with establishing clinics that provide care for patients with these long-term effects.

If you are unable to attend the live COCA Call, the recording will be available for viewing on the COCA Call webpage a few hours after the live event ends.

The slide set will be available on the day of the call under "Call Materials" on the COCA Call webpage.

Free Continuing Education (CE) will be offered for this COCA Call.

Advanced registration is not required.

a doctor consulting her patient

Date: Thursday, January 28, 2021

Time: 2:00 PM – 3:00 PM ET

A few minutes before the webinar starts, please click on the Zoom link below to join:

Activity-specific Objectives

At the conclusion of the session, the participant will be able to accomplish the following—

1. Identify signs and symptoms of long COVID which occur after the acute phase of SARS-CoV-2 infection.
2. Identify potential multidisciplinary teams for patient care.
3. Describe common challenges to post-acute COVID-19 care.
4. Describe examples of patient-centered, interdisciplinary post-acute COVID-19 care.

COCA Call Objectives

At the conclusion of the session, the participant will be able to accomplish the following—

1. Cite background information on the topic covered during the presentation.
2. Discuss CDC's role in the topic covered during the presentation.
3. Describe the topic's implications for clinicians.
4. Discuss concerns and/or issues related to preparedness for and/or response to urgent public health threats.
5. Promote health improvement, wellness, and disease prevention in cooperation with patients, communities, at-risk populations, and other members of an interprofessional team of health care providers.

Accreditation Statement

CME: The Centers for Disease Control and Prevention is accredited by the Accreditation Council for Continuing Medical Education (ACCME®) to provide continuing medical education for physicians.

The Centers for Disease Control and Prevention designates this live activity for a maximum of **1.0** AMA PRA Category 1 Credit™. Physicians should only claim credit commensurate with the extent of their participation in the activity.

CNE: The Centers for Disease Control and Prevention is accredited as a provider of Continuing Nursing Education by the American Nurses Credentialing Center's Commission on Accreditation.

This activity provides **1.0** contact hour.

CEU: The Centers for Disease Control and Prevention is authorized by IACET to offer 0.1 CEU's for this program.

CECH: Sponsored by the Centers for Disease Control and Prevention, a designated provider of continuing education contact hours (CECH) in health education by the National Commission for Health Education Credentialing, Inc. This program is designated for Certified Health Education Specialists (CHES) and/or Master Certified Health Education Specialists (MCHES) to receive up to total 1.0 total Category I continuing education contact hours. Maximum advanced level continuing education contact hours available are 0. CDC provider number 98614.

CPE: The Centers for Disease Control and Prevention is accredited by the Accreditation Council for Pharmacy Education as a provider of continuing pharmacy education. This program is a designated event for pharmacists to receive) **0.1** CEUs in pharmacy education.

The Universal Activity Number is **JA4008229-0000-21-014-L04-P** and enduring **JA4008229-0000-21-015-H04-P** course category.

This activity has been designated as Knowledge-Based.

Once credit is claimed, an unofficial statement of credit is immediately available on TCEOnline. Official credit will be uploaded within 60 days on the NABP/CPE Monitor.

For Certified Public Health Professionals (CPH)
The Centers for Disease Control and Prevention is a pre-approved provider of Certified in Public Health (CPH) recertification credits and is authorized to offer 1.0 CPH recertification credit for this program.

AAVSB/RACE: This program was reviewed and approved by the AAVSB RACE program for **1.0** hours of continuing education. Participants should be aware that some boards have limitations on the number of hours accepted in certain categories and/or restrictions on certain methods of delivery of continuing education. Please contact the AAVSB RACE program at race@aavsb.org if you have any comments/concerns regarding this program's validity or relevancy to the veterinary profession.

DISCLOSURE: In compliance with continuing education requirements, CDC, our planners, our presenters, and their spouses/partners wish to disclose they have no financial interests or other relationships with the manufacturers of commercial products, suppliers of commercial services, or commercial supporters. Planners have reviewed content to ensure there is no bias. The presentation will not include any discussion of the unlabeled use of a product or a product under investigational use. CDC did not accept commercial support for this continuing education activity.

The Emergency Risk Communication Branch in the Division of Emergency Operations, Center for Preparedness and Response is responsible for the management of all COCA products.

Subject: FACT SHEET: President Biden Takes Aggressive and Immediate Action to Contain COVID-19 Crisis

FOR IMMEDIATE RELEASE
January 21, 2021

FACT SHEET:
President Biden Takes Aggressive and Immediate Action to Contain COVID-19 Crisis

The President to Release National COVID-19 Strategy and Sign Executive Actions to Expand Testing, Administer Vaccines, Advance Racial Equity, and Safely Reopen Schools and Businesses

Today, President Joe Biden will release the National Strategy for the COVID-19 Response and Pandemic Preparedness -- a comprehensive roadmap to guide America out of this pandemic. To jumpstart this strategy, he will immediately sign 10 Executive Orders and other directives and take additional actions to move quickly to contain the COVID-19 crisis by expanding testing, administering vaccines, advancing racial equity, and safely reopening schools and businesses. These steps build on actions President Biden took yesterday to rejoin the World Health Organization, encourage masking, and to create his White House COVID-19 Response Team.

Below are more details on the steps that President Biden will take today to immediately put his National Strategy into action.

IMMEDIATELY EXPAND EMERGENCY RELIEF AND EXERCISE THE DEFENSE PRODUCTION ACT (DPA)

Manufacture and Deliver Supplies for Vaccination, Testing, and Personal Protective Equipment (PPE)
President Biden is taking immediate action to fill supply shortfalls for vaccination supplies, testing supplies, and PPE, and to ensure that these critical supplies equitably reach American communities, especially communities of color and other underserved communities hit hardest by the virus. The President will issue an Executive Order directing relevant agencies to exercise all appropriate authorities, including the DPA, to accelerate manufacturing, delivery, and administration to meet shortfalls in equipment and supplies needed for the COVID-19 response, beginning with action to increase the availability of critical supplies such as N95 masks, isolation gowns, nitrile gloves, PCR sample collection swabs, test reagents, pipette tips, laboratory analysis machines for PCR tests, high-absorbency foam swabs, nitrocellulose material for rapid antigen tests, rapid test kits, and all the necessary equipment and material to accelerate the manufacture, delivery, and administration of COVID-19 vaccine.

Reimburse States So They Can Deploy the Emergency Personnel and Supplies Americans Need

The President will issue a Presidential Memorandum directing the Federal Emergency Management Administration (FEMA) to increase federal reimbursement to states and Tribes from 75 percent to 100 percent of the cost for National Guard personnel and emergency supplies, such as PPE, cleaning and sanitizing efforts, and the personnel and equipment needed to create vaccination centers. The order also includes restoring full reimbursement for eligible costs necessary to support safe school reopening through the FEMA Disaster Relief Fund. To help address the health and financial crises faced by Tribal Nations throughout our country and to advance Tribal sovereignty in our COVID-19 response, this Memorandum also expands FEMA resources for Tribal governments.

MITIGATE SPREAD THROUGH EXPANDING TESTING, TREATMENT, AND THE PUBLIC HEALTH WORKFORCE, AND ESTABLISHING CLEAR PUBLIC HEALTH STANDARDS

Establish the Pandemic Testing Board, Expand Testing, and Strengthen the Public Health Workforce

To control the COVID-19 pandemic and safely reopen schools and businesses, the U.S. must have wide-spread testing. President Biden will issue an Executive Order that establishes the COVID-19 Pandemic Testing Board to bring the full force of the federal government's expertise to expanding testing supply and increasing access to testing. The federal government will increase testing capacity by directing the use of the DPA and other authorities to procure more tests and expand manufacturing capacity where possible. The Executive Order will promote surge capacity for testing in the United States, onshore test manufacturing, expand the public health workforce, support COVID-19 screening for schools, and ensure that underserved communities, including communities of color, can equitably access tests.

Bolster Access to COVID-19 Treatments and Clinical Care

Effective treatments for COVID-19 are critical to saving lives. President Biden will sign an Executive Order directing studies, including large-scale randomized trials, to identify treatments for COVID-19 and to ensure that such studies address the needs of diverse populations. The Executive Order establishes a comprehensive, integrated, equitable, and coordinated preclinical drug discovery and development program to allow therapeutics to be evaluated and developed in response to pandemic threats. The Order also outlines steps to improve clinical care, provide assistance to long-term care facilities and intermediate care facilities for people with disabilities, increase health care workforce capacity, expand access to programs designed to meet long-term health needs of patients recovering from COVID-19, and support access to safe and effective COVID-19 therapies for those without coverage.

Improve Data to Combat COVID-19

Metrics and metric-driven public health guidance will be essential to controlling the pandemic. President Biden's Executive Order will enhance the United States' collection, production, sharing, and analysis of data to support an equitable COVID-19 response and recovery. The federal government will work with state, local, Tribal and territorial governments to aggregate and analyze data to track access to vaccines and testing, reopen schools and businesses, and address disparities in COVID-19 infections and health outcomes. And, the federal government will create publicly available dashboards with national and state-by-state level information, consistent with privacy protections, on cases, testing, vaccinations, and hospital admissions to make real-time information available to policymakers and the public.

MOUNT A SAFE, EFFECTIVE, COMPREHENSIVE VACCINATION CAMPAIGN

Take Immediate Actions to Convert Vaccines into Vaccinations

The Biden-Harris Administration will spare no effort to ensure the public can get vaccinated safely, effectively and equitably. To meet the aggressive vaccination target of 100 million shots by the end of his first 100 days in office, President Biden will take immediate action to improve the vaccination

program. Yesterday, he directed FEMA to begin standing up the first federally-supported community vaccination centers, with the goal of standing up 100 centers in the next month. The Centers for Disease Control and Prevention (CDC) will also launch the federal pharmacy program -- making vaccines available to communities in their local pharmacies beginning next month. And, he tasked the U.S. Public Health Services Commissioned Corps with expanding its workforce and preparing for deployment. Central to this effort will be expanded support and collaboration with state, local, Tribal and territorial governments, including the establishment of COVID Response Liaisons for each state -- a model based on the response to Hurricane Sandy.

SAFELY REOPEN SCHOOLS, BUSINESSES, AND TRAVEL WHILE PROTECTING OUR WORKERS

Direct Action to Support Students & Safely Reopen Schools
President Biden will issue an Executive Order directing the Departments of Education and Health and Human Services (HHS) to provide guidance on safe reopening and operating for schools, child care providers, and institutions of higher education. Ensuring the safety of students and educators and adherence to science will be paramount. And, the Order directs the Departments of Education and Health and Human Services to collect data around reopening and school closures so state and local officials have metrics to inform decision-making and can better understand the impact of closures on students from families with low-incomes, students of color, English-language learners, students with disabilities and others.

The COVID-19 Response Team will work to ensure that testing materials, support for contact tracing, and vaccinations for teachers are equitably provided to support in-person care and learning. Finally, the order encourages the Federal Communications Commission to increase connectivity options for students lacking reliable home broadband, so that they can continue to learn if their schools are operating remotely.

This work will be supported by the Presidential Memorandum directing FEMA to offer reimbursement for eligible emergency supplies, such as PPE for schools and child care providers.

The Administration will engage with educators and their unions, students and their families, state and local education and public health officials, civil rights advocates, and other experts in the field. And, the Department of Education will work with HHS to ensure that guidance for schools is updated based on the latest science and any developments in the pandemic, including the spread of new coronavirus variants that may have a higher transmission rate. The Administration will always be honest about the challenges we face, directly addressing how and whether changes in the pandemic may impact the reopening of schools or the ability of schools to remain open.

Help Protect Workers from COVID-19
Millions of Americans, many of whom are people of color, immigrants, and low-wage workers, continue to put their lives on the line to keep the country functioning through the pandemic. President Biden will sign an Executive Order calling on the Occupational Safety and Health Administration (OSHA) to immediately release clear guidance for employers to help keep workers safe from COVID-19 exposure. It also asks OSHA and Mine Safety and Health Administration to determine whether to establish emergency temporary standards that require employers to take steps to keep workers safe from COVID-19 and it directs OSHA to enforce worker health and safety requirements, targeting the worst violators. With the goal of protecting all workers from COVID-19, the order instructs agencies to explore ways to protect workers who are not always covered by OSHA standards, such as those who are self-employed.

Promote Safe Travel
To protect travelers from COVID-19, President Biden will issue an Executive Order to require mask-wearing in airports, on certain modes of public

transportation, including many trains, airplanes, maritime vessels, and intercity buses. For air travel, this Executive Order also requires international travelers to produce proof of a negative COVID-19 test prior to departing for the United States and to comply with CDC guidelines for self-isolation and self-quarantine upon arrival. The Executive Order also calls for the consideration of additional public health measures in domestic travel and for consultation with foreign governments and other stakeholders to implement public health measures for safe travel, including at land and sea borders.

PROTECT THOSE MOST AT RISK AND ADDRESS INEQUITIES FACED BY COMMUNITIES OF COLOR AND OTHER UNDERSERVED GROUPS

Advance Health Equity in the Nation's COVID-19 Response
In order to address the disproportionate and severe impact of COVID-19 on communities of color and other underserved populations, President Biden will issue an Executive Order to ensure an equitable pandemic response and recovery. The order establishes a COVID-19 Health Equity Task Force to provide specific recommendations to the President for allocating resources and funding in communities with inequities in COVID-19 outcomes by race, ethnicity, geography, disability, and other considerations. The federal government will expand equity data collection; increase access to PPE, testing, therapies, and vaccines in underserved communities and high-risk settings; and assess and update pandemic response plans to ensure equity. The health workforce, including community-based workers, will be expanded to assist with contact tracing, vaccination, and linkage to care. Additionally, the Biden Administration will work with states, local jurisdictions, Tribal communities, and territories to address unmet basic needs, including food, housing, and childcare, for individuals and families affected by COVID-19.

RESTORE U.S. GLOBAL LEADERSHIP AND BUILD BETTER PREPAREDNESS

Advance U.S. Global Leadership, Support the Health and Humanitarian Response to COVID-19, and Protect Against Future Biological Threats
America's withdrawal from the world stage and retreat from the World Health Organization has impeded progress on the global COVID-19 response and left the United States and the world more vulnerable to future pandemics. Yesterday, President Biden signed letters to the United Nations Secretary General and World Health Organization Director General to cease America's withdrawal from the organization and to outline U.S. intent to work constructively with the WHO to strengthen and reform it.
Today, President Biden will sign a Presidential Directive to restore America's leadership, support the international pandemic response effort, promote resilience for future threats, and advance global health security and the Global Health Security Agenda. This directive restores U.S. leadership and seeks to support the international health and humanitarian response to the COVID-19 pandemic and its secondary impacts, global health security and diplomacy, and better biopreparedness and resilience for emerging and future biological threats.

RACIAL EQUITY IMPACT

The COVID-19 crisis has shined a light on and exacerbated the persistent racial inequities in our healthcare system and our economy. Americans of color are being infected and dying from COVID-19 at higher rates, while workers of color disproportionately put themselves at risk of exposure to COVID-19 on the frontline of this crisis to keep our country running. Changing the course of the COVID-19 crisis requires mobilizing an equitable response across the whole of our government. The new COVID-19 Health Equity Task Force will intensely focus on these issues. The actions to expand the availability of testing and vaccines in communities of color, and other underserved communities, ensure that new clinical treatments are developed to serve diverse Americans, and safely reopen our schools so that children who are facing disproportionately

high risks of learning loss can get back into the classroom. These actions will also support Native communities and Tribal governments to address the health and economic crises in Indian country.

WORKER IMPACT

These executive actions will help keep millions of workers healthy and safe from COVID-19. They direct agencies to provide new guidance so that employers and schools know what they need to do to keep workers safe. They'll increase access to personal protective equipment, testing, and vaccines that will help reduce the spread of COVID-19 in workplaces across the country. They'll help ensure more people are wearing masks when they travel, immediately providing more protection to many airline workers, bus drivers, and other transportation workers, and providing Americans safe ways to travel to work.

With the support of funding from the President's American Rescue Package, the President's plan to safely reopen schools will help students engage in in-person learning, parents return to work and prevent more educators from being laid off, as we combat the virus and make schools safe for students and educators again.

These measures will help keep workers safe and healthy, get more Americans back to work, and ultimately reduce the spread of the virus.

January 22, 2021

Allergic Reactions Including Anaphylaxis After Receipt of the First Dose of Moderna COVID-19 Vaccine — United States, December 21, 2020–January 10, 2021

CDC COVID-19 Response Team; Food and Drug Administration

As of January 20, 2021, a total of 24,135,690 cases of coronavirus disease 2019 (COVID-19) and 400,306 associated deaths had been reported in the United States (https://covid.cdc.gov/covid-data-tracker/#cases_casesper100klast7days). On December 18, 2020, the Food and Drug Administration (FDA) issued an Emergency Use Authorization (EUA) for Moderna COVID-19 vaccine administered as 2 doses, 1 month apart to prevent COVID-19. On December 19, 2020, the Advisory Committee on Immunization Practices (ACIP) issued an interim recommendation for use of Moderna COVID-19 vaccine (*1*). As of January 10, 2021, a reported 4,041,396 first doses of Moderna COVID-19 vaccine had been administered in the United States, and reports of 1,266 (0.03%) adverse events after receipt of Moderna COVID-19 vaccine were submitted to the Vaccine Adverse Event Reporting System (VAERS). Among these, 108 case reports were identified for further review as possible cases of severe allergic reaction, including anaphylaxis. Anaphylaxis is a life-threatening allergic reaction that occurs rarely after vaccination, with onset typically within minutes to hours (*2*). Among these case reports, 10 cases were determined to be anaphylaxis (a rate of 2.5 anaphylaxis cases per million Moderna COVID-19 vaccine doses administered), including nine in persons with a documented history of allergies or allergic reactions, five of whom had a previous history of anaphylaxis. The median interval from vaccine receipt to symptom onset was 7.5 minutes (range = 1–45 minutes). Among eight persons with follow-up information available, all had recovered or been discharged home. Among the remaining case reports that were determined not to be anaphylaxis, 47 were assessed to be nonanaphylaxis allergic reactions, and 47 were considered nonallergic adverse events. For four case reports, investigators have been unable to obtain sufficient information to assess the likelihood of anaphylaxis. This report summarizes the clinical and epidemiologic characteristics of case reports of allergic reactions, including anaphylaxis and nonanaphylaxis allergic reactions, after receipt of the first dose of Moderna COVID-19 vaccine during December 21, 2020–January 10, 2021, in the United States. CDC has issued updated interim clinical considerations for use of mRNA COVID-19 vaccines currently authorized in the United States (*3*) and interim considerations for preparing for the potential management of anaphylaxis (*4*).

Using methods previously described (*5*), CDC and FDA identified reports of suspected anaphylaxis in VAERS, the national passive surveillance (i.e., spontaneous reporting) system for monitoring adverse events after immunization (*6*). CDC physicians screened VAERS reports describing suspected severe allergic reactions and anaphylaxis and applied Brighton Collaboration case definition criteria for anaphylaxis* (*7*). After initial screening, reports with sufficient evidence to suggest anaphylaxis were followed up by collecting information from medical records and through direct outreach to health care facilities and treating health care providers, and, in some cases, vaccine recipients. Physician reviewers classified all initially identified case reports as anaphylaxis or not anaphylaxis and used clinical judgment to further categorize reports that were considered not anaphylaxis as nonanaphylaxis allergic reactions or nonallergic adverse events. Nonallergic adverse events, mostly vasovagal (e.g., fainting or the sensation of fainting) or suspected anxiety-related, were excluded from the final

* Brighton level 1 represents the highest level of diagnostic certainty that a reported case is indeed a case of anaphylaxis; levels 2 and 3 represent successively lower levels of diagnostic certainty. Level 4 is a case reported as "anaphylaxis" but that does not meet the Brighton Collaboration case definition. Level 5 is a case that was neither reported as anaphylaxis nor meets the case definition.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-002082

analyses. Anaphylaxis and nonanaphylaxis allergic reaction cases with symptom onset occurring later than the day after vaccination (i.e., outside the 0–1-day risk window) were also excluded because of the difficulty in clearly attributing allergic reactions with onset later than this to vaccination.[†]

During December 21, 2020–January 10, 2021, the administration of 4,041,396 first doses of Moderna COVID-19 vaccine (2,465,411 to females [61%], 1,450,966 to males [36%], and 125,019 to persons whose sex was not recorded [3%]) was reported to CDC. During the same period, reports of 1,266 (0.03%) adverse events after receipt of the first dose of Moderna COVID-19 vaccine had been submitted to VAERS. Among these, 108 case reports were identified for further review as possible cases of severe allergic reaction, including anaphylaxis, based on descriptions of signs and symptoms; 10 of these reports, all describing events in females, met the Brighton Collaboration case definition criteria for anaphylaxis (Table 1), corresponding to an initial estimated rate of 2.5 anaphylaxis cases per million first Moderna COVID-19 vaccine doses administered. The median age of persons with anaphylaxis was 47 years (range = 31–63 years). The median interval from vaccine receipt to symptom onset was 7.5 minutes (range = 1–45 minutes); nine patients had onset within 15 minutes, and one had onset after 30 minutes (Figure). In all 10 reports, patients received epinephrine as part of initial emergency treatment; the route of administration was confirmed or presumed to be intramuscular based on the description of treatment and the clinical course of the event as documented in the VAERS report. Six patients were hospitalized (including five in intensive care, four of whom required endotracheal intubation), and four were treated in an emergency department; eight patients with follow-up information available are known to have been discharged home or had recovered at the time of report to VAERS. No deaths from anaphylaxis were reported after receipt of Moderna COVID-19 vaccine. Nine of the 10 anaphylaxis

[†] Anaphylaxis and nonanaphylaxis allergic reaction cases with symptom onset occurring later than the day after vaccination (i.e., outside of the 0–1-day risk window) were excluded because of the difficulty in clearly attributing allergic reactions with onset outside this risk window to vaccination.

TABLE 1. Characteristics of reported cases of anaphylaxis (n = 10) after receipt of the first dose of Moderna COVID-19 vaccine — Vaccine Adverse Events Reporting System (VAERS), United States, December 21, 2020–January 10, 2021

Age, yrs	Sex	Past history: Allergies or allergic reactions*	Past history: Previous anaphylaxis episode	Onset after receipt (mins)	Signs and symptoms	Treatment setting[†]	Epi received	Brighton level[§]	Outcome or disposition[¶]
37	F	Penicillin, phenytoin, ibuprofen	No	1	Respiratory failure, vomiting	Inpatient	Yes	2	Discharged home

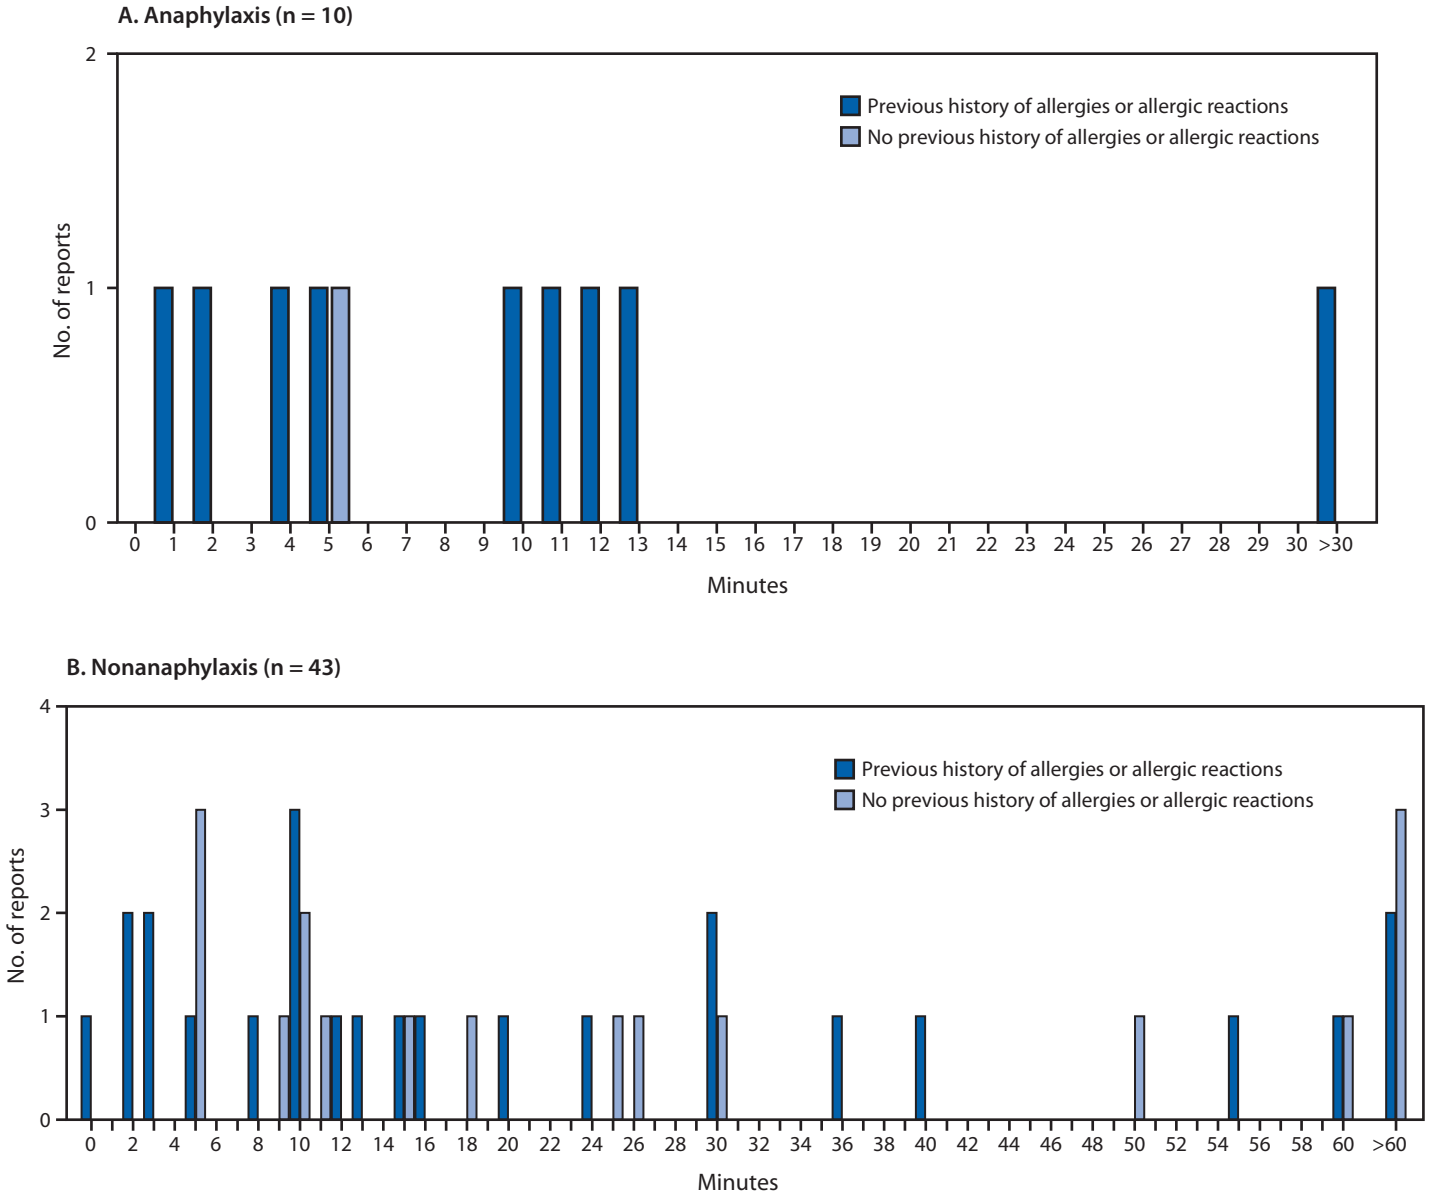
FIGURE. Minutes from vaccine receipt to onset of anaphylaxis (A)* and nonanaphylaxis allergic reactions (B)† after receipt of the first dose of Moderna COVID-19 vaccine — Vaccine Adverse Events Reporting System (VAERS), United States, December 21, 2020–January 10, 2021



Abbreviation: COVID-19 = coronavirus disease 2019.

* The interval from vaccine receipt to symptom onset was >30 minutes for one anaphylaxis case (45 minutes).

† The interval from vaccine receipt to symptom onset was ≥60 minutes for three nonanaphylaxis patients who had a documented history of allergies or allergic reactions at 60, 90, and 98 minutes and for four who did not have a documented history of allergies or allergic reactions (60 minutes, 10 hours, 20 hours, and 24 hours). The interval from vaccine receipt to symptom onset was missing in two case reports, both of which documented a history of allergies or allergic reactions. Four cases of nonanaphylaxis allergic reactions with symptom onset occurring later than the day after vaccination (i.e., outside of the 0–1-day risk window) were excluded from the final analysis.

case reports included a patient history of allergies or allergic reactions, including to drugs (six), contrast media (two), and foods (one); five patients had experienced an episode of anaphylaxis in the past, none of which was associated with receipt of a vaccine (Table 2). No geographic clustering of anaphylaxis cases was observed, and the cases occurred after receipt of doses from multiple vaccine lots. At the time of this publication, despite follow-up efforts, investigators have been unable to obtain sufficient information to assess the likelihood of anaphylaxis in four of the initial 108 suspected cases reported.

MS-DOH-21-1816-A-002084

TABLE 2. Characteristics of patients with reported anaphylaxis and nonanaphylaxis allergic reactions after receipt of the first dose of Moderna COVID-19 vaccine — Vaccine Adverse Events Reporting System (VAERS), United States, December 21, 2020–January 10, 2021

Characteristic	Type of reported reaction, no. (%)	
	Anaphylaxis (n = 10)	Nonanaphylaxis allergic reactions (n = 43)*
Median age, yrs (range)	47 (31–63)	43 (22–96)
Female	10 (100)	39 (91)
Minutes to symptom onset, median (range)	7.5 (1–45)	15 (<1–1,440 [24 hrs])
Symptom onset ≤15 mins	9 (90)	21 (51)†
Symptom onset ≤30 mins	9 (90)	30 (73)†
Documented history of allergies or allergic reactions	9 (90)§	26 (60)

Abbreviation: COVID-19 = coronavirus disease 2019.

* Four of the initial 47 nonanaphylaxis allergic reaction reports were excluded from the final analysis because symptom onset occurred later than the day after vaccination (i.e., outside the 0–1-day risk window).

† Two nonanaphylaxis allergic reaction reports were missing information on time of symptom onset; percentage calculated among 41 case reports with onset documented.

§ Five anaphylaxis reports included a patient history of a previous anaphylaxis episode.

Summary

What is already known about this topic?

Anaphylaxis is a severe, life-threatening allergic reaction that occurs rarely after vaccination.

What is added by this report?

During December 21, 2020–January 10, 2021, monitoring by the Vaccine Adverse Event Reporting System detected 10 cases of anaphylaxis after administration of a reported 4,041,396 first doses of Moderna COVID-19 vaccine (2.5 cases per million doses administered). In nine cases, onset occurred within 15 minutes of vaccination. No anaphylaxis-related deaths were reported.

What are the implications for public health practice?

Locations administering COVID-19 vaccines should adhere to CDC guidance, including screening recipients for contraindications and precautions, having necessary supplies and staff members available to manage anaphylaxis, implementing recommended postvaccination observation periods, and immediately treating suspected anaphylaxis with intramuscular epinephrine injection.

Among the 43 cases of nonanaphylaxis allergic reaction after receipt of Moderna COVID-19 vaccination with symptom onset within the 0–1-day risk window, 26 (60%) were classified as nonserious.§ Commonly reported symptoms included pruritus, rash, itchy sensations in the mouth and throat, sensations of throat closure, and respiratory symptoms. The median patient age was 43 years (range = 22–96 years), and 39 (91%) of the reported reactions occurred in women. The median interval from vaccine receipt to symptom onset was 15 minutes (range = <1 minute–24 hours); in 30 (73%) cases, onset occurred within 30 minutes, in 11 cases, onset occurred after 30 minutes, and for two cases, time of onset was missing. For 26 (60%) case reports, a past history of allergies or allergic reactions, mostly to foods and drugs, was documented (Figure).

Discussion

Early safety monitoring of Moderna COVID-19 vaccine detected 10 cases of anaphylaxis after reported administration of 4,041,396 first doses of Moderna COVID-19 vaccine (2.5 cases per million Moderna COVID-19 vaccine doses administered) as well as cases of less severe nonanaphylaxis allergic reactions, based on U.S. data for December 21, 2020–January 10, 2021. Anaphylaxis is potentially life-threatening and requires immediate treatment (*4*). Based on this early monitoring, anaphylaxis after receipt of Moderna COVID-19 vaccine appears to be a rare event; however, comparisons of anaphylaxis risk with that associated with non–COVID-19 vaccines are constrained at this time by the limited data available this early in the COVID-19 vaccination program. A previous analysis of the Pfizer-BioNTech COVID-19 vaccine, also an mRNA vaccine, estimated an initial rate of 11.1 cases per million doses administered after receipt of the first dose of the Pfizer-BioNTech vaccine (*5*). CDC and FDA will continue enhanced monitoring for anaphylaxis among recipients of COVID-19 vaccines and will review case reports to VAERS.

In nine of 10 cases of anaphylaxis after receipt of Moderna COVID-19 vaccine, patients had symptom onset within 30 minutes of vaccination, and nine anaphylaxis patients also had a history of allergies or allergic reactions, including some with previous anaphylaxis events; up to 30% of persons in the general population might have some type of allergy or history of allergic reactions.¶ All 10 anaphylaxis cases reported after receipt of Moderna COVID-19 vaccine occurred in women. Whereas a previous review of anaphylaxis reports to VAERS found that 80% of cases reported in adults involved females (*8*), the current finding could be affected by the observation that more women than men had received a first dose of Moderna COVID-19 vaccine during the analytic period (61% of doses administered versus 36%, respectively). In a previous analysis of the Pfizer-BioNTech COVID-19 vaccine, two thirds of first doses were administered in women (*5*). The clinical and

§ Four of the initial 47 nonanaphylaxis allergic reactions were excluded from the final analysis. Based on the Code of Federal Regulations, a serious adverse event is defined if one of the following is reported: death, life-threatening illness, hospitalization or prolongation of hospitalization, permanent disability, congenital anomaly, or birth defect. https://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfcfr/cfrsearch.cfm?fr = 312.32

¶ https://www.aaaai.org/about-aaaai/newsroom/allergy-statistics

MS-DOH-21-1816-A-002085

epidemiologic characteristics of anaphylaxis case reports after receipt of Moderna COVID-19 vaccine are similar to those reported after receipt of the Pfizer-BioNTech COVID-19 vaccine (*5*). For both vaccines, symptom onset after vaccination occurred quickly, usually within minutes. A strong female predominance of anaphylaxis case reports exists for both vaccines. Finally, many persons experiencing anaphylaxis after receiving either vaccine had a history of allergies or allergic reactions, with several having experienced an anaphylaxis episode in the past. Similar patient characteristics in case reports of nonanaphylaxis allergic reactions were observed among the two vaccines.

The findings in this report are subject to at least two limitations. First, analyses of passive surveillance data include reporting biases, both underreporting because of lack of awareness or compliance with reporting requirements and reporting guidance, as well as stimulated reporting related to increased awareness from media or other public information sources. Second, incomplete information in reports and potential data lags because of processing times might result in an undercount of cases, and lags in reporting for vaccine doses administered might underestimate denominator data. However, reporting efficiency to VAERS for clinically severe adverse events is believed to be high (*9*). It is reasonable to expect that diagnosis and reporting of an acute and clinically severe condition such as anaphylaxis occurs relatively quickly, and VAERS is likely sensitive at capturing anaphylaxis cases occurring after COVID-19 vaccination.

Mortality from COVID-19 in populations at increased risk for severe illness is substantial (*10*), and treatment options are limited. Widespread vaccination against COVID-19 with highly effective vaccines represents a critical tool in efforts to control the pandemic and save lives. CDC and FDA will continue to monitor for adverse events, including anaphylaxis, after administration of COVID-19 vaccines and will regularly assess the benefits and risks of vaccination in the context of the evolving epidemiology of the pandemic. Continued monitoring in VAERS and additional monitoring in population-based surveillance systems, such as the CDC's Vaccine Safety Datalink (https://www.cdc.gov/vaccinesafety/ensuringsafety/monitoring/vsd/index.html), will help to further characterize the risk for anaphylaxis after administration of COVID-19 vaccines.

CDC guidance on use of mRNA COVID-19 vaccines and management of anaphylaxis is available (*3*,*4*). Persons with an immediate allergic reaction to the first dose of an mRNA COVID-19 vaccine should not receive additional doses of either of the mRNA COVID-19 vaccines. In addition to screening for contraindications and precautions before administering COVID-19 vaccines, vaccine locations should have the necessary supplies and trained staff members available to manage anaphylaxis, implement postvaccination observation periods, immediately treat persons experiencing anaphylaxis signs and symptoms with intramuscular injection of epinephrine, and transport patients to facilities where they can receive advanced medical care. In addition, all patients should be instructed to seek immediate medical care if they develop signs or symptoms of an allergic reaction after their observation period ends and they have left the vaccination location. Health care providers can play an important role in vaccine safety monitoring by being vigilant in recognizing and reporting adverse events after immunization to VAERS at https://vaers.hhs.gov/reportevent.html.

Percentage of Adolescents Meeting Federal Fruit and Vegetable Intake Recommendations — Youth Risk Behavior Surveillance System, United States, 2017

Samantha J. Lange, MPH[1,2]; Latetia V. Moore, PhD[2]; Diane M. Harris, PhD[2]; Caitlin L. Merlo, MPH[3]; Seung Hee Lee, PhD[2]; Zewditu Demissie, PhD[4]; Deborah A. Galuska, PhD[2]

According to the 2020–2025 Dietary Guidelines for Americans, persons should consume fruits and vegetables as part of a healthy eating pattern to reduce their risk for diet-related chronic diseases, such as cardiovascular disease, type 2 diabetes, some cancers, and obesity.* A healthy diet is important for healthy growth in adolescence, especially because adolescent health behaviors might continue into adulthood (*1*). The U.S. Department of Agriculture (USDA) recommends minimum daily intake of 1.5 cups of fruit and 2.5 cups of vegetables for females aged 14–18 years and 2 cups of fruit and 3 cups of vegetables for males aged 14–18 years.† Despite the benefits of fruit and vegetable consumption, few adolescents consume these recommended amounts (*2–4*). In 2013, only 8.5% of high school students met the recommendation for fruit consumption, and only 2.1% met the recommendation for vegetable consumption (*2*). To update the 2013 data, CDC analyzed data from the 2017 national and state Youth Risk Behavior Surveys (YRBSs) to describe the percentage of students who met intake recommendations, overall and by sex, school grade, and race/ethnicity. The median frequencies of fruit and vegetable consumption nationally were 0.9 and 1.1 times per day, respectively. Nationally, 7.1% of students met USDA intake recommendations for fruits (95% confidence interval [CI] = 4.0–10.3) and 2.0% for vegetables (upper 95% confidence limit = 7.9) using previously established scoring algorithms. State-specific estimates of the percentage of students meeting fruit intake recommendations ranged from 4.0% (Connecticut) to 9.3% (Louisiana), and the percentage meeting vegetable intake recommendations ranged from 0.6% (Kansas) to 3.7% (New Mexico). Additional efforts to expand the reach of existing school and community programs or to identify new effective strategies, such as social media approaches, might help address barriers and improve adolescent fruit and vegetable consumption.

The Youth Risk Behavior Surveillance System monitors prevalence of youth health behaviors that contribute to the leading causes of death and disability at the national, state, territorial, tribal, and large urban school district levels.§ Students

complete anonymous, self-administered questionnaires during one class period. CDC conducts the national YRBS biennially and uses a three-stage cluster sample design to obtain nationally representative samples of students in grades 9–12 who attend public and private schools. In 2017, the school and student response rates were 75% and 81% respectively, resulting in an overall response rate of 60%.¶

State education and health agencies conduct state YRBSs and employ a two-stage cluster sample design to obtain state-representative samples of students in grades 9–12 who attend public schools. These samples are independent of the national YRBS. Among 46 states that administered YRBS in 2017, 33 states asked all six questions included in the national YRBS about fruits and vegetables, had sufficient response rates (>60%) to obtain weighted state-representative data, and gave CDC permission to include their data. State response rates ranged from 60% to 82%.

The six questions about fruit and vegetable consumption in the 2017 YRBS assess how many times per day or week students consumed 100% fruit juice, fruit, green salad, potatoes (excluding French fries, fried potatoes, and potato chips), carrots, and other vegetables.** The seven response options were 0, 1–3 or 4–6 times during the past 7 days; or 1, 2, 3, or 4 or more times daily. Daily frequency of fruit and vegetable intake was calculated by using the midpoint for intake ranges (e.g., five for 4–6 times during past 7 days) and dividing by seven for intakes reported by week. Student-reported race/ethnicity was classified into non-Hispanic White, non-Hispanic Black, Hispanic, and non-Hispanic other. Estimates for non-Hispanic other are not presented because this category includes multiple racial groups, which makes it difficult to provide meaningful interpretation, but are included in overall and other demographic estimates.

Among 14,765 students in the national YRBS, 1,411 (9.6%) were excluded, including 988 who did not answer fruit and vegetable questions; 376 who did not report sex, grade, or race/ethnicity; and 47 who were aged ≤14 years (to correspond to the age range used in the algorithm described in this report). The final analytic sample was 13,354 students. Similar exclusions were made on state-specific data with 5%–18% excluded across the states.

Median frequencies of fruit and vegetable intake were determined nationally and for 33 states. Previously established scoring algorithms (*2*), developed using 24-hour recall data from the National Health and Nutrition Examination Survey, were used to predict whether students met recommendations for their age and sex based on the number of times per day they reported consuming fruits and vegetables, separately, and accounting for race/ethnicity (*2*). Balanced repeated replication, replicate weights, and Taylor linearization were used to

calculate 95% CIs for the percentage meeting recommendations (*2*). For vegetables, given CIs that include zero, only upper bounds are shown. T-tests were used to examine statistical differences by demographics (p-value <0.05). Analyses were performed using SAS (version 9.4; SAS Institute) survey procedures to account for complex sampling designs and Stata (version 14.0; StataCorp) to conduct t-tests.

Among students in grades 9–12 in 2017, the median reported daily intake was 0.9 times per day for fruits and 1.1 times per day for vegetables (Table 1). Nationally, 7.1% of high school students met federal intake recommendations for fruits (95% CI = 4.0–10.3), and 2.0% met these recommendations for vegetables (upper 95% CI = 7.9). State-specific estimates ranged from 4.0% (Connecticut) to 9.3% (Louisiana) for fruits and from 0.6% (Kansas) to 3.7% (New Mexico) for vegetables. Estimates were consistently low across demographic groups. Nationally, the percentage of students meeting recommendations for fruit consumption was higher among males (9.7%) than among females (4.7%), and higher among non-Hispanic Black persons (11.9%) and Hispanic persons (7.9%) than among

Abbreviations: CI = confidence interval; CL = confidence limit.

* Fruit consists of solid fruit and 100% fruit juice. Vegetable consists of green salad, potatoes (excluding French fries, fried potatoes, and potato chips), carrots, and other vegetables.

† Minimum daily intake recommendations for adolescents aged 14–18 years are: 1.5 cups of fruit and 2.5 cups of vegetables for females, and 2 cups of fruit and 3 cups of vegetables for males, per the U.S. Department of Agriculture. Additional information available at https://www.choosemyplate.gov/eathealthy/vegetables and https://www.choosemyplate.gov/eathealthy/fruits. Previously established scoring algorithms, developed using 24-hour recall data from the National Health and Nutritional Examination Survey, were used to predict whether students met recommendations for their age and sex based on the number of times per day they reported consuming fruits and vegetables, separately, and accounting for race/ethnicity.

§ Number of respondents aged 14–18 years with complete data for fruit and vegetable intake and demographic information.

¶ One-sided 95% CLs (i.e., upper bound only) are presented because of low prevalence of percentage meeting vegetable recommendations and CIs that include zero.

MS-DOH-21-1816-A-002090

non-Hispanic White persons (5.9%). These differences were not statistically significant, and patterns were similar in most states (Table 2). Similar, albeit less pronounced differences by sex and race/ethnicity were observed for the percentage of students meeting vegetable recommendations, nationally and in some states (Table 3). Estimates were similar across grade levels.

Discussion

The proportion of U.S. high school students meeting federal intake recommendations remained low in 2017, with 7.1% consuming enough fruits and 2.0% consuming enough vegetables to meet USDA recommendations. Although estimating the tail ends of distributions can be less precise than estimating mean intake (2), results still indicate that consumption across all demographic groups was insufficient to meet dietary recommendations. These findings are consistent with other studies indicating that adolescents consume fruits and vegetables much less frequently than is recommended for proper nutrition (*2*–*4*).

Reasons for insufficient consumption of fruits and vegetables by adolescents are complex. Adolescents might face barriers to consumption, including high availability of inexpensive, unhealthy food options, lack of taste preference for fruits and vegetables, and lack of home availability (*5*). Interventions to address some of these barriers are occurring in schools and community programs. For example, the National School Lunch Program†† requires that meals include a fruit and vegetable option daily. However, on average, 39% of high school

* National data are weighted and representative of all private and public school students in grades 9–12 in the United States. State data are weighted and representative of all public school students in grades 9–12 in the respective jurisdiction.
† One-sided 95% CLs (i.e., upper bound only) are presented because of low prevalence of percentage meeting vegetable recommendations and CIs that include zero.
§ White and Black students are non-Hispanic. Hispanic students could be of any race. Non-Hispanic other group not reported because this group includes multiple racial groups, which makes it difficult to provide meaningful interpretation, but included in overall estimates and estimates by other demographic characteristics.
¶ Female sex, grade 9, and White race/ethnicity were used as referents.
** Dashes indicate that estimates in states where the sample sizes were <100 were considered unstable and were not reported.

students participate in the National School Lunch Program (*6*), and fewer (14%) participate in the School Breakfast Program; participation is particularly low among students who do not qualify for free or reduced-price meals. Smart Snacks Standards ensure that foods and beverages sold in vending machines, school stores, and fundraisers include nutritious options, including fruits and vegetables (*7*). In addition, state and local farm-to-school programs support experiential learning activities, including cooking and taste-testing, to engage students in preparing and eating fruits and vegetables.§§

Community programs can also reduce barriers to fruit and vegetable consumption, including lack of home availability of fruits and vegetables, which is a consistent correlate of intake among adolescents (*8*). For example, projects funded by the Gus Schumacher Nutrition Incentive Program¶¶ support families with low income by providing financial incentives to purchase more produce. Additional communication approaches, including parent-directed messaging about exposing children to nutritious foods early and repeatedly at home,*** might enhance preferences for fruits and vegetables. Further, social marketing and health-branding strategies, such as those used by the FNV Campaign,††† to positively influence attitudes

MS-DOH-21-1816-A-002092

and societal norms about eating fruits and vegetables, might appeal to adolescents, particularly those who use social media. Consistently low fruit and vegetable intake among adolescents suggests that additional efforts are needed to expand the reach of existing programs or to identify new effective strategies such as communication approaches including social media.

The findings in this report are subject to at least two limitations. First, YRBS data are self-reported, which might overestimate fruit and vegetable intake (*9*). Second, intake recommendations are based on adolescents who do not engage in ≥30 minutes of physical activity daily, and active persons should consume more. These results might overestimate percentages meeting recommendations because 46.5% of U.S. students were active for ≥60 minutes per day on 5 or more days.[§§§]

YRBS data are highly representative of the adolescent population because 96% of adolescents aged 14–17 years attend school (*10*). Despite the benefits of healthy eating, these findings indicate that most high school students do not consume enough fruits and vegetables to meet USDA recommendations. Continued efforts to identify and address barriers to consumption might help adolescents eat more fruits and vegetables and support their overall health.

Summary

What is already known about this topic?

Consuming fruits and vegetables is associated with reduced risk for cardiovascular disease, type 2 diabetes, some cancers, and obesity. Healthy dietary habits established during adolescence might continue into adulthood. However, few U.S. high-school students eat enough fruits and vegetables to meet U.S. Department of Agriculture recommendations.

What is added by this report?

Adolescents in all demographic groups consume too few fruits and vegetables, consistent with previous findings. In 2017, 7.1% met fruit intake recommendations, and 2.0% met vegetable intake recommendations.

What are the implications for practice?

Efforts to expand the reach of existing school and community programs as well as identify new strategies, such as social media approaches, might be needed to increase fruit and vegetable consumption among adolescents.

Vaccination Coverage with Selected Vaccines and Exemption Rates Among Children in Kindergarten — United States, 2019–20 School Year

Ranee Seither, MPH[1]; Michael T. McGill, PhD[1,2]; Jennifer L. Kriss, PhD[1]; Jenelle L. Mellerson, MPH[1,2]; Caitlin Loretan, MPH[1,3]; Kendra Driver, MSc[1,4]; Cynthia L. Knighton[1]; Carla L. Black, PhD[1]

State and local school vaccination requirements serve to protect students against vaccine-preventable diseases (*1*). This report summarizes data collected by state and local immunization programs* on vaccination coverage among children in kindergarten (kindergartners) in 48 states, exemptions for kindergartners in 49 states, and provisional enrollment and grace period status for kindergartners in 28 states for the 2019–20 school year, which was more than halfway completed when most schools moved to virtual learning in the spring because of the coronavirus 2019 (COVID-19) pandemic. Nationally, vaccination coverage† was 94.9% for the state-required number of doses of diphtheria and tetanus toxoids, and acellular pertussis vaccine (DTaP); 95.2% for 2 doses of measles, mumps, and rubella vaccine (MMR); and 94.8% for the state-required number of varicella vaccine doses. Although 2.5% of kindergartners had an exemption from at least one vaccine,§ another 2.3% were not up to date for MMR and did not have a vaccine exemption. Schools and immunization programs can work together to ensure that undervaccinated students are caught up on vaccinations in preparation for returning to in-person learning. This follow-up is especially important in the current school year, in which undervaccination is likely higher because of disruptions in vaccination during the ongoing COVID-19 pandemic (*2–4*).

To meet state and local school entry requirements, parents and guardians submit children's vaccination records or exemption forms to schools, or schools obtain records from state immunization information systems. Federally funded immunization programs work with departments of education, school nurses, and other school personnel to assess vaccination and exemption status of children, typically those aged 4–6 years, enrolled in public and private kindergartens and to report unweighted counts, aggregated by school type, to CDC via a web-based questionnaire in the Secure Access Management System.¶ CDC uses these data to produce state- and national-level estimates of vaccination coverage (*5*). During the 2019–20 school year, 48 states reported coverage for all state-required vaccines among public school kindergartners, and 47 states reported on private school kindergartners.** Forty-nine states reported exemption data among public school kindergartners, and 48 states reported on private school kindergartners.** This report provides data on overall national and median vaccination coverage for the state-required number of doses of DTaP, MMR, and varicella vaccine. Hepatitis B and poliovirus vaccination coverage data, which are not included in this report, are available at SchoolVaxView (*6*). Twenty-eight states reported data on kindergartners who, at the time of assessment, were attending school under a grace period (attendance without proof of complete vaccination or exemption during a set interval) or provisional enrollment (school attendance while completing a catch-up vaccination schedule). Coverage and exemptions from U.S. territories and associated

* Federally funded immunization programs are located in the 50 states and the District of Columbia (DC), five other cities or counties, and eight U.S territories and freely associated states (territories). Two cities reported data to CDC, which were also included in data by their state, to calculate medians and national estimates. Immunization programs in U.S. territories reported vaccination coverage and exemptions to CDC; however, these data were not included in overall national calculations.

† National and median vaccination coverage was determined using estimates for 48 states; Alaska, Delaware, and the District of Columbia did not report school coverage data because of problems with data collection. Data from cities were included with their state data. Data from territories were not included in national and median calculations.

§ National and median exemption rates were determined using estimates for 49 states; Colorado, Minnesota, and Missouri did not collect information on the number of kindergartners with an exemption but instead reported the number of exemptions for each vaccine, which could count some children more than once. For these states, the percentage of kindergartners exempt from the vaccine with the highest number of exemptions (the lower bound of the potential range of exemptions) was included in the national and median exemption rates. Delaware and the District of Columbia did not report school vaccine exemption data because of problems with data collection. Data from cities were included with their state data. Data from territories were not included in national estimates.

¶ Assessment date varied by state and area. Four states assess on the first day of school; 14 states assess by December 31; 16 states assess by some other date, ranging from 30 days after admission to April 30; 15 states assess on a rolling basis.

** Ten states reported coverage and exemption data for at least some homeschooled kindergartners as follows: California included data for students who attend virtual partial or full charter schools with some or all online instruction and students receiving individualized education program services because they are medically unable to attend school in public school data, and data for homeschools with six or more students in private school data. Kansas included data for students educated through public virtual schools in the public school data. New Mexico included all homeschooled students in public school data. North Dakota reported some homeschool data separately. Oregon reported data for students enrolled in exclusively online homeschool programs separately; online students of otherwise traditional public schools were included in the public school data. Pennsylvania included all homeschooled students in their public school data. South Carolina and Wisconsin included homeschooled students in their public or private school data if the students also attended classes, extracurricular activities, or had other contact with a school. Vermont included homeschooled students in their public and private school data if the students were enrolled in one or more classes at a school. Wyoming reported homeschooled students in their public school data if the students also attend classes or extracurricular activities at a public school.

MS-DOH-21-1816-A-002094

states are presented; however, national estimates, medians, and summary measures include only U.S. states.

Vaccination coverage and exemption estimates were adjusted according to survey type and response rates.[††] National estimates measure coverage and exemptions among all kindergartners, and medians measure the midpoint of state-level coverage regardless of population size. Reported estimates for the 2019–20 school year are based on 3,675,882 kindergartners surveyed for vaccination coverage, 3,914,961 for exemptions, and 2,955,220 for grace period and provisional enrollment among the 4,025,574 children reported as enrolled in kindergarten by immunization programs for 49 states.[§§] Potentially achievable coverage with MMR, defined as the sum of the percentage of children who are up to date with 2 doses of MMR and those with no documented vaccination exemption but who are not up to date, was calculated for each state. Nonexempt students include those provisionally enrolled, in a grace period, or otherwise without documentation of vaccination. SAS (version 9.4; SAS Institute Inc.) was used for all analyses.

Vaccination assessments varied by immunization program because of differences in states' required vaccines and number of doses, vaccines assessed, methods of data collection, and data reported (Supplementary Table 1, https://stacks.cdc.gov/view/cdc/100473). The majority of states reported kindergartners as up to date for a given vaccine if they had received all doses of that vaccine required for school entry.[¶¶] Seven states[***] reported kindergartners as up-to-date for any given vaccine only if they had received all doses of all vaccines required for school entry.

Nationally, 2-dose MMR coverage was 95.2% (range = ≥86.6% [Alabama] to ≥99.1% [Mississippi]). Coverage of ≥95% was reported by 20 states and coverage of <90% by three states (Table). DTaP coverage was 94.9% (range = 84.0% [Indiana] to ≥99.1% [Mississippi]), with 20 states reporting coverage of ≥95%, and three states reporting <90% coverage. Coverage with 2 doses (or 1 dose, as required) of varicella vaccine was 94.8% (range = ≥86.6% [Alabama] to ≥99.1% [Mississippi]), with 21 states reporting coverage ≥95%, and four states reporting <90% coverage.

The percentage of kindergartners with an exemption from one or more required vaccines (not limited to MMR, DTaP, and varicella vaccines) remained unchanged from the 2018–19 school year at 2.5% (range = 0.1% [New York and West Virginia] to 7.6% [Idaho]) (Table). Nationally, 0.3% of kindergartners had a medical exemption, and 2.2% had a nonmedical exemption (Supplementary Table 2, https://stacks.cdc.gov/view/cdc/100473). Only 95.2% of kindergartners were up to date with MMR; 2.5% had an exemption from at least one vaccine,[§] and another 2.3% were not up to date with MMR and did not have a vaccine exemption (Table).

The percentage of kindergartners attending school within a grace period or provisionally enrolled among the 28 states reporting these data was 1.6% (range = <0.1% [Hawaii and Mississippi] to 6.1% [Ohio]) (Table). Of the 28 states with MMR coverage <95%, 24 states could potentially achieve ≥95% MMR coverage if all nonexempt kindergartners, many of whom were within a grace period or provisionally enrolled, were vaccinated (Figure 1). Among the 30 states reporting a decrease in the percentage of kindergartners who were not up to date for MMR and did not have an exemption in 2019–2020 compared with 2018–2019, an increase of MMR coverage in 2019–2020 was also reported by 26 states (Figure 2). In three states with MMR coverage <95% in 2018–2019 (Illinois, North Carolina, and South Carolina), coverage increased to ≥95% in 2019–2020.

Discussion

The purpose of vaccination assessment is to identify populations at risk and aid in taking programmatic steps to increase vaccination coverage. Although the COVID-19 pandemic led to late, truncated, or incomplete assessment of kindergarten vaccination status in the 2019–20 school year compared with the 2018–19 school year in some states (*7*), most student vaccinations would have already occurred before the start of the 2019–20 school year and would not have been affected by the pandemic. National coverage among kindergartners remained approximately 95% (*5*) for MMR, DTaP, and varicella vaccines. However, coverage and exemption rates varied by state. Measles outbreaks that affected school-aged children across multiple states during the 2018–19 school year underscore the importance of both school vaccination requirements for preventing

[††] Most immunization programs that used census or voluntary response provided CDC with data aggregated at the state or local (city or territory) level. Coverage and exemption data based on a census or voluntary response were adjusted for nonresponse using the inverse of the response rate, stratified by school type (public, private, and homeschool, where available). Programs that used complex sample surveys provided CDC with deidentified data aggregated at the school or county level for weighted analysis. Weights were calculated to account for sample design and adjusted for nonresponse for data collected through complex sample design wherever possible.

[§§] The totals reported here are the summations of the kindergartners surveyed among programs reporting data for coverage, exemptions, grace periods, and provisional enrollment. Data from cities and territories were not included in these totals.

[¶¶] All states required 2 doses of a measles-containing vaccine. Local DTaP requirements varied: Nebraska required 3 doses, four states (Illinois, Maryland, Virginia, and Wisconsin) required 4 doses, and all other states required 5 doses, unless the fouth dose was administered on or after the fourth birthday. The reported coverage estimates represent the percentage of kindergartners with the state-required number of DTaP doses, except for Kentucky, which required 5 doses of DTaP by age 5 years but reported 4-dose coverage for kindergartners. Seven states required 1 dose of varicella vaccine; 44 states required 2 doses.

[***] Alabama, Florida, Georgia, Iowa, Mississippi, New Hampshire, and New Jersey did not assess coverage for individual vaccines, but instead considered kindergartners up to date only if they had received all doses of all vaccines required for school entry. For these states, estimates are shown with the "≥" symbol.

U.S. Virgin Islands	NR	NR	NR	NR	NR	NR	NR	NA

Abbreviations: NA = not available; NP = no grace period/provisional policy; NR = not reported to CDC; NReq = not required for school entry.

* Estimates are adjusted for nonresponse and weighted for sampling where appropriate.

† Estimates based on a completed vaccine series (i.e., not vaccine-specific) use the "≥" symbol. Coverage might include history of disease or laboratory evidence of immunity.

§ A grace period is a set number of days during which a student can be enrolled and attend school without proof of complete vaccination or exemption. Provisional enrollment allows a student without complete vaccination or exemption to attend school while completing a catch-up vaccination schedule. In states with one or both of these policies, the estimates represent the number of kindergartners within a grace period, provisionally enrolled, or some combination of these categories.

¶ Exemptions, grace period/provisional enrollment and vaccination coverage status might not be mutually exclusive. Some children enrolled under a grace period/provisional enrollment might be exempt from one or more vaccinations, while children with exemptions might be fully vaccinated with one or more required vaccines.

** The kindergarten population is an approximation provided by each program.†† The number surveyed represents the number of kindergartners surveyed for vaccination coverage. For Alaska, this number represents the number surveyed for exemptions as coverage was not reported. The national total excludes the 10,381 kindergartners from Alaska. Exemption estimates are based on 34,011 kindergartners for Kansas, 65,938 kindergartners for South Carolina, 97,236 kindergartners for Virginia, and 67,391 kindergartners for Wisconsin.

§§ Most states require 2 doses of MMR; Alaska, New Jersey, and Oregon require 2 doses of measles, 1 dose of mumps, and 1 dose of rubella vaccines. California, Georgia, New York, New York City, North Carolina, and Virginia require 2 doses of measles and mumps and 1 dose of rubella vaccines. Iowa requires 2 doses of measles and 2 doses of rubella vaccines.

¶¶ Pertussis vaccination coverage might include some diphtheria, tetanus toxoids, and pertussis vaccine (DTP) vaccinations if administered in another country or by a vaccination provider who continued to use DTP after 2000. Most states require 5 doses of DTaP for school entry, or 4 doses if the fourth dose was received on or after the fourth birthday; Illinois, Maryland, Virginia, and Wisconsin require 4 doses; Nebraska requires 3 doses. The reported coverage estimates represent the percentage of kindergartners with the state-required number of DTaP doses, except for Kentucky, which requires ≥5 but reports ≥4 doses of DTaP.

*** Most states require 2 doses of varicella vaccine for school entry; Alabama, Arizona, Hawaii, Maine, New Jersey, Oklahoma, and Oregon require 1 dose. Reporting of varicella vaccination status for kindergartners with a history of varicella disease varied within and among states; some were reported as vaccinated against varicella and others as medically exempt.

††† National coverage estimates and medians calculated from data from 48 states (i.e., do not include Alaska, Delaware, and the District of Columbia). National grace period/provisional enrollment estimates and medians were calculated from data from 28 states that have either a grace period or a provisional enrollment policy and that reported relevant data to CDC. National exemption estimates and medians were calculated from data from 49 states (i.e., do not include Delaware and the District of Columbia). Other jurisdictions excluded were Houston, New York City, American Samoa, Guam, Marshall Islands, Federated States of Micronesia, North Mariana Islands, Palau, Puerto Rico, or U.S. Virgin Islands. Data reported from 3,675,882 kindergartners assessed for coverage, 3,914,961 for exemptions, and 2,955,220 for grace period/provisional enrollment. Estimates represent rates for populations of 4,015,193; 4,025,574; and 3,056,534 kindergartners for coverage, exemptions, and grace period/provisional enrollment, respectively.

§§§ Philosophical exemptions were not allowed.

¶¶¶ Alaska did not report kindergarten vaccination coverage because of problems with data collection. Vaccination coverage among children aged 6 years in VacTrAK, Alaska's Immunization Information System, was 75.5% for MMR, 85.1 for DTaP, and 73.0 for varicella vaccine.

**** Religious exemptions were not allowed.

†††† Counted some or all vaccine doses received regardless of Advisory Committee on Immunization Practices—recommended age and time interval; vaccination coverage rates reported might be higher than those calculated using only valid doses.

§§§§ Program did not report the number of children with exemptions, but instead reported the number of exemptions for each vaccine, which could count some children more than once. Lower bounds of the percentage of children with any exemptions were estimated using the individual vaccines with the highest number of exemptions.

¶¶¶¶ The proportion surveyed likely was <100% but is reported as 100% based on incomplete information about the actual current enrollment.

***** Did not include some types of schools, such as online schools or those located in military bases or correctional facilities, or tribal lands.

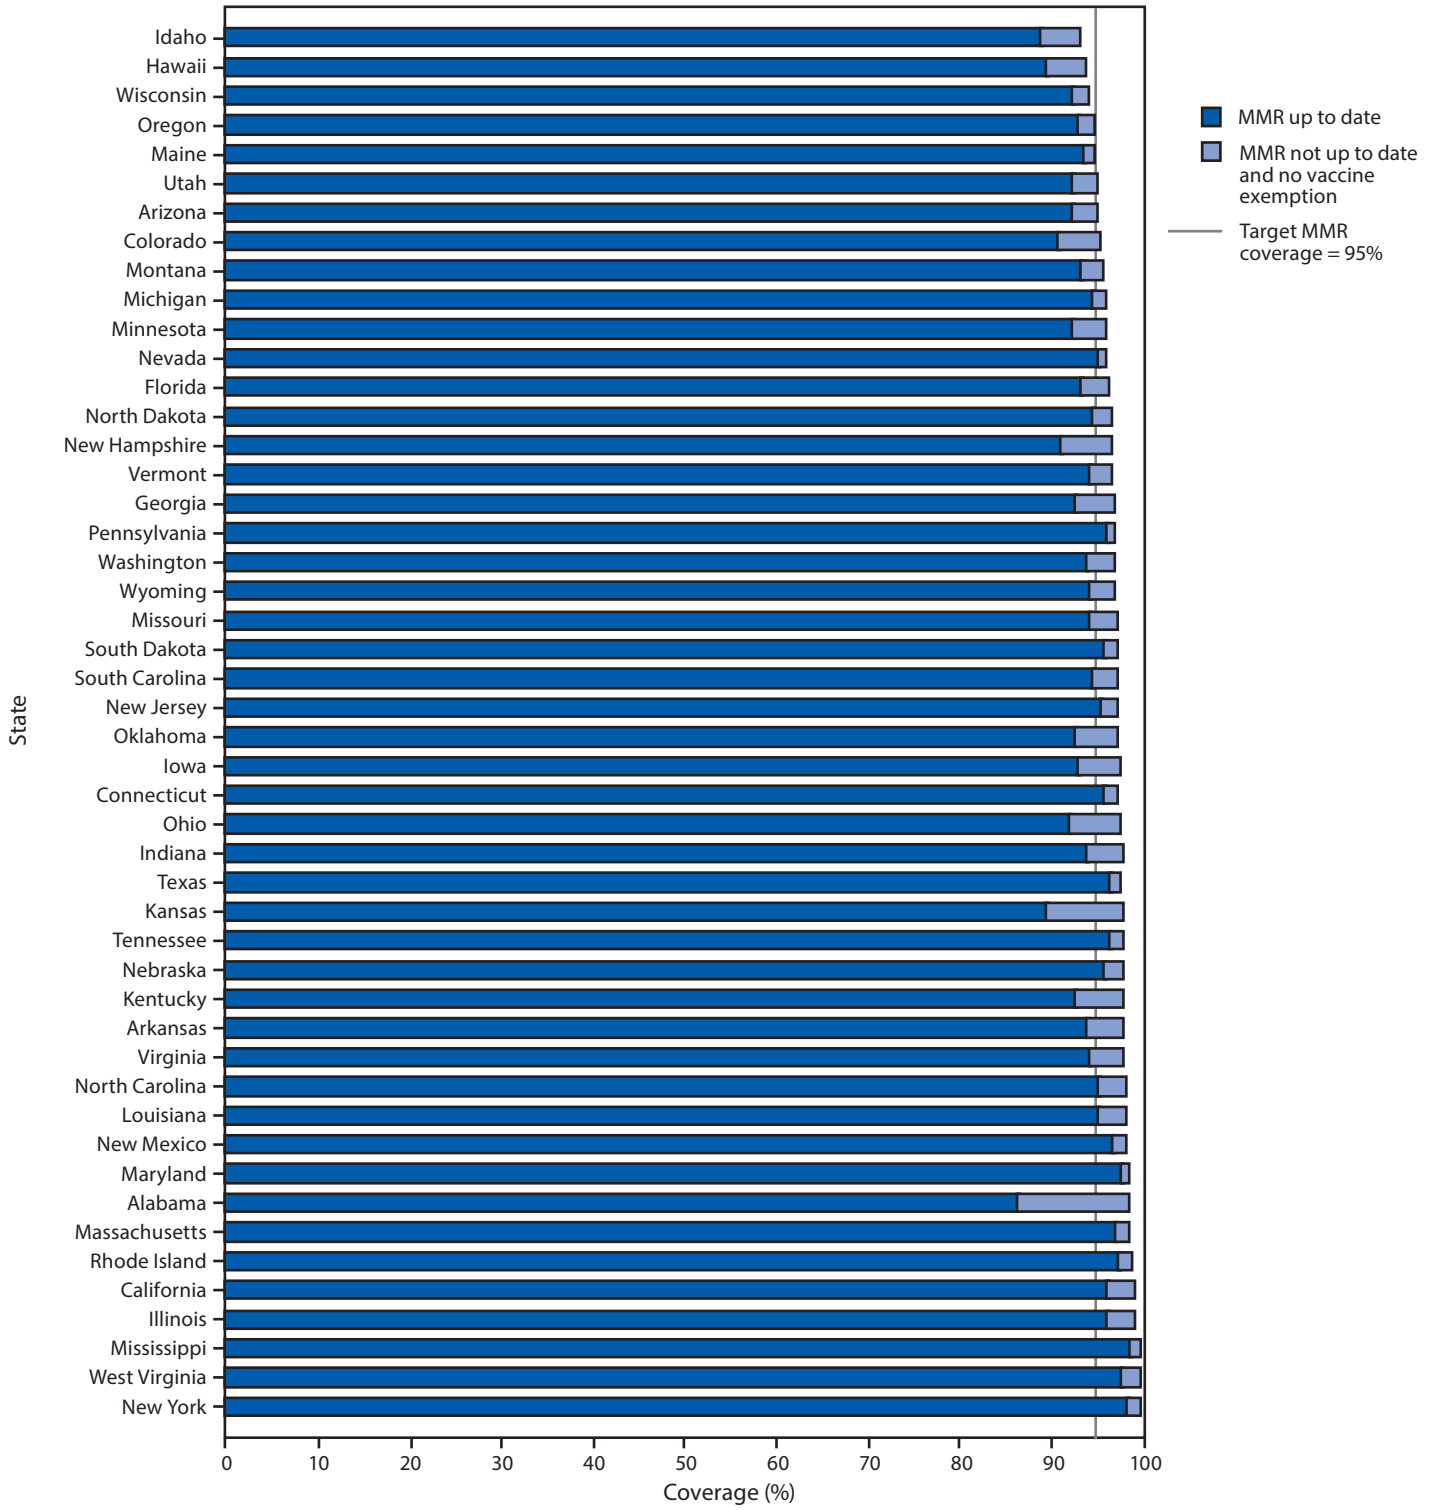
††††† Kindergarten vaccination coverage data were collected from a sample, and exemption data were collected from a census of kindergartners.

§§§§§ Reported public school data only.

¶¶¶¶¶ For Palau, estimates represent coverage among children in first grade.

MS-DOH-21-1816-A-002097

FIGURE 1. Potentially achievable coverage*,†,§ with measles, mumps, and rubella vaccine (MMR) among kindergartners, by state — 48 states, 2019–20 school year



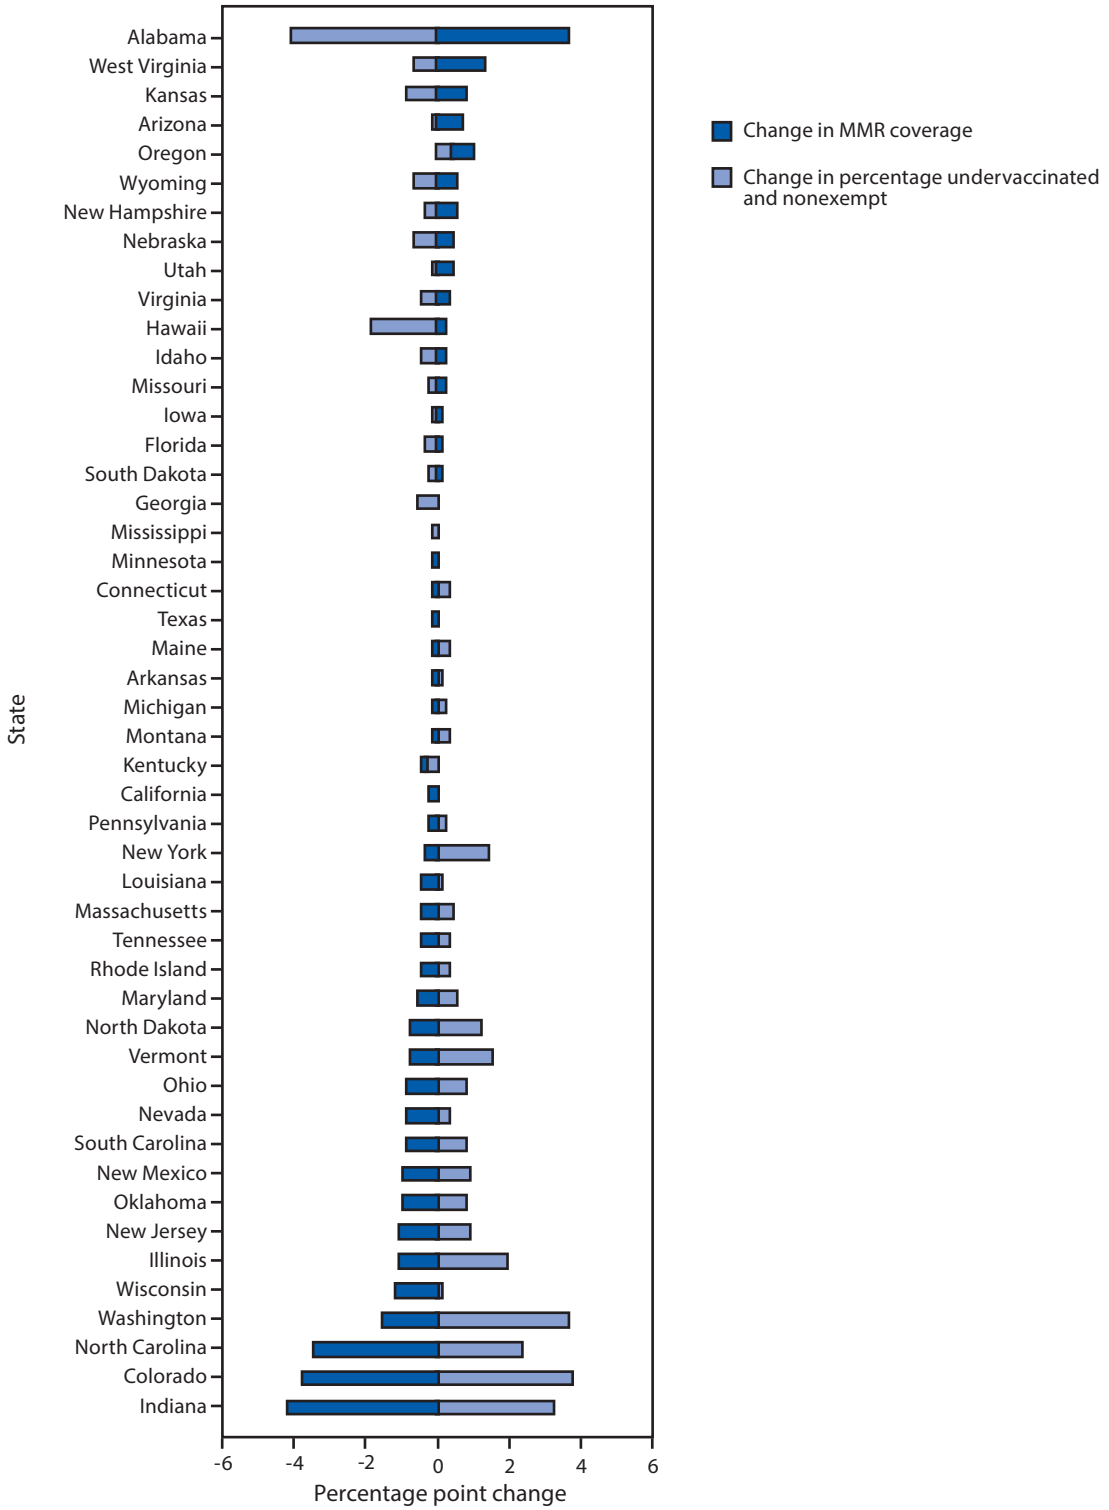
* States are ranked from lowest to highest potentially achievable coverage. Potentially achievable coverage is estimated as the sum of the percentage of students with up-to-date MMR and the percentage of students without up-to-date MMR and without a documented vaccine exemption.

† The exemptions used to calculate the potential increase in MMR coverage for Arizona, Arkansas, Colorado, Idaho, Illinois, Maine, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Rhode Island, Texas, Utah, Vermont, Wisconsin, and Wyoming are the number of children with exemptions specifically for MMR vaccine. For all other states, numbers are based on an exemption to any vaccine.

§ Alaska, Delaware, and the District of Columbia did not report kindergarten vaccination coverage for the 2019–20 school year and are excluded from this analysis.

MS-DOH-21-1816-A-002098

FIGURE 2. Change in percentage of kindergartners who are fully vaccinated with measles, mumps, and rubella vaccine (MMR) and in the percentage who are undervaccinated and nonexempt,*,†,§ by state — 48 states, 2018–19 to 2019–20 school years



* States are ranked from greatest decrease to highest increase in the percentage of kindergartners who are undervaccinated and nonexempt. The exemptions used to calculate the MMR not up to date and no documented vaccine exemptions for Arizona, Arkansas, Colorado, Idaho, Illinois, Maine, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Rhode Island, Texas, Utah, Vermont, Wisconsin, and Wyoming are the number of children with exemptions specifically for MMR vaccine. For all other states, numbers are based on an exemption to any vaccine.

† Alaska, Delaware, and the District of Columbia did not report kindergarten vaccination coverage for the 2019–20 school year and are excluded from this analysis.

§ California, Michigan, New Jersey, New York, Oregon, Pennsylvania, Texas, and Washington experienced >15 cases of measles during the 2018–2019 outbreak.

MS-DOH-21-1816-A-002099

disease spread and school coverage assessments to identify pockets of low coverage (*8*). Among eight states with measles outbreaks of ≥15 cases during the 2018–19 school year (*8*), six reported increases in MMR coverage during 2019–2020. Increases in some states were likely attributable to changes in state laws eliminating nonmedical vaccination exemptions (*9*), and vaccination campaigns in response to the outbreaks could also have contributed to the increases in MMR coverage.

The overall percentage of children with an exemption remained at approximately 2.5%; children with exemptions represent a small proportion of kindergartners nationally and in most states. In 25 states, the number of nonexempt undervaccinated kindergartners equaled or exceeded the number of those with exemptions. In many states, nonexempt undervaccinated students are attending school in a grace period or are provisionally enrolled. Follow-up with undervaccinated students can increase vaccination coverage in this group.

Twenty-six states successfully increased MMR coverage by reducing the number of nonexempt students who are not up to date, with three states (Illinois, North Carolina, and South Carolina) reaching coverage of ≥95%. Some states have implemented policies and activities focused on improving coverage. In Colorado, MMR coverage increased from 87.4% in 2018–2019 to 91.1% in 2019–2020. This was accomplished by prioritizing high MMR coverage. In addition to providing technical assistance, media toolkits, strategies, and local kindergarten MMR data and targets, the state health department furnished lists of elementary schools with low coverage to local public health agencies, which implemented community-specific strategies. These included digital media campaigns aimed at parents, vaccination reminder/recall, efforts to improve school compliance, outbreak tabletop exercises with schools, and incentives to families (Diana Herrero, Colorado Department of Public Health and Environment, personal communication, November 13, 2020). Almost all states could achieve ≥95% MMR coverage if nonexempt undervaccinated children were vaccinated according to local and state vaccination policies.

The findings in this report are subject to at least six limitations. First, comparability is limited because of variation in states' requirements, data collection methods, exemptions allowed, and definitions of grace period and provisional enrollment. Second, representativeness might be negatively affected because of data collection methods that missed some schools or students or occurred at different times. Third, results might be underestimated or overestimated because of incomplete documentation. Fourth, national coverage estimates include only 48 of 50 states but use lower bound estimates for seven states; exemption estimates include 49 states but use lower bound estimates for three states; and grace period or provisional enrollment estimates include only 28 states for the 2019–20 school year. Fifth, estimates of potentially achievable MMR coverage are approximations and are underestimated for states that do not report vaccine-specific exemptions (*5*,*7*). Finally, because of the COVID-19 pandemic, schools were closed, and state and local health department staff members were deployed to response activities, limiting the quantity and quality of student vaccination data collected and reported to CDC (CDC, unpublished data, 2020).

Based on measurements from other data sources, CDC expects that the COVID-19 pandemic has already reduced actual vaccination coverage of kindergarten-aged children through reduced appointment availability at providers' offices, parents delaying preventive health care visits, and other barriers to vaccination, and that those disruptions will reduce kindergarten vaccination coverage in the 2020–21 school year (*2*–*4*). In addition, schools in many states began the 2020–21 school year remotely and might not have enforced the usual vaccination policies. Providers, schools, and immunization programs will need to increase follow-up with undervaccinated students and find ways to overcome pandemic-related barriers to maintain the high level of vaccination coverage necessary to continue protecting school-aged children, their family members, and communities from vaccine-preventable diseases during virtual learning and as schools return to in-person instruction. Jurisdictions should provide resources as appropriate, such as guidance to parents about the importance of maintaining preventive care during the pandemic, lists of immunization providers in the area for children who are unable to be vaccinated by their usual health care provider, or special vaccination clinics at schools or health departments.

Summary

What is already known about this topic?

State immunization programs conduct annual kindergarten vaccination assessments to monitor school-entry vaccination coverage with all state-required vaccines.

What is added by this report?

For the 2019–20 school year, national coverage was approximately 95% for diphtheria and tetanus toxoids, and acellular pertussis; measles, mumps, and rubella; and varicella vaccines. The national exemption rate remained low at 2.5%.

What are the implications for public health practice?

Disruptions caused by the COVID-19 pandemic are expected to reduce vaccination coverage in the 2020–21 school year. Increased follow-up of undervaccinated students is needed from schools and immunization programs to maintain the high vaccination coverage necessary to protect students in preparation for schools returning to in-person learning.

COVID-19 Case Investigation and Contact Tracing Efforts from Health Departments — United States, June 25–July 24, 2020

Kimberly D. Spencer, MSPH[1]; Christina L. Chung, MPH[2]; Alison Stargel, MPH[1]; Alvin Shultz, MSPH[1]; Phoebe G. Thorpe, MD[3]; Marion W. Carter, PhD[3]; Melanie M. Taylor, MD[3]; Mary McFarlane, PhD[3]; Dale Rose, PhD[3]; Margaret A. Honein, PhD[3]; Henry Walke, MD[3]

Case investigation and contact tracing are core public health tools used to interrupt transmission of pathogens, including SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19); timeliness is critical to effectiveness (*1*,*2*). In May 2020, CDC funded* 64 state, local, and territorial health departments† to support COVID-19 response activities. As part of the monitoring process, case investigation and contact tracing metrics for June 25–July 24, 2020, were submitted to CDC by 62 health departments. Descriptive analyses of case investigation and contact tracing load, timeliness, and yield (i.e., the number of contacts elicited divided by the number of patients prioritized for interview) were performed. A median of 57% of patients were interviewed within 24 hours of report of the case to a health department (interquartile range [IQR] = 27%–82%); a median of 1.15 contacts were identified per patient prioritized for interview§ (IQR = 0.62–1.76), and a median of 55% of contacts were notified within 24 hours of identification by a patient (IQR = 32%–79%). With higher caseloads, the percentage of patients interviewed within 24 hours of case report was lower (Spearman coefficient = –0.68), and the number of contacts identified per patient prioritized for interview also decreased (Spearman coefficient = –0.60). The capacity to conduct timely contact tracing varied among health departments, largely driven by investigators' caseloads. Incomplete identification of contacts affects the ability to reduce transmission of SARS-CoV-2. Enhanced staffing capacity and ability and improved community engagement could lead to more timely interviews and identification of more contacts.

During July 31–August 14, 2020, baseline data on four metrics for June 25–July 24, 2020 (the evaluation period) were submitted by 62 of 64 (97%) health departments funded through the Epidemiology and Laboratory Capacity for Prevention and Control of Emerging Infectious Diseases Cooperative Agreement (ELC)¶ to the Research Electronic Data Capture (REDCap) platform (*3*). These metrics, developed by the CDC COVID-19 Contact Tracing Innovations Support Team, were vetted by public health partners, including a number of ELC-funded health departments, and include the following: 1) average caseload per case investigator (the total number of probable and confirmed COVID-19 patients assigned for interview during the evaluation period divided by the total number of case investigators), average contact tracing load (the total number of contacts assigned for follow-up divided by the total number of contact tracers), and staffing model (separate, mostly separate, or the same health department staffing for case investigation and contact tracing); 2) case investigation timeliness (the percentage of persons with probable and confirmed COVID-19 prioritized for interview successfully reached within 24 hours by a health department staff member or representative); 3) contact tracing timeliness (the percentage of contacts notified of potential exposure to COVID-19 within 24 hours of elicitation of contact information by a patient); and 4) contact tracing yield, calculated as the number of contacts elicited divided by number of patients prioritized for interview. Because guidance for prioritization of patient interviews was not provided, health departments developed their own criteria, examples of which included interviewing patients when they became known to the health department or prioritizing patient interviews based on whether the patients were symptomatic, had underlying medical conditions, lived in congregate settings, or worked in health care occupations. Descriptive analyses of the four metrics were performed using SAS (version 9.4; SAS Institute). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.**

Among the 62 funded health departments, four (6.5%) (all U.S.-affiliated Pacific islands) reported no cases, and two (3.2%) submitted partial data and were excluded. Data from the remaining 56†† (90%) health departments were analyzed.

MS-DOH-21-1816-A-002102

Because completeness of reporting by health departments varied by metric, denominators varied. Health departments with incomplete data for a metric were excluded for that specific metric.

Among reporting health departments, the median caseload per investigator during the evaluation period was 31, ranging from one to 196, among 54 (96%) health departments with complete data for this metric (Table). Among patients prioritized for interview by these 54 health departments, a median of 57% were interviewed within 24 hours of report to the health department. Among 53 health departments that provided information on the average number of contacts assigned for follow-up per contact tracer, the median was 29, ranging from 0.5 to 200; a median of 55% of contacts were notified within 24 hours of elicitation by a patient. Among 48 health departments that reported information on contact notification, 27 (56%) reported that at least one half of contacts were notified within 24 hours of elicitation. However, 12 health departments reported that fewer than one third (<32%) of contacts were reached within 24 hours.

Caseload and timeliness of case investigation were inversely correlated among 49 health departments with complete data for these metrics (Spearman correlation coefficient = –0.68) (Figure 1). Health departments with smaller average caseloads per investigator completed a larger proportion of patient interviews within 24 hours of report. Among four health departments that interviewed >90% of patients within 24 hours, investigators' average caseloads were fewer than 30 patients each, whereas among four health departments with average caseloads >130 patients per investigator, <30% of interviews were completed within 24 hours.

When restricted to patients prioritized for interview (9,013), among 53 health departments that submitted complete data, 42 (79%) reported fewer than two contacts elicited per patient (median = 1.15). The number of contacts elicited per patient prioritized for interview was smaller in health departments with larger caseloads (Spearman correlation coefficient = –0.60) (Figure 2). These trends persisted in jurisdictions that allocated different staff members, mostly different staff members, or the same staff members to be case investigators and contact tracers (Spearman correlation coefficients = –0.89, –0.69, and –0.32, respectively).

Discussion

Health departments' capacity and ability to conduct timely and effective case investigation and contact tracing varied widely across the United States. The ideal workforce size to adequately conduct case investigation and contact tracing per jurisdiction[§§] likely depends on several factors (*4*); however, the inverse relationship between staff member workload and completeness and timeliness of case investigation and contact tracing suggest that increases in staffing capacity might help reduce delays in interviewing patients and identify more contacts. Most state health departments are hiring more staff members to perform contact tracing[¶¶] (*1*). Health departments might choose to prioritize case investigation and contact tracing based on whether persons are likely to be at higher risk for severe disease, live or work in congregate settings, or are part of a known cluster (*5*). Surges in cases might exceed the workforce capacity of jurisdictions to maintain high coverage of case investigation and contact tracing. Continued efforts to ensure notification of patients of their infection and contacts of their exposure are needed. CDC recommends use of prioritization measures to reach populations at risk as well as use of innovative technologies (*6*) to support this public health imperative.

Approximately one half of health departments were able to achieve a median interval of ≤24 hours from first notification of the patient to interview; likewise, approximately one half also were able to achieve a median interval of ≤24 hours from patient interview to contact notification, although these two groups did not always comprise the same health departments. These findings

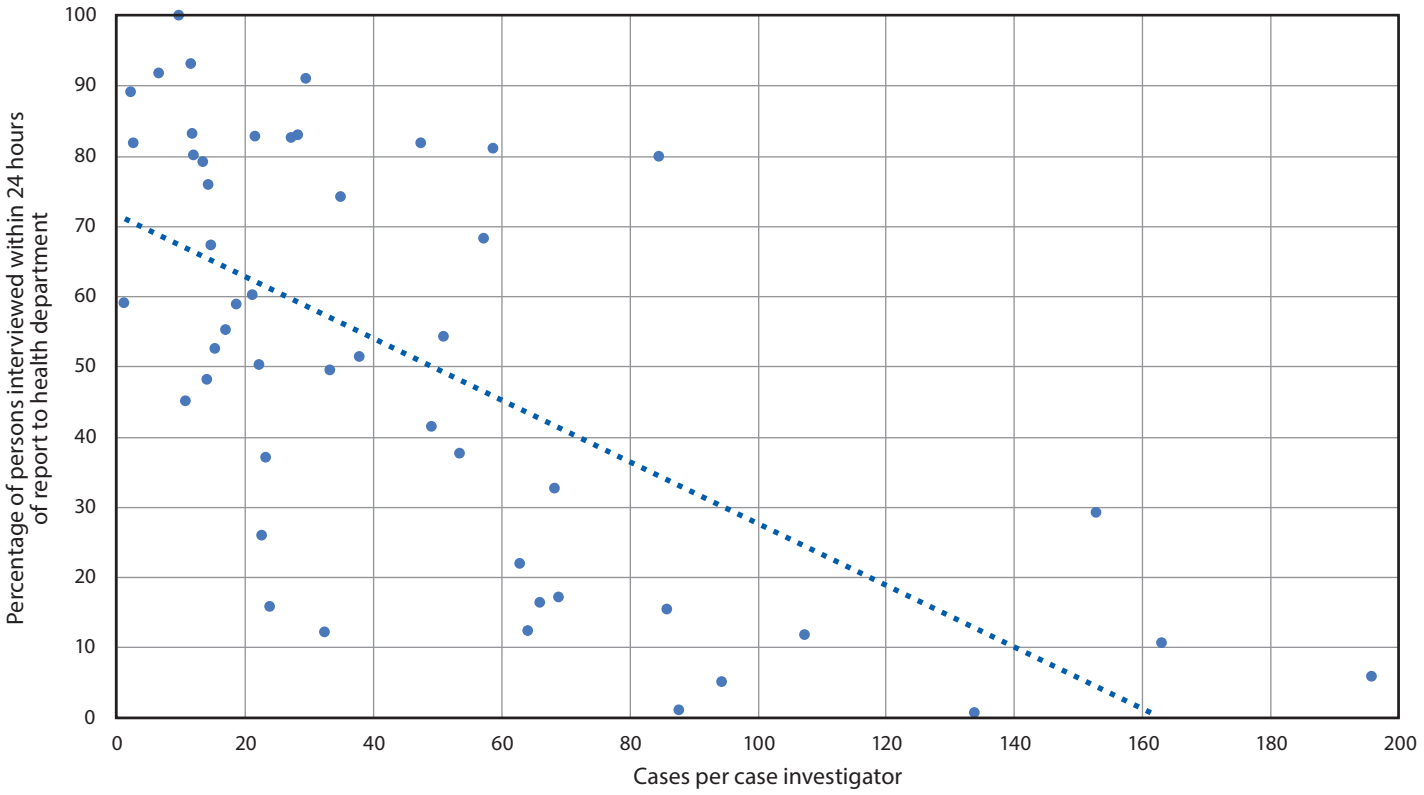
TABLE. COVID-19 case investigation and contact tracing metrics — 56 health departments, United States, June 25–July 24, 2020

Metric	Median* (IQR) [total range]	No. (%) of health departments
Case investigation		
Total cases assigned for interview during reporting period	8,306 (1,781–19,671) [22–280,033]	56 (100)
Average no. of cases assigned for interview per case investigator (caseload)	31 (15–68) [1–196]	54 (96)
Prioritized persons interviewed within 24 hrs	57 (27–82) [1–100]	54 (96)
Contact tracing		
Contacts elicited from cases during reporting period	7,498 (2,236–19,937) [124–95,775]	54 (96)
Average no. of contacts assigned for follow-up per contact tracer (contact tracing load)	29 (17–44) [0.5–200]	53 (95)
Contacts notified within 24 hrs of identification by a patient	55 (32–79) [4–100]	48 (86)

Abbreviations: COVID-19 = coronavirus disease 2019; IQR = interquartile range.
* Median caseload and contact tracing loads represent the median of the average per investigator or contact tracer.

MS-DOH-21-1816-A-002103

FIGURE 1. Association between COVID-19 caseload per health department investigator and timeliness of case interviews — 49 health departments, United States, June 25–July 24, 2020*



Abbreviation: COVID-19 = coronavirus disease 2019.
* The trendline represents the inverse correlation between the average caseload per case investigator and the timeliness of case investigations among 49 health departments.

are comparable with those in recent reports that described median intervals of 1 day from patient report to interview and 1 and 3 days from case investigation to contact notification in two U.S. counties (*1*,*7*). The evaluation period in this report, June 25–July 24, 2020, corresponded to a time of increased COVID-19 incidence (*8*); the capacity of health departments in jurisdictions with large numbers of cases to conduct timely patient follow-up and contact notification could be overwhelmed.

The median number of contacts elicited per patient prioritized for interview was 1.15. The number of contacts elicited per patient would have been higher if limited to the number of patients who completed an interview rather than those who were prioritized for an interview; however, the number of patients who completed an interview was not collected at this time, and the calculation was not possible. A recent assessment of two North Carolina counties reported an average of 3.0 and 4.6 contacts named per interviewed patient during a similar time frame (*1*). A contact tracing team in central Pennsylvania identified 953 contacts elicited among 536 confirmed patients (1.8 contacts per patient) during March 24–May 28; the lower number of contacts per patient might be related to the widespread stay-at-home orders that were in effect during that time (*9*).

One contributor to low numbers of contacts elicited might be related to reluctance to engage in contact tracing efforts*** or to name persons other than household contacts (*1*). The number of contacts elicited might vary by caseload, owing to worker fatigue or inexperience; with higher caseloads, contact tracers might be less likely to persist with questioning to identify additional contacts.

The findings in this report are subject to at least four limitations. First, these data are self-reported by health departments and were likely generated from new data systems designed to monitor case investigation and contact tracing. New systems could be prone to errors and might not reflect complete performance within the jurisdiction. Second, data validity might be affected by health departments' varying interpretations of definitions of metrics. These data include that obtained during health departments' first reporting period on these metrics, which will continue to be refined. Third, these data precluded calculation of the average number of contacts elicited per patient who completed an interview, and therefore do not align with other

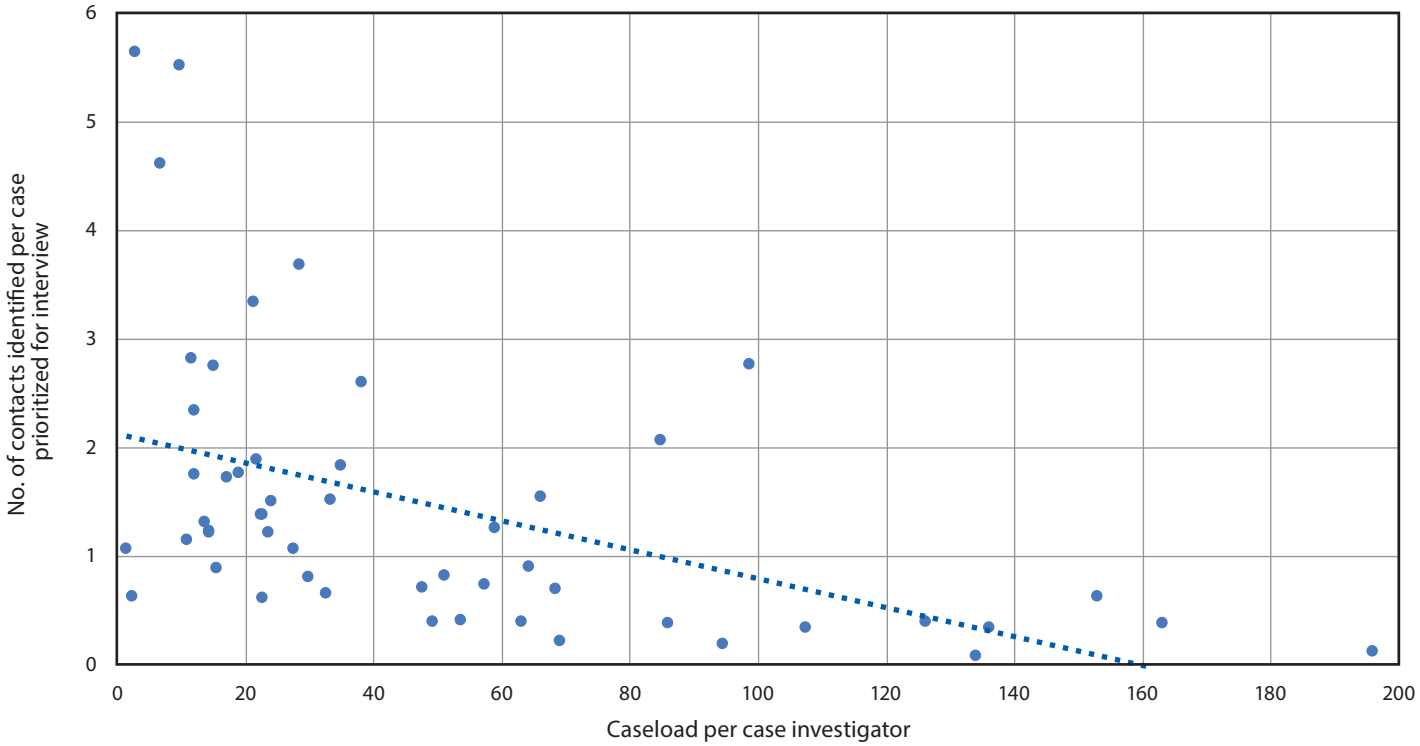
FIGURE 2. Association between the COVID-19 caseload per health department investigator and number of close contacts identified per case prioritized for interview — 52 health departments, United States, June 25–July 24, 2020*



Abbreviation: COVID-19 = coronavirus disease 2019.
* The trendline represents the inverse correlation between the average caseload per case investigator and the number of contacts elicited per patient prioritized for interview among 52 health departments.

studies' methods of calculating contacts elicited (*1*); the actual number is likely higher, warranting cautious interpretation. Finally, an important component of contact tracing is laboratory test timeliness, which is not included in these data. During the COVID-19 pandemic, delays from the time of laboratory specimen collection to report to the health department can have substantial impact on total time to reach a contact (*2*,*9*); the absence of these data in an assessment of contact tracing timeliness is an especially important limitation of this report.

Delays in interviewing COVID-19 patients decrease the likelihood of quickly identifying and quarantining contacts. Low ascertainment of contacts affects the nation's potential to interrupt the transmission of SARS-CoV-2 through rapid notification, quarantining, and testing. Caseloads within jurisdictions influence how quickly health departments can reach patients, which might influence the completeness of data used to reach contacts. Increasing staffing capacity might improve the timeliness of case interviews. Strengthening awareness regarding state and local health department contact tracing efforts might improve community perception or willingness to provide more complete lists of contacts.

Summary

What is already known about this topic?

Resources have been allocated to supplement the U.S. case investigation and contact tracing workforce as a public health tool to interrupt the spread of COVID-19.

What is added by this report?

Analysis of case investigation and contact tracing metric data reported by 56 U.S. health departments found wide variation in capacity and ability to conduct timely and effective contact tracing. Investigator caseload was inversely related to timely interviewing of patients and number of contacts identified per case.

What are the implications for public health practice?

Enhanced staffing capacity and ability and improved community engagement could lead to more timely contact tracing interviews and identification of more contacts.

Acknowledgments

COVID-19 Trends Among Persons Aged 0–24 Years — United States, March 1–December 12, 2020

Eva Leidman, MSPH[1]; Lindsey M. Duca, PhD[1]; John D. Omura, MD[1]; Krista Proia, MPH[1]; James W. Stephens, PhD[1]; Erin K. Sauber-Schatz, PhD[1]

On January 13, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

Coronavirus disease 2019 (COVID-19) case and electronic laboratory data reported to CDC were analyzed to describe demographic characteristics, underlying health conditions, and clinical outcomes, as well as trends in laboratory-confirmed COVID-19 incidence and testing volume among U.S. children, adolescents, and young adults (persons aged 0–24 years). This analysis provides a critical update and expansion of previously published data, to include trends after fall school reopenings, and adds preschool-aged children (0–4 years) and college-aged young adults (18–24 years) (*1*). Among children, adolescents, and young adults, weekly incidence (cases per 100,000 persons) increased with age and was highest during the final week of the review period (the week of December 6) among all age groups. Time trends in weekly reported incidence for children and adolescents aged 0–17 years tracked consistently with trends observed among adults since June, with both incidence and positive test results tending to increase since September after summer declines. Reported incidence and positive test results among children aged 0–10 years were consistently lower than those in older age groups. To reduce community transmission, which will support schools in operating more safely for in-person learning, communities and schools should fully implement and strictly adhere to recommended mitigation strategies, especially universal and proper masking, to reduce COVID-19 incidence.

Children, adolescents, and young adults were stratified into five age groups: 0–4, 5–10, 11–13, 14–17, and 18–24 years to align with educational groupings (i.e., pre-, elementary, middle, and high schools, and institutions of higher education), and trends in these groups were compared with those in adults aged ≥25 years. Confirmed COVID-19 cases, defined as positive real-time reverse transcription–polymerase chain reaction (RT-PCR) test results for SARS-CoV-2, the virus that causes COVID-19, were identified from individual-level case reports submitted by state and territorial health departments during March 1–December 12, 2020.* COVID-19 case data for all confirmed cases were analyzed to examine demographic characteristics, underlying health conditions,† and outcomes. Trends in COVID-19 incidence were analyzed using a daily 7-day moving average, aggregated by week,§ and expressed as cases per 100,000 persons.¶

Trends in laboratory testing volume and percentage of positive test results were assessed using COVID-19 electronic laboratory reporting data. SARS-CoV-2 RT-PCR test results for May 31–December 12, 2020 were obtained from electronic laboratory reporting data submitted to CDC by health departments from 44 states, the District of Columbia, two territories, and one freely associated state; when information was unavailable in state-submitted data, records submitted directly by public health, commercial, and reference laboratories were used.** Data represent test results, not number of persons receiving tests; test result date was used for analyses. The weekly percentage of positive SARS-CoV-2 RT-PCR test results was calculated as the number of positive test results divided by the sum of positive and negative test results. Because some data elements are incomplete for more than 47% of cases, percentages were calculated only from among those with available information. This project was deemed nonresearch public health practice by the CDC and conducted consistent with applicable federal law and CDC policy.†† Analyses were conducted using R software (version 4.0.2; The R Foundation).

* CDC official counts of COVID-19 cases and deaths, released daily at https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/cases-in-us.html, are aggregate counts from reporting jurisdictions. Individual-level case report data were available for approximately 75% of the aggregate number of confirmed cases. Cases reported without sex or age data and in persons repatriated to the United States from Wuhan, China, or the Diamond Princess cruise ship were excluded from this analysis.

† Underlying health conditions were defined based on the categories included in the COVID-19 Case Report Form. https://www.cdc.gov/coronavirus/2019-ncov/downloads/pui-form.pdf.

§ Weekly incidence date based on the earliest symptom onset date reported for each COVID-19 case. If symptom onset date was missing, earliest onset date was populated with the earliest date in a series of variables submitted by the jurisdiction, including symptom resolution date, positive specimen date, diagnosis date, specimen collection date (for sputum, nasopharyngeal, oropharyngeal, or other specimen type), hospital or ICU admission or discharge date, date of death, or the date of case reporting to CDC.

¶ Population estimates used in calculating incidence were obtained from the Kids Count Data Center. https://datacenter.kidscount.org/data.

** COVID-19 Electronic Laboratory Reporting data submitted by state health departments from all laboratories performing SARS-CoV-2 RT-PCR testing were used for 44 states, the District of Columbia, Guam, Marshall Islands, and Northern Mariana Islands. SARS-CoV-2 RT-PCR testing data from a subset of public health, commercial, and reference laboratories were used for six states for which data were not directly submitted by state health departments (Maine, Missouri, Ohio, Oklahoma, Washington, and Wyoming), Puerto Rico, and the U.S. Virgin Islands. The data might not include results from all testing sites within a jurisdiction and therefore might reflect the majority of, but not all, SARS-CoV-2 RT-PCR tests in the United States. The data represent laboratory test totals, not individual persons tested, and exclude antibody and antigen tests.

†† 45 C.F.R. part 46, 21 C.F.R. part 56; 42 U.S.C. Sect. 241(d); 5 U.S.C. Sect. 552a; 44 U.S.C. Sect. 3501 et seq.

MS-DOH-21-1816-A-002107

During March 1–December 12, 2020, a total of 2,871,828 laboratory-confirmed cases of COVID-19 in children, adolescents, and young adults aged 0–24 years were reported in the United States. Among these cases, the majority (57.4%) occurred among young adults aged 18–24 years; children and adolescents aged 14–17 years accounted for 16.3% of cases, those 11–13 years for 7.9%, those 5–10 years for 10.9%, and those 0–4 years for 7.4% (Table). Overall, 51.8% of cases occurred in females. Among the 1,504,165 (52.4%) children, adolescents, and young adults with COVID-19 with complete information on race/ethnicity, 50.2% were non-Hispanic White, 27.4% were Hispanic/Latino (Hispanic), and 11.7% were non-Hispanic Black. The proportion of cases among Hispanic persons decreased with increasing age from 34.4% among those aged 0–4 years to 24.6% among those aged 18–24 years.[§§]

Among persons aged 0–24 years, weekly incidence was higher in each successively increasing age group; weekly incidence among adults aged 25–64 years and ≥65 years exceeded that among children and adolescents aged 0–13 years throughout the review period (Figure 1). Weekly incidence was highest during the final week of the review period (the week of December 6) in all age groups: 99.9 per 100,000 (0–4 years), 131.4 (5–10 years), 180.6 (11–13 years), 255.6 (14–17 years), and 379.3 (18–24 years). Trends in weekly incidence for all age groups aged 0–17 years paralleled those observed among adults since June. The trend in incidence among young adults aged 18–24 years had a distinct and more prominent peak during the week of September 6.

Weekly SARS-CoV-2 laboratory testing among children, adolescents, and young adults increased 423.3% from 435,434 tests during the week beginning May 31 to 2,278,688 tests during the week beginning December 6 (Figure 2).[¶¶] At their peak during the week of November 15, tests conducted among children and adolescents aged 0–17 years represented 9.5% of all tests performed, and tests among young adults aged 18–24 years represented 15.3% (Supplementary Figure 1, URL https://stacks.cdc.gov/view/cdc/100246). As observed in trends in incidence, weekly percentage of positive test results among children and adolescents paralleled those of adults, declining between July and September, and then increasing through December (Supplementary Figure 2, URL https://stacks.cdc.gov/view/cdc/100246). Percentage of positive test results among young adults aged 18–24 years peaked earlier in June and increased slightly in late August; this was not observed among other age groups. In contrast to incidence, percentage of positive test results among children and adolescents aged 11–17 years exceeded that among younger children for all weeks and that of all age groups since the week beginning September 6; test volumes over time were lowest among children and adolescents aged 11–13 years, suggesting incidence among these age groups might be underestimated.

Among cases reviewed, data were available for 41.9%, 8.9%, and 49.1% of cases for hospitalizations, intensive care unit (ICU) admissions, and deaths, respectively. Among children, adolescents, and young adults with available data for these outcomes, 30,229 (2.5%) were hospitalized, 1,973 (0.8%) required ICU admission, and 654 (<0.1%) died (Table), compared with 16.6%, 8.6%, and 5.0% among adults aged ≥25 years, respectively. Among children, adolescents, and young adults, the largest percentage of hospitalizations (4.6%) and ICU admissions (1.8%) occurred among children aged 0–4 years. Among 379,247 (13.2%) children, adolescents, and young adults with COVID-19 and available data on underlying conditions, at least one underlying condition or underlying health condition was reported for 114,934 (30.3%), compared with 836,774 (60.4%) among adults aged ≥25 years.

Discussion

Reported weekly incidence of COVID-19 and percentage of positive test results among children, adolescents, and young adults increased during the review period, with spikes in early summer, followed by a decline and then steeply increased in October through December. In general, trends in incidence and percentage of positive test results among preschool-aged children (0–4 years) and school-aged children and adolescents (5–17 years) paralleled those among adults throughout the summer and fall, including during the months that some schools were reopening or open for in-person education. In addition, reported incidence among children, adolescents, and young adults increased with age; among children aged 0–10 years, incidence and percentage of positive test results were consistently lower than they were among older age groups. Case data do not indicate that increases in incidence or percentage of positive test results among adults were preceded by increases among preschool- and school-aged children and adolescents. In contrast, incidence among young adults (aged 18–24 years) was higher than that in other age groups throughout the summer and fall, with peaks in mid-July and early September that preceded increases among other age groups, suggesting that young adults might contribute more to community transmission than do younger children.

Findings from national case and laboratory surveillance data complement available evidence regarding risk for transmission in school settings. As of December 7, nearly two thirds

[§§] In 2019, children and adolescents of Hispanic/Latino ethnicity accounted for 26% of children aged 0–17 years; children and adolescents of non-Hispanic Black race accounted for 14% of children aged 0–17 years; and children and adolescents of non-Hispanic White race accounted for 50% of children and adolescents aged 0–17 years in the United States. https://datacenter.kidscount.org/data/customreports/1/103/compared,single#ind103.

[¶¶] The percentage increase in test volume between the weeks beginning May 31 and December 6 by age group were 328.0% (0–4 years), 644.1% (5–10 years), 669.2% (11–13 years), 536.3% (14–17 years), and 368.1% (18–24 years).

(62.0%) of U.S. kindergarten through grade 12 (K–12) school districts offered either full or partial (hybrid with virtual) in-person learning.*** Despite this level of in-person learning, reports to CDC of outbreaks within K–12 schools have been limited,††† and as of the week beginning December 6, aggregate COVID-19 incidence among the general population in counties where K–12 schools offer in-person education (401.2 per 100,000) was similar to that in counties offering only virtual/online education (418.2 per 100,000).§§§ Several U.S. school districts with routine surveillance of in-school cases report lower incidence among students than in the

*** https://www.mchdata.com/covid19/schoolclosings.

††† In addition to routine case surveillance reports, CDC receives regular updates from state, local, and tribal health departments, as well as various school districts. School-based outbreaks have been periodically reported to CDC at the time jurisdictions request technical assistance. In the context of childcare and K–12 schools, requests for assistance have more frequently been in response to a single case or small clusters of cases. Reports of large outbreaks in these settings have been rare.

§§§ Data presented are for the week beginning December 6, 2020. Aggregate case incidence is the rate derived after summing the case and population values for counties that currently have that K–12 teaching plans. Among the 2,717 counties having school districts with currently known teaching plans, 1,696 had school districts with differing methods. For these counties, case incidence and positive test result data are proportionately allocated into a specific plan based on the ratio of total enrollment for school districts that currently have that plan type to the total enrollment for all school districts in that county. Population estimates were obtained from the Vintage 2019 Bridged-Race Postcensal Population Estimates for Calculating Vital Rates (https://www.cdc.gov/nchs/nvss/bridged_race/data_documentation.htm). County-level case counts were obtained from CDC County Aggregate figures (extracted December 28, 2020). School enrollment data and school reopening plans were obtained from MCH Strategic Data (https://www.mchdata.com/covid19/schoolclosings, extracted December 28, 2020). Data were extracted and analyzed by the Johns Hopkins University Applied Physics Laboratory.

Abbreviations: ICU = intensive care unit; N/A = not available.

* Data are missing for more than 47% of cases. Percentages are calculated from among those with available information only.

† Cases reported as Hispanic or Latino were categorized as "Hispanic/Latino" regardless of availability of race data.

§ Underlying conditions were defined based on the categories included in the COVID-19 Case Report Form including diabetes mellitus, hypertension, severe obesity, cardiovascular disease, chronic renal disease, chronic liver disease, chronic lung disease (asthma, emphysema, and chronic obstructive pulmonary disease [COPD]), other (specified) chronic diseases, other (specified) underlying condition or risk behavior, immunosuppressive conditions, autoimmune conditions, being a current or former smoker, substance abuse or misuse, disability, and psychological/psychiatric condition. Although obesity in children is defined using body mass index percentile, these data are drawn from the COVID-19 Case Report Form, in which severe obesity is defined as noted.

¶ Status of underlying health conditions were known for 421,078 persons aged 0–24 years. Condition status was classified as "known" if any of the conditions included in the COVID-19 Case Report Form were reported as present or absent. Proportion of cases with each individual condition were calculated among persons with known condition status.

** Disability included neurologic or neurodevelopmental disorders, intellectual or physical disability, and vision or hearing impairment.

†† Body mass index ≥40 kg/m2. Although obesity in children is defined using body mass index percentile, these data are drawn from the COVID-19 Case Report Form, in which severe obesity is defined as noted.

surrounding communities¶¶¶ (*2*), and a recent study found no increase in COVID-19 hospitalization rates associated with in-person education (*3*). In contrast to the evidence regarding K–12 school reopenings, previous studies provide evidence for increased community incidence in counties where institutions of higher education reopened for in-person instruction (*4*), and presented case surveillance data showed unique trends.

Success in preventing introduction and transmission of SARS-CoV-2 in schools depends upon both adherence to mitigation strategies in schools and controlling transmission in communities (*5*). In settings with low community incidence, where testing and effective mitigation strategies were in place, studies of in-school transmission have provided preliminary evidence of success in controlling secondary transmission in child care centers and schools (*6–8*). Schools provide a structured environment that can support adherence to critical mitigation measures to help prevent and slow the spread of COVID-19. When community transmission is high, cases in schools should be expected, and as with any group setting, schools can contribute to COVID-19 transmission (*5–7*), especially when mitigation measures, such as universal and proper masking, are not implemented or followed.

The findings in this report are subject to at least four limitations. First, COVID-19 incidence is likely underestimated among children and adolescents because testing volume among these age groups was lower than that for adults, the rate of

Summary

What is already known about this topic?

Studies have consistently shown that children, adolescents, and young adults are susceptible to SARS-CoV-2 infections. Children and adolescents have had lower incidence and fewer severe COVID-19 outcomes than adults.

What is added by this report?

COVID-19 cases in children, adolescents, and young adults have increased since summer 2020, with weekly incidence higher in each successively increasing age group. Trends among children and adolescents aged 0–17 years paralleled those among adults.

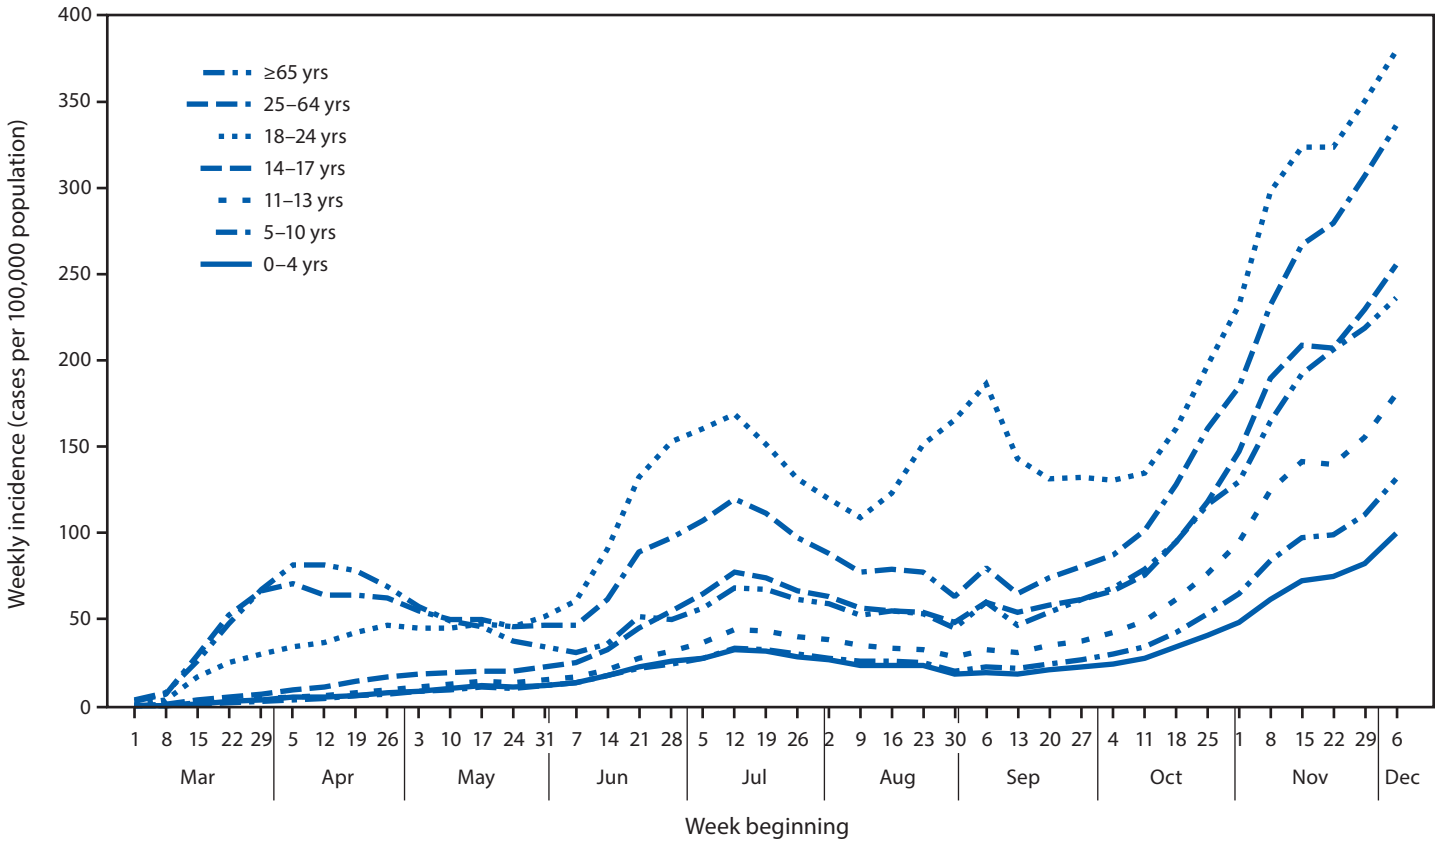
What are the implications for public health practice?

To enable safer in-person learning, schools and communities should fully implement and strictly adhere to multiple mitigation strategies, especially universal and proper mask wearing, to reduce both school and community COVID-19 incidence to help protect students, teachers, and staff members from COVID-19.

¶¶¶ Cases and enrollment reported by the New York Department of Health (https://schoolcovidreportcard.health.ny.gov/#/summary) since October 12, 2020, are analyzed on the National COVID-19 School Response Dashboard (https://covidschooldashboard.com) which presents case and infection rates.

MS-DOH-21-1816-A-002110

FIGURE 1. COVID-19 weekly incidence,*,† by age group — United States, March 1–December 12, 2020§



Abbreviation: COVID-19 = coronavirus disease 2019.
* The 7-day moving average of new cases (current day + 6 preceding days/7) was calculated to smooth expected variation in daily case counts.
† Incidence was calculated per 100,000 population using 2019 U.S. Census population estimates obtained from Kids Count Data Center (https://datacenter.kidscount.org/data).
§ Data included through December 12, 2020, so that each week has a full 7 days of data.

positive test results was generally higher among children and adolescents (particularly those aged 11–17 years) than that among adults, and testing frequently prioritized persons with symptoms; asymptomatic infection in children and adolescents occurs frequently (*9*). Second, data on race/ethnicity, symptom status, underlying conditions, and outcomes are incomplete, and completeness varied by jurisdiction; therefore, results for these variables might be subject to reporting biases and should be interpreted with caution. Future reporting would be enhanced by prioritizing completeness of these indicators for all case surveillance efforts. Third, the reporting of laboratory data differs by jurisdiction and might underrepresent the actual volume of laboratory tests performed; as well, reporting of laboratory and case data are not uniform.**** Finally, the presented analysis explores case surveillance data for children, adolescents, and young adults; trends in cases among teachers and school staff members are not available because cases are not routinely reported nationally by occupations other than health care workers.

Lower incidence among younger children and evidence from available studies (*2*–*8*) suggest that the risk for COVID-19 introduction and transmission among children associated with reopening child care centers and elementary schools might be lower than that for reopening high schools and institutions of higher education. However, for schools to operate safely to accommodate in-person learning, communities should fully implement and strictly adhere to multiple mitigation strategies, especially universal and proper masking, to reduce COVID-19 incidence within the community as well as within schools to protect students, teachers, and staff members. CDC recommends that K–12 schools be the last settings to close after all other mitigation measures have been employed and the first to reopen when they can do so safely (*10*). CDC offers tools†††† to help child care programs, schools, colleges and universities, parents, and caregivers plan, prepare, and respond to

**** Percentage positive for laboratory data for some states relied on data reported directly to CDC from public health laboratories and a sample of six large commercial laboratories.

Emergence of SARS-CoV-2 B.1.1.7 Lineage — United States, December 29, 2020–January 12, 2021

Summer E. Galloway, PhD[1]; Prabasaj Paul, PhD[1]; Duncan R. MacCannell, PhD[2]; Michael A. Johansson, PhD[1]; John T. Brooks, MD[1]; Adam MacNeil, PhD[1]; Rachel B. Slayton, PhD[1]; Suxiang Tong, PhD[1]; Benjamin J. Silk, PhD[1]; Gregory L. Armstrong, MD[2]; Matthew Biggerstaff, ScD[1]; Vivien G. Dugan, PhD[1]

On January 15, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

On December 14, 2020, the United Kingdom reported a SARS-CoV-2 variant of concern (VOC), lineage B.1.1.7, also referred to as VOC 202012/01 or 20I/501Y.V1.* The B.1.1.7 variant is estimated to have emerged in September 2020 and has quickly become the dominant circulating SARS-CoV-2 variant in England (*1*). B.1.1.7 has been detected in over 30 countries, including the United States. As of January 13, 2021, approximately 76 cases of B.1.1.7 have been detected in 12 U.S. states.† Multiple lines of evidence indicate that B.1.1.7 is more efficiently transmitted than are other SARS-CoV-2 variants (*1*–*3*). The modeled trajectory of this variant in the U.S. exhibits rapid growth in early 2021, becoming the predominant variant in March. Increased SARS-CoV-2 transmission might threaten strained health care resources, require extended and more rigorous implementation of public health strategies (*4*), and increase the percentage of population immunity required for pandemic control. Taking measures to reduce transmission now can lessen the potential impact of B.1.1.7 and allow critical time to increase vaccination coverage. Collectively, enhanced genomic surveillance combined with continued compliance with effective public health measures, including vaccination, physical distancing, use of masks, hand hygiene, and isolation and quarantine, will be essential to limiting the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19). Strategic testing of persons without symptoms but at higher risk of infection, such as those exposed to SARS-CoV-2 or who have frequent unavoidable contact with the public, provides another opportunity to limit ongoing spread.

Global genomic surveillance and rapid open-source sharing of viral genome sequences have facilitated near real-time detection, comparison, and tracking of evolving SARS-CoV-2 variants that can inform public health efforts to control the pandemic. Whereas some mutations in the viral genome emerge and then recede, others might confer a selective advantage to the variant, including enhanced transmissibility, so that such a variant can rapidly dominate other circulating variants. Early in the pandemic, variants of SARS-CoV-2 containing the D614G mutation in the spike (S) protein that increases receptor binding avidity rapidly became dominant in many geographic regions (*5*,*6*).

In late fall 2020, multiple countries reported detecting SARS-CoV-2 variants that spread more efficiently. In addition to the B.1.1.7 variant, notable variants include the B.1.351 lineage first detected in South Africa and the recently identified B.1.1.28 subclade (renamed "P.1") detected in four travelers from Brazil during routine screening at the Haneda (Tokyo) airport.§ These variants carry a constellation of genetic mutations, including in the S protein receptor-binding domain, which is essential for binding to the host cell angiotensin-converting enzyme-2 (ACE-2) receptor to facilitate virus entry. Evidence suggests that other mutations found in these variants might confer not only increased transmissibility but might also affect the performance of some diagnostic real-time reverse transcription–polymerase chain reaction (RT-PCR) assays¶ and reduce susceptibility to neutralizing antibodies (*2*,*3*,*5*–*10*). A recent case report documented the first case of SARS-CoV-2 reinfection in Brazil with a SARS-CoV-2 variant that contained the E484K mutation,** which has been shown to reduce neutralization by convalescent sera and monoclonal antibodies (*9*,*10*).

This report focuses on the emergence of the B.1.1.7 variant in the United States. As of January 12, 2021, neither the B.1.351 nor the P.1 variants have been detected in the United States. For information about emerging SARS-CoV-2 variants of concern, CDC maintains a webpage dedicated to providing information on emerging SARS-CoV-2 variants.††

B.1.1.7 lineage (20I/501Y.V1)

The B.1.1.7 variant carries a mutation in the S protein (N501Y) that affects the conformation of receptor-binding domain. This variant has 13 other B.1.1.7 lineage-defining

MS-DOH-21-1816-A-002114

Summary

What is already known about this topic?

A more highly transmissible variant of SARS-CoV-2, B.1.1.7, has been detected in 12 U.S. states.

What is added by this report?

Modeling data indicate that B.1.1.7 has the potential to increase the U.S. pandemic trajectory in the coming months. CDC's system for genomic surveillance and the effort to expand sequencing will increase the availability of timely U.S. genomic surveillance data.

What are the implications for public health practice?

The increased transmissibility of the B.1.1.7 variant warrants universal and increased compliance with mitigation strategies, including distancing and masking. Higher vaccination coverage might need to be achieved to protect the public. Genomic sequence analysis through the National SARS-CoV-2 Strain Surveillance program will enable a targeted approach to identifying variants of concern in the United States.

mutations (Table), several of which are in the S protein, including a deletion at positions 69 and 70 (del69–70) that evolved spontaneously in other SARS-CoV-2 variants and is hypothesized to increase transmissibility (*2*,*7*). The deletion at positions 69 and 70 causes S-gene target failure (SGTF) in at least one RT-PCR–based diagnostic assay (i.e., with the ThermoFisher TaqPath COVID-19 assay, the B.1.1.7 variant and other variants with the del69–70 produce a negative result for S-gene target and a positive result for the other two targets); SGTF has served as a proxy in the United Kingdom for identifying B.1.1.7 cases (*1*).

Multiple lines of evidence indicate that B.1.1.7 is more efficiently transmitted compared with other SARS-CoV-2 variants circulating in the United Kingdom. U.K. regions with a higher proportion of B.1.1.7 sequences had faster epidemic growth than did other areas, diagnoses with SGTF increased faster than did non-SGTF diagnoses in the same areas, and a higher proportion of contacts were infected by index patients with B.1.1.7 infections than by index patients infected with other variants (*1*,*3*).

Variant B.1.1.7 has the potential to increase the U.S. pandemic trajectory in the coming months. To illustrate this effect, a simple, two-variant compartmental model was developed. The current U.S. prevalence of B.1.1.7 among all circulating viruses is unknown but is thought to be <0.5% based on the limited number of cases detected and SGTF data (*8*). For the model, initial assumptions included a B.1.1.7 prevalence of 0.5% among all infections, SARS-CoV-2 immunity from previous infection of 10%–30%, a time-varying reproductive number (R_t) of 1.1 (mitigated but increasing transmission) or 0.9 (decreasing transmission) for current variants, and a reported incidence of 60 cases per 100,000 persons per day on January 1, 2021. These assumptions do not precisely represent any single U.S. location, but rather, indicate a generalization of conditions common across the country. The change in R_t over time resulting from acquired immunity and increasing prevalence of B.1.1.7, was modeled, with the B.1.1.7 R_t assumed to be a constant 1.5 times the R_t of current variants, based on initial estimates from the United Kingdom (*1*,*3*).

Next, the potential impact of vaccination was modeled assuming that 1 million vaccine doses were administered per day beginning January 1, 2021, and that 95% immunity was achieved 14 days after receipt of 2 doses. Specifically, immunity against infection with either current variants or the B.1.1.7 variant was assumed, although the effectiveness and duration of protection against infection remains uncertain, because these were not the primary endpoint of clinical trials for initial vaccines.

In this model, B.1.1.7 prevalence is initially low, yet because it is more transmissible than are current variants, it exhibits rapid growth in early 2021, becoming the predominant variant in March (Figure 1). Whether transmission of current variants is increasing (initial R_t = 1.1) or slowly decreasing (initial R_t = 0.9) in January, B.1.1.7 drives a substantial change in the transmission trajectory and a new phase of exponential growth. With vaccination that protects against infection, the early epidemic trajectories do not change and B.1.1.7 spread still occurs (Figure 2). However, after B.1.1.7 becomes the dominant variant, its transmission was substantially reduced. The effect of vaccination on reducing transmission in the near term was greatest in the scenario in which transmission was already decreasing (initial R_t = 0.9) (Figure 2). Early efforts that can limit the spread of the B.1.1.7 variant, such as universal and increased compliance with public health mitigation strategies, will allow more time for ongoing vaccination to achieve higher population-level immunity.

Discussion

Currently, there is no known difference in clinical outcomes associated with the described SARS-CoV-2 variants; however, a higher rate of transmission will lead to more cases, increasing the number of persons overall who need clinical care, exacerbating the burden on an already strained health care system, and resulting in more deaths. Continued genomic surveillance to identify B.1.1.7 cases, as well as the emergence of other variants of concern in the United States, is important for the COVID-19 public health response. Whereas the SGTF results can help identify potential B.1.1.7 cases that can be confirmed by sequencing, identifying priority variants that do not exhibit SGTF relies exclusively on sequence-based surveillance.

Abbreviations: del = deletion; E = envelope protein; N = nucleocapsid protein; ORF = open reading frame; S = spike protein.

The experience in the United Kingdom and the B.1.1.7 models presented in this report illustrate the impact a more contagious variant can have on the number of cases in a population. The increased transmissibility of this variant requires an even more rigorous combined implementation of vaccination and mitigation measures (e.g., distancing, masking, and hand hygiene) to control the spread of SARS-CoV-2. These measures will be more effective if they are instituted sooner rather than later to slow the initial spread of the B.1.1.7 variant. Efforts to prepare the health care system for further surges in cases are warranted. Increased transmissibility also means that higher than anticipated vaccination coverage must be attained to achieve the same level of disease control to protect the public compared with less transmissible variants.

In collaboration with academic, industry, state, territorial, tribal, and local partners, CDC and other federal agencies are coordinating and enhancing genomic surveillance and virus characterization efforts across the United States. CDC coordinates U.S. sequencing efforts through the SARS-CoV-2 Sequencing for Public Health Emergency Response, Epidemiology, and Surveillance (SPHERES)[§§] consortium, which includes approximately 170 participating institutions and promotes open data-sharing to facilitate the use of SARS-CoV-2 sequence data. To track SARS-CoV-2 viral evolution, CDC is implementing multifaceted genomic surveillance to understand the epidemiologic, immunologic, and evolutionary processes that shape viral phylogenies (phylodynamics); guide outbreak investigations; and facilitate the detection and characterization of possible reinfections, vaccine breakthrough cases, and emerging viral variants. In November 2020, CDC established the National SARS-CoV-2 Strain Surveillance (NS3) program to improve the representativeness of domestic SARS-CoV-2 sequences. The program collaborates with 64 U.S. public health laboratories to support a genomic surveillance system; NS3 is also building a collection of SARS-CoV-2 specimens and sequences to support public health response and scientific research to evaluate the impact of concerning mutations on existing recommended medical countermeasures. CDC has also contracted with several large commercial clinical laboratories to rapidly sequence tens of thousands of SARS-CoV-2–positive specimens each month and has funded seven academic institutions to conduct genomic surveillance in partnership with public health agencies, thereby adding substantially to the availability of timely genomic surveillance data from across the United States. In addition to these national initiatives, many state and local public health agencies are sequencing

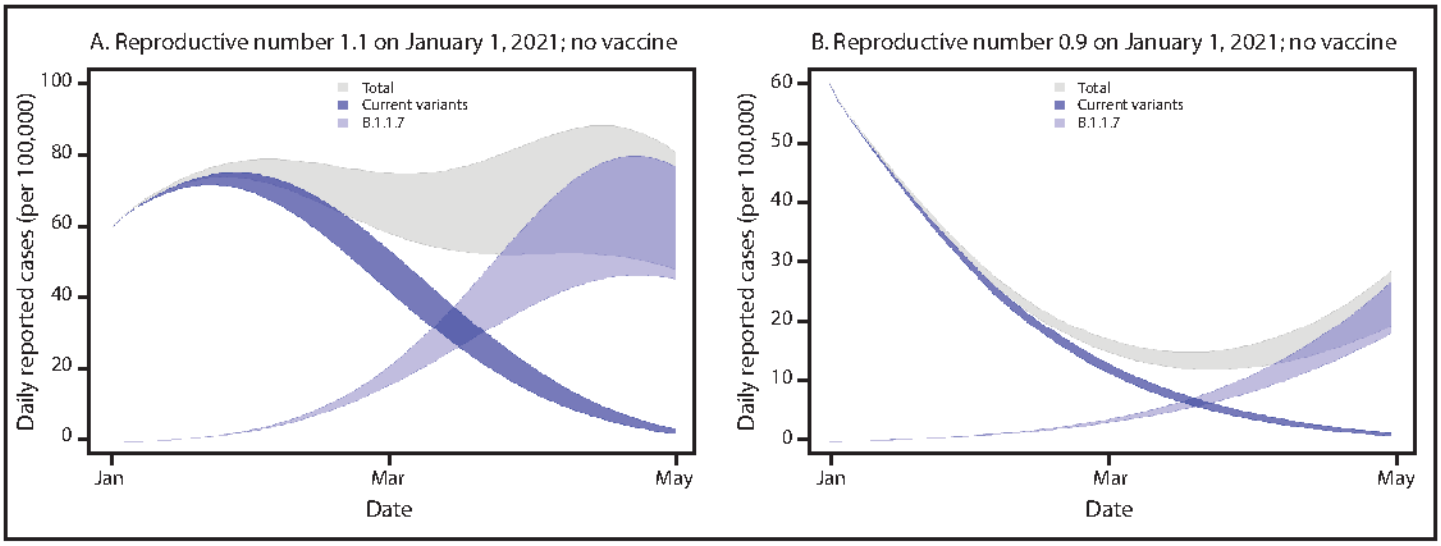
FIGURE 1. Simulated case incidence trajectories* of current SARS-CoV-2 variants and the B.1.1.7 variant,† assuming no community vaccination and either initial R_t = 1.1 (A) or initial R_t = 0.9 (B) for current variants — United States, January–April 2021

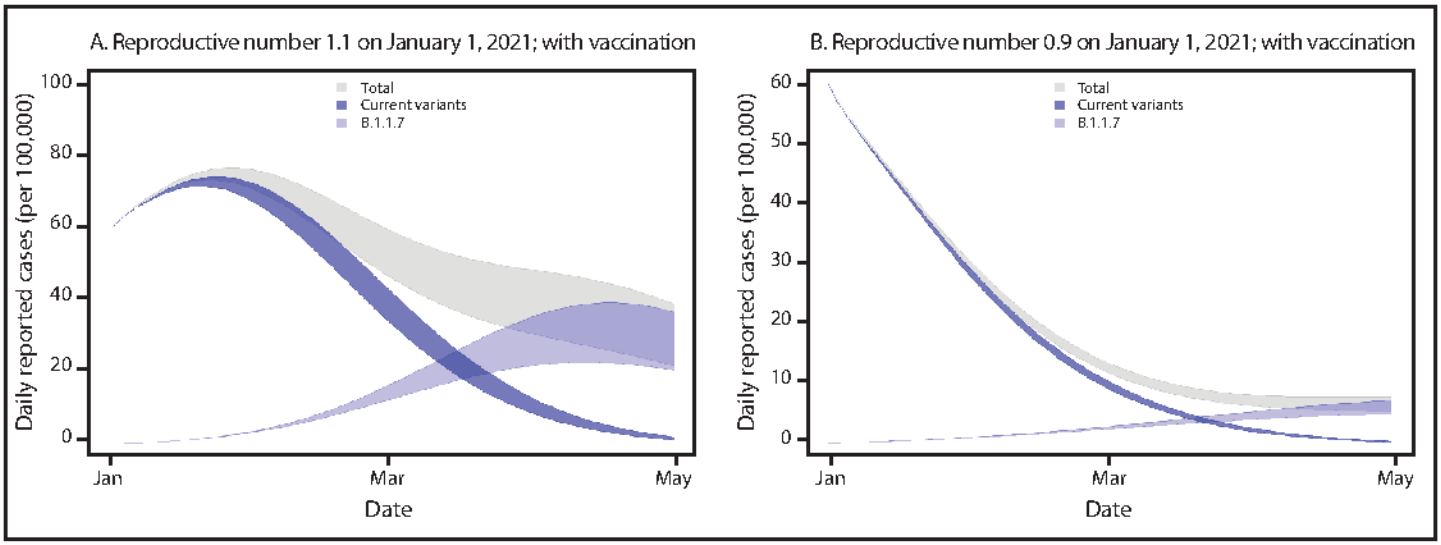


Abbreviation: R_t = time-varying reproductive number.

* For all simulations, it was assumed that the reporting rate was 25% and that persons who were seropositive or infected within the simulation became immune. The simulation was initialized with 60 reported cases of SARS-CoV-2 infection per 100,000 persons (approximately 200,000 cases per day in the U.S. population) on January 1, 2021. Bands represent simulations with 10%–30% population-level immunity as of January 1, 2021.

† Initial B.1.1.7 prevalence is assumed to be 0.5% among all infections and B.1.1.7 is assumed to be 50% more transmissible than current variants.

FIGURE 2. Simulated case incidence trajectories* of current SARS-CoV-2 variants and the B.1.1.7 variant,† assuming community vaccination§ and initial R_t = 1.1 (A) or initial R_t = 0.9 (B) for current variants — United States, January–April 2021



Abbreviation: R_t = time-varying reproductive number.

* For all simulations, it was assumed that the reporting rate was 25% and that persons who were seropositive or infected within the simulation became immune. The simulation was initialized with 60 reported cases of SARS-CoV-2 infection per 100,000 persons (approximately 200,000 cases per day in the U.S. population) on January 1, 2021. Bands represent simulations with 10%–30% population-level immunity as of January 1, 2021.

† Initial B.1.1.7 prevalence is assumed to be 0.5% among all infections and B.1.1.7 is assumed to be 50% more transmissible than current variants.

§ For vaccination, it was assumed that 300 doses were administered per 100,000 persons per day (approximately 1 million doses per day in the U.S. population) beginning January 1, 2021, that 2 doses achieved 95% immunity against infection, and that there was a 14-day delay between vaccination and protection.

MS-DOH-21-1816-A-002117

SARS-CoV-2 to better understand local epidemiology and support public health response to the pandemic.

The findings in this report are subject to at least three limitations. First, the magnitude of the increase in transmissibility in the United States compared with that observed in the United Kingdom remains unclear. Second, the prevalence of B.1.1.7 in the United States is also unknown at this time, but detection of variants and estimation of prevalence will improve with enhanced U.S. surveillance efforts. Finally, local mitigation measures are also highly variable, leading to variation in R_t. The specific outcomes presented here are based on simulations and assumed no change in mitigations beyond January 1.

The increased transmissibility of the B.1.1.7 variant warrants rigorous implementation of public health strategies to reduce transmission and lessen the potential impact of B.1.1.7, buying critical time to increase vaccination coverage. CDC's modeling data show that universal use of and increased compliance with mitigation measures and vaccination are crucial to reduce the number of new cases and deaths substantially in the coming months. Further, strategic testing of persons without symptoms of COVID-19, but who are at increased risk for infection with SARS-CoV-2, provides another opportunity to limit ongoing spread. Collectively, enhanced genomic surveillance combined with increased compliance with public health mitigation strategies, including vaccination, physical distancing, use of masks, hand hygiene, and isolation and quarantine, will be essential to limiting the spread of SARS-CoV-2 and protecting public health.

On January 19, 2021, this report was posted as an MMWR *Early Release on the* MMWR *website (https://www.cdc.gov/mmwr).*

Rapid antigen tests, such as the Abbott BinaxNOW COVID-19 Ag Card (BinaxNOW), offer results more rapidly (approximately 15–30 minutes) and at a lower cost than do highly sensitive nucleic acid amplification tests (NAATs) (*1*). Rapid antigen tests have received Food and Drug Administration (FDA) Emergency Use Authorization (EUA) for use in symptomatic persons (*2*), but data are lacking on test performance in asymptomatic persons to inform expanded screening testing to rapidly identify and isolate infected persons (*3*). To evaluate the performance of the BinaxNOW rapid antigen test, it was used along with real-time reverse transcription–polymerase chain reaction (RT-PCR) testing to analyze 3,419 paired specimens collected from persons aged ≥10 years at two community testing sites in Pima County, Arizona, during November 3–17, 2020. Viral culture was performed on 274 of 303 residual real-time RT-PCR specimens with positive results by either test (29 were not available for culture). Compared with real-time RT-PCR testing, the BinaxNOW antigen test had a sensitivity of 64.2% for specimens from symptomatic persons and 35.8% for specimens from asymptomatic persons, with near 100% specificity in specimens from both groups. Virus was cultured from 96 of 274 (35.0%) specimens, including 85 (57.8%) of 147 with concordant antigen and real-time RT-PCR positive results, 11 (8.9%) of 124 with false-negative antigen test results, and none of three with false-positive antigen test results. Among specimens positive for viral culture, sensitivity was 92.6% for symptomatic and 78.6% for asymptomatic individuals. When the pretest probability for receiving positive test results for SARS-CoV-2 is elevated (e.g., in symptomatic persons or in persons with a known COVID-19 exposure), a negative antigen test result should be confirmed by NAAT (*1*). Despite a lower sensitivity to detect infection, rapid antigen tests can be an important tool for screening because of their quick turnaround time, lower costs and resource needs, high specificity, and high positive predictive value (PPV) in settings of high pretest probability. The faster turnaround time of the antigen test can help limit transmission by more rapidly identifying infectious persons for isolation, particularly when used as a component of serial testing strategies.

Paired upper respiratory swabs were collected at the same timepoint from persons aged ≥10 years receiving testing for SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), at two Pima County Health Department community testing sites during November 3–17 (site A) and November 8–16 (site B). The sites offered SARS-CoV-2 testing to anyone in the community who wanted testing. A questionnaire capturing demographic information and current and past–14-day symptoms was administered to all participants. At both sites, a health care professional first collected a bilateral anterior nasal swab, using a swab provided in the BinaxNOW kit, immediately followed by a bilateral nasopharyngeal (NP) swab for real-time RT-PCR testing. Anterior nasal swabs were immediately tested on-site using the BinaxNOW antigen test according to the manufacturer's instructions (*4*). NP swabs were stored in phosphate buffered saline at 39°F (4°C) and analyzed within 24–48 hours by real-time RT-PCR using either the CDC 2019-nCoV Real-Time RT-PCR Diagnostic Panel for detection of SARS-CoV-2 (*5*) (2,582 swabs) or the Fosun COVID-19 RT-PCR Detection Kit (*6*) (837 swabs). Viral culture[*,†] was attempted on 274 of 303 residual real-time RT-PCR specimens if either the real-time RT-PCR or BinaxNOW antigen test result was positive (the remaining 29 were not available for viral culture). Results from real-time RT-PCR and the BinaxNOW antigen test were compared to evaluate sensitivity, specificity, negative predictive value (NPV), and PPV. Statistical analyses were performed using SAS (version 9.4; SAS Institute). Cycle threshold (Ct) values from real-time RT-PCR were compared using a Mann-Whitney U Test; 95% confidence intervals (CIs)

[*] Specimens were used to perform a limiting-dilution inoculation of Vero CCL-81 cells, and cultures showing evidence of cytopathic effect were tested by real-time RT-PCR for the presence of SARS-CoV-2 RNA. Viral recovery was defined as any culture in which the first passage had an N1 Ct value at least two Ct values lower than the corresponding clinical specimen.

MS-DOH-21-1816-A-002119

were calculated using the exact binomial method. The investigation protocol was reviewed by CDC and determined to be nonresearch and was conducted consistent with applicable federal law and CDC policy.[§]

Paired upper respiratory swabs were collected from 3,419 persons, including 1,458 (42.6%) from site A and 1,961 (57.4%) from site B (Table 1). Participants ranged in age from 10 to 95 years (median = 41 years) with 236 (6.9%) aged 10–17 years, 1,885 (55.1%) aged 18–49 years, 743 (21.7%) aged 50–64 years, and 555 (16.2%) aged ≥65 years. Approximately one third (31.4%) of participants identified as Hispanic or Latino, and three quarters (75.1%) identified as White.

At the time of testing, 827 (24.2%) participants reported at least one COVID-19–compatible sign or symptom,[¶] and 2,592 (75.8%) were asymptomatic. Among symptomatic participants, 113 (13.7%) received a positive BinaxNOW antigen test result, and 176 (21.3%) received a positive real-time RT-PCR test result. Among asymptomatic participants, 48 (1.9%) received a positive BinaxNOW antigen test result, and 123 (4.7%) received a positive real-time RT-PCR test result.

Testing among symptomatic participants indicated the following for the BinaxNOW antigen test (with real-time RT-PCR as the standard): sensitivity, 64.2%; specificity, 100%; PPV, 100%; and NPV, 91.2% (Table 2); among asymptomatic persons, sensitivity was 35.8%; specificity, 99.8%; PPV, 91.7%; and NPV, 96.9%. For participants who were within 7 days of symptom onset, the BinaxNOW antigen test sensitivity was 71.1% (95% CI = 63.0%–78.4%), specificity was 100% (95% CI = 99.3%–100%), PPV was 100% (95% CI = 96.4%–100%), and NPV was 92.7% (95% CI = 90.2%–94.7%). Using real-time RT-PCR as the standard, four false-positive BinaxNOW antigen test results occurred, all among specimens from asymptomatic participants. Among 299 real-time RT-PCR positive results, 142 (47.5%) were false-negative BinaxNOW antigen test results (63 in specimens from symptomatic persons and 79 in specimens from asymptomatic persons).

Virus was recovered from 96 (35.0%) of 274 analyzed specimens that were positive by either test, including 85 (57.8%) of 147 with concordant positive results and 11 (8.9%) of 124 with false-negative BinaxNOW antigen test results. Virus was not recovered from any of the three available specimens with false-positive BinaxNOW antigen test results. Among the 224 specimens undergoing viral culture that were analyzed with the CDC 2019-nCoV Real-Time RT-PCR Diagnostic Panel for detection of SARS-CoV-2, median Ct values[**] were significantly higher for specimens with false-negative BinaxNOW antigen test results, indicating lower viral RNA levels than in those with concordant positive results (33.9 versus 22.0 in specimens from symptomatic persons [p<0.001] and 33.9 versus 22.5 in specimens from asymptomatic persons [p<0.001]) (Figure). Median Ct values for SARS-CoV-2 culture-positive specimens (22.1) were significantly lower than were those for culture-negative specimens (32.8) (p<0.001), indicating higher levels of viral RNA in culture-positive specimens. Among specimens with positive viral culture, the sensitivity of the BinaxNOW antigen test compared with real-time RT-PCR in specimens from symptomatic participants was 92.6% (95% CI = 83.7%–97.6%) and in those from asymptomatic participants was 78.6% (95% CI = 59.1%–91.7%).

Discussion

In this evaluation, using real-time RT-PCR as the standard, the sensitivity of the BinaxNOW antigen test was lower among specimens from asymptomatic persons (35.8%) than among specimens from symptomatic persons (64.2%). Specificity (99.8%–100%) was high in specimens from both asymptomatic and symptomatic groups. The prevalence of having SARS-CoV-2 real-time RT-PCR positive test results in this population was moderate (8.7% overall; 4.7% for asymptomatic participants); administering the test in a lower prevalence setting will likely result in a lower PPV.[††] Among 11 participants with antigen-negative, real-time RT-PCR–positive specimens with positive viral culture, five were symptomatic and six asymptomatic. Some antigen-negative, real-time RT-PCR–positive specimens possibly could represent noninfectious viral particles, but some might also represent infectious virus not detected by the antigen test. In a clinical context, real-time RT-PCR provides the most sensitive assay to detect infection. Viral culture, although more biologically relevant than real-time RT-PCR, is still an artificial system and is subject to limitations. Numerous biological (e.g., individual antibody status and specific sequence of the virus) and environmental (e.g., storage conditions and number of freeze-thaw cycles) variables can affect the sensitivity and

outcome of viral culture. Despite the limitations of interpreting culture-negative specimens, a positive viral culture is strong evidence for the presence of infectious virus. The performance of the BinaxNOW antigen test compared with real-time RT-PCR was better for those specimens with positive viral culture than for all specimens, with a sensitivity of 92.6% for specimens from symptomatic persons and 78.6% for those from asymptomatic persons. The results of the current evaluation differ from those of an evaluation of the BinaxNOW antigen test in a community screening setting in San Francisco (*7*), which found a BinaxNOW antigen test overall sensitivity of 89.0% among specimens from all 3,302 participants, regardless of the Ct value of the real-time RT-PCR–positive specimens.

The findings in this investigation are subject to at least five limitations. First, anterior nasal swabs were used for BinaxNOW antigen testing, but NP swabs were used for real-time RT-PCR testing, which might have contributed to increased detection for the real-time RT-PCR assay (*8*). Second, participants might have inadvertently reported common nonspecific symptoms as COVID-19–compatible symptoms. Third, this investigation evaluated the BinaxNOW antigen test, and results presented here cannot be generalized to other FDA-authorized SARS-CoV-2 antigen tests. Fourth, the BinaxNOW antigen test characteristics might be different depending on whether an individual had previously tested positive. Finally, many factors might limit the ability to culture virus from a specimen, and the inability to detect culturable virus should not be interpreted to mean that a person is not infectious.

Public health departments are implementing various strategies to reduce or prevent SARS-CoV-2 transmission, including expanded screening testing for asymptomatic persons (*3*). Because estimates suggest that over 50% of transmission occurs from persons who are presymptomatic or asymptomatic (*9*), expanded screening testing, potentially in serial fashion for reducing transmission in specific venues (e.g., institutions of higher education, schools, and congregate housing settings), is essential to interrupting transmission (*3*).

Rapid antigen tests can be an important tool for screening because of their quick turnaround time, lower requirement for resources, high specificity, and high PPV in settings of high pretest probability (e.g., providing testing to symptomatic persons, to persons with a known COVID-19 exposure, or where community transmission is high). Importantly, the faster time from testing to results reporting can speed isolation of infectious persons and will be particularly important in communities with high levels of transmission.

Although the sensitivity of the BinaxNOW antigen test to detect infection was lower compared with real-time RT-PCR, it was relatively high among specimens with positive viral culture, which might reflect better performance for detecting infection in a person with infectious virus present. Community testing strategies focused on preventing transmission using antigen testing should consider serial testing (e.g., in kindergarten through grade 12 schools, institutions of higher education, or congregate housing settings), which might improve test sensitivity in decting infection (*10*). When the pretest probability for receiving positive SARS-CoV-2 test results is elevated (e.g. for symptomatic persons or for persons with a known COVID-19 exposure) a negative antigen test result should be confirmed by NAAT. Asymptomatic persons who receive a positive BinaxNOW antigen test result in a setting with a high risk for adverse consequences resulting from false-positive results (e.g. in long-term care facilities) should also receive confirmatory testing by NAAT (*1*).

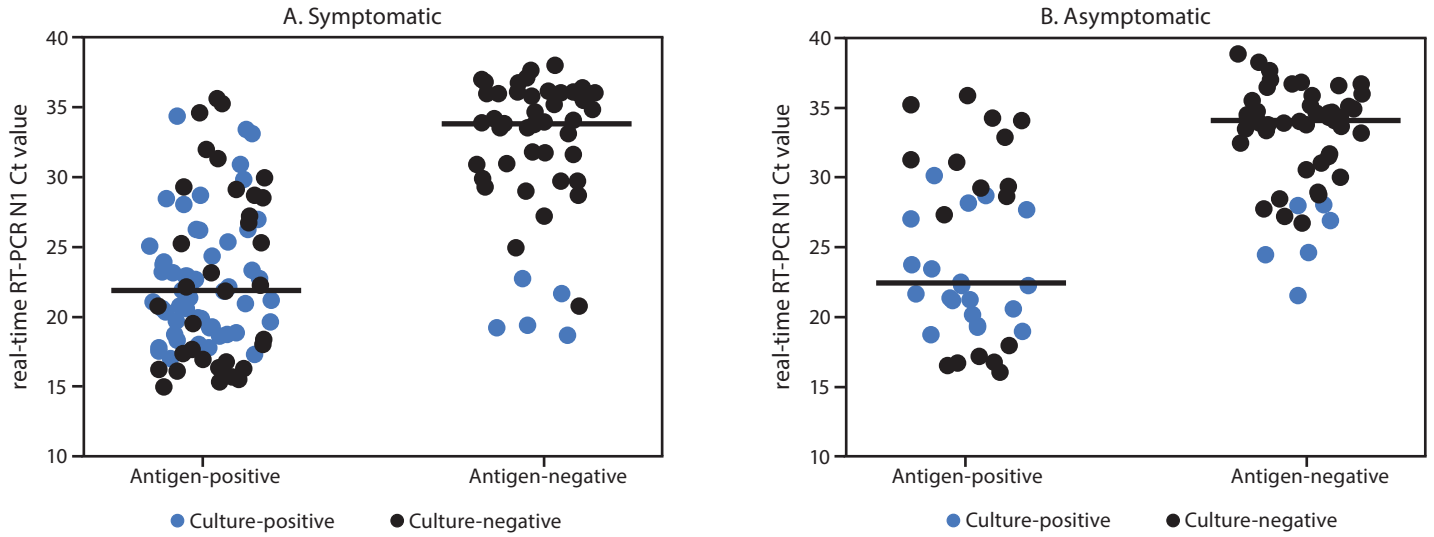
FIGURE. Abbott BinaxNOW COVID-19 Ag Card Point of Care Diagnostic Test (antigen test) results, N1 cycle threshold (Ct) values,* and viral culture results† among A) symptomatic (N = 136)§ and B) asymptomatic (N = 88)¶ participants receiving positive SARS-CoV-2 real-time reverse transcription–polymerase chain reaction (RT-PCR) test results at two community-based testing sites — Pima County, Arizona, November 2020



* Only those specimens that were analyzed using the CDC 2019-nCoV Real-Time RT-PCR Diagnostic Panel for detection of SARS-CoV-2 and that were analyzed using viral culture are included in the graph.

† Twenty specimens with Ct values <18 had positive antigen and real-time RT-PCR results but were culture negative. The culture showed evidence of cytopathic effects and had presence of SARS-CoV-2 RNA as detected by real-time RT-PCR in the first passage culture, but viral recovery was not two Ct values lower than the corresponding clinical specimen Ct.

§ Antigen test results: 88 positive and 48 negative; median Ct values indicated with black line: 22.0 for antigen-positive specimens and 33.9 for antigen-negative specimens.

¶ Antigen test results: 37 positive and 51 negative; median Ct values indicated with black line: 22.5 for antigen-positive specimens and 33.9 for antigen-negative specimens.

Summary

What is already known about this topic?

The BinaxNOW rapid antigen test received Emergency Use Authorization by the Food and Drug Administration for testing specimens from symptomatic persons; performance among asymptomatic persons is not well characterized.

What is added by this report?

Sensitivity of the BinaxNOW antigen test, compared with polymerase chain reaction testing, was lower when used to test specimens from asymptomatic (35.8%) than from symptomatic (64.2%) persons, but specificity was high. Sensitivity was higher for culture-positive specimens (92.6% and 78.6% for those from symptomatic and asymptomatic persons, respectively); however, some antigen test-negative specimens had culturable virus.

What are the implications for public health practice?

The high specificity and rapid BinaxNOW antigen test turnaround time facilitate earlier isolation of infectious persons. Antigen tests can be an important tool in an overall community testing strategy to reduce transmission.

Despite their reduced sensitivity to detect infection compared with real-time RT-PCR, antigen tests might be particularly useful when real-time RT-PCR tests are not readily available or have prolonged turnaround times. Persons who know their positive test result within 15–30 minutes can isolate sooner, and contact tracing can be initiated sooner and be more effective than if a test result is returned days later. Serial antigen testing can improve detection, but consideration should be given to the logistical and personnel resources needed. All persons receiving negative test results (NAAT or antigen) should be counseled that wearing a mask, avoiding close contact with persons outside their household, and washing hands frequently remain critical to preventing the spread of COVID-19.§§

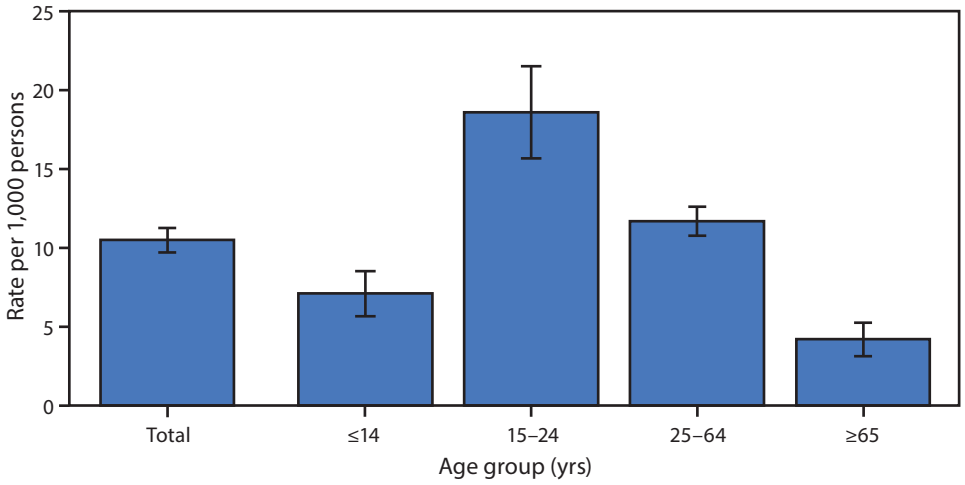
QuickStats

FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Emergency Department Visit Rates* for Motor Vehicle Crashes,† by Age Group — United States, 2018§



* Visit rates are based on the July 1, 2018, set of estimates of the U.S. civilian noninstitutionalized population as developed by the U.S. Census Bureau, Population Division. 95% confidence intervals indicated with error bars.

† Motor vehicle crashes defined as a visit with *International Classification of Diseases, Tenth Revision, Clinical Modification* codes: [V02–V04] (with fourth character = 1, 9), V09.2, V09.3, [V12–V14, V20–V28] (with fourth character = 3, 4, 5, 9), V19.4–V19.6, V19.9, V29.4–V29.9, [V30–V79] (with fourth character = 4, 5, 6, 7, 8, 9), [V83–V86] (with fourth character = 0, 1, 2, 3), V80.3–V80.5, V81.1, V82.1, V87.0–V87.8, V89.2, X81.0, X82, Y02.0, Y03, Y32. Injured persons included motor vehicle occupants, motorcyclists, pedal cyclists, and pedestrians.

§ Based on a sample of visits to emergency departments in noninstitutional general and short-stay hospitals, exclusive of federal, military, and Veterans Administration hospitals, located in the 50 U.S. states and the District of Columbia.

In 2018, the U.S. emergency department (ED) visit rate for motor vehicle crashes was 10.5 visits per 1,000 persons. The ED visit rate for motor vehicle crashes among persons aged 0–14 years was 7.1 ED visits per 1,000 persons. The visit rate for motor vehicle crashes was highest for persons aged 15–24 years (18.6) and declined with age to 11.7 for those aged 25–64 years and to 4.2 for those aged ≥65 years.

National Strategy for the COVID-19 Response and Pandemic Preparedness
January 21, 2021
Executive Summary

We can and will beat COVID-19. America deserves a response to the COVID-19 pandemic that is driven by science, data, and public health — not politics. Through the release of the National Strategy for the COVID-19 Response and Pandemic Preparedness, the United States is initiating a coordinated pandemic response that not only improves the effectiveness of our fight against COVID-19, but also helps restore trust, accountability and a sense of common purpose in our government.

On January 9, 2020, the World Health Organization announced that there were 59 cases of coronavirus-related pneumonia. Just one year later, the United States has experienced over 24 million confirmed COVID-19 cases and over 400,000 COVID-19 deaths. America has just 4% of the world's population, but 25% of the world's COVID-19 cases and 20% of all COVID-19 deaths. And our nation continues to experience the darkest days of the pandemic, with record numbers of cases, hospitalizations and deaths. Over 77,000 Americans lost their lives to COVID-19 in December, and across our nation businesses are closing, hospitals are full, and families are saying goodbye to their loved ones remotely.

The National Strategy provides a roadmap to guide America out of the worst public health crisis in a century. It outlines an actionable plan across the federal government to address the COVID-19 pandemic, including twelve initial executive actions that will be issued by President Biden during his first two days in office:

The National Strategy is organized around seven goals:

1. Restore trust with the American people.
2. Mount a safe, effective, and comprehensive vaccination campaign.
3. Mitigate spread through expanding masking, testing, treatments, data, health care workforce, and clear public health standards.
4. Immediately expand emergency relief and exercise the Defense Production Act.
5. Safely reopen schools, businesses, and travel while protecting workers.
6. Protect those most at risk and advance equity, including across racial, ethnic and rural/urban lines.
7. Restore U.S. leadership globally and build better preparedness for future threats.

To execute on the National Strategy, the White House will establish a COVID-19 Response Office responsible for coordinating the pandemic response across

all federal departments and agencies. Through implementation of the National Strategy, the United States will make immediate progress on the seven goals. To monitor outcomes, the National Strategy will establish a data-driven, evidence-based approach to evaluating America's progress in the fight against COVID-19.

The federal government cannot solve this crisis alone. Full implementation of the National Strategy for COVID-19 will require sustained, coordinated, and complementary efforts of the American people, as well as groups across the country, including State, local, territorial, and Tribal governments; health care providers; businesses; manufacturers critical to the supply chain; civic, religious and civil rights organizations; and unions. It will also require a global effort to contain the virus and advance health security.

America has always risen to the challenge and we will do so now. In collaboration with the people of this country, the United States government will lead an effective COVID-19 response that gets us back to our lives and loved ones. As we've seen during this pandemic, we can't solve our problems as a divided nation. The only way we come through this is together as fellow Americans and as the United States of America.

Goal 1: Restore trust with the American people.

The federal government should be the source of truth for the public to get clear, accessible, and scientifically accurate information about COVID-19. To rebuild the trust of the American people, the National Strategy will signal clear public leadership and a commitment to a robust whole-of-government response that puts science first. The federal government will be transparent with the American people, maintaining an open line of communication with the public and all stakeholders. To continue to restore trust, the United States will:

Establish a national COVID-19 response structure where decision-making is driven by science and equity. The Biden-Harris Administration has developed a unified plan to rebuild expert leadership across the government and regain the trust of the American public. As part of the strategy, on his first day in office, President Biden issued Executive Order *Organizing and Mobilizing the U.S. Government to Provide a Unified And Effective Response to Combat COVID-19 and to Provide United States Leadership on Global Health and Security* establishing a White House COVID-19 national response structure to coordinate across the U.S. Government and restoring the White House Directorate on Global Health Security and Biodefense established by the Obama-Biden Administration. The COVID-19 Response office will establish clear lines of communications with all governors, state public health officials and immunization managers, and local leaders.

Conduct regular expert-led, science-based public briefings. The federal government will conduct regular, expert-led, science-based public briefings and release regular reports on the state of the pandemic. Experts and scientists at the U.S. Centers for Disease Control and Prevention (CDC) will also develop clear, evidence-based, metric-driven public health guidance and effectively and frequently communicate and distribute guidance and updates to the American people.

Publicly share data around key response indicators. Metrics and metric-driven public health guidance will be essential to controlling the pandemic. President Biden will issue Executive Order *Ensuring a Data-Driven Response to COVID-19 and Future High Consequence Public Health Threats* directing steps to enhance federal agencies' collection, production sharing, and analysis of, and collaboration with respect to, data to support an equitable COVID-19 response and recovery. As further detailed in National Strategy Goals Two, Three, and Six, the federal government will track a range of performance measures and data including cases, testing, vaccinations, and hospital admissions, and will make real-time information readily available to the public and to policymakers at the federal, state, and local level. The CDC will also maintain a public dashboard tracking COVID-19 cases at the county

level, so that Americans can gauge the level of transmission in their own communities to make their own informed choices.

Engage the American people. The federal government cannot solve this crisis alone. It will take regular engagement with the public, state and local leaders, the private sector, unions, community volunteers, and health care providers to guide policy and implementation. The Administration will prioritize outreach to state and local governments, the public and private sectors, vulnerable communities, students, workers, and community leaders, using input from these stakeholders to drive the government's COVID-19 response.

Lead science-first public health campaigns. The Administration will lead world-class public education campaigns — covering topics like masking, testing, vaccinations and vaccine hesitancy — designed with diversity and inclusivity in mind, including communications in multiple languages, to maximize reach and effectiveness. The campaigns will be coordinated, across national, state, and local levels, and engage with the private and public sector. They will be anchored by science and fact-based public health guidance. The Administration will work to counter misinformation and disinformation by ensuring that Americans are obtaining science-based information.

Goal 2: Mount a safe, effective, comprehensive vaccination campaign.

The United States will spare no effort to ensure Americans can get vaccinated quickly, effectively, and equitably. The federal government will execute an aggressive vaccination strategy, focusing on the immediate actions necessary to convert vaccines into vaccinations, including improving allocation, distribution, administration, and tracking. Central to this effort will be additional support and funding for state, local, Tribal, and territorial governments -- and improved line of sight into supply -- to ensure that they are best prepared to mount local vaccination programs. At the same time, the federal government will mount an unprecedented public campaign that builds trust around vaccination and communicates the importance of maintaining public health measures such as masking, physical distancing, testing, and contact tracing even as people receive safe and effective vaccinations. To mount a safe, effective, comprehensive vaccination campaign, the United States will:

Ensure the availability of safe, effective vaccines for the American public. The national vaccination effort will be one of the greatest operational challenges America has ever faced. To ensure all Americans can be vaccinated quickly, the President has developed a plan for expanding vaccine manufacturing and purchasing COVID-19 vaccine doses for the U.S. population by fully leveraging contract authorities, including the Defense Production Act; deploying onsite support to monitor contract manufacturing operations; and purchasing additional FDA-authorized vaccines to deliver as quickly as possible. The effort includes prioritizing supplies that could cause bottlenecks, including glass vials, stoppers, syringes, needles, and the "fill and finish" capacity to package vaccine into vials.

Accelerate getting shots into arms and get vaccines to the communities that need them most. The success of the national vaccination effort will depend on reaching communities across the United States. To achieve this, the federal government will take a series of steps to simplify and strengthen the allocation and distribution process. In order to expand the supply available to states, the Administration will end the policy of holding back significant levels of doses, instead holding back a small reserve and monitoring supply to ensure that everyone receives the full regimen as recommended by the FDA. The United States will accelerate the pace of vaccinations by encouraging states and localities to move through the priority groups more quickly -- expanding access to frontline essential workers and individuals over the age of 65, while staying laser-focused on working to ensure that the highest-risk members of the public, including those in congregate facilities, can access the vaccine where and when they need it. The

Administration will also improve the allocation process by providing states and localities with clear, consistent projections to inform their planning. Through it all, the United States will work to ensure that the vaccine is distributed quickly, effectively and equitably, with a focus on making sure that high-risk and hard-to-reach communities are not left behind.

Create as many venues as needed for people to be vaccinated. The federal government -- in partnership with state and local governments -- will create as many venues for vaccination as needed in communities and settings that people trust. This includes, but is not limited to federally run community vaccination centers, in places like stadiums and conference centers, federally-supported state and locally operated vaccination sites in all 50 states and 14 territories, pharmacies and retail stores, federal facilities like Veterans Affairs hospitals, community health centers, rural health clinics, critical access hospitals, physician offices, health systems, urgent care centers, and mobile and on-site occupational clinics**.**

Focus on hard-to-reach and high-risk populations. As the United States accelerates the pace of vaccinations nationwide, we remain focused on building programs to meet the needs of hard-to-reach and high-risk populations, and meeting communities where they are to make vaccinations as accessible and equitable as possible. The federal government will deploy targeted strategies to meet the needs of individuals at increased risk and others who need to take extra precautions, according to the CDC, as well as the communities hardest hit by this pandemic. Local public health officials will play a critical role.

Fairly compensate providers, and states and local governments for the cost of administering vaccinations. Fairly compensating providers, and state and local governments for the costs of vaccine administration will be critical to expanding vaccination participation. President Biden will work with Congress to expand the Federal Medicaid Assistance Percentage (FMAP) to 100 percent for vaccinations of Medicaid enrollees—with the goal of alleviating state costs for administration of these vaccines and supporting states in their work to meet the needs of their communities. The Department of Health and Human Services will ask the Centers for Medicare & Medicaid Services to consider whether current payment rates for vaccine administration are appropriate or whether a higher rate may more accurately compensate providers. The federal government will fund vaccine supply and will greatly expand funding for vaccine administration by allowing state and local governments to reimburse vaccination administration expenses through the FEMA Disaster Relief Fund and by ensuring that workforce and equipment expenses for state and local-run sites are also eligible.

Drive equity throughout the vaccination campaign and broader pandemic response. The federal government will drive equity in vaccinations by using demographic data to identify communities hit hardest by the virus and supporting them, ensuring no out-of-pocket costs for vaccinations, and making sure vaccines reach those communities. Working with state, local, and community-based organizations and trusted health care providers, like community health centers, will be central to this effort.

Launch a national vaccinations public education campaign. The United States will build public trust through an unprecedented vaccination public health campaign at the federal, State, Tribal, territorial, local and community level. The public education campaign will support vaccination programs, address vaccine hesitancy, help simplify the vaccination process for Americans, and educate the public on effective prevention measures. The campaign will be tailored to meet the needs of diverse communities, get information to trusted, local messengers, and outline efforts to deliver a safe and effective vaccine as part of a national strategy for beating COVID-19.

Bolster data systems and transparency for vaccinations. The operational complexity of vaccinating the public will make robust data and its use in decision-making related to vaccinations more important than ever. The

federal government, with CDC, will track distribution and vaccination progress, working hand-in-hand with states and localities to support their efforts. The Administration will build on and strengthen the federal government's approach to data collection related to vaccination efforts, removing impediments and developing communication and technical assistance plans for jurisdictions and providers. The Administration, through HHS and other federal partners, will rely on data to drive decision-making and the national vaccinations program.

Monitor vaccine safety and efficacy. The Administration will ensure that scientists are in charge of all decisions related to vaccine safety and efficacy. The FDA will also continue to honor its commitment to make relevant data on vaccine safety and efficacy publicly available and to provide opportunities for public, non-governmental expert input. Through expanded and existing systems, the CDC and FDA will ensure ongoing, real-time safety monitoring. Through it all, the Administration will communicate clearly with the American public to continue to build trust around the vaccine and its benefits for individuals, their families and communities.

Surge the health care workforce to support the vaccination effort. A diverse, community-based health care workforce is essential to an effective vaccination program. The United States will address workforce needs by taking steps to allow qualified professionals to administer vaccines and encourage states to leverage their flexibility fully to surge their workforce, including by expanding scope of practice laws and waiving licensing requirements as appropriate.

Goal 3: Mitigate spread through expanding masking, testing, treatment, data, workforce, and clear public health standards.

A comprehensive national public health effort to control the virus — even after the vaccination program ramps up — will be critical to saving lives and restoring economic activity. The federal government will partner with state, local, Tribal, and territorial leaders to implement a cohesive strategy to significantly reduce the spread of COVID-19 and release clear public health guidance to the public about what to do and when, including implementing mask mandates; expanding testing; strengthening the public health workforce; modernizing data collection and reporting capabilities for COVID-19 and future epidemics; and providing equitable access to treatment and clinical care. To mitigate the spread of COVID-19 through clear public health standards, the United States will:

Implement masking nationwide by working with governors, mayors, and the American people. The President has asked the American people to do what they do best: step up in a time of crisis and wear masks. He has issued Executive Order *Protecting the Federal Workforce and Requiring Mask-Wearing* which directs compliance with CDC guidance on masking and physical distancing in federal buildings, on federal lands, and by federal employees and contractors. Additionally, the President will issue Executive Order *Promoting COVID-19 Safety in Domestic and International Travel* which directs applicable agencies to take immediate action to require mask-wearing on some airplanes, trains, and certain other forms of public transportation in the United States. He has called on governors, public health officials, mayors, business leaders, and others to implement masking, physical distancing, and other CDC public measures to control COVID-19.

Scale and expand testing. To control the COVID-19 pandemic and safely reopen schools and businesses, America must have wide-spread testing. A national testing strategy is a cornerstone to reducing the spread of COVID-19 and controlling outbreaks, and clear federal guidance and a unified national approach to implementation are essential. The President will issue Executive Order *Establishing the National Pandemic Testing Board and Ensuring a Sustainable Public Health Workforce for COVID-19 and Other Biological Threats* which establishes the COVID-19 Pandemic Testing Board to oversee implementation of a clear, unified approach to testing. The federal government will expand the rapid testing supply and double test supplies and increase testing capacity. The Administration will also increase onshore test

manufacturing, fill testing supply shortfalls, enhance laboratory capacity to conduct testing over the short- and long-term, and expand surveillance for hotspots and variants.

Effectively distribute tests and expand access to testing. The federal government will support school screening testing programs to help schools reopen. The Administration will also stand up a dedicated CDC Testing Support Team, fund rapid test acquisition and distribution for priority populations, work to spur development and manufacturing of at-home tests and work to ensure that tests are widely available. Through Executive Order *Establishing the National Pandemic Testing Board and Ensuring a Sustainable Public Health Workforce for COVID-19 and Other Biological Threats* the President will direct agencies to facilitate testing free of charge for those who lack health insurance and to clarify insurers' obligation to cover testing. The federal government will also provide testing protocols to inform the use of testing in congregate settings, schools, and other critical areas and among asymptomatic individuals. Further, technical assistance will support more widespread adoption of testing to improve timely diagnosis and public confidence in the safety of settings like schools.

Prioritize therapeutics and establish a comprehensive, integrated COVID-19 treatment discovery and development program. Effective treatments for COVID-19 are critical to saving lives. The federal government will establish a comprehensive, integrated, and coordinated preclinical drug discovery and development program, with diverse clinical trials, to allow therapeutics to be evaluated and developed rapidly in response to COVID-19 and other pandemic threats. This includes promoting the immediate and rapid development of therapeutics that respond to COVID-19 by developing new antivirals directed against the coronavirus family, accelerating research and support for clinical trials for therapeutics in response to COVID-19 with a focus on those that can be readily scaled and administered, and developing broad-spectrum antivirals to prevent future viral pandemics. President Biden will issue Executive Order *Improving and Expanding Access to Care and Treatment for COVID-19* which also outlines steps to bolster clinical care capacity, provide assistance to long-term care facilities and intermediate care facilities for people with disabilities, increase health care workforce capacity, expand access to programs designed to meet long-term health needs of patients recovering from COVID-19, and support access to safe and effective COVID-19 therapies for those without coverage.

Develop actionable, evidence-based public health guidance. CDC will develop and update public health guidance on containment and mitigation that provides metrics for measuring and monitoring the incidence and prevalence of COVID-19 in health care facilities, schools, workplaces, and the general public, including metric-driven reopening guidance that the federal government communicates widely. Informed by up-to-date national and state data, the CDC will provide and update guidance on key issues such as physical distancing protocols, testing, contact tracing, reopening schools and businesses, and masking. The CDC also will provide focused guidance for older Americans and others at higher risk, including people with disabilities.

Expand the U.S. public health workforce and increase clinical care capacity for COVID-19.
In addition to supporting the surge in health care workers for vaccination efforts detailed in Goal Two, the federal government will also build and support an effective public health workforce to fight COVID-19 and the next public health threat. As part of the President's commitment to provide 100,000 COVID-19 contact tracers, community health workers, and public health nurses, the Administration will establish a U.S. Public Health Jobs Corps, provide support for community health workers, and mobilize Americans to support communities most at-risk. The United States will also provide technical support for testing, contact tracing, and other urgent public health workforce needs to better prepare for public health crises.

Improve data to guide the response to COVID-19. Federal agencies will

make increased use of data to guide the public health response against COVID-19. To that end, Agencies will collect, aggregate, share, and analyze non-personally identifiable data, and take steps to make it publicly available and in a machine-readable form to enhance COVID-19 response efforts. And the federal government will facilitate evidence-based decision-making through focused data-based projects. These efforts will require collaboration with state, local, Tribal, and territorial governments to aggregate and analyze data for critical decisions to track access to vaccines and testing, reopen schools and businesses, address disparities in COVID-19 infections and health outcomes, and enhance critical monitoring capacity where needed. In addition, critical response activities such as workforce mobilization and vaccination appointment scheduling may require new technology solutions. The federal government will provide technical support to ensure that these systems meet mission critical requirements to support a robust response.

Goal 4: Immediately expand emergency relief and exercise the Defense Production Act.

It's past time to fix America's COVID-response supply shortage problems for good. The United States will immediately address urgent supply gaps, which will require monitoring and strengthening supply chains, while also steering the distribution of supplies to areas with the greatest need. As new vaccines, testing protocols, and treatments are developed, they will also need to be manufactured in sufficient supply. To respond to this unprecedented operational challenge, the President is immediately expanding emergency relief by giving state and local governments the support they need. To make vaccines, tests, Personal Protective Equipment (PPE), and other critical supplies available for the duration of the pandemic, the President has directed the use of all available legal authorities, including the Defense Production Act (DPA), instructing departments and agencies to expand the availability of critical supplies, to increase stockpiles so that PPE is available to be used in the recommended safe manner, and to start to fill all supply shortfalls immediately. To expand emergency relief and strengthen the supply chain, the government will:

Increase emergency funding to states and bolster the Federal Emergency Management Agency (FEMA) response. The President will issue a Presidential Memorandum entitled *Extend Federal Support to Governors' Use of National Guard to Respond to COVID-19 and to Increase Reimbursement and other Assistance Provided to States,* directing FEMA to fully reimburse states for the cost of National Guard personnel and emergency supplies, including emergency supplies like PPE for schools and child care providers.

Fill supply shortfalls by invoking the Defense Production Act (DPA). The United States is taking immediate action to fill supply shortfalls for vaccination supplies, testing supplies, and PPE. The President will issue Executive Order *A Sustainable Public Health Supply Chain* which directs agencies to fill supply shortfalls using all available legal authorities, including the DPA, and the United States has identified twelve immediate supply shortfalls that will be critical to the pandemic response, including shortages in the dead-space needle syringes available to administer the vaccine. The President has directed relevant agencies to exercise all appropriate authorities, including the DPA, to accelerate manufacturing, delivery, and administration to meet shortfalls in these twelve categories of critical supplies, including taking action to increase the availability of supplies like N95 masks, isolation gowns, nitrile gloves, polymerase chain reaction **(**PCR) sample collection swabs, test reagents, pipette tips, laboratory analysis machines for PCR tests, high-absorbency foam swabs, nitrocellulose material for rapid antigen tests, rapid test kits, low dead-space needles and syringes, and all the necessary equipment and material to accelerate the manufacture, delivery, and administration of COVID-19 vaccine.

Identify and solve urgent COVID-19 related supply gaps and strengthen the supply chain. The *A Sustainable Public Health Supply Chain* executive order will also direct federal agencies to fill supply shortfalls

using all available legal authorities.The federal government will focus on the near-term goal of building a stable, secure, and resilient supply chain with increased domestic manufacturing in four key critical sectors:

- Antigen and molecular-based testing;
- PPE and durable medical equipment;
- Vaccine development and manufacturing; and
- Therapeutics and key drugs.

The federal government will immediately focus on procuring supplies that will be critical to control the spread of COVID-19 by initiating contracts, entering into purchase commitments, making investments to produce supplies and expanding manufacturing capacity.

Secure the pandemic supply chain and create a manufacturing base in the United States. To respond more effectively to this crisis, and ensure that the United States is able to respond more quickly and efficiently to the next pandemic, we need a resilient, domestic public health industrial base. The U.S. Government will not only secure supplies for fighting the COVID-19 pandemic, but also build toward a future, flexible supply chain and expand an American manufacturing capability where the United States is not dependent on other countries in a crisis. To this end, *A Sustainable Public Health Supply Chain* will direct the development of a new Pandemic Supply Chain Resilience Strategy.

Improve distribution and expand availability of critical materials. After conducting a review of existing COVID-19 and related pandemic supply chain distribution plans and working in consultation with state and regional compacts, the United States will coordinate distribution plans, prioritizing areas of highest-risk and highest need, and set up a structure to improve the distribution of critical materials. To work toward expanding the affordability and accessibility of supplies, *A Sustainable Public Health Supply Chain* will direct the Department of Defense (DOD), HHS, and Department of Homeland Security (DHS) to develop recommendations to address the pricing of COVID-19 supplies. The federal government will also reduce the opacity of the market for critical supplies and supply chains by clearly and rapidly communicating with states, health care providers, and manufacturers about federal interventions.

Goal 5: Safely reopen schools, businesses, and travel, while protecting workers.

Reopening schools, businesses, travel, and our economy will require major, unified federal investments in rapid testing, an expanded rapid response public health workforce, clear guidance and protections, and support for people to stay home when they are infected to stop the spread of COVID-19. At the same time that the United States takes immediate steps to achieve an overall decrease in COVID-19 spread, it will also support the safe operation of schools, businesses, and travel. To protect workers and safely reopen, schools, businesses, and travel, the United States will:

Implement a national strategy to support safely reopening schools. The United States is committed to ensuring that students and educators are able to resume safe, in-person learning as quickly as possible, with the goal of getting a majority of K-8 schools safely open in 100 days. The President will issue Executive Order *Supporting the Reopening and Continuing Operation of Schools and Early Childhood Education Providers* which directs a national strategy for safely reopening schools, including requiring the Departments of Education and HHS to provide guidance on safe reopening and operating, and to develop a Safer Schools and Campuses Best Practices Clearinghouse to share lessons learned and best practices from across the country. Presidential Memorandum *Extend Federal Support to Governors' Use of National Guard to Respond to COVID-19 and to Increase Reimbursement and other Assistance Provided to States* will restore full reimbursement for eligible costs necessary to support safe school reopening through the FEMA Disaster Relief Fund and the President has called on Congress to provide at least $130 billion

in dedicated funding to schools, $350 billion in flexible state and local relief funds that will help districts avoid lay-offs and close budget gaps, and additional resources so that schools can safely reopen, including funds to implement screening testing. The Administration will release a handbook that helps schools and local leaders implement the precautions and strategies necessary for safe reopening. It will also work with states and local school districts to support screening testing in schools, including working with states to ensure an adequate supply of test kits.

Support safe operations at child care centers and at-home providers. With enrollments down and costs up due to COVID-19 precautions, child care providers are struggling to stay afloat while providing vital services to their communities. Due to increased costs and lower enrollment, a recent survey of child care providers showed that most child care providers expect that they will close within a few months without relief, or are uncertain how long they can stay open.[1] If not addressed, child care providers will close and millions of parents will be left to make devastating choices between caring for their children and working to put food on the table. President Biden has called on Congress to provide $25 billion in emergency stabilization to support hard-hit child care providers through the pandemic. These funds would help providers pay rent, utilities, and payroll, as well as cover pandemic-related costs like personal protective equipment, ventilation supplies, smaller group sizes, and alterations to physical spaces that improve safety. The President has also called on Congress to provide $15 billion to help families struggling to afford child care.

Support equitable reopening and operation in higher education. College enrollment for high school graduates was down more than 20% in 2020 compared to 2019, and students from low-income families are nearly twice as likely to report canceling their plans to attend college. Reopening and keeping colleges open is critical to ensuring that all Americans have a shot at a college credential -- but it must be done safely, to protect the health of students, faculty, staff, and the broader community. To support colleges through the pandemic, President Biden has requested that Congress provide an additional $35 billion in emergency stabilization funds for higher education.

Protect workers and issue stronger worker safety guidance. It is critical that the federal government protect the health and safety of America's workers and take swift action to prevent workers from contracting COVID-19 in the workplace. The President will issue Executive Order *Protecting Worker Health and Safety* which directs the Occupational Safety and Health Administration (OSHA) to issue updated guidance on COVID-19 worker protections. It also directs OSHA and the Mine Safety and Health Administration (MSHA) to consider whether emergency temporary standards, including with respect to mask-wearing, are necessary. President Biden is taking steps to cover workers not typically covered by OSHA or MSHA by directing agencies like the Department of Transportation to keep workers safe. He has also called on Congress to extend and expand emergency paid leave; to allow OSHA to issue standards covering a broad set of workers, like many public workers on the frontlines; to provide additional funding for worker health and safety enforcement, and to provide grant funding for organizations to help keep vulnerable workers healthy and safe from COVID-19.

Provide guidance and support to safely open businesses. To maintain safe operations during the pandemic, businesses need to know how to change their practices to protect employees and customers. As the conditions of the pandemic continue to evolve and more Americans get vaccinated, the business community needs clear information from the federal government on what to expect and how to adapt their operations. Many businesses affected by the pandemic–particularly the smallest ones–need additional support to adjust their physical spaces and purchase PPE and supplies. The United States will immediately work to prioritize funds under the recent COVID relief package to the companies hardest hit by COVID-19 and in compliance with public health restrictions, ensuring that small businesses have the funds they need to operate safely. Further, the Small Business Administration will work with the

Department of Labor to disseminate updated OSHA guidance on worker safety and support businesses in implementing the updated guidance.

Promote Safe Travel. Ensuring that people can safely travel will be critical for families and to jumpstarting the economy, which is why the President will issue an executive order that requires mask-wearing on certain public modes of transportation and at ports of entry to the United States. For international air travel, Executive Order *Promoting COVID-19 Safety in Domestic and International Travel* will require a recent negative COVID-19 test result prior to departure and quarantine on arrival, consistent with CDC guidelines. The Executive Order will also direct agencies to develop options for expanding public health measures for domestic travel and cross-border land and sea travel and calls for incentives to support and encourage compliance with CDC guidelines on public transportation.

Goal 6: Protect those most at risk and advance equity, including across racial, ethnic and rural/urban lines.

The COVID-19 pandemic has exposed and exacerbated severe and pervasive health inequities among communities defined by race, ethnicity, geography, disability, sexual orientation/gender identity, and other factors. Addressing this pandemic's devastating toll is both a moral imperative and pragmatic policy. The federal government will address disparities in rates of infection, illness and death. Each of the goals of this National Strategy include comprehensive actions that will address these disparities and advance equity. In addition, the United States will:

Establish the COVID-19 Health Equity Task Force. The President will issue Executive Order *Ensuring an Equitable Pandemic Response and Recovery* which establishes a high-level task force to address COVID-19 related health and social inequities and help coordinate an equitable pandemic response and recovery. The Task Force will convene national experts on health equity and provide recommendations on how to mitigate COVID-19 health inequities.

Increase data collection and reporting for high risk groups. The fragmented and limited availability of data by race, ethnicity, geography, disability and other demographic variables delays recognition of risk and a targeted response. President Biden will issue the Executive Order *Ensuring a Data-Driven Response to COVID-19 and Future High-Consequence Public Health Threats* directing federal agencies to expand their data infrastructure to increase collection and reporting of health data for high risk populations, while reaffirming data privacy. Using these data, the federal government will identify high-risk communities, track resource distribution and evaluate the effectiveness of the response. Finally, HHS will optimize data collection from public and private entities to increase the availability of data by race, ethnicity, geography, disability, and other demographic variables, as feasible.

Ensure equitable access to critical COVID-19 PPE, tests, therapies and vaccines. The continued surge of COVID-19 highlights the critical importance of meaningful access to PPE, tests, therapies, and vaccines to prevent spread and reduce illness and death in high-risk populations and settings. The federal government will center equity in its COVID-19 response, providing PPE, tests, vaccines, therapeutics and other resources in a fair and transparent way. A targeted, stakeholder- and data-informed vaccination communication campaign will be launched to encourage vaccination in all communities. Additionally, the CDC will work with states and localities to update their pandemic plans. Finally, through prioritizing diverse and inclusive representation in clinical research and strengthening enforcement of anti-discrimination requirements, the federal government will increase access to effective COVID-19 care and treatment.

Expand access to high quality health care. The federal government will work to expand affordable coverage to increase access to care during this pandemic, and the Task Force will provide recommendations to align federal incentives with improved clinical outcomes. Specific actions include efforts to

increase funding for community health centers, provide greater assistance to safety net institutions, strengthen home- and community-based services, expand mental health care, and support care and research on the effects of long COVID.

Expand the clinical and public health workforce, including community-based workers. In order to assure equitable PPE distribution, testing, contact tracing, social support for quarantine and isolation and vaccination, there must be sufficient workforce to serve the communities in greatest need. The federal government will augment the health workforce, including with community based workers, as outlined in Goal Three above, to help fill this critical gap. The federal government will create a United States Public Health Workforce Program of new community based workers to assist with testing, tracing and vaccination. Additionally, it will deploy federal workers to assist with the COVID-19 response in under-resourced areas.

Strengthen the social service safety net to address unmet basic needs. With millions of families already struggling pre-pandemic to meet basic needs, including food, housing and transportation, COVID-19 has exacerbated these challenges. These challenges contribute to difficulties by many to adhere to public health guidance regarding social distancing and quarantine/isolation. This Administration is committed to addressing these needs in multiple ways, including providing paid sick leave, child care support, and rental assistance, with requested Congressional appropriations. Additionally, it will undertake agency actions to designate COVID-19 health equity leads and extend eligibility and enrollment flexibilities for select programs during the pandemic, as well work with community-based, multi-sector organizations to align health and social interventions.

Support communities most at-risk for COVID-19. The federal government is committed to supporting populations that are most vulnerable to COVID-19. Whether residing in congregate settings (such as prisons, nursing and group homes, and homeless shelters), serving as essential workers, living as a person with a disability, or bearing the burden of chronic medical conditions, these vulnerable populations are disproportionately composed of people of color. The CDC will develop and update clear public health guidance for such high-risk populations and settings to further minimize the risk of COVID infection, and work with states to update their pandemic plans to incorporate such guidance as necessary.

Goal 7: Restore U.S. leadership globally and build better preparedness for future threats.

U.S. international engagement to combat COVID-19, promote health, and advance global health security is urgent to save lives, promote economic recovery, and develop resilience against future biological catastrophes. America's withdrawal from the world stage has impeded progress on a global COVID-19 response and left the U.S. more vulnerable to future pandemics. The Biden-Harris Administration will restore America's role in leading the world through global crises, advancing global health security and the Global Health Security Agenda, including by supporting the international pandemic response effort, providing humanitarian relief and global health assistance, and building resilience for future epidemics and pandemics. The President will issue a National Security Directive that directs steps to restore U.S. leadership globally and build better preparedness. In addition, the United States of America will:

Restore the U.S. relationship with the World Health Organization and seek to strengthen and reform it. The World Health Organization (WHO) is essential to coordinating the international response to COVID-19 and improving the health of all people**.** On his first day in office, the President sent letters informing the UN Secretary-General and the WHO Director General of his decision to cease the previous Administration's process of withdrawal from the WHO and meet its financial obligations. The United States is participating in the WHO Executive Board meeting this month, and will take actions to strengthen and reform the WHO.

Surge the international COVID-19 public health & humanitarian response. The United States will commit to multilateralism in the international COVID-19 public health and humanitarian response. The President will restore U.S. leadership on the global COVID-19 response and health security, laying out an active role for the United States in surging the health and humanitarian response to COVID-19, and supporting global vaccine distribution and research and development for treatments, tests, and vaccines. The United States will support the Access to COVID-19 Tools (ACT) Accelerator, join the COVID-19 Vaccines Global Access (COVAX) Facility, and seek to strengthen other existing multilateral initiatives, such as the Coalition for Epidemic Preparedness Innovations; Gavi, the Vaccine Alliance; and the Global Fund to Fight AIDS, Tuberculosis, and Malaria. The United States will also take steps to enhance humanitarian relief and support for the capacity of the most vulnerable communities to prevent, detect, respond to, mitigate, and recover from impacts of COVID-19, such as food insecurity and gender-based violence.

Restore U.S. leadership to the international COVID-19 response and advance global health security and diplomacy. The United States will promote sustainable global health and global health security, rebuild health security alliances, elevate U.S. efforts to support the Global Health Security Agenda, and revitalize U.S. leadership. The United States will advance global health security financing, promote efforts to harmonize crisis response and early warning for public health emergencies, and strengthen global pandemic supply chains. The United States will also work within the UN Security Council and with partners to strengthen multilateral public health and humanitarian cooperation on the COVID-19 response, global institutions to combat disease, and a global health security architecture to prevent, detect, and respond to future biological threats.

Build better biopreparedness and expand resilience for biological threats. The United States is committed to strengthening U.S. biopreparedness and capacity to counter COVID-19 and future biological threats. The President has immediately restored the White House National Security Council Directorate for Global Health Security and Biodefense, originally established by the Obama-Biden administration. He has reconstituted White House and Administration-wide infrastructure for monitoring and responding to emerging biological risks. And to improve the United States' preparedness, the Administration will work to secure funding and Congressional support to establish an integrated, National Center for Epidemic Forecasting and Outbreak Analytics to modernize global early warning and trigger systems to prevent, detect, and respond to biological threats. The United States will also review and seek to strengthen our pandemic supply chain, public health workforce, medical countermeasure development and distribution, bioeconomic investment and technology-related risks.

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- Department of Education Resources for Reopening Schools [Attachment]
    - Please see attached for information regarding:
        - The Department of Education's virtual National Safe School Reopening Summit occurring **tomorrow**, Wednesday, **March 24** (registration is available here)
        - Details on a "Safer Schools and Campuses Best Practices Clearinghouse," which includes a "Lessons from the Field" webinar series that will begin **Wednesday, March 31** (information is available here)
        - The upcoming release of Volume 2 of the K-12 COVID-19 Handbook for districts, schools, and educators
- CDC Lab Update: CMS Posts FAQ for Reporting Sequencing Results for SARS-CoV-2 Variants [Attachment, Link]
    - Please see the following message from CDC's Laboratory Outreach Communication System (LOCS):
        - *On March 19, 2021, the U.S. Centers for Medicare & Medicaid Services (CMS) posted the "CLIA SARS-CoV-2 Variant Testing Frequently Asked Question" document to provide information for facilities that perform sequencing to identify SARS- CoV-2 genetic variants. CMS will not cite CLIA-certified laboratories that perform SARS-CoV-2 genetic variant testing on identified specimens and report*

patient-specific variant results to state or local public health departments without establishing performance specifications as required by §493.1253(b)(2), provided that the laboratory only reports patient-specific results to a public health department and the results are not intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment. If at any time the SARS-CoV-2 genetic variant result is intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment, the test must be performed in a CLIA-certified laboratory and in compliance with all applicable CLIA regulations."

- The FAQ document is available on CMS' website here.

- CSTE Webinar: "Unpacking the COVID-19 Genomic Epidemiology Toolkit" [Link]
  - The next installment of CSTE's membership webinar series will take place **Thursday, March 25** at **3:00 pm EDT**. The webinar, co-hosted by CSTE and CDC's Office of Advanced Molecular Detection (AMD), will cover the recently released COVID-19 Genomic Epidemiology Toolkit. This toolkit is designed to help epidemiologists use genomic data to track and investigate SARS-CoV-2 in their jurisdictions, and consists of brief, modular video presentations with audio transcripts. During the webinar, featured presenters will showcase toolkit features and answer questions.
  - Call capacity is limited to 1,000 participants, and is first-come, first-served. Call information is below:
    - Weblink: https://webinar.ringcentral.com/j/1466093845
      Telephone: (470) 860-2200 *[East]* | (773) 231-9226 *[North]* | (469) 445-0100 *[South]* | (623) 404-9000 *[West]* | (720) 902-7700 *[Central]*

- CDC Call to Action: "Help Kids' Safe Return to School - Get Caught Up on Recommended Vaccines" [Attachment]
  - Please see below for a message from CDC's COVID-19 Vaccine Task Force Partnership Team:
    - *"COVID-19 disrupted both in-person learning and routine well-child visits for many children over the last year. As a result, too many children have fallen behind on receiving recommended vaccines. We all want our kids to be back in school safely, and that means getting caught up on vaccines that were missed over the last year. Please find attached a Call to Action, which outlines efforts needed to get children caught up on vaccinations. This letter will be posted on the CDC website soon and we will be hosting a partner webinar in the near future to discuss this important topic. Thank you for your continued partnership and attention to this critical issue."*
  - The referenced Call to Action is attached to this email.

- CDC Priority Science Questions [Attachment, Link]
  - Please see attached for a message from CDC's State, Tribal, Local and Territorial

Support Task Force, regarding the release of a new set of *Priority Science Questions* intended to guide prioritization of CDC's scientific research portfolio related to COVID-19, including articles published in *MMWR* and other scientific journals. These questions are in response to the objectives in CDC's *Science Agenda for COVID-19*.
    - The new set of Priority Science Questions is now available on CDC's website here.

Standing Updates

- CDC Partner Update Call: "Understanding the Role of Telehealth Usage During the COVID-19 Pandemic" [Link]
    - CDC will host the next installment of its weekly partner call **Monday, March 29** at **3:00 pm EDT**. Dr. Cynthia Ogden will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Drs Hanna B Demeke, Paramjit Sandhu, and Antoni Neri will discuss highlights on the usage of telehealth systems during the COVID-19 Response.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 3/29" in the subject line. The call will be recorded and posted to CDC's website here.
- CDC Partner Update – March 22 [Attachment]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – March 22 [Attachment]
    - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
    - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please visit this link.

Help Kids' Safe Return to School - Get Caught Up on Recommended Vaccines

COVID-19 disrupted both in-person learning and routine well-child visits for many children over the last year. As a result, too many children have fallen behind on receiving recommended vaccines[1]. We all want our kids to be back in school safely, and that means getting caught up on vaccines that were missed over the last year. CDC's public sector vaccine ordering data show a 14% drop in 2020-2021 compared to 2019, and measles vaccine is down by more than 20%. Kids need to get caught up now so that they are protected as they go back to in-person learning. Catch-up vaccination will require efforts from healthcare systems, health care providers, schools, state and local governments, and families.

Healthcare systems and healthcare providers should:

- Identify families whose children have missed doses and contact them to schedule appointments
- Prompt clinicians when these children are seen to deliver vaccines that are due or overdue
- Let families know what precautions are in place for safe delivery of in-person services

Healthcare provider organizations should:

- Encourage members to identify and follow up with families whose children have missed doses to get appointments scheduled

Schools and state and local governments agencies should:

- Send reminders to families about school immunization requirements
- Follow-up with families of children who are not in compliance with requirements to encourage compliance
- Use the state's immunization information system's reminder-recall capacity to notify families whose children have fallen behind on vaccines

We all should:

- Communicate directly to families the importance of well-child visits and getting caught up on any recommended vaccines that were missed

Help us protect children by doing what you can to get kids caught up on recommended vaccines.

Sincerely,

Nancy Messonnier, MD
Senior Official, CDC COVID-19 Vaccine Task Force
Director, National Center for Immunization and Respiratory Diseases

CLIA SARS-CoV-2 Variant Testing Frequently Asked Question
Date: 3/19/2021

Does a facility that performs surveillance testing to identify SARS- CoV-2 genetic variants need a CLIA certificate?

CMS is temporarily exercising enforcement discretion under CLIA for SARS-CoV-2 genetic variant testing on identified specimens in which patient-specific results are reported to State or local Public Health Departments. As defined by Centers for Disease Control and Prevention (CDC), public health surveillance testing for SARS-CoV-2 is intended to monitor community- or population-level outbreaks of disease, or to characterize the incidence and prevalence of disease. Public health surveillance testing is performed on de-identified specimens, and thus results are not linked to individuals. Public health surveillance testing cannot be used for individual decision-making. See CDC's Testing Strategies for SARS-CoV-2 (Frequently Asked Questions about Coronavirus (COVID-19) for Laboratories).

Generally, surveillance testing using sequencing technology to identify SARS-CoV-2 genetic variants can be performed in a facility that is NOT CLIA certified, provided that patient-specific results are **not** reported to (1) the individual who was tested or (2) their health care provider. If at any time a facility intends to perform testing on identified specimens and report a patient-specific SARS-CoV-2 genetic variant test result to the individual who was tested or to their health care provider, the facility must comply with CLIA and is thereby required to obtain the appropriate CLIA certificate in accordance with 42 CFR Part 493, laboratory requirements.

However, as indicated above, CMS will not take action against non-CLIA certified facilities that perform SARS-CoV-2 genetic variant testing on identified specimens and report patient-specific results to State or local Public Health Departments, provided that the facility only reports patient-specific results to a Public Health Department and the results are not intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment. The Public Health Departments should only use these results for public health purposes, such as contact tracing, outbreak detection, etc. If at any time the SARS-CoV-2 genetic variant result is intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment, the test must be performed in a CLIA certified laboratory and in compliance with all applicable CLIA regulations (42 CFR part 493).

CLIA-certified laboratories continue to be permitted to report patient-specific results to authorized persons, which may include the individual who was tested, their health care provider, or a Public Health Department[1], as applicable, for SARS-CoV-2 genetic variant testing and other tests. If a CLIA certified laboratory performing SARS-CoV-2 genetic variant testing decides to report patient-specific results to an individual or their healthcare provider, then the laboratory must establish performance specifications for their assay. See 42 CFR §493.1253(b)(2). CLIA regulations are not prescriptive as to the number of samples required to establish performance specifications. When a genetic variant is discovered during a public health emergency, there may be very limited number of samples available for the establishment of performance specifications. This does not necessarily prevent laboratories from utilizing assays testing for the novel variant. When the number of samples that a laboratory would normally run for the establishment of performance specifications are not available, it is the responsibility of the laboratory director (LD) to ensure that procedures used are adequate to establish the accuracy, precision, and other pertinent performance characteristics of the method. While initially there may not be many samples to establish performance specifications, as time goes on, and as more samples become

[1] While most if not all public health departments would likely meet the CLIA definition of an "authorized person", see 42 CFR §493.2 ("Authorized person means an individual authorized under State law to order tests or receive test results, or both."), this would technically be determined on a case-by-case basis.

available, the LD may choose to enhance their assay to the level of other tests in their laboratory. *However, CMS will not cite CLIA certified laboratories that perform SARS-CoV-2 genetic variant testing on identified specimens and report patient-specific variant results to* State or local *Public Health Departments without establishing performance specifications as required by §493.1253(b)(2), provided that the laboratory only reports patient-specific results to a Public Health Department and the results are not intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment. If at any time the SARS-CoV-2 genetic variant result is intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment, the test must be performed in a CLIA-certified laboratory and in compliance with all applicable CLIA regulations.*

CDC All-State, Tribal, Local, and Territorial (STLT) Update Call

- **CDC All-STLT Update Call (Formerly All-State Update Call):** We are excited to announce that on Monday, March 22, the All-STLT Update Call transitioned to a Zoom webinar format. Click here to register for the Zoom webinar. Once you register you will receive a confirmation link. **Please save this link,** it will work for the entire series. The weekly call series will continue to be held each Monday from 2:00-2:45 PM EST. If you have any questions about this transition or would like to join our distribution list, please email eocevent424@cdc.gov.

CDC Resources

- **COVID Data Tracker**: Provides maps and charts tracking cases, deaths, and trends of COVID-19 in the United States, updated daily by 8:00 PM EST.
- **COVID Data Tracker Weekly Review:** This webpage and newsletter highlights key data from COVID Data Tracker, CDC's home for COVID-19 data, along with high priority supplemental information, narrative interpretations of the data, and visualizations from the week. The *Weekly Review* also summarizes important trends in the pandemic and provides CDC data and reporting in a centralized location. Sign up to have the COVID Data Tracker Weekly Review delivered to your inbox every Friday.
- **COVID-19 Science Update**: Released March 19, 2021, this Science Update provides summaries of detection, burden, and impact of SARS—CoV-2; transmission among primary and secondary students and staff; natural history of SARS-CoV-2 infection; and prevention, mitigation, and intervention strategies.

Upcoming Meetings

- **NAACHO's Nursing Home TeleICAR Training**: Thursday, March 25, 3:00-4:00 PM EST. This webinar covers a high-level overview of the TeleICAR process, including scheduling and outreach, conducting the ICAR, providing feedback, documenting observations, and follow-up. This training is recommended for jurisdictions that are new to the TeleICAR process or are onboarding new staff that will be tasked with conducting ICARs in nursing home settings.
- **Precision Public Health in the Pandemic:** Wednesday, May 26, 1:00-2:00 PM EST. MicrobeTrace is a secure, local, and user-friendly data visualization tool developed by the CDC, initially for HIV cluster detection and response, that has been rapidly retooled and adopted for the COVID-19 response. MicrobeTrace allows users to map transmission networks based on person-to-person contacts, pathogen-to-pathogen genetic distance, or person-to-place exposures. This webinar will provide an overview of how MicrobeTrace can be used in the COVID-19 response and will present examples of how MicrobeTrace has been used in investigations of COVID-19 outbreaks in poultry facilities, K-12 schools, institutes of higher education, and nursing homes.

The Department of Education will convene a virtual National Safe School Reopening Summit 3/24/2021 to share best practices, discuss successful prevention and reopening strategies, and learn from students, educators, and other experts. The Summit will offer a forum for researchers and practitioners to discuss strategies for addressing the social, emotional, and academic needs of students—with a focus on those students most underserved—as many schools across the country continue their work to safely reopen. It will also feature experts from Centers for Disease Control and Prevention (CDC) and the U.S. Department of Education who will discuss how schools can safely reopen and how the Biden Administration is providing support and resources to schools, educators, and students as they work to reopen safely and address student needs. Agenda and registration can be found at Agenda - National Safe School Reopening Summit (cvent.com)

The Department is launching the "Safer Schools and Campuses Best Practices Clearinghouse" called for in President Biden's Executive Order, starting with the "Lessons from the Field" webinar series. The Clearinghouse will highlight lessons learned and best practices that can help schools and districts identify opportunities to best utilize American Rescue Plan funds to meet their unique needs. The Clearinghouse will include resources that target the needs of students and teachers, faculty and staff in early childhood programs, K-12 schools, and colleges and universities in three main areas:

- **Safe and Healthy Environments:** School and campus approaches to implementing the Centers for Disease Control and Prevention's (CDC) recommended prevention strategies and preparing for and sustaining in-person operations safely.
- **Providing Supports to Students:** School and campus strategies to meet student social, emotional, mental health, academic, financial, and other needs, including access to food and other basic needs.
- **Teacher, Faculty, and Staff Well-Being, Professional Development, and Supports:** School and campus strategies to address the social, emotional, health, and other needs of teachers, faculty, and staff.

The Clearinghouse's "Lessons from the Field" webinar series will begin on March 31. The Department welcomes lessons learned and best practices from the field for consideration for the Clearinghouse, including those with an educational equity focus. Submissions should be sent via email to: Bestpracticesclearinghouse@ed.gov. Please visit https://bestpracticesclearinghouse.ed.gov/ for more information about the Clearinghouse.

The Department will release Volume 2 of the K-12 COVID-19 Handbook for districts, schools, and educators in early April. This volume will provide research-based strategies to address the impact of COVID-19 on students, educators, and staff, especially for historically underserved students and communities that have been hit hardest by the pandemic. In February, the Department released the first volume of the COVID-19 Handbook, which provided educators and staff with practical examples, roadmaps, and tools to implement CDC's K-12 operational strategy for in-person learning, including the recommended five key prevention measures. Since the release of Volume 1, the Department and CDC have transmitted the handbook and offered technical assistance to educators; state and local elected officials in every state and

territory, including governors, chief state school officers, state boards of education, state legislative leaders and staff, mayors, and superintendents; and thousands of stakeholder organizations across the country.

To: Baker, Michael (OS/IEA) <Michael.Baker@hhs.gov>
Subject: HHS COVID-19 Update - 3/22

Dear Partner—

HHS Office of Intergovernmental and External Affairs COVID-19 update for March 22, 2021:

Highlights from Friday and Monday's White House COVID-19 Response Team briefings:

Jeff Zients:

- **Increasing Vaccine Supply:** The President has taken aggressive action to move up the production timelines for all three vaccines — Pfizer, Moderna, and Johnson & Johnson. As a result, by the end of May, we will have enough vaccine for every adult in the United States. This week, about 22 million doses went out to states, Tribes, and territories, and through the federal channels, including pharmacies and community health centers.
- **Increasing the Number of Vaccinators:** The Administration has deployed nearly 6,000 federal personnel to serve as vaccinators and support vaccinations, including over 2,000 active-duty military men and women. At the President's direction, that number will grow to more than 6,000 active-duty troops over the coming weeks.
- **Increasing the Number of Places to get Vaccinated**: The Administration has provided federal support for more than 600 community vaccination sites and more than 1 million shots have been administered at federally run community vaccination sites across the country with more than 60 percent of those vaccinations administered to minority populations. The American Rescue Plan will allow the Administration to continue to increase the number of community vaccination centers. The Administration is already sending vaccines directly to 250 community health centers and by the end of April, vaccines will be delivered to an additional 700 community health centers.
- **Global Efforts to Address the Pandemic**: Under the President's direction, the U.S. reengaged with the World Health Organization on day one of his presidency and the Administration is committed to providing the most funding to COVAX than any country in the world: $4 billion. We are also announcing that we are loaning about 4 million doses of our releasable AstraZeneca vaccines to Mexico and to Canada. This loan will not reduce the available supply of vaccines to Americans. The doses we are loaning are not approved for use in the United States. No American will be without a vaccine because of this action.

Andy Slavitt

- **Number of People Vaccinated:** This weekend was the first time that the U.S. reported vaccinating more than 3 million people on consecutive days. There are now a total of 81 million people — or nearly 1 in 3 adults — with at least one vaccine dose in the U.S., and 44 million who are fully vaccinated. Nearly 69 percent of seniors have now received their first vaccination, and 42 percent are fully vaccinated.
- **Federal Vaccination Sites:** Today, the state of Washington will receive its first federally-supported community vaccination site. The Yakima County CVC will be able to offer up to 1,200 shots per day. Local residents will be able to drive through the Central Washington State Fair Park and get a shot. This is the 22nd federally run vaccination site opened. Combined, they deliver nearly 100,000 shots per day.

Dr. Walensky:

- **Case Update:** The most recent seven-day average is about 53,800 cases per day, which is a slight increase from the previous seven-day period. And over the past two weeks, cases have continued to fluctuate somewhere between 50,000 and 60,000 daily cases. Hospital admissions have been relatively stable over the last two weeks, hovering around 4,500 to 5,000 admissions per day and deaths continue to decline with slightly under 1,000 deaths per day, but the rate of decline in deaths has slowed which is concerning.
- **Variant Spread:** Increasingly, states are seeing a growing proportion of their COVID-19 cases attributed to variants. The newly identified variant, B1427/B1429, is estimated to account for 52 percent of cases in California, 41 percent in Nevada, and 25 percent in Arizona. And the B117 variant is estimated to be responsible for 9 percent of cases in New Jersey and 8 percent in Florida.
- **Avoiding a Surge:** Taken together, these statistics should serve as a warning sign for the American people. As I've stated before, the continued relaxation of prevention measures while cases are still high, and while concerning variants are spreading rapidly throughout the United States, is a serious threat to the progress we have made as a nation. I'm calling the American people to action, whether vaccinated or not, to recommit to doing the right thing. Take the steps we know work to stop COVID-19: Wear a well-fitted mask, socially distant, avoid crowds and travel, and be ready to roll up your sleeve to get vaccinated when the vaccine is available to you.
- **Science on Safe Reopening of Schools:** Safe in-person instruction gives our children access to the critical, social, and mental health services that prepare them for the future, in addition to the vital educational needs that they need to succeed. Last week, the Journal of Clinical Infectious Diseases published a study that looked at COVID-19 in 251 Massachusetts school districts over a four-month period of time. It found that physical distancing of at least three feet between students could safely be adopted in school settings when everyone — students and staff — wore a mask at all times. CDC published additional studies that add to this evidence base (see below). Overall, all of the studies found that layered mitigation strategies, including strict use of masks among students and a distance of at least three feet between students, were common factors among the schools in these studies that demonstrated decreased transmission from COVID-19. This additional evidence continues to underscore why it is so important for schools to use layered prevention strategies to provide the greatest level of protection.
- **Updated CDC Guidance on School Reopening:** CDC updated their recommendations for physical distancing between students and classrooms in our K-12 operational strategy. Specifically, in elementary schools, CDC is now recommending that all students remain at least three feet apart in classrooms where everyone is wearing a mask, regardless of whether community COVID-19 risk is low, moderate, substantial, or high. In middle and high schools, CDC is also recommending that students be at least three feet apart in classrooms where everyone is wearing a mask and the community level of risk is low, moderate, or substantial. CDC recommends that middle and high school students should be at least six feet apart in communities where COVID 19 risk is high, unless cohorting (when groups of students are kept together with the same peers and staff, without close interaction with other groups or cohorts) is possible.

Dr. Fauci:

- **B.1.1.7 Variant (UK Variant):** The UK variant likely accounts now for about 20 to 30 percent of the infections in this country, and that number is growing. Of concern is that there are about 50 percent increase in transmission with this particular variant that has been documented in the UK, and there's likely an increase in severity of disease if infected with this variant. The way we can counter 117,

which is a growing threat in our country, is to do two things: to get as many people vaccinated as quickly and as expeditiously as possible with the vaccine that we know works against this variant; and finally, to implement the public health measures: masking, physical distancing, and avoiding congregate settings, particularly indoors.

- **Results from AstraZeneca Trial:** The vector that is used in this platform is a chimp adenovirus in which the SARs-CoV spike protein DNA was inserted (similar to Johnson & Johnson vaccine). Their efficacy data showed: 78.9 percent vaccine efficacy of preventing symptomatic disease; importantly, with regard to severe or critical disease requiring hospitalization, there was zero in the vaccine arm and five in the placebo arm. The good news is also that there was comparable efficacy across ethnicity and age; namely, a very good efficacy — 79.9 percent — in participants who are 65 years of age or older. The vaccine was well-tolerated, and the Data and Safety Monitoring Board identified no specific safety concerns related to the vaccines. Importantly, and this is a quote from the DSMB, "No evidence of disproportionate risk of thrombosis or events characterized by thrombosis among the 21,583 participants who received at least one dose. An in-depth search of the database for venous thrombosis revealed no events in this study." Importantly, this vaccine can be stored, transported, and handled at refrigerator temperatures for at least six months. And also, importantly, conditional marketing authorization or emergency use is already in play in more than 70 countries across six continents, and it has been given emergency use listing by the WHO.

Vaccine Updates

Investigational AstraZeneca Vaccine Prevents COVID-19: Results from a large clinical trial in the United States and South America indicate that AstraZeneca's COVID-19 vaccine, AZD1222, is well-tolerated and protects against symptomatic COVID-19 disease, including severe disease or hospitalization. The independent Data and Safety Monitoring Board (DSMB) overseeing the trial identified no safety concerns related to the vaccine. The United Kingdom-based global biopharmaceutical company AstraZeneca developed the vaccine and led the trial as regulatory sponsor.

Vaccines and Health Departments. This page provides states, tribes, localities, and territories health facilities with key resources on COVID-19 vaccination information including operational guidance, funding, reporting, training and more. As the COVID-19 vaccination program is implemented across the United States, jurisdictions and organizations confront this historic and challenging undertaking, tailoring programs to their population's needs. Learn about their unique approaches to distributing the COVID-19 vaccine and educating their populations.

Use of Social Media to Engage Long-Term Care Residents: As COVID-19 vaccines roll out across the country, states continue to find ways to communicate with their communities and citizens about COVID-19, including the importance of getting vaccinated. The need to keep physically distant from one another has presented unique challenges for talking with people about the importance of vaccination. The Connecticut Long Term Care Ombudsman Program (LTCOP) turned to social media to educate and answer questions about the COVID-19 vaccine.

Vaccination for Communities: CDC updated their resources and information on COVID-19 vaccinations for communities.

Vaccines for Disproportionally Affected Communities: CDC updated their resources for disproportionately affected communities. View vaccination FAQs for people experiencing homelessness.

Vaccines for Long-Term Care Facilities: CDC updated their resources and information on COVID-19 vaccinations for long-term care facilities. View information for long-term care facilities (LTCFs) to prepare staff, residents, and their families for COVID-19 vaccination.

Testing

Machine Learning-Based Screening Device to Identify Certain Biomarkers: The FDA issued an emergency use authorization (EUA) for the first machine learning-based Coronavirus Disease 2019 (COVID-19) non-diagnostic screening device that identifies certain biomarkers that are indicative of some types of conditions, such as hypercoagulation (a condition causing blood to clot more easily than normal). The Tiger Tech COVID Plus Monitor is intended for use by trained personnel to help prevent exposure to and spread of SARS-CoV-2, the virus that causes COVID-19. The device identifies certain biomarkers that may be indicative of SARS-CoV-2 infection as well as other hypercoagulable conditions (such as sepsis or cancer) or hyper-inflammatory states (such as severe allergic reactions), in asymptomatic individuals over the age of 5. The Tiger Tech COVID Plus Monitor is designed for use following a temperature reading that does not meet criteria for fever in settings where temperature check is being conducted in accordance with Centers for Disease Control and Prevention (CDC) and local institutional infection prevention and control guidelines. This device is not a substitute for a COVID-19 diagnostic test and is not intended for use in individuals with symptoms of COVID-19.

Screening for COVID-19: The FDA posted a new web page on FDA.gov, screening for COVID-19: deciding which test to use when establishing testing programs. This resource is intended for schools, workplaces, communities and others looking to establish testing programs to screen people without symptoms and with no known or suspected exposure to COVID-19. The FDA also posted a new template for test developers to help facilitate submission of an emergency use authorization (EUA) request for certain COVID-19 tests for screening using a serial testing approach.

Testing updates: As of Friday, 341 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs). These include 254 molecular tests and sample collection devices, 72 antibody and other immune response tests, and 15 antigen tests. There are 38 molecular authorizations that can be used with home-collected samples. There is one molecular prescription at-home test, two antigen prescription at-home test, one over-the-counter (OTC) at-home antigen test, and one OTC molecular test.

Treatment

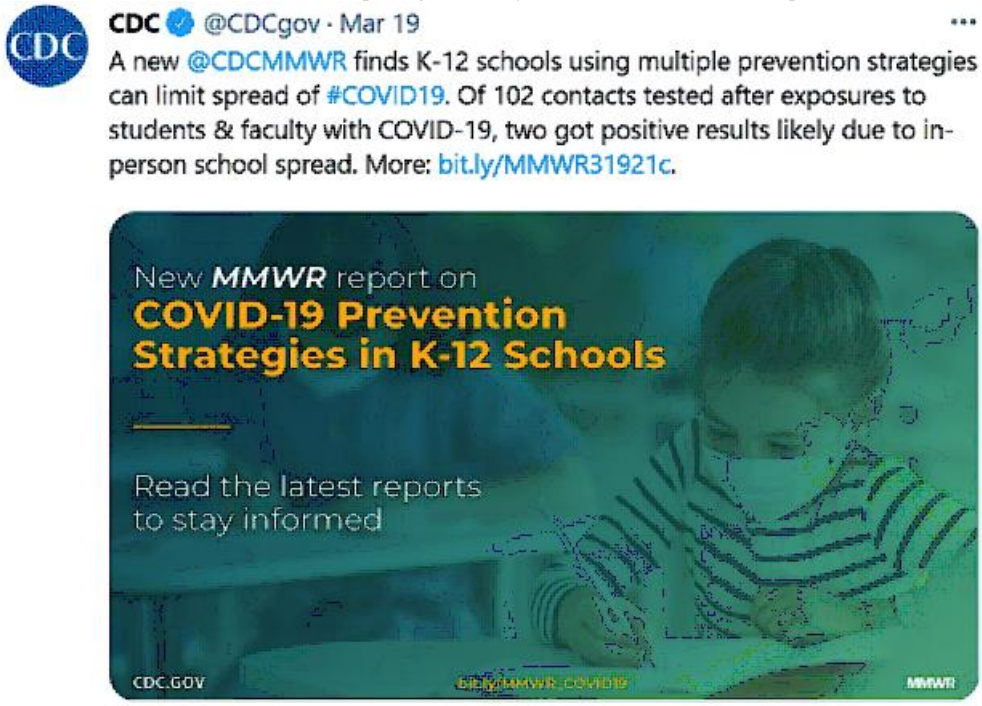
Monoclonal Antibodies' Responses to Variants: The FDA authorized revised fact sheets for health providers on March 18. The fact sheets now include additional information on susceptibility of specific SARS-CoV-2 variants to each of the three monoclonal antibody (mAb) therapies authorized for treating mild-to-moderate COVID-19 in at-risk patients: bamlanivimab, bamlanivimab with etesevimab, and casirivimab with imdevimab. Resistance by a variant may make a therapy less effective.

- The authorized mAb therapies continue to be available for direct ordering, except where contraindicated.
- Given concerns that the clinical activity of bamlanivimab is impacted by variants B.1.429 and B.1.427, ASPR is limiting distribution of

bamlanivimab to California, Arizona, and Nevada, where these variants are circulating in high numbers.

Reopening Schools Research and Updated Guidance

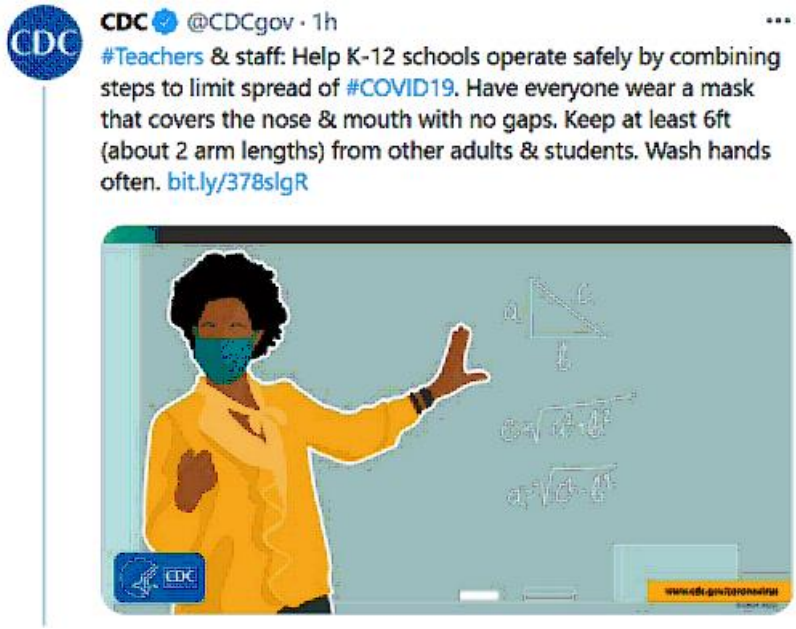
COVID-19 in Primary and Secondary School Settings: CDC released an MMWR on COVID-19 in primary and secondary school settings during the first semester of school reopening. COVID-19 school-related disease incidence among Florida students was correlated with community incidence in the counties observed and was highest in smaller counties, districts without mask requirements, and those that reopened earliest after closure in March 2020. Incidence increased with the proportion of students receiving in-person instruction. Fewer than 1% of registered students were identified as having school-related COVID-19. Both community-level and school-based mitigation measures are important in limiting transmission of COVID-19; school reopening can likely be achieved without widespread student illness in K–12 settings.



Low SARS-CoV-2 Transmission in Elementary Schools: CDC released an MMWR on low SARS-CoV-2 transmission in elementary schools in Salt Lake Country, Utah. SARS-CoV-2 testing was offered to 1,041 school contacts of 51 index patients across 20 elementary schools in Salt Lake County, Utah. In a high community transmission setting, low school-associated transmission was observed with a 0.7% secondary attack rate. Mask adherence was high, but students' classroom seats were <6 ft apart and a median of 3 ft apart. These findings add to evidence that in-person elementary schools can be opened safely with minimal in-school transmission when critical prevention strategies including mask use are implemented, even though maintaining ≥6 ft between students' seats might not be possible.

Investigation of SARS-CoV-2 Secondary Transmission in K-12 Schools: CDC released an MMWR on the pilot investigation of SARS-CoV-2 secondary transmission in Kindergarten through Grade 12 Schools implementing mitigation strategies in St. Louis County and City of Springfield, Missouri. In 22 participating K–12 schools implementing multiple COVID-19 mitigation strategies, school-based SARS-CoV-2 secondary transmission was detected in two of 102 tested close contacts of 37 persons with COVID-19. Among 21 tested student contacts participating in a modified quarantine, all SARS-CoV-2 test results were negative. Schools implementing strategies including mask mandates, physical distancing, and increased ventilation had much lower SARS-CoV-2 transmission than in the community. K–12 schools should continue implementing these measures and following CDC isolation and quarantine guidance to minimize secondary transmission in schools.

K-12 School Operational Strategy: CDC updated their K-12 school operational strategy. These changes include: revised physical distancing recommendations to reflect at least 3 feet between students in classrooms and provide clearer guidance when a greater distance (such as 6 feet) is recommended, clarified that ventilation is a component of strategies to clean and maintain healthy facilities, removed recommendation for physical barriers, clarified the role of community transmission levels in decision-making, and added guidance on interventions when clusters occur. View CDC's guidance and considerations for operating schools during COVID-19.



Transmission of SARS-CoV-2 in K-12 Schools: In the spring of 2020, all public kindergarten to grade 12 (K-12) schools in the United States closed for in-person instruction as a strategy to slow the spread of SARS-CoV-2. With the beginning of the fall term 2020, K-12 schools have variably used several models of instruction, including in-person, virtual, and hybrid models of instruction. Other countries have opened schools at varying points in the pandemic. Their experiences have contributed to our knowledge of the nature of SARS-CoV-2 transmission in schools and their surrounding communities.

Vaccines for Teachers, School Staff, and Childcare Workers: CDC updated their recommendations and information on COVID-19 vaccinations for school staff and childcare workers. On March 2, the U.S. Department of Health and Human Services issued a directive that all states immediately make teachers, school staff, and childcare workers eligible for COVID-19 vaccination across all vaccination providers.

Information for Specific Populations

Alcohol & Substance Use: CDC updated their resources for alcohol and substance use. Increased stress can lead to increases in alcohol and substance use. You may experience increased stress during this pandemic.

Pandemic Planning Scenarios: CDC and the Office of the Assistant Secretary for Preparedness and Response (ASPR) have developed five COVID-19 Pandemic Planning Scenarios that are designed to advance public health preparedness and planning and help inform decisions by public health officials who use mathematical modeling and by mathematical modelers throughout the federal government. A summary of these recent changes include: the Infection Fatality Ratio (IFR) parameter has been updated to reflect recently published estimates, the healthcare utilization statistics in Table 2 have been updated to include a 0–17-years-old age group, and this will be the final update to the COVID-19 Pandemic Planning Scenarios, as there is now a substantial body of published literature that modelers can draw on to inform parameter estimates and assumptions for their models for the general population and for sub-populations of interest.

Handlers of Service & Therapy Animals: CDC updated their guidance for handlers of service and therapy animals. These updates include vaccination and prevention information was added for service animal handlers and their household members.

Animal Testing Guidance: CDC updated their guidance for testing of animals for SARS-CoV-2. This guidance was developed for use by state public health veterinarians, state animal health officials, veterinarians, biologists, and wildlife health specialists.

Use of Inspectional Tools for Ensuring Access to Safe, Quality Food and Medical Products: In a March 18 FDA Voices, FDA leaders explain that over the past year, the agency's approach to foreign and domestic inspections for food and medical products has been both risk-based and deliberate. The COVID-19 pandemic required us to rework our business operations so that we could carry out our public health mission while protecting our workforce, and the workforces of those we regulate.

Non COVID-19 News

HHS Secretary Sworn In: On March 19, Xavier Becerra was sworn in as the 25th Secretary of the Department of Health and Human Services. Follow the Secretary on Twitter at @SecBecerra.

11th Anniversary of the Affordable Care Act: Today, HHS Secretary Xavier Becerra released the following statement on the eve of 11th anniversary of the Affordable Care Act: "In the eleven years since it became law, the Affordable Care Act has saved lives, brought down health care costs, and expanded Medicaid to our most vulnerable neighbors. The lifesaving law has been a game changer, protecting roughly 133 million people with pre-existing conditions and extending quality, affordable health care to millions more… Beginning on April 1, millions of Americans will be eligible for even more affordable options on HealthCare.gov. Because of the American Rescue Plan, four out of five enrollees will be able to qualify for coverage for as little as $10 per month."

Emergency Preparedness & Response

Coronavirus Disease (COVID-19)

From: Centers for Disease Control and Prevention <no-reply@emailupdates.cdc.gov>
Sent: Monday, March 22, 2021 2:00 PM EDT
To: commandcenter@cste.org <commandcenter@cste.org>
Subject: Laboratory Update: CMS Posts FAQ for Reporting Sequencing Results for SARS-CoV-2 Variants

Audience: Facilities Performing Whole Genome Sequencing to Identify SARS- CoV-2 Genetic Variants
Level: Laboratory Update

On March 19, 2021, the U.S. Centers for Medicare & Medicaid Services (CMS) posted the "CLIA SARS-CoV-2 Variant Testing Frequently Asked Question" document to provide information for facilities that perform sequencing to identify SARS- CoV-2 genetic variants.

CMS will not cite CLIA-certified laboratories that perform SARS-CoV-2 genetic variant testing on identified specimens and report patient-specific variant results to state or local public health departments without establishing performance specifications as required by §493.1253(b)(2), provided that the laboratory only reports patient-specific results to a public health department and the results are not intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment.

If at any time the SARS-CoV-2 genetic variant result is intended to be used for purposes of an individual's diagnosis, prevention, treatment, or health assessment, the test must be performed in a CLIA-certified laboratory and in compliance with all applicable CLIA regulations.

Please share this message with your networks and invite them to opt in to LOCS to receive future updates.

Dear Partners,

In late 2020, CDC released a *Science Agenda for COVID-19*, which articulates key areas of scientific inquiry and opportunities to guide the development of actionable, evidence-based public health guidance to limit the spread and impact of SARS-CoV-2 and ultimately end the COVID-19 pandemic. As the evidence base and public health response to the COVID-19 pandemic continues to evolve, this *Science Agenda* has helped promote efforts to fill critical, time-sensitive scientific gaps and to inform evidence-based decision making.

To help achieve the objectives outlined in the *Science Agenda for COVID-19,* CDC initiated an effort during February-March 2021 to systematically identify *Priority Science Questions* that are relevant, actionable near-term, and reflect the evolving needs of the ongoing public health response. On Friday, March 19th, a new set of 19 *Priority Science Questions* will be released, which comprise of content from six major topic areas:

- Variants
- Prevention Strategies and Non-Pharmaceutical Interventions
- Vaccines
- Testing
- Natural History, Reinfection, Health Impacts
- Transmission Risk, Dynamics

Moving forward, these *Priority Science Questions* will be used to help guide prioritization of CDC's scientific research portfolio related to COVID-19, including articles published in *MMWR* and other scientific journals. To that end, these new questions reflect the broad scope of CDC and other public health partner's scientific work related to COVID-19, including surveillance, research, implementation science, and evaluation. Importantly, these questions also serve to expand the evidence base to accelerate progress towards reducing COVID-19 disparities and achieving health equity.

The new set of *Priority Science Questions* will be available on Friday, March 19th, 2021 at 1pm ET at the following link:
https://www.cdc.gov/coronavirus/2019-ncov/more/science-agenda-covid19.html

We hope you will find these questions informative for building the evidence base necessary to further drive public health action and help end the COVID-19 pandemic. If you have any questions related to the *Science Agenda* or the new *Priority Science Questions,* they can be directed to the Strategic Science Unit (SSU) of the CDC COVID-19 Response at: EOCevent538@cdc.gov.

Best regards,
Aliki

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of recent Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

- CDC Travel Planner Public Launch [Attachment]
  - Please see attached for a letter from CDC's Global Migration Task Force announcing the public-facing launch of **CDC Travel Planner**. This web portal serves as a centralized communication platform for COVID-19 travel restrictions and policies enacted by STLT governments. If you have not done so already, add your jurisdiction's information using the instructions listed in the attached letter. You can also promote the Travel Planner using marketing materials linked within.
- CDC Recommendations: "Prioritizing Case Investigations and Contact Tracing for COVID-19 in High Burden Jurisdictions" [Link]
  - Today, CDC released new recommendations for prioritizing case investigations and contact tracing to assist health departments experiencing escalating COVID-19 cases. These new recommendations further refine existing prioritization recommendations and presents new modeling data regarding timeframes to maximize the effectiveness of contact tracing activities.

CDC Guidance: "Considerations for Restaurant and Bar Operators" [Link]

- Released Wednesday, November 18

- White House National State, Local, Tribal COVID-19 Briefing Call [Link]
  - The White House Office of Intergovernmental Affairs (IGA) will host its next weekly briefing call for STLT leaders **Wednesday, December 2** at **1:00 pm EST**. RSVPs will be allocated in the order they are received. To register, click here.
- CDC COCA Call: The Impact of Telehealth on Health Equity from the Perspective of Large Healthcare Systems during the COVID-19 Pandemic [Attachment]
  - CDC Clinician Outreach and Community Activity (COCA) will host a webinar **Tuesday, December 8** at **2:00 pm EST** to discuss how telehealth has affected health equity in their patient populations before and during the COVID-19 pandemic. Presenters from Kaiser Permanente and the Veteran's Health Administration will share strategies to expand access that can reduce disparities and improve culturally responsive care to help achieve health equity within each organization. Call information is below:
    - Weblink: https://www.zoomgov.com/j/1600369650
      Telephone: (669) 254 5252 or (646) 828 7666
      Webinar ID: 160 036 9650
      Post-Event
      Recording: https://emergency.cdc.gov/coca/calls/2020/callinfo_120820.asp
- MMWR Early Release: "The Advisory Committee on Immunization Practices' Ethical Principles for Allocating Initial Supplies of COVID-19 Vaccine — United States, 2020" [Attachment, Link]
  - From the summary: *"In addition to scientific data and implementation feasibility, four ethical principles will assist ACIP in formulating recommendations for the initial allocation of COVID-19 vaccine: 1) maximizing benefits and minimizing harms; 2) promoting justice; 3) mitigating health inequities; and 4) promoting transparency."*
- MMWR Early Release: "COVID-19 Outbreak Associated with a 10-Day Motorcycle Rally in a Neighboring State — Minnesota, August–September 2020" [Attachment, Link]
  - From the summary: *"Following a 10-day motorcycle rally in South Dakota attended by approximately 460,000 persons, 51 confirmed primary event-associated cases, 21 secondary cases, and five tertiary cases were identified in Minnesota residents. An additional nine likely rally-associated secondary or tertiary cases occurred. Four patients were hospitalized, and one died. Genomic sequencing supported the associations with the motorcycle rally."*
- MMWR Early Release: "Trends in County-Level COVID-19 Incidence in Counties With and Without a Mask Mandate — Kansas, June 1–August 23, 2020" [Attachment, Link]
  - From the summary: *"The governor of Kansas issued an executive order requiring wearing masks in public spaces, effective July 3, 2020, which was subject to county authority to opt out. After July 3, COVID-19 incidence decreased in 24 counties with mask mandates but continued to increase in 81 counties without mask mandates."*
- Reminder: CDC Partner Update Call: Resilience and Mental Health for the Holidays [Link]
  - CDC will host a webinar **Monday, November 30** at **3:00 pm EST** focusing on the

upcoming holiday season. Dr. Cliff McDonald will share updates on CDC's COVID-19 response, including the latest scientific information and what everyone should know about protecting themselves and others. Additionally, Dr. Kathleen Ethier will discuss strategies for building resilience and mental health during the COVID-19 pandemic and the holiday season.
    - Registration is available here. Please email questions in advance to eocevent337@cdc.gov with "Partner Call 11/30" in the subject line. The call will be recorded and posted to CDC's website here.
- CDC Response Website Updates [Attachment]
    - for November 13–20
- CDC COVID-19 Science Update [Attachment, Link]
    - Published November 17
- Reminder: Request Form for CSTE COVID-19 Call Topics [Link]

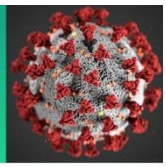
COVID-19 Science Update



From the Office of the Chief Medical Officer, CDC COVID-19 Response, and the CDC Library, Atlanta, GA.
Intended for use by public health professionals responding to the COVID-19 pandemic.

***** Available on-line at https://www.cdc.gov/library/covid19 *****

*****This week and next week the CDC COVID-19 Science Update will only be produced on Tuesday, 11/17 and Tuesday, 11/24. The CDC COVID-19 Science Update will not be produced on Friday, 11/20, or Friday, 11/27.*****

COVID-19 and Return to College

The increase in COVID-19 cases among younger persons points to a need to implement effective mitigation strategies to protect college students returning to campus, as well as the neighboring communities. Six out of 10 colleges and universities re-opened in the fall with in-person classes, either full-time or combined with online classes. Safely bringing students and faculty back to campus will require testing and mitigation measures to prevent SARS-CoV-2 transmission. Optimal testing strategies for in-person classes and variables associated with likelihood of holding in-person classes at colleges and universities are discussed in the following papers.

PEER-REVIEWED

Evaluation of COVID-19 testing strategies for repopulating college and university campuses: A decision tree analysis. Van Pelt *et al.* Journal of Adolescent Health (November 3, 2020).

Key findings:

- Strategies that included RT-PCR testing of in-coming students identified more cases than symptom-based screening alone; however, all strategies failed to detect a portion of the cases.
    - Using only symptom-based screening, less than 50% of true positive cases will be detected.
    - Testing all students on arrival, and again 7 days later, will detect the greatest number of cases.
- At higher prevalence of infection, repeat testing will detect more true positives per test, but will cost more.

Methods: A decision tree analysis was used to evaluate testing strategies for safely repopulating a university with 20,000 students. The analysis evaluated five strategies: (1) classifying students with symptoms as having COVID-19 (no testing); 2) testing done on symptomatic students, (3) testing all students, (4) testing all students and retesting *symptomatic* students with a negative first test, and (5) testing all students and retesting *all* students with a negative first test. Costs estimates for given strategies were estimated. *Limitations:* Disease prevalence was based on national estimates; no analyses of testing strategies later in the semester.

MS-DOH-21-1816-A-002163

PREPRINTS (NOT PEER-REVIEWED)

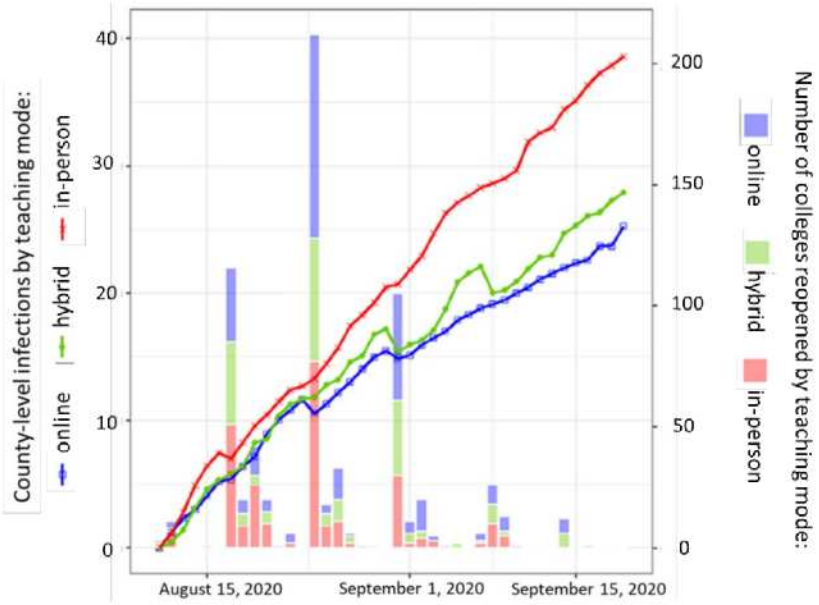
Causal impacts of teaching modality on U.S. COVID-19 spread in fall 2020 semester. Badruddoza & Amin. MedRxiv. (November 3, 2020).

Key findings:

- Reopening colleges was associated with increased COVID-19 cases and deaths.
- Colleges with in-person classes are in counties with rapidly increasing COVID-19 cases (Figure).
    - Daily new COVID-19 cases increased in the fall 2020 semester by 1.87 cases per 100,000 population.
- The variables most strongly associated ($p < 0.05$) with adopting online teaching modes vs in-person enrollment were higher student enrollments, larger endowments per student, being a public (vs private) institution, individual mask policies, and prevalence of specific political party affiliation in the community.
- There was a negative association between the percentage of county residents staying home and disease spread.

Methods: Use of metrics of new daily COVID-19 cases and COVID-19-related deaths in the county to describe the effects of college teaching modality on spread of disease for 745 US institutions and surrounding communities. The probability of choosing each teaching mode was calculated with multinomial logistic regression. *Limitations:* Student-specific infections are not addressed; method for classifying counties with multiple colleges with different teaching modes not explained.

Figure:



Note: From Badruddoza *et al*. County-level growth of COVID-19 cases in counties by teaching modality for in-person, online, or hybrid classes. Opening date for colleges by teaching modality shown in bars from August 10 to September 19, 2020. Licensed under CC-BY-ND 4.0.

Implications for 2 studies (Van Pelt *et al.* and Badurddoza & Amin) These two articles highlight measures that colleges and universities can use to mitigate COVID-19. As discussed in Walke *et al.*, institutional resources, cost of testing, and the possibility of distance learning need to be considered when re-opening schools. These articles show that decisions regarding type of teaching are also influenced by the surrounding communities, such as locally enacted preventative measures and the local political environment. Being aware of these influences may guide administrators in decision-making regarding re-opening campuses.

Immunity

Antibodies to SARS-CoV-2, particularly neutralizing antibodies, appear to wane over time. Long-term protection against SARS-CoV-2 may rely on the maintenance of memory immune cells that quickly re-activate upon secondary infection, primarily B cells that produce antibodies and T cells that help B cells and kill virus-infected cells. The duration of SARS-CoV-2-specific cell-mediated immunity – i.e. immunity not mediated by antibody – is not well understood. Following are two recent pre-print studies examining the longevity of memory B and T cell responses against SARS-CoV-2.

PREPRINTS (NOT PEER-REVIEWED)

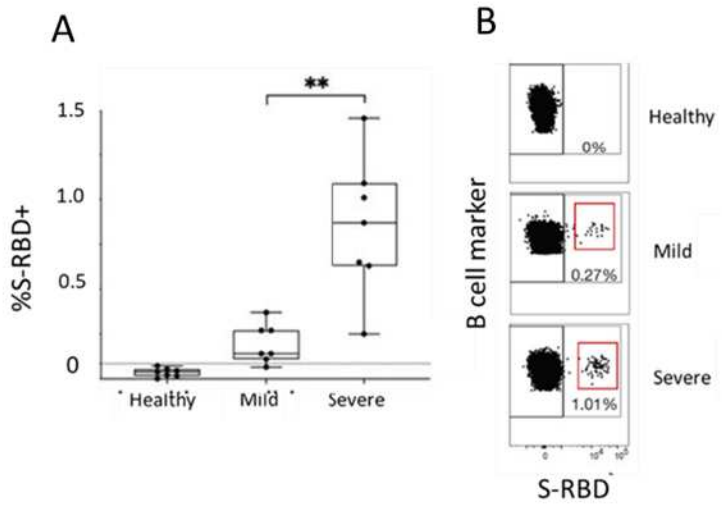
Durable SARS-CoV-2 B cell immunity after mild or severe disease. Ogega *et al.* MedRxiv (October 30, 2020).

Key findings:

- B cells recognizing SARS-CoV-2 spike protein receptor binding domain (S-RBD) were detected in 13 of 14 participants with COVID-19 (Figure, A).
    - Four (57%) of seven patients with mild COVID-19 had S-RBD-specific immature B cells and antibody-secreting cells (ASC) and six (86%) had detectable memory B cells (MBC).
    - 100% of moderate-to-severe COVID-19 patients had S-RBD-specific B cells of all types (immature, ASC, and MBC).
- The frequency of S-RBD specific MBC was significantly higher in patients with moderate-to-severe COVID-19 compared with mild COVID-19 (mean S-RBD+ frequency 0.85% vs. 0.20%, p = 0.004) (Figure, B).
    - The single individual with SARS-CoV-2 infection but without detectable S-RBD-specific MBC was asymptomatic.

Methods: S-RBD-specific B cells from seven ambulatory patients with mild COVID-19 and seven hospitalized patients with moderate-to-severe COVID-19, and cryopreserved cells from healthy blood donors collected prior to the COVID-19 pandemic were evaluated. *Limitations*: Maximum time from symptom onset to B cell sampling was 104 days (median 54 days); small sample size.

Figure:



Note: Adapted from Ogega *et al.* The percent of S-RBD-specific memory B cells from healthy participants, participants with mild-COVID-19, or participants with severe COVID-19. A. Box and whiskers plots show summary of participants (whiskers are minimum to maximum). B. dot plot shows representative data from each group, with **the population of B cells binding to S-RBD highlighted in the box**. ** Indicates p ≤0.01. Licensed under CC-BY-ND 4.0.

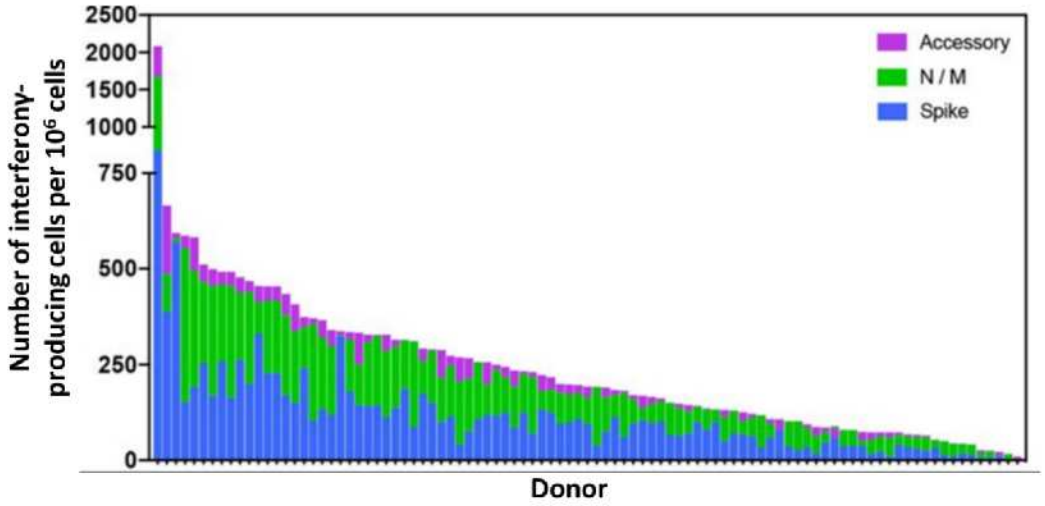
Robust SARS-CoV-2-specific T cell immunity is maintained at 6 months following primary infection. Zuo *et al.* BioRxiv (November 2, 2020).

Key findings:

- Evidence of SARS-CoV-2-specific T cell responses was found in all donors at 6 months (Figure).
- Median T cell responses were 50% higher in donors who had symptomatic infection compared with asymptomatic infection.
- T cell responses at six months correlated with peak antibody levels against the SARS-CoV-2 nucleoprotein, receptor binding domain (RBD), and spike proteins.

Methods: Blood samples from 100 convalescent plasma donors were analyzed to characterize the cellular immune response measured by production of interferon-γ six months after SARS-CoV-2 infection, and to measure peak antibody levels against SARS-CoV-2 nucleoprotein, RBD, and spike proteins. *Limitations*: No assessment of immune responses beyond six months.

Figure:



Note: Adapted from Zuo *et al.* Cellular response against SARS-CoV-2 proteins (spike, nucleoprotein/membrane proteins [N/M], and a pool of other SARS-CoV-2 peptides [accessory]) at six months following primary infection. Licensed under CC-BY-ND 4.0.

Implications for 2 studies (Ogega *et al.* & Zuo *et al.*): Memory B and T cells could provide durable immunity to SARS-CoV-2 even after serum antibodies decline, particularly in symptomatic individuals. A commentary from Wise, J. highlights that durable T cell responses against a range of SARS-CoV-2 proteins might point to potential new vaccine targets.

Epidemiology

PEER-REVIEWED

Transmission of SARS-CoV-2 on mink farms between humans and mink and back to humans. Munnink *et al.* Science (November 10, 2020).

Key findings:

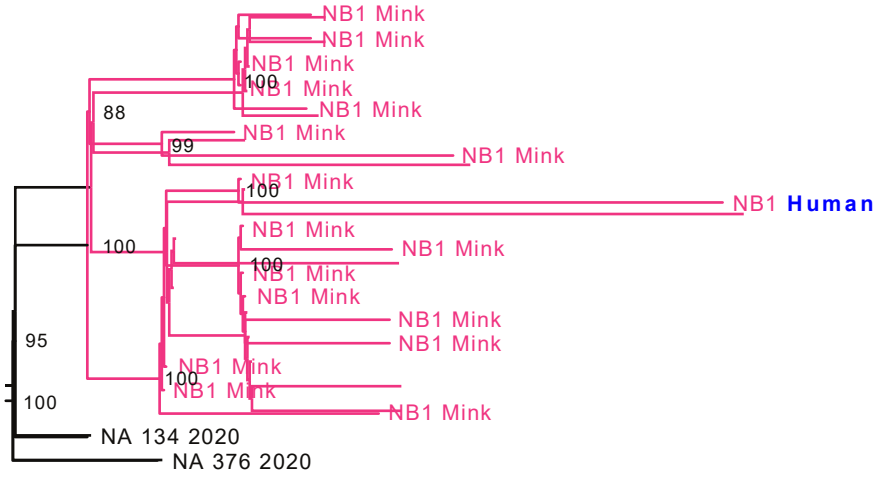
- Of 97 mink farm employees tested, 43/88 (49%) were positive by RT-PCR, 38/75 (51%) had detectable antibodies, and 66/97 (67%) had evidence of SARS-CoV-2 infection by RT-PCR or serology.
- The mink and human strains clustered closely together (Figure).

    - There was greater phylogenetic relatedness between farm-related human and mink cases than between farm-related human and community cases within the same postal code.
- Potential mink-to-human transmitted SARS-CoV-2 infections did not have differences in signs, duration, or severity compared with human-to-human transmitted infections.

Methods: Outbreak investigations were performed when respiratory signs and increased mortality for minks were reported to the Dutch Agriculture authorities. Investigations at 16 mink farms sought to identify the source of the outbreak, trace contacts and track movement of animals, vehicles, and people. SARS-CoV-2 diagnostic testing for mink and human samples was performed using RT-PCR and by antibody testing. Viral genomes were sequenced for PCR-positive samples with Ct values ≤32. *Limitations*: The investigation could not exclude the role that exposures from untested animals or humans might have played in transmission; temporary farm workers not tested.

Implications: SARS-CoV-2 outbreaks in mink farms are well-documented and resulted in recently-abandoned plans to cull Denmark's 17 million minks. This paper provides phylogenetic data suggestive of mink-to-human SARS-CoV-2 transmission; however, directionality of transmission is challenging to definitively demonstrate using phylogenetics. Concerns about potential mutations in SARS-CoV-2 from animal-to-human transmission that may lead to more rapid spread or jeopardize vaccine efficacy may be premature.

Figure:



Note: Adapted from Munnink *et al*. Phylogenetic tree of **mink** and **human** sequences found in a single farm (NB1) and the closest matching human sequences from the **national SARS-CoV-2 database** (NA 134 2020, and NA 376 2020). Numbers in black represent the bootstrapping values using all Dutch SARS-CoV-2 sequences. Permission request in process.

Repeated cross-sectional sero-monitoring of SARS-CoV-2 in New York City. Stadlbauer *et al.* Nature (November 3, 2020).

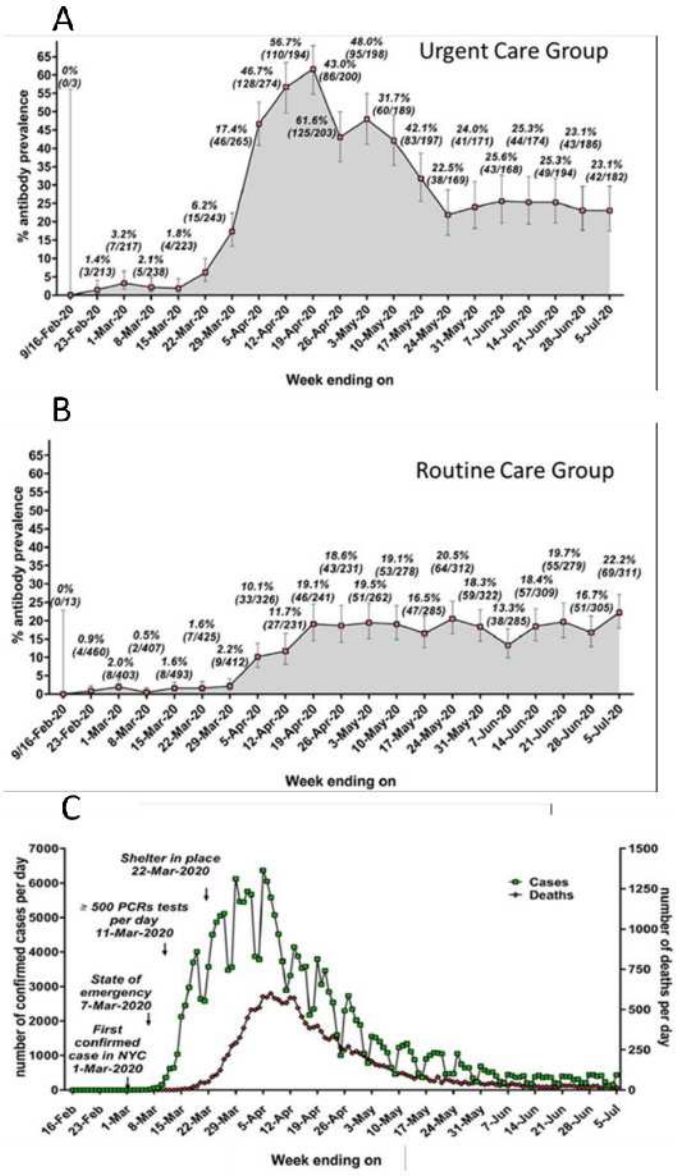
Key findings:

- A rapid rise in SARS-CoV-2 seroprevalence (6.2%) was detected in the urgent care (UC) group (Figure, A) compared with the routine care (RC) group, coinciding with the surge of new confirmed SARS-CoV-2 infections and related hospitalizations in New York City.
    - The uptick in seropositivity lagged approximately 1–2 weeks behind the increase in new cases (Figure A, C).
- There was a longer delay between the increase in confirmed cases and the increase in seroprevalence in the RC group (Figure B, C).
- Seroprevalence in the UC group declined to levels seen in the RC group coinciding with a drop in incidence of SARS-CoV-2 cases between May and July 2020 (Figures A, C).

Methods: Weekly cross-sectional analysis of anti-SARS-CoV-2 spike antibodies on 10,691 plasma samples randomly collected from patients at Mount Sinai Hospital in New York City from February 9 to July 5, 2020. Seroprevalence was compared between an UC group (meant to capture seropositive individuals) and a RC group (meant to capture visits unrelated to COVID-19 and resemble the general population). ***Limitations***: Non-random, non-representative sampling.

Implications: This will be the first of a series of repeated cross-sectional seroprevalence studies to understand the dynamics of SARS-CoV-2 transmission, seroconversion, and the stability of antibody responses over the course of a COVID-19 outbreak.

Figure:



Note: Adapted from Stadlbauer *et al.* Serum antibody prevalence in the UC group **(A)** and in the RC group **(B)**, and **number of confirmed cases/day** and **number of deaths per day,** February–July 2020 **(C)**. Permission request in process.

Outcomes of contact tracing in San Francisco, California—test and trace during shelter-in-place. Sachdev *et al.* JAMA Internal Medicine (November 2, 2020).

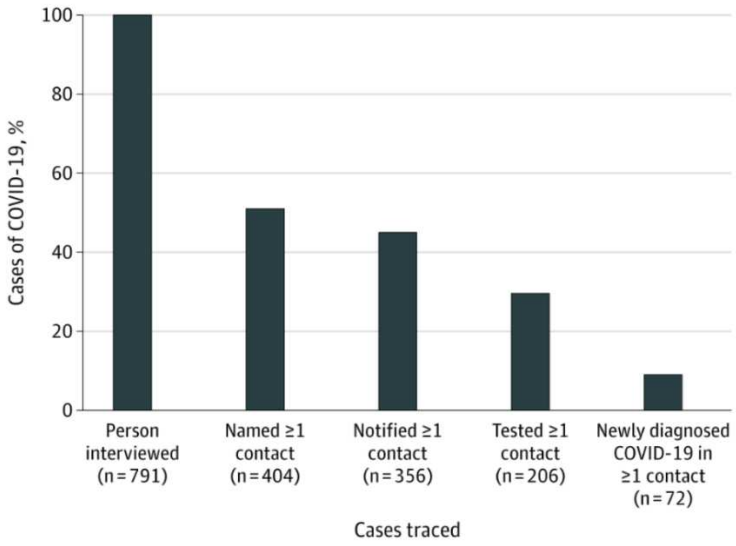
Key findings:

- COVID-19 contact tracing program reached more than 85.4% of cases (Figure) and 83.8% of contacts.
- The secondary attack rate was higher among household compared with non-household contacts (111 of 983 [11.3%] and 9 of 231 [3.9%], respectively; p <0.001).
- Median time from symptom onset for a case to notifying and testing the contact was 6 days.
    - The median time from symptom onset to receipt of test results was 5 days.
    - Case interviews occurred on average 1 day after the test result and the first contact was notified on average 1 day after that.

Methods: Case investigation and contact tracing for 1,394 COVID-19 cases identified in San Francisco, California between April 13 and June 8, 2020. The study period included dates after which universal testing for COVID-19 contacts, regardless of symptoms, was recommended. The proportion of people who were interviewed and for whom close contacts were identified, with at least 1 contact being notified, was calculated. Median number of days (with IQR) taken to process each step was reported. *Limitations*: Underreporting of close contacts.

Implications: In order to maximize the impact of contact tracing on mitigating the spread of COVID-19, metrics such as these are needed, and efforts must be made to address testing delays and to improve contact identification.

Figure:



Note: Adapted from Sachdev *et al*. Percentages for people with COVID-19 at selected stages of contact tracing implementation. Reproduced with permission from JAMA Internal Medicine. Sachdev *et al.*, Outcomes of contact tracing in San Francisco, California—test and trace during shelter-in-place. DOI:10.1001/jamainternmed.2020.5670. Copyright© 2020 American Medical Association. Proportion of asymptomatic infection among COVID-19 positive persons and their transmission potential: A systematic review and meta-analysis. Yanes-Lane *et al.* PLOS One (November 7, 2020).

Key findings:

- 24 studies report that the proportion of asymptomatic individuals among individuals testing positive for SARS-CoV-2 ranged from:
  - 20%–75% for the general population.
  - 8.2%–50% for contacts of known cases.
  - 45%–100% of obstetric patients presenting to hospitals.
  - 42%–66.7% of nursing home residents; 0%–50% of nursing home staff.
  - 50%–87.8% in congregate settings such as temporary homeless shelter.
  - 76.2% of retail workers (single study).
- 18.8% (18/96) of contacts of asymptomatic index patients were SARS-CoV-2 positive in pooled analysis of 5 transmission studies.

Methods: Review of 28 moderate or high-quality studies systematically testing for COVID-19 through June 22, 2020, assessing the proportion of infections occurring in asymptomatic individuals and transmission. *Limitations*: Included mainly small studies of people with COVID-19 (n <100), limiting estimate precision; contact tracing in studies was limited which may bias the results; study heterogeneity limited ability to analyze by age group or sex.

Implications: The proportion of asymptomatic infections appears high in many groups. As asymptomatic individuals may have considerable transmission potential, symptom-based testing is insufficient to eliminate transmission. High quality studies in representative general population samples are needed to better understand the role of asymptomatic individuals in the transmission of SARS-CoV-2.

Diagnostics

Antigen (Ag) tests may provide an easier point-of-care alternative to RT-PCR testing to detect infected individuals by detecting SARS-CoV-2 proteins rather than RNA. The Abbott BinaxNOW™ COVID-19 Ag Card (Binax-CoV2) is a 15-minute test that recently received an emergency use authorization by the US Food and Drug Administration for testing symptomatic individuals for SARS-CoV-2 infection. The US Department of Health and Human Services has ordered 150 million Binax-CoV2 rapid antigen tests, many of which are targeted for high-risk settings.

PREPRINTS (NOT PEER-REVIEWED)

Performance characteristics of a rapid SARS-CoV-2 antigen detection assay at a public plaza testing site in San Francisco. Pilarowski *et al.* MedRxiv (posted November 12, 2020).

Key findings:

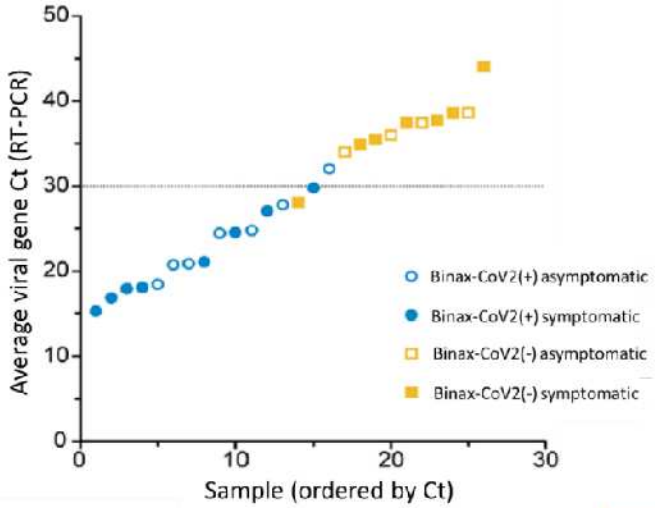
- Criteria for a positive test for the Binax-CoV2 rapid Ag test had to be adjusted when used to screen asymptomatic individuals.
  - When using the manufacturer's recommendation to read any line as "positive," 9 (64%) of 14 Binax-CoV2-positive tests were likely false positives.
- Performance in asymptomatic subjects improved when a positive result was defined as a band extending the full width of the testing strip, regardless of intensity.
  - Sensitivity was 93.8% (95% CI 68.1%-99.8%, n = 16) and specificity was 100%, (95% CI 99.6%-100%, n = 855).
- Samples with false negative Binax-CoV2 tests had low viral loads (high Ct values) (Figure).

Methods: In September 2020, 878 people participated in testing in San Francisco, CA. Binax-CoV2 cards were read by 2 independent observers with a third on hand to be a "tie-breaker." Lab confirmation was done via RT-PCR

testing. *Limitations*: The Binax-CoV2 Ag test currently is validated on symptomatic COVID-19 patients, full validation on asymptomatic individuals has not been done.

Implications: Since the Binax-CoV2 rapid test may be used to screen asymptomatic individuals, the data shown here will be critical in establishing guidance for validating this use case. Manabe *et al.* outline the need for screening tests that can rapidly identify infectious individuals to prevent outbreaks.

Figure:



Note: Adapted from Pilarowski *et al.* Average Ct from all 26 RT-PCR-positive participants for **Binax-CoV2(+)** and **Binax-CoV2(-)** participants with and without symptoms. Licensed under CC-BY-NC-ND 4.0.

The Advisory Committee on Immunization Practices' Ethical Principles for Allocating Initial Supplies of COVID-19 Vaccine — United States, 2020

Nancy McClung, PhD[1]; Mary Chamberland, MD[1,2]; Kathy Kinlaw, MDiv[3]; Dayna Bowen Matthew, JD, PhD[4]; Megan Wallace, DrPH[1,5]; Beth P. Bell, MD[6]; Grace M. Lee, MD[7]; H. Keipp Talbot, MD[8]; José R. Romero, MD[9]; Sara E. Oliver, MD[1]; Kathleen Dooling, MD[1]

To reduce the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19) and its associated impacts on health and society, COVID-19 vaccines are essential. The U.S. government is working to produce and deliver safe and effective COVID-19 vaccines for the entire U.S. population. The Advisory Committee on Immunization Practices (ACIP)* has broadly outlined its approach for developing recommendations for the use of each COVID-19 vaccine authorized or approved by the Food and Drug Administration (FDA) for Emergency Use Authorization or licensure (*1*). ACIP's recommendation process includes an explicit and transparent evidence-based method for assessing a vaccine's safety and efficacy as well as consideration of other factors, including implementation (*2*). Because the initial supply of vaccine will likely be limited, ACIP will also recommend which groups should receive the earliest allocations of vaccine. The ACIP COVID-19 Vaccines Work Group and consultants with expertise in ethics and health equity considered external expert committee reports and published literature and deliberated the ethical issues associated with COVID-19 vaccine allocation decisions. The purpose of this report is to describe the four ethical principles that will assist ACIP in formulating recommendations for the allocation of COVID-19 vaccine while supply is limited, in addition to scientific data and implementation feasibility: 1) maximize benefits and minimize harms; 2) promote justice; 3) mitigate health inequities; and 4) promote transparency. These principles can also aid state, tribal, local, and territorial public health authorities as they develop vaccine implementation strategies within their own communities based on ACIP recommendations.

The ACIP COVID-19 Vaccines Work Group has met several times per month (approximately 25 meetings) since its establishment in April 2020. Work Group discussions included review of the epidemiology of COVID-19 and consultation with experts in ethics and health equity to inform the development of an ethically principled decision-making process. The Work Group reviewed the relevant literature, including frameworks for pandemic influenza planning and COVID-19 vaccine allocation (*3*–*8*); summarized this information; and presented it to ACIP. ACIP supported four fundamental ethical principles to guide COVID-19 vaccine allocation decisions in the setting of a constrained supply. Essential questions that derive from these principles can assist in vaccine allocation planning (Table 1).

Maximize benefits and minimize harms. Allocation of COVID-19 vaccine should maximize the benefits of vaccination to both individual recipients and the population overall. These benefits include the reduction of SARS-CoV-2 infections and COVID-19–associated morbidity and mortality, which in turn reduces the burden on strained health care capacity and facilities; preservation of services essential to the COVID-19 response; and maintenance of overall societal functioning. Identification of groups whose receipt of the vaccine would lead to the greatest benefit should be based on scientific evidence, accounting for those at highest risk for SARS-CoV-2 infection or severe COVID-19–related disease or death, and the essential role of certain workers. The ability of essential workers, including health care workers and non–health care

*The ACIP includes 15 voting members responsible for making vaccine recommendations. Fourteen of the members have expertise in vaccinology, immunology, pediatrics, internal medicine, nursing, family medicine, virology, public health, infectious diseases, and/or preventive medicine; one member is a consumer representative who provides perspectives on the social and community aspects of vaccination. In addition to the 15 voting members, ACIP includes eight ex officio members who represent other federal agencies with responsibility for immunization programs in the United States, and 30 nonvoting representatives of liaison organizations that bring related immunization expertise. https://www.cdc.gov/vaccines/acip/members/index.html.

MS-DOH-21-1816-A-002178

TABLE 1. Essential questions for COVID-19 vaccine allocation planning related to ethical principles — United States, 2020

Ethical principle	Essential question
Maximize benefits and minimize harms	What groups are at highest risk for SARS-CoV-2 infection, COVID-19 disease, hospitalization, and death?
	What groups are essential to the COVID-19 response?
	What groups are essential to maintaining critical functions of society?
	What are the important characteristics of these groups (e.g., size or geographic distribution) that might inform the magnitude of benefit based on the amount of vaccine available or its characteristics?
Promote justice	Does the allocation plan result in fair and equitable access of the vaccine for all groups?
	How do characteristics of the vaccine and logistical considerations affect fair access for all persons?
	Does allocation planning include input from groups who are disproportionately affected by COVID-19 or face health inequities resulting from social determinants of health, such as income and health care access?
Mitigate health inequities	Does the plan identify and address barriers to vaccination among any groups who are disproportionately affected by COVID-19 or who face health inequities resulting from social determinants of health, such as income and health care access?
	Does the allocation plan contribute to a reduction in health disparities in COVID-19 disease and death?
	What health inequities might inadvertently result from the allocation plan, and what interventions could remove or reduce them?
	Is there a mechanism for timely assessment of vaccination coverage among groups experiencing disadvantage and the possibility for course correction if inequities are identified?
Promote transparency	How does development of the allocation plan include diverse input, and if possible, public engagement?
	Are the allocation plan and evidence-based methods publicly available?
	Is the allocation plan clear about what is known and unknown and about the quality of available evidence?
	What is the process for revision of allocation plans based on new information?
	Is there a mechanism to report demographic data elements for vaccine recipients (e.g., age, race/ethnicity, and occupation) to support equitable vaccination coverage?

Abbreviation: COVID-19 = coronavirus disease 2019.

workers, to remain healthy has a multiplier effect (i.e., their ability to remain healthy helps to protect the health of others or to minimize societal and economic disruption). Some of these workers are at increased risk for SARS-CoV-2 infection because of their limited ability to maintain physical distance in the workplace or because they do not have consistent access to recommended personal protective equipment.

Promote justice. Inherent in the principle of justice is an obligation to protect and advance equal opportunity for all persons to enjoy the maximal health and well-being possible. Justice rests on the belief in the fundamental value and dignity of all persons. Allocation of COVID-19 vaccine should promote justice by intentionally ensuring that all persons have equal opportunity to be vaccinated, both within the groups recommended for initial vaccination, and as vaccine becomes more widely available. This includes a commitment to removing unfair, unjust, and avoidable barriers to vaccination that disproportionately affect groups that have been economically or socially marginalized, as well as a fair and consistent implementation process. Input from a range of external entities, partners, and community representatives is particularly important in developing and assessing allocation plans.

Mitigate health inequities. Health equity is achieved when every person has the opportunity to attain his or her full health potential and no one is disadvantaged from achieving this potential because of social position or other socially determined circumstances.[†] Disparities in the severity of COVID-19 and COVID-19–related death, as well as inequities in social determinants of health that are linked to COVID-19 risk, such as income or health care access and utilization, are well documented among certain racial and ethnic minority groups (*9*). Vaccine allocation strategies should aim to both reduce existing disparities and to not create new disparities. Efforts should be made to identify and remove obstacles and barriers to receiving COVID-19 vaccine, including limited access to health care or residence in rural, hard-to-reach areas.

Promote transparency. Transparency relates to the decision-making process and is essential to building and maintaining public trust during vaccine program planning and implementation. The underlying principles, decision-making processes, and plans for COVID-19 vaccine allocation must be evidence-based, clear, understandable, and publicly available. To the extent possible, considering the urgency of the COVID-19

[†] https://www.cdc.gov/chronicdisease/healthequity/index.htm.

MS-DOH-21-1816-A-002179

response, public participation in the creation and review of the decision-making process should be facilitated. In addition, when feasible, tracking administration of vaccine to the groups recommended for initial vaccine allocation can contribute to transparency and trust in the process. In an ongoing public health response, the situation continually evolves as new information becomes available. Transparency includes being clear about the level of certainty in the available evidence and communicating new information that might change recommendations in a timely fashion.

For the period when the supply of COVID-19 vaccine will be limited, ACIP has considered four groups for initial vaccine allocation. These include health care personnel, other essential workers, adults with high-risk medical conditions, and adults aged ≥65 years (including residents of long-term care facilities) (Table 2). These groups were selected based on available scientific data, vaccine implementation considerations, and ethical principles. The principle of transparency is applied across the entirety of the vaccine allocation decision-making process. ACIP's meetings are open to the public, meeting minutes and archived webcasts are available online, and data (including data from vaccine clinical trials) and analytic methods used in developing ACIP recommendations are publicly available.[§] Members of the public are invited to submit written comments to the Federal Register or provide oral comment during ACIP meetings. ACIP's 30 nonvoting representatives from liaison organizations facilitate engagement with professional medical and public health organizations and other stakeholders and partners.

All four groups proposed for initial allocation of COVID-19 vaccine merit strong consideration from an ethical perspective. Current planning scenarios estimate, however, that the expected number of doses during the first weeks of vaccine distribution might only be sufficient to vaccinate approximately 20 million persons.[¶] Although there is considerable overlap between groups[**] (*10*), the initial supply will not be adequate to vaccinate the entirety of all four groups; for example, there are approximately 100 million health care personnel and essential workers (Table 2). Published frameworks for COVID-19 allocation and ACIP discussions indicate a clear consensus that the first allocation of COVID-19 vaccine supplies should be directed to health care personnel (*1*,*5*–*8*); discussion of allocation to the other three groups is ongoing. As additional vaccine supplies become available, other groups may be vaccinated concurrent with health care personnel.

[§] https://www.cdc.gov/vaccines/acip/index.html.

[¶] https://www.cdc.gov/vaccines/imz-managers/downloads/COVID-19-Vaccination-Program-Interim_Playbook.pdf.

[**] There is overlap among these four groups. For example, in one analysis, among the 3.8% of U.S. adults who work directly with patients as health care workers, 38.6% have high-risk medical conditions or are aged >65 years.

Discussion

During a pandemic, ethical guidelines can help steer and support decisions around prioritization of limited resources (*3*,*4*). Consideration of ethical values and principles has featured prominently in discussions about allocation of COVID-19 vaccines. This consideration is particularly relevant because the COVID-19 pandemic has highlighted long-standing, systemic health and social inequities. Although various frameworks for COVID-19 vaccine allocation demonstrate differences in their structure (e.g., based on varying combinations of different goals, objectives, criteria, and other structural elements) and emphasis (e.g., inclusion of global and national considerations), nearly all reference values and principles similar to those which ACIP considers fundamental (*5*–*8*). ACIP viewed the following characteristics as critical for its ethical approach to COVID-19 vaccine allocation when supply is limited: simplicity in structure and definitions; acceptability to stakeholders; and ease of application, both at the national and state, tribal, local, and territorial levels.

Allocation of limited vaccine supplies is complicated by efforts to address the multiple goals of a vaccine program, most notably those related to the reduction of morbidity and mortality and the minimization of disruption to society and the economy. If the goals of a pandemic vaccination program are not clearly articulated and prioritized, drawing distinctions between groups that merit consideration for allocation of vaccine when supply is constrained can become difficult. The unanimity in opinion for early vaccination of health care personnel indicates that maintenance of health care capacity has emerged as a high priority in the context of a severe pandemic. This perspective aligns with ethical considerations for pandemic influenza planning (*3*,*4*). If vaccine supply remains constrained, it might be necessary to identify subsets of other groups for subsequent early allocation of COVID-19 vaccine. At the national, state, tribal, local, and territorial levels, such decisions should be guided, in part, by ethical principles and consideration of essential questions, with particular consideration of mitigation of health inequities in persons experiencing disproportionate COVID-19 morbidity and mortality. In the setting of a constrained supply, the benefits of vaccination will be delayed for some persons; however, as supply increases, there will eventually be enough vaccine for everyone.

In addition to ethical considerations, ACIP's recommendations regarding receipt of the initial allocations of COVID-19 vaccine during the period of constrained supply will be based on science (e.g., available information about the vaccine's characteristics such as safety and efficacy in older adults and epidemiologic risk) and feasibility of implementation (e.g., storage and handling requirements). Thus, ACIP's allocation recommendations will

MS-DOH-21-1816-A-002180

TABLE 2. Application of ethical principles to four candidate groups for initial COVID-19 vaccine allocation — United States, 2020

Principles (with transparency across the decision-making process)	Candidate groups* (approximate no.)			
	Health care personnel† (21 million)	**Other essential workers† (87 million)**	**Adults with high-risk medical conditions§ (>100 million)**	**Adults aged ≥65 years (53 million)**
Maximize benefits and minimize harms	Preserves health care services essential to the COVID-19 response and the overall health care system	Preserves services essential to the COVID-19 response and overall functioning of society	Reduces morbidity and mortality in persons with high incidence of COVID-19 disease and death**	Reduces morbidity and mortality in persons with high incidence of COVID-19 disease and death††
	Multiplier effect¶	Multiplier effect¶		
Promote justice	Addresses elevated occupational risk for SARS-CoV-2 exposure for those unable to work from home	Addresses elevated occupational risk for SARS-CoV-2 exposure for those unable to work from home	Will require focused outreach to vaccinate persons in this group who have no or limited access to health care or experience inequities in social determinants of health	Will require focused outreach to vaccinate persons in this group who have no or limited access to health care or experience inequities in social determinants of health
	Promotes access to vaccine across a spectrum of HCP job types and settings	Promotes access to vaccine and reduces barriers to vaccination in occupations with low vaccine uptake§§		
Mitigate health inequities	Racial and ethnic minority groups are disproportionately represented in low-wage HCP¶¶	Racial and ethnic minority groups are disproportionately represented in many essential industries***	Increased prevalence of obesity and diabetes (most prevalent conditions in this group) among some racial and ethnic minority groups; increased prevalence of some medical conditions for persons in rural areas§§§	Although racial and ethnic minority groups are underrepresented among adults aged ≥65 years, certain groups have disproportionate COVID-19–related hospitalization and death rates¶¶¶
		Approximately one quarter of essential workers live in low-income families†††	Could increase health inequities because diagnosis of high-risk medical conditions requires access to health care	Strict age-based criterion could increase disparities due to racial and social inequities, such as occupation, income, access to health care

Abbreviations: COVID-19 = coronavirus disease 2019; HCP = health care personnel.

* Health care personnel: paid and unpaid persons serving in health care settings who have the potential for direct or indirect exposure to patients or infectious materials; other essential workers: person who conduct operations vital for continuing critical infrastructure, such as food, agriculture, transportation, education, and law enforcement; adults with high risk medical conditions: adults who have one or more high-risk medical conditions, such as obesity, diabetes, and cardiovascular disease; adults aged ≥65 years: includes adults living at home and approximately 3 million living in long-term care facilities. There is considerable overlap between groups, for example, many adults aged ≥65 years also have high-risk medical conditions.

† Essential workers during the COVID-19 response have been defined by the U.S. Department of Homeland Security Cybersecurity and Infrastructure Security Agency. https://www.cisa.gov/sites/default/files/publications/Version_4.0_CISA_Guidance_on_Essential_Critical_Infrastructure_Workers_FINAL%20AUG%2018v2_0.pdf.

§ Medical conditions considered high-risk are updated routinely based on the best available scientific data: https://www.cdc.gov/coronavirus/2019-ncov/need-extra-precautions/people-with-medical-conditions.html.

¶ The ability of one or more groups to remain healthy helps protect the health of others and/or minimize disruption to society and the economy.

** As of October 31, 2020, nearly 90% of persons with COVID-19–associated hospitalizations have at least one high-risk condition. Data are routinely updated through COVID-19–Associated Hospitalization Surveillance Network (COVID-NET) (https://gis.cdc.gov/grasp/COVIDNet/COVID19_5.html); in-hospital deaths reported to COVID-NET during March–May, 2020 were associated with certain underlying medical conditions (https://academic.oup.com/cid/advance-article/doi/10.1093/cid/ciaa1012/5872581).

†† As of November 12, 2020, 80% of COVID-19 deaths were among adults aged ≥65 years. Data are routinely updated through CDC case-based surveillance (https://covid.cdc.gov/covid-data-tracker/#demographics); long-term care residents account for a large proportion of deaths among adults aged ≥65 years (https://data.cms.gov/stories/s/COVID-19-Nursing-Home-Data/bkwz-xpvg/).

§§ Influenza vaccination coverage is low among many non–health care essential workers; such coverage is lowest among construction workers (10.7%) (https://www.cdc.gov/niosh/docs/2012-161/pdfs/2012-161.pdf?id = 10.26616/NIOSHPUB2012161).

The Advisory Committee on Immunization Practices' Ethical Principles for Allocating Initial Supplies of COVID-19 Vaccine — United States, 2020

Nancy McClung, PhD[1]; Mary Chamberland, MD[1,2]; Kathy Kinlaw, MDiv[3]; Dayna Bowen Matthew, JD, PhD[4]; Megan Wallace, DrPH[1,5]; Beth P. Bell, MD[6]; Grace M. Lee, MD[7]; H. Keipp Talbot, MD[8]; José R. Romero, MD[9]; Sara E. Oliver, MD[1]; Kathleen Dooling, MD[1]

To reduce the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19) and its associated impacts on health and society, COVID-19 vaccines are essential. The U.S. government is working to produce and deliver safe and effective COVID-19 vaccines for the entire U.S. population. The Advisory Committee on Immunization Practices (ACIP)* has broadly outlined its approach for developing recommendations for the use of each COVID-19 vaccine authorized or approved by the Food and Drug Administration (FDA) for Emergency Use Authorization or licensure (*1*). ACIP's recommendation process includes an explicit and transparent evidence-based method for assessing a vaccine's safety and efficacy as well as consideration of other factors, including implementation (*2*). Because the initial supply of vaccine will likely be limited, ACIP will also recommend which groups should receive the earliest allocations of vaccine. The ACIP COVID-19 Vaccines Work Group and consultants with expertise in ethics and health equity considered external expert committee reports and published literature and deliberated the ethical issues associated with COVID-19 vaccine allocation decisions. The purpose of this report is to describe the four ethical principles that will assist ACIP in formulating recommendations for the allocation of COVID-19 vaccine while supply is limited, in addition to scientific data and implementation feasibility: 1) maximize benefits and minimize harms; 2) promote justice; 3) mitigate health inequities; and 4) promote transparency. These principles can also aid state, tribal, local, and territorial public health authorities as they develop vaccine implementation strategies within their own communities based on ACIP recommendations.

The ACIP COVID-19 Vaccines Work Group has met several times per month (approximately 25 meetings) since its establishment in April 2020. Work Group discussions included review of the epidemiology of COVID-19 and consultation with experts in ethics and health equity to inform the development of an ethically principled decision-making process. The Work Group reviewed the relevant literature, including frameworks for pandemic influenza planning and COVID-19 vaccine allocation (*3*–*8*); summarized this information; and presented it to ACIP. ACIP supported four fundamental ethical principles to guide COVID-19 vaccine allocation decisions in the setting of a constrained supply. Essential questions that derive from these principles can assist in vaccine allocation planning (Table 1).

Maximize benefits and minimize harms. Allocation of COVID-19 vaccine should maximize the benefits of vaccination to both individual recipients and the population overall. These benefits include the reduction of SARS-CoV-2 infections and COVID-19–associated morbidity and mortality, which in turn reduces the burden on strained health care capacity and facilities; preservation of services essential to the COVID-19 response; and maintenance of overall societal functioning. Identification of groups whose receipt of the vaccine would lead to the greatest benefit should be based on scientific evidence, accounting for those at highest risk for SARS-CoV-2 infection or severe COVID-19–related disease or death, and the essential role of certain workers. The ability of essential workers, including health care workers and non–health care

*The ACIP includes 15 voting members responsible for making vaccine recommendations. Fourteen of the members have expertise in vaccinology, immunology, pediatrics, internal medicine, nursing, family medicine, virology, public health, infectious diseases, and/or preventive medicine; one member is a consumer representative who provides perspectives on the social and community aspects of vaccination. In addition to the 15 voting members, ACIP includes eight ex officio members who represent other federal agencies with responsibility for immunization programs in the United States, and 30 nonvoting representatives of liaison organizations that bring related immunization expertise. https://www.cdc.gov/vaccines/acip/members/index.html.

TABLE 1. Essential questions for COVID-19 vaccine allocation planning related to ethical principles — United States, 2020

Ethical principle	Essential question
Maximize benefits and minimize harms	What groups are at highest risk for SARS-CoV-2 infection, COVID-19 disease, hospitalization, and death?
	What groups are essential to the COVID-19 response?
	What groups are essential to maintaining critical functions of society?
	What are the important characteristics of these groups (e.g., size or geographic distribution) that might inform the magnitude of benefit based on the amount of vaccine available or its characteristics?
Promote justice	Does the allocation plan result in fair and equitable access of the vaccine for all groups?
	How do characteristics of the vaccine and logistical considerations affect fair access for all persons?
	Does allocation planning include input from groups who are disproportionately affected by COVID-19 or face health inequities resulting from social determinants of health, such as income and health care access?
Mitigate health inequities	Does the plan identify and address barriers to vaccination among any groups who are disproportionately affected by COVID-19 or who face health inequities resulting from social determinants of health, such as income and health care access?
	Does the allocation plan contribute to a reduction in health disparities in COVID-19 disease and death?
	What health inequities might inadvertently result from the allocation plan, and what interventions could remove or reduce them?
	Is there a mechanism for timely assessment of vaccination coverage among groups experiencing disadvantage and the possibility for course correction if inequities are identified?
Promote transparency	How does development of the allocation plan include diverse input, and if possible, public engagement?
	Are the allocation plan and evidence-based methods publicly available?
	Is the allocation plan clear about what is known and unknown and about the quality of available evidence?
	What is the process for revision of allocation plans based on new information?
	Is there a mechanism to report demographic data elements for vaccine recipients (e.g., age, race/ethnicity, and occupation) to support equitable vaccination coverage?

Abbreviation: COVID-19 = coronavirus disease 2019.

workers, to remain healthy has a multiplier effect (i.e., their ability to remain healthy helps to protect the health of others or to minimize societal and economic disruption). Some of these workers are at increased risk for SARS-CoV-2 infection because of their limited ability to maintain physical distance in the workplace or because they do not have consistent access to recommended personal protective equipment.

Promote justice. Inherent in the principle of justice is an obligation to protect and advance equal opportunity for all persons to enjoy the maximal health and well-being possible. Justice rests on the belief in the fundamental value and dignity of all persons. Allocation of COVID-19 vaccine should promote justice by intentionally ensuring that all persons have equal opportunity to be vaccinated, both within the groups recommended for initial vaccination, and as vaccine becomes more widely available. This includes a commitment to removing unfair, unjust, and avoidable barriers to vaccination that disproportionately affect groups that have been economically or socially marginalized, as well as a fair and consistent implementation process. Input from a range of external entities, partners, and community representatives is particularly important in developing and assessing allocation plans.

Mitigate health inequities. Health equity is achieved when every person has the opportunity to attain his or her full health potential and no one is disadvantaged from achieving this potential because of social position or other socially determined circumstances.[†] Disparities in the severity of COVID-19 and COVID-19–related death, as well as inequities in social determinants of health that are linked to COVID-19 risk, such as income or health care access and utilization, are well documented among certain racial and ethnic minority groups (*9*). Vaccine allocation strategies should aim to both reduce existing disparities and to not create new disparities. Efforts should be made to identify and remove obstacles and barriers to receiving COVID-19 vaccine, including limited access to health care or residence in rural, hard-to-reach areas.

Promote transparency. Transparency relates to the decision-making process and is essential to building and maintaining public trust during vaccine program planning and implementation. The underlying principles, decision-making processes, and plans for COVID-19 vaccine allocation must be evidence-based, clear, understandable, and publicly available. To the extent possible, considering the urgency of the COVID-19

[†] https://www.cdc.gov/chronicdisease/healthequity/index.htm.

MS-DOH-21-1816-A-002184

response, public participation in the creation and review of the decision-making process should be facilitated. In addition, when feasible, tracking administration of vaccine to the groups recommended for initial vaccine allocation can contribute to transparency and trust in the process. In an ongoing public health response, the situation continually evolves as new information becomes available. Transparency includes being clear about the level of certainty in the available evidence and communicating new information that might change recommendations in a timely fashion.

For the period when the supply of COVID-19 vaccine will be limited, ACIP has considered four groups for initial vaccine allocation. These include health care personnel, other essential workers, adults with high-risk medical conditions, and adults aged ≥65 years (including residents of long-term care facilities) (Table 2). These groups were selected based on available scientific data, vaccine implementation considerations, and ethical principles. The principle of transparency is applied across the entirety of the vaccine allocation decision-making process. ACIP's meetings are open to the public, meeting minutes and archived webcasts are available online, and data (including data from vaccine clinical trials) and analytic methods used in developing ACIP recommendations are publicly available.[§] Members of the public are invited to submit written comments to the Federal Register or provide oral comment during ACIP meetings. ACIP's 30 nonvoting representatives from liaison organizations facilitate engagement with professional medical and public health organizations and other stakeholders and partners.

All four groups proposed for initial allocation of COVID-19 vaccine merit strong consideration from an ethical perspective. Current planning scenarios estimate, however, that the expected number of doses during the first weeks of vaccine distribution might only be sufficient to vaccinate approximately 20 million persons.[¶] Although there is considerable overlap between groups[**] (*10*), the initial supply will not be adequate to vaccinate the entirety of all four groups; for example, there are approximately 100 million health care personnel and essential workers (Table 2). Published frameworks for COVID-19 allocation and ACIP discussions indicate a clear consensus that the first allocation of COVID-19 vaccine supplies should be directed to health care personnel (*1*,*5*–*8*); discussion of allocation to the other three groups is ongoing. As additional vaccine supplies become available, other groups may be vaccinated concurrent with health care personnel.

[§] https://www.cdc.gov/vaccines/acip/index.html.

[¶] https://www.cdc.gov/vaccines/imz-managers/downloads/COVID-19-Vaccination-Program-Interim_Playbook.pdf.

[**] There is overlap among these four groups. For example, in one analysis, among the 3.8% of U.S. adults who work directly with patients as health care workers, 38.6% have high-risk medical conditions or are aged >65 years.

Discussion

During a pandemic, ethical guidelines can help steer and support decisions around prioritization of limited resources (*3*,*4*). Consideration of ethical values and principles has featured prominently in discussions about allocation of COVID-19 vaccines. This consideration is particularly relevant because the COVID-19 pandemic has highlighted long-standing, systemic health and social inequities. Although various frameworks for COVID-19 vaccine allocation demonstrate differences in their structure (e.g., based on varying combinations of different goals, objectives, criteria, and other structural elements) and emphasis (e.g., inclusion of global and national considerations), nearly all reference values and principles similar to those which ACIP considers fundamental (*5*–*8*). ACIP viewed the following characteristics as critical for its ethical approach to COVID-19 vaccine allocation when supply is limited: simplicity in structure and definitions; acceptability to stakeholders; and ease of application, both at the national and state, tribal, local, and territorial levels.

Allocation of limited vaccine supplies is complicated by efforts to address the multiple goals of a vaccine program, most notably those related to the reduction of morbidity and mortality and the minimization of disruption to society and the economy. If the goals of a pandemic vaccination program are not clearly articulated and prioritized, drawing distinctions between groups that merit consideration for allocation of vaccine when supply is constrained can become difficult. The unanimity in opinion for early vaccination of health care personnel indicates that maintenance of health care capacity has emerged as a high priority in the context of a severe pandemic. This perspective aligns with ethical considerations for pandemic influenza planning (*3*,*4*). If vaccine supply remains constrained, it might be necessary to identify subsets of other groups for subsequent early allocation of COVID-19 vaccine. At the national, state, tribal, local, and territorial levels, such decisions should be guided, in part, by ethical principles and consideration of essential questions, with particular consideration of mitigation of health inequities in persons experiencing disproportionate COVID-19 morbidity and mortality. In the setting of a constrained supply, the benefits of vaccination will be delayed for some persons; however, as supply increases, there will eventually be enough vaccine for everyone.

In addition to ethical considerations, ACIP's recommendations regarding receipt of the initial allocations of COVID-19 vaccine during the period of constrained supply will be based on science (e.g., available information about the vaccine's characteristics such as safety and efficacy in older adults and epidemiologic risk) and feasibility of implementation (e.g., storage and handling requirements). Thus, ACIP's allocation recommendations will

MS-DOH-21-1816-A-002185

TABLE 2. Application of ethical principles to four candidate groups for initial COVID-19 vaccine allocation — United States, 2020

Principles (with transparency across the decision-making process)	Candidate groups* (approximate no.)			
	Health care personnel† (21 million)	**Other essential workers† (87 million)**	**Adults with high-risk medical conditions§ (>100 million)**	**Adults aged ≥65 years (53 million)**
Maximize benefits and minimize harms	Preserves health care services essential to the COVID-19 response and the overall health care system	Preserves services essential to the COVID-19 response and overall functioning of society	Reduces morbidity and mortality in persons with high incidence of COVID-19 disease and death**	Reduces morbidity and mortality in persons with high incidence of COVID-19 disease and death††
	Multiplier effect¶	Multiplier effect¶		
Promote justice	Addresses elevated occupational risk for SARS-CoV-2 exposure for those unable to work from home	Addresses elevated occupational risk for SARS-CoV-2 exposure for those unable to work from home	Will require focused outreach to vaccinate persons in this group who have no or limited access to health care or experience inequities in social determinants of health	Will require focused outreach to vaccinate persons in this group who have no or limited access to health care or experience inequities in social determinants of health
	Promotes access to vaccine across a spectrum of HCP job types and settings	Promotes access to vaccine and reduces barriers to vaccination in occupations with low vaccine uptake§§		
Mitigate health inequities	Racial and ethnic minority groups are disproportionately represented in low-wage HCP¶¶	Racial and ethnic minority groups are disproportionately represented in many essential industries***	Increased prevalence of obesity and diabetes (most prevalent conditions in this group) among some racial and ethnic minority groups; increased prevalence of some medical conditions for persons in rural areas§§§	Although racial and ethnic minority groups are underrepresented among adults aged ≥65 years, certain groups have disproportionate COVID-19–related hospitalization and death rates¶¶¶
		Approximately one quarter of essential workers live in low-income families†††	Could increase health inequities because diagnosis of high-risk medical conditions requires access to health care	Strict age-based criterion could increase disparities due to racial and social inequities, such as occupation, income, access to health care

Abbreviations: COVID-19 = coronavirus disease 2019; HCP = health care personnel.

* Health care personnel: paid and unpaid persons serving in health care settings who have the potential for direct or indirect exposure to patients or infectious materials; other essential workers: person who conduct operations vital for continuing critical infrastructure, such as food, agriculture, transportation, education, and law enforcement; adults with high risk medical conditions: adults who have one or more high-risk medical conditions, such as obesity, diabetes, and cardiovascular disease; adults aged ≥65 years: includes adults living at home and approximately 3 million living in long-term care facilities. There is considerable overlap between groups, for example, many adults aged ≥65 years also have high-risk medical conditions.

† Essential workers during the COVID-19 response have been defined by the U.S. Department of Homeland Security Cybersecurity and Infrastructure Security Agency. https://www.cisa.gov/sites/default/files/publications/Version_4.0_CISA_Guidance_on_Essential_Critical_Infrastructure_Workers_FINAL%20AUG%2018v2_0.pdf.

COVID-19 Outbreak Associated with a 10-Day Motorcycle Rally in a Neighboring State — Minnesota, August–September 2020

Melanie J. Firestone, PhD[1,2]; Haley Wienkes, MPH[1]; Jacob Garfin[1]; Xiong Wang, DVM, PhD[1]; Kelley Vilen, MPH[1]; Kirk E. Smith, DVM, PhD[1]; Stacy Holzbauer, DVM[1,3]; Matthew Plumb, MS[1]; Kelly Pung[1]; Carlota Medus, PhD[1]; Joseph D. Yao, MD[4]; Matthew J. Binnicker, PhD[4]; Andrew C. Nelson, MD, PhD[5]; Sophia Yohe, MD[5]; Kathryn Como-Sabetti, MPH[1]; Kris Ehresmann, MPH[1]; Ruth Lynfield, MD[1]; Richard Danila, PhD[1]

During August 7–16, 2020, a motorcycle rally was held in western South Dakota that attracted approximately 460,000 persons from across the United States to numerous indoor and outdoor events over a 10-day period. During August–September 2020, the Minnesota Department of Health (MDH) investigated a coronavirus disease 2019 (COVID-19) outbreak associated with the rally in Minnesota residents. Fifty-one primary event-associated cases were identified, and 35 secondary or tertiary cases occurred among household, social, and workplace contacts, for a total of 86 cases; four patients were hospitalized, and one died. Approximately one third (34%) of 87 counties in Minnesota had at least one primary, secondary, or tertiary case associated with this rally. Genomic sequencing supported the associations with the motorcycle rally. These findings support current recommendations for mask use, physical distancing, reducing the number of attendees at gatherings, isolation for patients with COVID-19, and quarantine for close contacts to slow the spread of SARS-CoV-2 (*1*). Furthermore, although these findings did not capture the impact of the motorcycle rally on residents of other states, they demonstrate the rationale for consistent mitigation measures across states.

Investigation and Findings

On August 21, 2020, MDH identified confirmed COVID-19 cases in persons who reported attending the motorcycle rally in the neighboring state of South Dakota. A primary, event-associated case was defined as an illness in a person who reported attending the rally or who traveled to western South Dakota by motorcycle during August 7–16 and who had symptom onset or specimen collection before August 30 (within 14 days after the end of the rally). Reverse transcription–polymerase chain reaction testing for SARS-CoV-2, the virus that causes COVID-19, was used to confirm cases. All confirmed cases among Minnesota residents were reported to MDH. MDH or local public health department staff members interviewed patients with confirmed SARS-CoV-2 infection to identify exposures and persons who might have been in contact with patients during their infectious period (2 days before through 10 days after symptom onset).* To assess exposures, interviews included questions about travel and being in specific settings, such as bars or restaurants, schools, health care facilities, or events or social gatherings in the 14 days before symptom onset. During August–September 2020, MDH and local health department staff members interviewed >80% of patients with a confirmed SARS-CoV-2 infection.

Secondary and tertiary cases were identified from case interview data. Confirmed secondary cases were defined as laboratory-confirmed infections in persons who did not attend the rally but who received SARS-CoV-2–positive test results after having contact with a person who had a primary case during their infectious period. Tertiary cases were laboratory-confirmed cases in persons who had contact with a person who had a secondary case during their infectious period. Likely event-associated secondary cases were confirmed infections in patients who had contact with a person who had symptoms of COVID-19 and had attended the motorcycle rally but who were not tested. Likely event-associated tertiary cases were confirmed infections in patients who had contact with persons who had a likely event-associated secondary case during their infectious period.

* The infectious period was estimated to begin 2 days before symptom onset and end 10 days after symptom onset, according to CDC guidance. https://www.cdc.gov/coronavirus/2019-ncov/php/contact-tracing/contact-tracing-plan/investigating-covid-19-case.html.

Centers for Disease Control and Prevention

MS-DOH-21-1816-A-002188

To investigate genomic similarity among COVID-19 cases, available SARS-CoV-2 RNA-positive clinical specimens were obtained from clinical laboratories, and whole genome sequencing was conducted at the MDH Public Health Laboratory on 38 specimens using previously described methods (*2*). Phylogenetic relationships, including distinct clustering of viral whole genome sequences, were inferred based on nucleotide differences via IQ-TREE[†] using general time reversible substitution models (*3*) as a part of the Nextstrain[§] workflow (*4*). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[¶]

This investigation identified 86 cases, including 51 (59%) primary event-associated cases,[**] 26 (30%) confirmed secondary and tertiary cases, and nine (10%) likely event-associated secondary or tertiary cases. Four patients were hospitalized, and one died (Table). The median interval between specimen collection and interview was 3 days (range = 1–13 days). Overall, 64 (74%) patients were symptomatic, including 39 (76%) of 51 patients with a primary case and 25 (71%) of 35 patients with secondary and tertiary cases. Among patients with primary cases and symptom onset after the start of the rally, onset dates ranged from August 8 to August 26 (Figure 1). Two patients reported symptom onset before the event and attended the rally during their infectious period. Among primary patients, the median age was 44 years (range = 26–76 years), and 31 (61%) were male. Sixteen (33%) of 48 interviewed patients reported working while infectious, including five who worked at the rally and four who worked in health care after returning from the rally.

Forty-one (80%) interviewed patients with primary event-associated COVID-19 reported having close contact[††] with others during their infectious period, with an average of 2.5 close contacts per patient (range = 1–8). Overall, 36 (75%) of 48 interviewed patients with primary event-associated cases reported having close contact with persons in their household while infectious, and 17 (35%) reported having other (social/workplace) close contacts while infectious. Patients reported a total of 59 household contacts (range = 0–4 per patient) and 43 social/workplace contacts (range = 0–6 per patient).

Among the 35 patients with confirmed or likely event-associated secondary/tertiary COVID-19, 25 (71%) were symptomatic, with symptom onset dates during August 12–29 (Table). The median age was 32 years (range = 1–83 years), and 13 (37%) were male. Fifteen (43%) persons with secondary or tertiary COVID-19 were household contacts of a person with a primary or secondary infection, 12 (34%) were social contacts, and eight (23%) were workplace contacts. Secondary transmission from this rally occurred via two workplace outbreaks, one wedding outbreak, and one funeral outbreak. Approximately one third (34%) of Minnesota's 87 counties had at least one primary, secondary, or tertiary case associated with this rally.

Whole Genome Sequencing

Specimens were obtained from 52 (60%) patients. Among these, 38 (73%) specimens (23 [61%] from primary and 15 [39%] from secondary and tertiary cases) were successfully sequenced, covering at least 98% of the SARS-CoV-2 genome. Six genetically similar clusters with known epidemiologic links were identified (i.e., cases in patients who were close contacts or who had common exposures at the rally), five of which demonstrated secondary or secondary and tertiary transmission. Cluster A (Figure 2) included genetically similar specimens for seven primary cases and one secondary case (specimen MN-MDH-1710). Among primary cases, specimens were collected from two patients who reported working at the rally, including one who worked at a restaurant. Two other patients in this cluster reported visiting that restaurant. Another patient who attended the rally also reported visiting the same restaurant; this patient was a household contact of the patient with specimen MN-MDH-1710. Cluster B represented a chain of transmission in a workplace setting that included five cases. The secondary case in this cluster (with specimen MN-MDH-STU0004) occurred in a workplace contact of a motorcycle rally attendee (specimen MN-MDH-STU0001) and a social contact of one of the persons with a tertiary case (specimen MN-MDH-STU0008). Another secondary case[§§] in this cluster was in a workplace contact of the rally attendee and was a household contact of two of the three patients with tertiary cases in this cluster (specimens MN-MDH-1708 and MN-MDH-1709). Cluster C represented secondary transmission from a rally attendee (specimen MN-MDH-1651) to a household contact (specimen MN-MD-1705). Cluster D represented likely event-associated cases of secondary transmission (specimens MN-MDH-STU0002, MN-MDH-1706, and MD-MDH-1712) and tertiary transmission (specimens MN-MDH-STU-0005 and MN-MDH-1711) related to a wedding. The index patient at this wedding reportedly had COVID-19–like symptoms at the wedding after attending the rally but did not receive testing. Cluster E comprised two

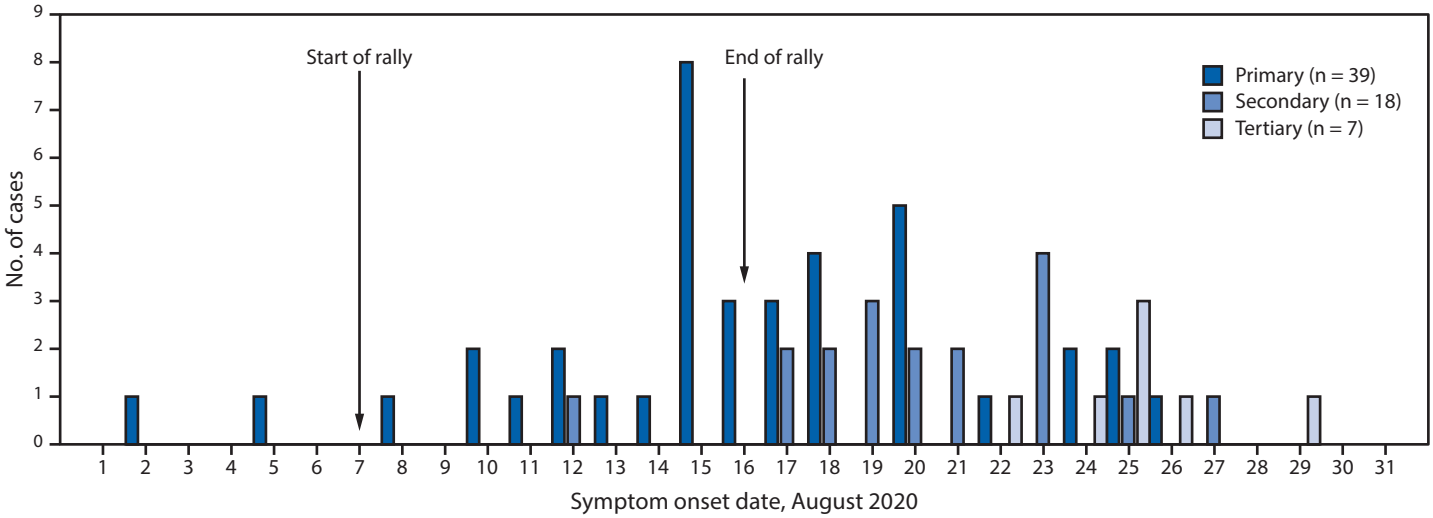
FIGURE 1. Date of symptom onset among symptomatic patients with primary,* secondary,† and tertiary§ COVID-19 (N = 64) associated with a motorcycle rally in a neighboring state — Minnesota, August 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Laboratory-confirmed SARS-CoV-2 infection in a person who attended the motorcycle rally or traveled to western South Dakota by motorcycle during August 7–16 and had symptom onset or specimen collection within 14 days of the end of the rally.

† Laboratory-confirmed infection in a person who had contact with a laboratory-confirmed primary case during the infectious period or with a symptomatic rally attendee who was not tested.

§ Laboratory-confirmed infection in a person who had contact with a secondary case or likely event-associated secondary case.

cases (specimens MN-MDH-1567 and MN-MH-1714) in persons who were household contacts, both of whom attended the rally. Cluster F represents workplace and household contacts (specimens MN-MDH-1715, MN-MDH-1716, MN-MDH-1713, and MN-MDH-STU0007) of the primary patient with specimen MN-MDH-1569. Specimen MN-MDH-1569 was from a musician who performed at the rally and later at another concert with a different band whose members did not attend the rally. Primary event-associated cases with specimens MN-MDH-1571 and MN-MDH-1572 had no known connection to each other or identified common exposure at the rally; however, the reported symptom onset dates and travel dates for these cases were identical. Similarly, primary event-associated cases with specimens MN-MDH-1568 and MN-MDH-1707 had no known epidemiologic link but had identical symptom onset dates. This might indicate a common exposure that was not identified through epidemiologic evidence.

Public Health Response

On August 5, MDH recommended through media events that motorcycle rally attendees quarantine for 14 days upon return and be tested 5–7 days later even if they were asymptomatic. Attendees and their close contacts with confirmed COVID-19 were instructed to self-isolate. Contacts of patients with confirmed COVID-19 were instructed to quarantine.

Discussion

Eighty-six Minnesota COVID-19 cases were associated with the South Dakota motorcycle rally; approximately one third of counties in Minnesota reported at least one case epidemiologically linked to this event. These findings highlight the far-reaching effects that gatherings in one area might have on another area. The motorcycle rally was held in a neighboring state that did not have policies regarding event size and mask use, underscoring the implications of policies within and across jurisdictions. The findings suggest that this rally not only had a direct impact on the health of attendees, but also led to subsequent SARS-CoV-2 transmission among household, social, and workplace contacts of rally attendees upon their return to Minnesota. Whole genome sequencing results supported the finding of secondary and tertiary transmission associated with this rally.

The findings in this report are subject to at least three limitations. First, despite in-depth epidemiologic investigation, the findings represent an underestimate of the motorcycle rally's impact in Minnesota and did not capture the impact within South Dakota or other states. Case interviews were voluntary, and patients could choose not to respond to certain questions. Ten patients reported having close contacts but refused to disclose additional details regarding these contacts. Therefore, it was not possible to identify all contacts of patients who attended the rally. Second, attendees and their contacts might not have been tested for SARS-CoV-2. Two rally attendees

§§ Symptom status was unknown for three patients with a primary case, three with a secondary/tertiary case, and one with a likely event-associated secondary/tertiary case.

indicated that their contacts had COVID-19–like symptoms but did not plan to be tested. As such, the findings underrepresent the number of cases, close contacts, and secondary and tertiary cases. Finally, only 52 specimens were received at the MDH Public Health Laboratory because many testing laboratories do not retain or store specimens long-term. Among these specimens, only 38 were successfully sequenced. The lack of whole genome sequencing data from all cases hindered establishment of complete genetic relatedness for epidemiologic investigation.

A large event in a neighboring state triggered chains of SARS-CoV-2 transmission within Minnesota. Other studies have shown that chains of transmission associated with gatherings are not uncommon within the United States (*5*,*6*). Despite underascertainment of the rally's full impact in Minnesota and other states, these findings highlight the importance of reducing the number of attendees at gatherings and emphasizing mask use, physical distancing, isolation for patients with COVID-19, and quarantine for close contacts as strategies for reducing the spread of COVID-19. Furthermore, these findings demonstrate the rationale for consistent mitigation measures across states.

MS-DOH-21-1816-A-002192

Summary

What is already known about this topic?

Gatherings present an opportunity for rapid spread of COVID-19.

What is added by this report?

Following a 10-day motorcycle rally in South Dakota attended by approximately 460,000 persons, 51 confirmed primary event-associated cases, 21 secondary cases, and five tertiary cases were identified in Minnesota residents. An additional nine likely rally-associated secondary or tertiary cases occurred. Four patients were hospitalized, and one died. Genomic sequencing supported the associations with the motorcycle rally.

What are the implications for public health practice?

The impact of gatherings as a source of virus transmission underscores the importance of reducing the number of attendees at gatherings, using face masks, and encouraging physical distancing to prevent ongoing transmission of SARS-CoV-2. Furthermore, these findings demonstrate the rationale for consistent mitigation measures across states.

All authors have completed and submitted the International Committee of Medical Journal Editors form for disclosure of potential conflicts of interest. Matthew J. Binnicker reports personal fees from DiaSorin Molecular for an educational webinar on COVID-19 diagnostics and as a member of the advisory board. No other potential conflicts of interest were disclosed.

COVID-19 Outbreak Associated with a 10-Day Motorcycle Rally in a Neighboring State — Minnesota, August–September 2020

Melanie J. Firestone, PhD[1,2]; Haley Wienkes, MPH[1]; Jacob Garfin[1]; Xiong Wang, DVM, PhD[1]; Kelley Vilen, MPH[1]; Kirk E. Smith, DVM, PhD[1]; Stacy Holzbauer, DVM[1,3]; Matthew Plumb, MS[1]; Kelly Pung[1]; Carlota Medus, PhD[1]; Joseph D. Yao, MD[4]; Matthew J. Binnicker, PhD[4]; Andrew C. Nelson, MD, PhD[5]; Sophia Yohe, MD[5]; Kathryn Como-Sabetti, MPH[1]; Kris Ehresmann, MPH[1]; Ruth Lynfield, MD[1]; Richard Danila, PhD[1]

During August 7–16, 2020, a motorcycle rally was held in western South Dakota that attracted approximately 460,000 persons from across the United States to numerous indoor and outdoor events over a 10-day period. During August–September 2020, the Minnesota Department of Health (MDH) investigated a coronavirus disease 2019 (COVID-19) outbreak associated with the rally in Minnesota residents. Fifty-one primary event-associated cases were identified, and 35 secondary or tertiary cases occurred among household, social, and workplace contacts, for a total of 86 cases; four patients were hospitalized, and one died. Approximately one third (34%) of 87 counties in Minnesota had at least one primary, secondary, or tertiary case associated with this rally. Genomic sequencing supported the associations with the motorcycle rally. These findings support current recommendations for mask use, physical distancing, reducing the number of attendees at gatherings, isolation for patients with COVID-19, and quarantine for close contacts to slow the spread of SARS-CoV-2 (*1*). Furthermore, although these findings did not capture the impact of the motorcycle rally on residents of other states, they demonstrate the rationale for consistent mitigation measures across states.

Investigation and Findings

On August 21, 2020, MDH identified confirmed COVID-19 cases in persons who reported attending the motorcycle rally in the neighboring state of South Dakota. A primary, event-associated case was defined as an illness in a person who reported attending the rally or who traveled to western South Dakota by motorcycle during August 7–16 and who had symptom onset or specimen collection before August 30 (within 14 days after the end of the rally). Reverse transcription–polymerase chain reaction testing for SARS-CoV-2, the virus that causes COVID-19, was used to confirm cases. All confirmed cases among Minnesota residents were reported to MDH. MDH or local public health department staff members interviewed patients with confirmed SARS-CoV-2 infection to identify exposures and persons who might have been in contact with patients during their infectious period (2 days before through 10 days after symptom onset).* To assess exposures, interviews included questions about travel and being in specific settings, such as bars or restaurants, schools, health care facilities, or events or social gatherings in the 14 days before symptom onset. During August–September 2020, MDH and local health department staff members interviewed >80% of patients with a confirmed SARS-CoV-2 infection.

Secondary and tertiary cases were identified from case interview data. Confirmed secondary cases were defined as laboratory-confirmed infections in persons who did not attend the rally but who received SARS-CoV-2–positive test results after having contact with a person who had a primary case during their infectious period. Tertiary cases were laboratory-confirmed cases in persons who had contact with a person who had a secondary case during their infectious period. Likely event-associated secondary cases were confirmed infections in patients who had contact with a person who had symptoms of COVID-19 and had attended the motorcycle rally but who were not tested. Likely event-associated tertiary cases were confirmed infections in patients who had contact with persons who had a likely event-associated secondary case during their infectious period.

* The infectious period was estimated to begin 2 days before symptom onset and end 10 days after symptom onset, according to CDC guidance. https://www.cdc.gov/coronavirus/2019-ncov/php/contact-tracing/contact-tracing-plan/investigating-covid-19-case.html.

To investigate genomic similarity among COVID-19 cases, available SARS-CoV-2 RNA-positive clinical specimens were obtained from clinical laboratories, and whole genome sequencing was conducted at the MDH Public Health Laboratory on 38 specimens using previously described methods (*2*). Phylogenetic relationships, including distinct clustering of viral whole genome sequences, were inferred based on nucleotide differences via IQ-TREE[†] using general time reversible substitution models (*3*) as a part of the Nextstrain[§] workflow (*4*). This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[¶]

This investigation identified 86 cases, including 51 (59%) primary event-associated cases,[**] 26 (30%) confirmed secondary and tertiary cases, and nine (10%) likely event-associated secondary or tertiary cases. Four patients were hospitalized, and one died (Table). The median interval between specimen collection and interview was 3 days (range = 1–13 days). Overall, 64 (74%) patients were symptomatic, including 39 (76%) of 51 patients with a primary case and 25 (71%) of 35 patients with secondary and tertiary cases. Among patients with primary cases and symptom onset after the start of the rally, onset dates ranged from August 8 to August 26 (Figure 1). Two patients reported symptom onset before the event and attended the rally during their infectious period. Among primary patients, the median age was 44 years (range = 26–76 years), and 31 (61%) were male. Sixteen (33%) of 48 interviewed patients reported working while infectious, including five who worked at the rally and four who worked in health care after returning from the rally.

Forty-one (80%) interviewed patients with primary event-associated COVID-19 reported having close contact[††] with others during their infectious period, with an average of 2.5 close contacts per patient (range = 1–8). Overall, 36 (75%) of 48 interviewed patients with primary event-associated cases reported having close contact with persons in their household while infectious, and 17 (35%) reported having other (social/workplace) close contacts while infectious. Patients reported a total of 59 household contacts (range = 0–4 per patient) and 43 social/workplace contacts (range = 0–6 per patient).

Among the 35 patients with confirmed or likely event-associated secondary/tertiary COVID-19, 25 (71%) were symptomatic, with symptom onset dates during August 12–29 (Table). The median age was 32 years (range = 1–83 years), and 13 (37%) were male. Fifteen (43%) persons with secondary or tertiary COVID-19 were household contacts of a person with a primary or secondary infection, 12 (34%) were social contacts, and eight (23%) were workplace contacts. Secondary transmission from this rally occurred via two workplace outbreaks, one wedding outbreak, and one funeral outbreak. Approximately one third (34%) of Minnesota's 87 counties had at least one primary, secondary, or tertiary case associated with this rally.

Whole Genome Sequencing

Specimens were obtained from 52 (60%) patients. Among these, 38 (73%) specimens (23 [61%] from primary and 15 [39%] from secondary and tertiary cases) were successfully sequenced, covering at least 98% of the SARS-CoV-2 genome. Six genetically similar clusters with known epidemiologic links were identified (i.e., cases in patients who were close contacts or who had common exposures at the rally), five of which demonstrated secondary or secondary and tertiary transmission. Cluster A (Figure 2) included genetically similar specimens for seven primary cases and one secondary case (specimen MN-MDH-1710). Among primary cases, specimens were collected from two patients who reported working at the rally, including one who worked at a restaurant. Two other patients in this cluster reported visiting that restaurant. Another patient who attended the rally also reported visiting the same restaurant; this patient was a household contact of the patient with specimen MN-MDH-1710. Cluster B represented a chain of transmission in a workplace setting that included five cases. The secondary case in this cluster (with specimen MN-MDH-STU0004) occurred in a workplace contact of a motorcycle rally attendee (specimen MN-MDH-STU0001) and a social contact of one of the persons with a tertiary case (specimen MN-MDH-STU0008). Another secondary case[§§] in this cluster was in a workplace contact of the rally attendee and was a household contact of two of the three patients with tertiary cases in this cluster (specimens MN-MDH-1708 and MN-MDH-1709). Cluster C represented secondary transmission from a rally attendee (specimen MN-MDH-1651) to a household contact (specimen MN-MD-1705). Cluster D represented likely event-associated cases of secondary transmission (specimens MN-MDH-STU0002, MN-MDH-1706, and MD-MDH-1712) and tertiary transmission (specimens MN-MDH-STU-0005 and MN-MDH-1711) related to a wedding. The index patient at this wedding reportedly had COVID-19–like symptoms at the wedding after attending the rally but did not receive testing. Cluster E comprised two

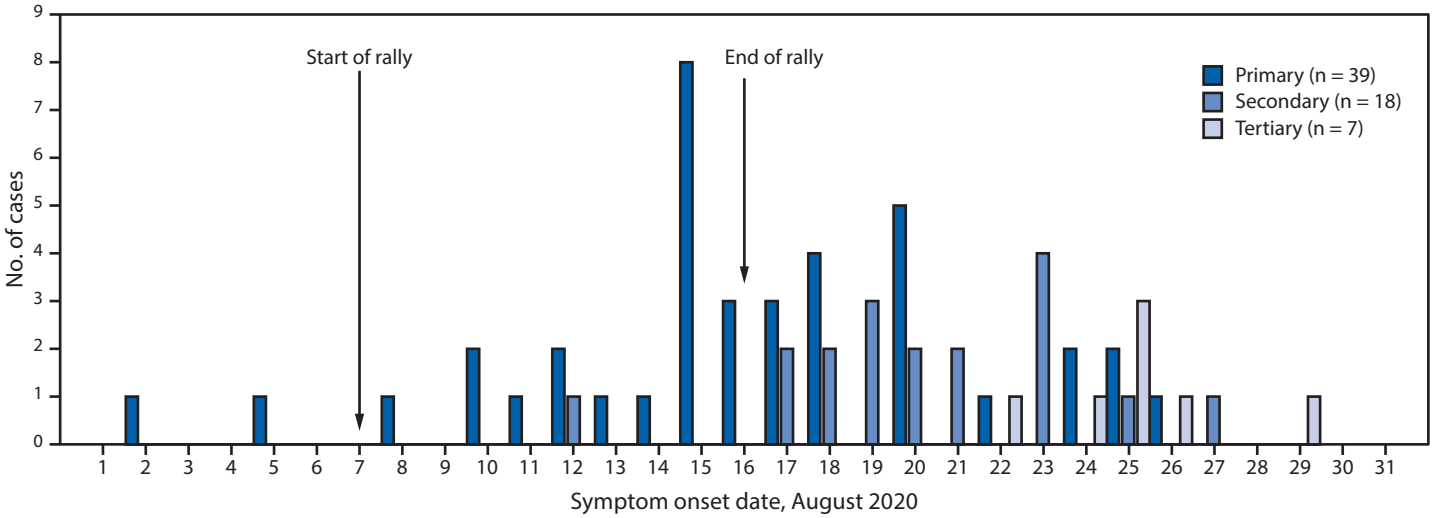
FIGURE 1. Date of symptom onset among symptomatic patients with primary,* secondary,† and tertiary§ COVID-19 (N = 64) associated with a motorcycle rally in a neighboring state — Minnesota, August 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Laboratory-confirmed SARS-CoV-2 infection in a person who attended the motorcycle rally or traveled to western South Dakota by motorcycle during August 7–16 and had symptom onset or specimen collection within 14 days of the end of the rally.

† Laboratory-confirmed infection in a person who had contact with a laboratory-confirmed primary case during the infectious period or with a symptomatic rally attendee who was not tested.

§ Laboratory-confirmed infection in a person who had contact with a secondary case or likely event-associated secondary case.

cases (specimens MN-MDH-1567 and MN-MH-1714) in persons who were household contacts, both of whom attended the rally. Cluster F represents workplace and household contacts (specimens MN-MDH-1715, MN-MDH-1716, MN-MDH-1713, and MN-MDH-STU0007) of the primary patient with specimen MN-MDH-1569. Specimen MN-MDH-1569 was from a musician who performed at the rally and later at another concert with a different band whose members did not attend the rally. Primary event-associated cases with specimens MN-MDH-1571 and MN-MDH-1572 had no known connection to each other or identified common exposure at the rally; however, the reported symptom onset dates and travel dates for these cases were identical. Similarly, primary event-associated cases with specimens MN-MDH-1568 and MN-MDH-1707 had no known epidemiologic link but had identical symptom onset dates. This might indicate a common exposure that was not identified through epidemiologic evidence.

Public Health Response

On August 5, MDH recommended through media events that motorcycle rally attendees quarantine for 14 days upon return and be tested 5–7 days later even if they were asymptomatic. Attendees and their close contacts with confirmed COVID-19 were instructed to self-isolate. Contacts of patients with confirmed COVID-19 were instructed to quarantine.

Discussion

Eighty-six Minnesota COVID-19 cases were associated with the South Dakota motorcycle rally; approximately one third of counties in Minnesota reported at least one case epidemiologically linked to this event. These findings highlight the far-reaching effects that gatherings in one area might have on another area. The motorcycle rally was held in a neighboring state that did not have policies regarding event size and mask use, underscoring the implications of policies within and across jurisdictions. The findings suggest that this rally not only had a direct impact on the health of attendees, but also led to subsequent SARS-CoV-2 transmission among household, social, and workplace contacts of rally attendees upon their return to Minnesota. Whole genome sequencing results supported the finding of secondary and tertiary transmission associated with this rally.

The findings in this report are subject to at least three limitations. First, despite in-depth epidemiologic investigation, the findings represent an underestimate of the motorcycle rally's impact in Minnesota and did not capture the impact within South Dakota or other states. Case interviews were voluntary, and patients could choose not to respond to certain questions. Ten patients reported having close contacts but refused to disclose additional details regarding these contacts. Therefore, it was not possible to identify all contacts of patients who attended the rally. Second, attendees and their contacts might not have been tested for SARS-CoV-2. Two rally attendees

indicated that their contacts had COVID-19–like symptoms but did not plan to be tested. As such, the findings underrepresent the number of cases, close contacts, and secondary and tertiary cases. Finally, only 52 specimens were received at the MDH Public Health Laboratory because many testing laboratories do not retain or store specimens long-term. Among these specimens, only 38 were successfully sequenced. The lack of whole genome sequencing data from all cases hindered establishment of complete genetic relatedness for epidemiologic investigation.

A large event in a neighboring state triggered chains of SARS-CoV-2 transmission within Minnesota. Other studies have shown that chains of transmission associated with gatherings are not uncommon within the United States (*5*,*6*). Despite underascertainment of the rally's full impact in Minnesota and other states, these findings highlight the importance of reducing the number of attendees at gatherings and emphasizing mask use, physical distancing, isolation for patients with COVID-19, and quarantine for close contacts as strategies for reducing the spread of COVID-19. Furthermore, these findings demonstrate the rationale for consistent mitigation measures across states.

Summary

What is already known about this topic?

Gatherings present an opportunity for rapid spread of COVID-19.

What is added by this report?

Following a 10-day motorcycle rally in South Dakota attended by approximately 460,000 persons, 51 confirmed primary event-associated cases, 21 secondary cases, and five tertiary cases were identified in Minnesota residents. An additional nine likely rally-associated secondary or tertiary cases occurred. Four patients were hospitalized, and one died. Genomic sequencing supported the associations with the motorcycle rally.

What are the implications for public health practice?

The impact of gatherings as a source of virus transmission underscores the importance of reducing the number of attendees at gatherings, using face masks, and encouraging physical distancing to prevent ongoing transmission of SARS-CoV-2. Furthermore, these findings demonstrate the rationale for consistent mitigation measures across states.

All authors have completed and submitted the International Committee of Medical Journal Editors form for disclosure of potential conflicts of interest. Matthew J. Binnicker reports personal fees from DiaSorin Molecular for an educational webinar on COVID-19 diagnostics and as a member of the advisory board. No other potential conflicts of interest were disclosed.

Trends in County-Level COVID-19 Incidence in Counties With and Without a Mask Mandate — Kansas, June 1–August 23, 2020

Miriam E. Van Dyke, PhD[1]; Tia M. Rogers, PhD[1]; Eric Pevzner, PhD[2]; Catherine L. Satterwhite, PhD[3]; Hina B. Shah, MPH[4]; Wyatt J. Beckman, MPH[4]; Farah Ahmed, PhD[5]; D. Charles Hunt, MPH[4]; John Rule[6]

Wearing masks is a CDC-recommended* approach to reduce the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), by reducing the spread of respiratory droplets into the air when a person coughs, sneezes, or talks and by reducing the inhalation of these droplets by the wearer. On July 2, 2020, the governor of Kansas issued an executive order† (state mandate), effective July 3, requiring masks or other face coverings in public spaces. CDC and the Kansas Department of Health and Environment analyzed trends in county-level COVID-19 incidence before (June 1–July 2) and after (July 3–August 23) the governor's executive order among counties that ultimately had a mask mandate in place and those that did not. As of August 11, 24 of Kansas's 105 counties did not opt out of the state mandate§ or adopted their own mask mandate shortly before or after the state mandate was issued; 81 counties opted out of the state mandate, as permitted by state law, and did not adopt their own mask mandate. After the governor's executive order, COVID-19 incidence (calculated as the 7-day rolling average number of new daily cases per 100,000 population) decreased (mean decrease of 0.08 cases per 100,000 per day; net decrease of 6%) among counties with a mask mandate (mandated counties) but continued to increase (mean increase of 0.11 cases per 100,000 per day; net increase of 100%) among counties without a mask mandate (nonmandated counties). The decrease in cases among mandated counties and the continued increase in cases in nonmandated counties adds to the evidence supporting the importance of wearing masks and implementing policies requiring their use to mitigate the spread of SARS-CoV-2 (*1*–*6*). Community-level mitigation strategies emphasizing wearing masks, maintaining physical distance, staying at home when ill, and enhancing hygiene practices can help reduce transmission of SARS-CoV-2.

The Kansas mandate requiring the wearing of face coverings in public spaces became effective July 3, 2020. Data on county mask mandates were obtained from the Kansas Health Institute.¶ A Kansas state law** enacted on June 9, 2020, authorizes counties to issue public health orders that are less stringent than the provisions of statewide executive orders issued by the governor, which allowed counties to opt out of the state mask mandate. For this study, counties in Kansas that, as of August 11, 2020, did not opt out of the state mandate or adopted their own mask mandate were considered to have a mask mandate in place; those that opted out of the state mandate and did not adopt their own mask mandate were considered to not have a mask mandate in place.

Centers for Disease Control and Prevention

MS-DOH-21-1816-A-002200

Daily county-level COVID-19 incidence (cases per 100,000 population) was calculated using case and population counts accessed from USAFacts[††] for Kansas counties during June 1–August 23.[§§] Rates were calculated as 7-day rolling averages. Segmented regression[¶¶] was used to examine changes in COVID-19 incidence before and after July 3, 2020, among mandated and nonmandated counties. Mandated and nonmandated counties were compared to themselves over time, allowing for the control of constant county-related characteristics (e.g., urbanicity or rurality) that might otherwise confound a comparison between mandated and nonmandated counties. Sensitivity analyses were also conducted by 1) examining incidence trends after July 3 separately among mandated counties with and without other public health mitigation strategies and 2) recategorizing nonmandated counties that included cities mandating masks (n=6) as mandated counties. Analyses were conducted using SAS software (version 9.4; SAS Institute).

As of August 11, 24 (23%) Kansas counties had a mask mandate in place, and 81 did not. Mandated counties accounted for two thirds of the Kansas population (1,960,703 persons; 67.3%)[***] and were spread throughout the state, although they tended to cluster together. Six (25%) mandated and 13 (16%) nonmandated counties were metropolitan areas.[†††] Thirteen (54%) mandated counties and seven (9%) nonmandated counties had implemented at least one other public health mitigation strategy not related to the use of masks (e.g., limits on size of gatherings and occupancy for restaurants). During June 1–7, 2020, the 7-day rolling average of daily COVID-19 incidence among counties that ultimately had a mask mandate was three cases per 100,000, and among counties that did not, was four per 100,000 (Table). By the week of the governor's executive order requiring masks (July 3–9), COVID-19 incidence had increased 467% to 17 per 100,000 in mandated counties and 50% to six per 100,000 among nonmandated counties. By August 17–23, 2020, the 7-day rolling average COVID-19 incidence had decreased by 6% to 16 cases per 100,000 among mandated counties and increased by 100% to 12 per 100,000 among nonmandated counties.

Trend analyses using segmented regression (Figure) indicated that during June 1–July 2, 2020, the COVID-19 7-day rolling average incidence increased each day in both counties that ultimately had mask mandates in place (mean increase = 0.25 cases per 100,000 per day; 95% confidence interval [CI] = 0.17–0.33) and counties that did not (mean increase = 0.08 cases per 100,000 per day; 95% CI = 0.01–0.14). After the governor's executive order, COVID-19 incidence decreased each day in mandated counties (mean decrease = 0.08 cases per 100,000 per day; 95% CI = –0.14 to –0.03); in nonmandated counties, incidence continued to increase each day (mean increase = 0.11 cases per 100,000 per day; 95% CI = 0.01–0.21).

Discussion

After implementation of mask mandates in 24 Kansas counties, the increasing trend in COVID-19 incidence reversed. Although rates were considerably higher in mandated counties than in nonmandated counties by the executive order, rates in mandated counties declined markedly after July 3, compared with those in nonmandated counties. Kansas counties that had mask mandates in place appear to have mitigated the transmission of COVID-19, whereas counties that did not have mask mandates continued to experience increases in cases.

The findings in this report are consistent with declines in COVID-19 cases observed in 15 states and the District of Columbia, which mandated masks, compared with states that did not have mask mandates (*7*). Mask requirements were also implemented as part of a multicomponent approach in Arizona, where COVID-19 incidence stabilized and then decreased after implementation of a combination of voluntary and enforceable community-level mitigation strategies, including mask requirements, limitations on public events, enhanced sanitation practices, and closures of certain services and businesses (*8*). The combining of community-level mitigation strategies including physical distancing and enhanced hygiene practices, in addition to consistent and correct use of masks, is a CDC-recommended approach.[§§§] The decreased COVID-19 incidence among mask-mandated counties in Kansas occurred during a time when the only other state mandates issued were focused on mitigation strategies for schools as they reopened in mid-August. In at least 13 (54%) of the 24 mandated counties, the mask mandates occurred alongside other county-level recommended or mandated mitigation strategies (e.g., limits on

[††] https://usafacts.org/visualizations/coronavirus-covid-19-spread-map.

[§§] August 23, 2020, was selected as the study end date because most Kansas counties had already started or were about to begin school the week of August 24, 2020. The implementation of in-person schooling would have signified an important change in events influencing COVID-19 incidence rates after the executive order.

[¶¶] Generalized estimating equation regression modeling with an autoregressive correlation variance structure was used to estimate trends over time within counties. Trends in 7-day rolling average of daily COVID-19 incidence among mask mandated counties and among non–mask-mandated counties were analyzed separately before (June 1–July 2, 2020) and after (July 3–August 23, 2020) the governor's executive order requiring masks, effective July 3.

[***] Total population in mask-mandated counties = 1,960,703; total population in non–mask-mandated counties = 952,611; based on 2019 U.S. Census data.

Abbreviations: COVID-19 = coronavirus disease 2019; mandated = counties with a mask mandate; N/A = not applicable; nonmandated = counties without a mask mandate.

* Counties that as of August 11 did not opt out of the state mandate or adopted their own mask mandate shortly before or after the state mandate include Allen, Atchison, Bourbon, Crawford, Dickinson, Douglas, Franklin, Geary, Gove, Harvey, Jewell, Johnson, Mitchell, Montgomery, Morris, Pratt, Reno, Republic, Saline, Scott, Sedgwick, Shawnee, Stanton and Wyandotte. Total population in mask-mandated counties = 1,960,703 based on 2019 U.S. Census Bureau data.

† Counties that took no official action to opt out of the state mask mandate or adopted their own mask mandate shortly before or after the state mandate were considered to have a mask mandate in place. Counties were considered to not have a mask mandate in place if they took official action to opt out of the state mask mandate and did not adopt their own mask mandate or if their official action used only the language of guidance (e.g., "should" or "recommend"). Total population in non–mask-mandated counties = 952,611 based on 2019 U.S. Census Bureau data.

§ Week of governor's executive order (effective July 3, 2020).

¶ Change in incidence = [(incidence in period – incidence in previous period)/incidence in previous period] X 100.

** Data on county orders were collected through point-in-time surveys of local health department and other county officials and were supplemented with online searches for published orders and announcements on social media and local news sites. Text in the county orders was analyzed to determine whether mask mandates were in place as of August 11, 2020.

†† Seven-day rolling average number of new daily cases.

§§ Seven-day rolling average number of new daily cases per 100,000 population.

size of gatherings and occupancy for restaurants), facilitating a potential synergistic effect resulting from combining community mitigation strategies. However, in sensitivity analyses, similar decreases in COVID-19 incidence after July 3 were observed among mandated counties with and without other mitigation strategies. Therefore, although implementing multiple mitigation strategies is the recommended approach, strategies related to mask use mandates appear to be important. Additional information on the utility and acceptability of mask mandates in public settings could help further inform health education campaigns aimed at increasing proper use of masks and strengthening mandate adherence.

The findings in this report are subject to at least four limitations. First, the ecologic design of this study and limited information on community mask-wearing behaviors and county implementation and enforcement provisions of mask mandates limit the ability to determine the extent to which the countywide mask mandates accounted for the observed declines in COVID-19 incidence in mandated counties. Second, this analysis did not account for mask ordinances in six cities in non–mask-mandated counties. However, in sensitivity analyses recategorizing nonmandated counties that included cities mandating masks as mandated counties, results were consistent with those in primary analyses, although they were attenuated. In those analyses, after the governor's executive order, COVID-19 incidence among mandated counties stabilized rather than decreased, and incidence continued to increase among nonmandated counties. Third, although the design of this study limits potential confounding from constant county-related characteristics, the findings in this report are conditional on the absence of any time-varying factors (e.g., mobility patterns, changes in other community-level mitigation strategies, and access to testing) within counties before and after July 3. Nonetheless, in additional analyses examining testing data among Kansas counties during the study period,

Summary

What is already known about this this topic?

Wearing face masks in public spaces reduces the spread of SARS-CoV-2.

What is added by this report?

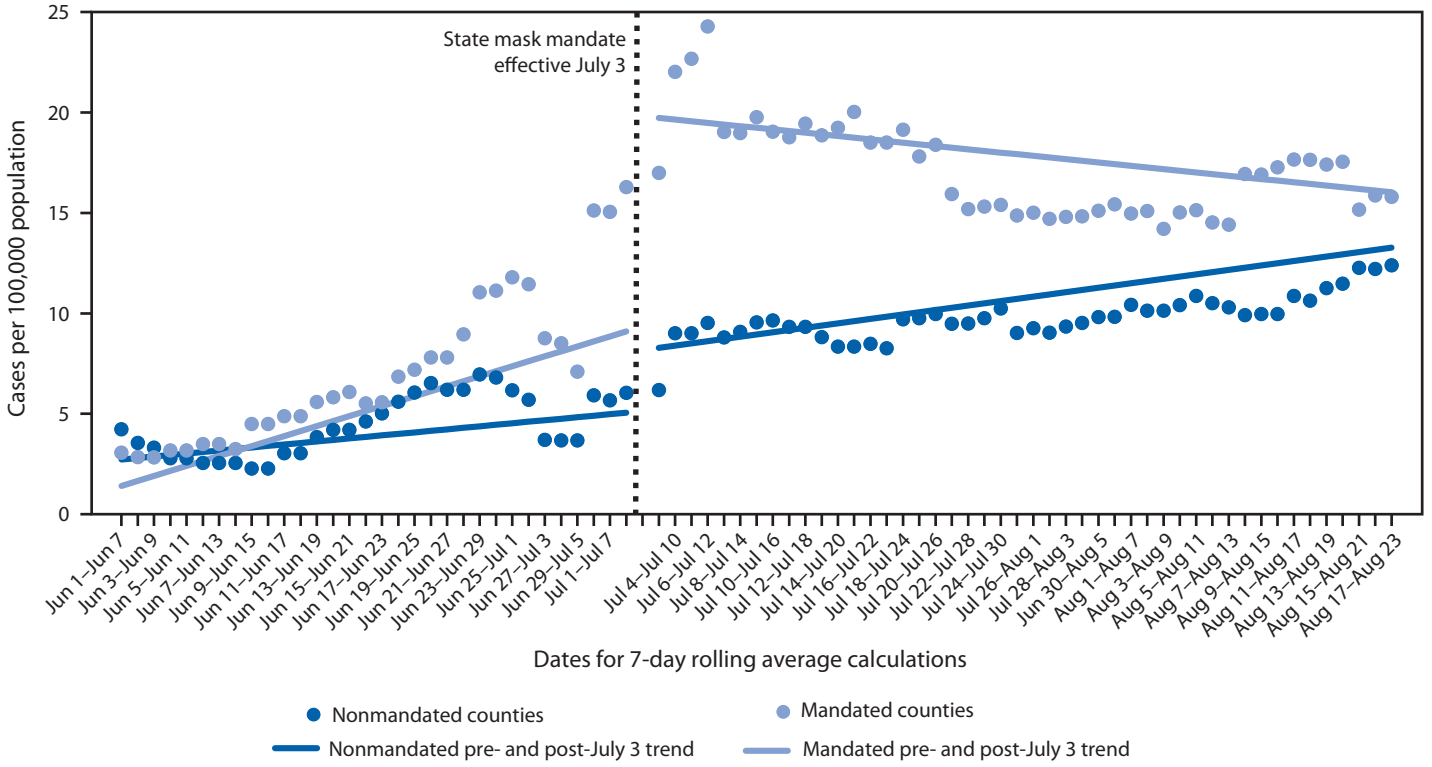
The governor of Kansas issued an executive order requiring wearing masks in public spaces, effective July 3, 2020, which was subject to county authority to opt out. After July 3, COVID-19 incidence decreased in 24 counties with mask mandates but continued to increase in 81 counties without mask mandates.

What are the implications for public health practice?

Countywide mask mandates appear to have contributed to the mitigation of COVID-19 transmission in mandated counties. Community-level mitigation strategies emphasizing use of masks, physical distancing, staying at home when ill, and enhanced hygiene practices can help reduce the transmission of SARS-CoV-2.

MS-DOH-21-1816-A-002202

FIGURE. Trends* in 7-day rolling average of new daily COVID-19 cases per 100,000 population among mask-mandated† and non–mask-mandated counties before (June 1–July 2)§ and after (July 3–August 23)¶ the governor's executive order requiring masks — Kansas, June 1–August 23, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

* Generalized estimating equation regression modeling with an autoregressive correlation variance structure was used to estimate trends over time within counties. Trends in 7-day rolling average of daily COVID-19 incidence among mask-mandated counties and non–mask-mandated counties were analyzed separately before (June 1–July 2, 2020) and after (July 3–August 23, 2020) the governor's executive order requiring masks, effective July 3.

† Kansas counties (n = 24) that as of August 11 did not opt out of the state mandate effective July 3, 2020, or adopted their own mask mandate shortly before or after the state mandate include Allen, Atchison, Bourbon, Crawford, Dickinson, Douglas, Franklin, Geary, Gove, Harvey, Jewell, Johnson, Mitchell, Montgomery, Morris, Pratt, Reno, Republic, Saline, Scott, Sedgwick, Shawnee, Stanton and Wyandotte. Data on county orders were collected through point-in-time surveys of local health department and other county officials and were supplemented with online searches for published orders and announcements on social media and local news sites. Text in the county orders was analyzed to determine whether mask mandates were in place as of August 11, 2020. Counties that took no official action to opt out of the state mask mandate or adopted their own mask mandate shortly before or after the state mandate were considered to have a mask mandate in place. Counties were considered to not have a mask mandate in place if they took official action to opt out of the state mask mandate and did not adopt their own mask mandate or if their official action used only the language of guidance (e.g., "should" or "recommend").

§ Before the mask mandate (June 1–July 2), 7-day rolling average COVID-19 incidence increased each day (mean increase = 0.25 cases per 100,000 persons per day; 95% confidence interval [CI] = 0.17–0.33) in mask-mandated counties and increased each day (mean increase = 0.08 cases per 100,000 per day; 95% CI = 0.01–0.14) in nonmandated counties.

¶ After the mask mandate (July 3–August 23), 7-day rolling average COVID-19 incidence decreased each day (mean decrease = 0.08 cases per 100,000 persons per day; 95% CI = –0.14 to –0.03) in mask-mandated counties and increased each day (mean increase = 0.11 cases per 100,000 per day; 95% CI = 0.01–0.21) in nonmandated counties.

testing rates were observed to increase overall over time. Therefore, despite increases in testing during this period, decreases in COVID-19 incidence were observed in mandated counties after July 3. Finally, counties in Kansas with a mask mandate might not be representative of other U.S. counties. However, the findings are consistent with observations from other states that mask mandates are associated with declines in COVID-19 cases (*7*).

Masks are an important intervention for mitigating the transmission of SARS-CoV-2 (*1*–*6*), and countywide mask mandates appear to have contributed to the mitigation of COVID-19 spread in Kansas counties that had them in place. Community-level mitigation strategies emphasizing use of masks, physical distancing, staying at home when ill, and enhanced hygiene practices can help reduce the transmission of SARS-CoV-2.

Trends in County-Level COVID-19 Incidence in Counties With and Without a Mask Mandate — Kansas, June 1–August 23, 2020

Miriam E. Van Dyke, PhD[1]; Tia M. Rogers, PhD[1]; Eric Pevzner, PhD[2]; Catherine L. Satterwhite, PhD[3]; Hina B. Shah, MPH[4]; Wyatt J. Beckman, MPH[4]; Farah Ahmed, PhD[5]; D. Charles Hunt, MPH[4]; John Rule[6]

Wearing masks is a CDC-recommended* approach to reduce the spread of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19), by reducing the spread of respiratory droplets into the air when a person coughs, sneezes, or talks and by reducing the inhalation of these droplets by the wearer. On July 2, 2020, the governor of Kansas issued an executive order† (state mandate), effective July 3, requiring masks or other face coverings in public spaces. CDC and the Kansas Department of Health and Environment analyzed trends in county-level COVID-19 incidence before (June 1–July 2) and after (July 3–August 23) the governor's executive order among counties that ultimately had a mask mandate in place and those that did not. As of August 11, 24 of Kansas's 105 counties did not opt out of the state mandate§ or adopted their own mask mandate shortly before or after the state mandate was issued; 81 counties opted out of the state mandate, as permitted by state law, and did not adopt their own mask mandate. After the governor's executive order, COVID-19 incidence (calculated as the 7-day rolling average number of new daily cases per 100,000 population) decreased (mean decrease of 0.08 cases per 100,000 per day; net decrease of 6%) among counties with a mask mandate (mandated counties) but continued to increase (mean increase of 0.11 cases per 100,000 per day; net increase of 100%) among counties without a mask mandate (nonmandated counties). The decrease in cases among mandated counties and the continued increase in cases in nonmandated counties adds to the evidence supporting the importance of wearing masks and implementing policies requiring their use to mitigate the spread of SARS-CoV-2 (*1*–*6*). Community-level mitigation strategies emphasizing wearing masks, maintaining physical distance, staying at home when ill, and enhancing hygiene practices can help reduce transmission of SARS-CoV-2.

The Kansas mandate requiring the wearing of face coverings in public spaces became effective July 3, 2020. Data on county mask mandates were obtained from the Kansas Health Institute.¶ A Kansas state law** enacted on June 9, 2020, authorizes counties to issue public health orders that are less stringent than the provisions of statewide executive orders issued by the governor, which allowed counties to opt out of the state mask mandate. For this study, counties in Kansas that, as of August 11, 2020, did not opt out of the state mandate or adopted their own mask mandate were considered to have a mask mandate in place; those that opted out of the state mandate and did not adopt their own mask mandate were considered to not have a mask mandate in place.

MS-DOH-21-1816-A-002205

Daily county-level COVID-19 incidence (cases per 100,000 population) was calculated using case and population counts accessed from USAFacts[††] for Kansas counties during June 1–August 23.[§§] Rates were calculated as 7-day rolling averages. Segmented regression[¶¶] was used to examine changes in COVID-19 incidence before and after July 3, 2020, among mandated and nonmandated counties. Mandated and nonmandated counties were compared to themselves over time, allowing for the control of constant county-related characteristics (e.g., urbanicity or rurality) that might otherwise confound a comparison between mandated and nonmandated counties. Sensitivity analyses were also conducted by 1) examining incidence trends after July 3 separately among mandated counties with and without other public health mitigation strategies and 2) recategorizing nonmandated counties that included cities mandating masks (n=6) as mandated counties. Analyses were conducted using SAS software (version 9.4; SAS Institute).

As of August 11, 24 (23%) Kansas counties had a mask mandate in place, and 81 did not. Mandated counties accounted for two thirds of the Kansas population (1,960,703 persons; 67.3%)[***] and were spread throughout the state, although they tended to cluster together. Six (25%) mandated and 13 (16%) nonmandated counties were metropolitan areas.[†††] Thirteen (54%) mandated counties and seven (9%) nonmandated counties had implemented at least one other public health mitigation strategy not related to the use of masks (e.g., limits on size of gatherings and occupancy for restaurants). During June 1–7, 2020, the 7-day rolling average of daily COVID-19 incidence among counties that ultimately had a mask mandate was three cases per 100,000, and among counties that did not, was four per 100,000 (Table). By the week of the governor's executive order requiring masks (July 3–9), COVID-19 incidence had increased 467% to 17 per 100,000 in mandated counties and 50% to six per 100,000 among nonmandated counties. By August 17–23, 2020, the 7-day rolling average COVID-19 incidence had decreased by 6% to 16 cases per 100,000 among mandated counties and increased by 100% to 12 per 100,000 among nonmandated counties.

Trend analyses using segmented regression (Figure) indicated that during June 1–July 2, 2020, the COVID-19 7-day rolling average incidence increased each day in both counties that ultimately had mask mandates in place (mean increase = 0.25 cases per 100,000 per day; 95% confidence interval [CI] = 0.17–0.33) and counties that did not (mean increase = 0.08 cases per 100,000 per day; 95% CI = 0.01–0.14). After the governor's executive order, COVID-19 incidence decreased each day in mandated counties (mean decrease = 0.08 cases per 100,000 per day; 95% CI = –0.14 to –0.03); in nonmandated counties, incidence continued to increase each day (mean increase = 0.11 cases per 100,000 per day; 95% CI = 0.01–0.21).

Discussion

After implementation of mask mandates in 24 Kansas counties, the increasing trend in COVID-19 incidence reversed. Although rates were considerably higher in mandated counties than in nonmandated counties by the executive order, rates in mandated counties declined markedly after July 3, compared with those in nonmandated counties. Kansas counties that had mask mandates in place appear to have mitigated the transmission of COVID-19, whereas counties that did not have mask mandates continued to experience increases in cases.

The findings in this report are consistent with declines in COVID-19 cases observed in 15 states and the District of Columbia, which mandated masks, compared with states that did not have mask mandates (*7*). Mask requirements were also implemented as part of a multicomponent approach in Arizona, where COVID-19 incidence stabilized and then decreased after implementation of a combination of voluntary and enforceable community-level mitigation strategies, including mask requirements, limitations on public events, enhanced sanitation practices, and closures of certain services and businesses (*8*). The combining of community-level mitigation strategies including physical distancing and enhanced hygiene practices, in addition to consistent and correct use of masks, is a CDC-recommended approach.[§§§] The decreased COVID-19 incidence among mask-mandated counties in Kansas occurred during a time when the only other state mandates issued were focused on mitigation strategies for schools as they reopened in mid-August. In at least 13 (54%) of the 24 mandated counties, the mask mandates occurred alongside other county-level recommended or mandated mitigation strategies (e.g., limits on

[††] https://usafacts.org/visualizations/coronavirus-covid-19-spread-map.

[§§] August 23, 2020, was selected as the study end date because most Kansas counties had already started or were about to begin school the week of August 24, 2020. The implementation of in-person schooling would have signified an important change in events influencing COVID-19 incidence rates after the executive order.

[¶¶] Generalized estimating equation regression modeling with an autoregressive correlation variance structure was used to estimate trends over time within counties. Trends in 7-day rolling average of daily COVID-19 incidence among mask mandated counties and among non–mask-mandated counties were analyzed separately before (June 1–July 2, 2020) and after (July 3–August 23, 2020) the governor's executive order requiring masks, effective July 3.

[***] Total population in mask-mandated counties = 1,960,703; total population in non–mask-mandated counties = 952,611; based on 2019 U.S. Census data.

¶ Change in incidence = [(incidence in period – incidence in previous period)/incidence in previous period] X 100.

** Data on county orders were collected through point-in-time surveys of local health department and other county officials and were supplemented with online searches for published orders and announcements on social media and local news sites. Text in the county orders was analyzed to determine whether mask mandates were in place as of August 11, 2020.

†† Seven-day rolling average number of new daily cases.

§§ Seven-day rolling average number of new daily cases per 100,000 population.

size of gatherings and occupancy for restaurants), facilitating a potential synergistic effect resulting from combining community mitigation strategies. However, in sensitivity analyses, similar decreases in COVID-19 incidence after July 3 were observed among mandated counties with and without other mitigation strategies. Therefore, although implementing multiple mitigation strategies is the recommended approach, strategies related to mask use mandates appear to be important. Additional information on the utility and acceptability of mask mandates in public settings could help further inform health education campaigns aimed at increasing proper use of masks and strengthening mandate adherence.

The findings in this report are subject to at least four limitations. First, the ecologic design of this study and limited information on community mask-wearing behaviors and county implementation and enforcement provisions of mask mandates limit the ability to determine the extent to which the countywide mask mandates accounted for the observed declines in COVID-19 incidence in mandated counties. Second, this analysis did not account for mask ordinances in six cities in non–mask-mandated counties. However, in sensitivity analyses recategorizing nonmandated counties that included cities mandating masks as mandated counties, results were consistent with those in primary analyses, although they were attenuated. In those analyses, after the governor's executive order, COVID-19 incidence among mandated counties stabilized rather than decreased, and incidence continued to increase among nonmandated counties. Third, although the design of this study limits potential confounding from constant county-related characteristics, the findings in this report are conditional on the absence of any time-varying factors (e.g., mobility patterns, changes in other community-level mitigation strategies, and access to testing) within counties before and after July 3. Nonetheless, in additional analyses examining testing data among Kansas counties during the study period,

Summary

What is already known about this this topic?

Wearing face masks in public spaces reduces the spread of SARS-CoV-2.

What is added by this report?

The governor of Kansas issued an executive order requiring wearing masks in public spaces, effective July 3, 2020, which was subject to county authority to opt out. After July 3, COVID-19 incidence decreased in 24 counties with mask mandates but continued to increase in 81 counties without mask mandates.

What are the implications for public health practice?

Countywide mask mandates appear to have contributed to the mitigation of COVID-19 transmission in mandated counties. Community-level mitigation strategies emphasizing use of masks, physical distancing, staying at home when ill, and enhanced hygiene practices can help reduce the transmission of SARS-CoV-2.

Subject: CDC's New Travel Planner is LIVE to travelers

Dear Health Department Partner,

CDC's new **COVID-19 Travel Planner is now LIVE to travelers**! Travel Planner is a centralized communication platform that travelers can search to find COVID-19 information for the state, local, territorial, and tribal communities they're passing through and for their destinations. We need your help to keep the web portal updated when your jurisdiction's restrictions and policies change.

As a health department, you can use Travel Planner to reach travelers and share your COVID-19 policies relevant to travelers entering and departing your jurisdiction.

I have not added my jurisdiction's information yet, can I still add it?

Yes, you can still add your information to Travel Planner. Identify a few people who can be responsible for inputting your health department's COVID-19 information, such as a communication specialist, administrative assistant, intern, or other staff member. If these staff members don't already have a CDC Secure Access Management Services (SAMS) account, they should email travelplanner@cdc.gov to request enrollment in SAMS and access to the COVID-19 Travel Planner webform. If they already have a SAMS account, they will need to email travelplanner@cdc.gov to request access to the COVID-19 Travel Planner webform.

Note: Due to delays in SAMS processing, at this time it would be best to identify someone who already has a SAMS account with Level 2 approvals.

How can I promote the Travel Planner?

We have provided materials you can use to help promote the Travel Planner to your residents, visitors, and those passing through your community:

- Graphic
- Social media posts
- A badge you can add to your website

We hope you will find the Travel Planner a helpful tool that reduces some of the inquiries you receive about travel restrictions and guidance in your jurisdiction. We welcome any questions or feedback at travelplanner@cdc.gov.

Thank you,

Global Migration Task Force
COVID-19 Response

[PureMessage: Suspect .eml attachment quarantined.]

Sent to State Epidemiologists, Deputy State Epidemiologists, CLUE, Infectious Disease Points of Contact, and the CSTE Executive Board

Good afternoon,

Please see below for a collection of recent Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

- CDC Lab Alert: FDA Issues Safety Letter about Potential for False Positive Results with Antigen Tests for Rapid Detection of SARS-CoV-2 [Attachment, Link]
    - Please see the following message from CDC's Laboratory Outreach Communication System (LOCS):
      "On November 3, 2020, the U.S. Food and Drug Administration (FDA) issued a Letter to Clinical Laboratory Staff and Health Care Providers to alert clinical laboratory staff and health care providers that false positive results can occur with antigen tests, including when users do not follow the instructions for use of antigen tests for the rapid detection of SARS-CoV-2. This letter includes important information about potential false positive results with antigen tests for rapid detection of SARS-CoV-2:
        - *Details on false positive results with antigen tests*
        - *Recommendations for health care providers and clinical laboratory staff*
        - *Actions FDA is taking*
        - *Instructions for reporting problems with a device*

      For questions about this letter, email COVID19DX@fda.hhs.gov."
- CDC Lab Advisory: CDC Updates Specimen Collection Guidelines for COVID-19 [Attachment, Link]
    - Please see the following message from CDC's Laboratory Outreach Communication

System (LOCS):
"On November 3, 2020, CDC updated the Interim Guidelines for Collecting, Handling, and Testing Clinical Specimens for COVID-19 web page. The updated guidelines provide more detailed recommendations for several methods of collecting specimens for SARS-CoV-2 testing:

- *Nasopharyngeal swabs*
- *Nasal mid-turbinate swabs*
- *Anterior nares specimen collection*
- *Saliva*

- MMWR Early Release: "Declines in SARS-CoV-2 Transmission, Hospitalizations, and Mortality After Implementation of Mitigation Measures— Delaware, March–June 2020" [Attachment, Link]
  - From the summary: *"State-mandated stay-at-home orders and public mask mandates coupled with case investigations with contact tracing contributed to an 82% reduction in COVID-19 incidence, 88% reduction in hospitalizations, and 100% reduction in mortality in Delaware during late April–June."*
- CDC Response Website Updates [Attachment]
  - for October 31–November 6
- CDC COVID-19 Science Update (November 3) [Attachment, Link]
  - The *COVID-19 Science Update* is a publication series from CDC that provides brief summaries of new COVID-19-related studies, intended for use by public health professionals responding to this pandemic. Summaries are released every Tuesday and Friday. All previous COVID-19 Science Updates are available on CDC's website here.
- Reminder: Request for CSTE COVID-19 Call Topics [Link]
  - To ensure timely and relevant information is provided to our members, CSTE has developed a topic submission form, available here. Please submit suggestions for topics (or speakers) to be discussed on future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations.

Neuropilin-1

The SARS-CoV-2 major spike protein (S) is cleaved by a host protease to create S1 and S2 functional polypeptides. The S1 polypeptide has a carboxy-terminal sequence that binds to host cell surface neuropilin-1 (NRP1) and neuropilin-2 (NRP2) receptors. NRP receptors facilitate viral entry for several viruses due to their abundance on cells that are exposed to the external environment – cells that paradoxically express low levels of angiotensin-converting enzyme-2 (ACE2), the known SARS-CoV-2 receptor. Here we present two articles that evaluated the potential for NRP1 to act as a co-receptor for SARS-CoV-2.

PEER-REVIEWED

Neuropilin-1 is a host factor for SARS-CoV-2 infection. Daly *et al.* Science (October 20, 2020).

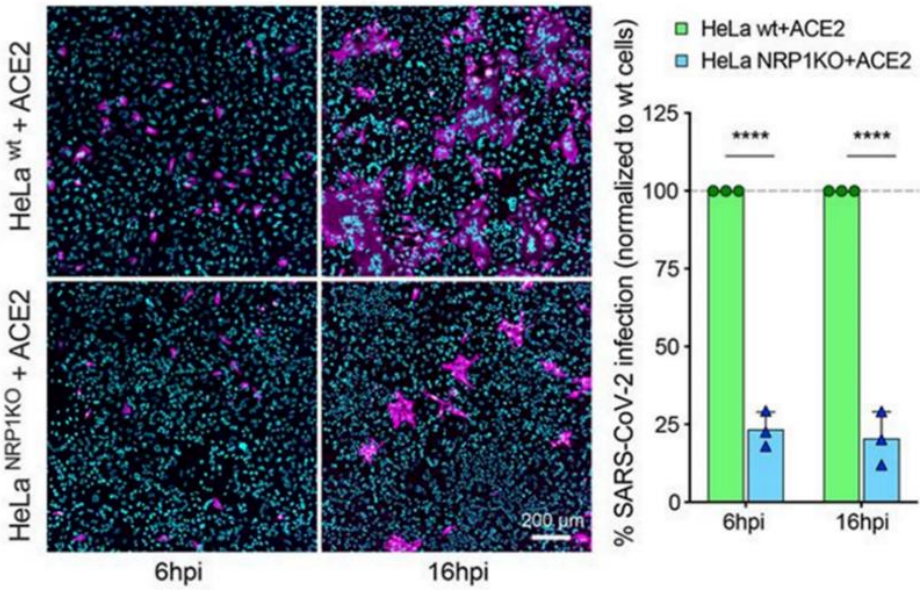
Key findings:

- The S1 fragment of the cleaved SARS-CoV-2 spike protein binds to the cell surface receptor neuropilin-1 (NRP1).
- SARS-CoV-2 utilizes NRP1 for cell entry as evidenced by decreased infectivity of cells in the presence of:
  - NRP1 deletion ($p < 0.0001$) (Figure).
  - Three different anti-NRP1 monoclonal antibodies ($p < 0.001$).
  - Selective NRP1 antagonist, EG00229 ($p < 0.01$).

Methods: Binding of the S1 fragment to NRP1 was assessed and ability of SARS-CoV-2 to use NRP1 to infect cells was measured in angiotensin-converting enzyme-2 (ACE-2)-expressing cell lines by knocking out NRP1 expression, blocking NRP1 with 3 different anti-NRP1 monoclonal antibodies, or using NRP1 small molecule antagonists.
Limitations: Upstream research and implications for treatment or prevention of infection unclear.

MS-DOH-21-1816-A-002213

Figure:



Note: Adapted from Daly *et al*. Fluorescent image of HeLa cells transfected to express ACE2 (SARS-CoV-2 receptor) with stains for SARS-CoV-2 nucleocapsid protein and nucleic acid, 6 and 16 hours post-infection (hpi). ACE-2 HeLa cells are wild-type (wt, top) or with a NRP1 deletion (NRP1KO, bottom). Bar graph shows % SARS-CoV-2-infected wild-type cells or NRP1-knockout cells. Licensed under CC-BY 4.0.

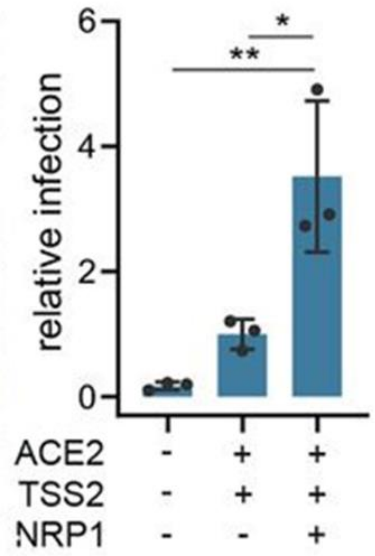
Neuropilin-1 facilitates SARS-CoV-2 cell entry and infectivity. Cantuti-Castelvetri *et al.* Science (October 20, 2020).

Key findings:

- Infectivity of cells expressing angiotensin converting enzyme-2 (ACE2, receptor for SARS-CoV-2), transmembrane protease serine-2 (TSS2, primes the Spike [S] protein), and neuropilin-1 (NRP1) with pseudovirus expressing the SARS-CoV-2 S1 protein was approximately 3-fold higher than in cells expressing either ACE2 or TSS2 alone ($p < 0.05$) (Figure 1).
- Analysis of autopsy tissue from COVID-19 patients showed co-localization of the SARS-CoV-2 spike (S) protein and NRP1 in olfactory and respiratory epithelium (Figure 2).

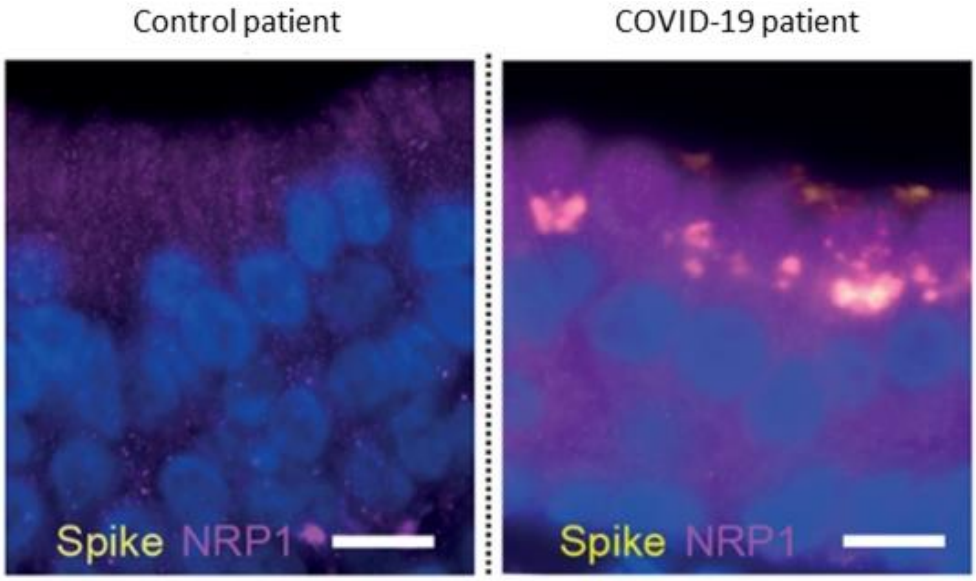
Methods: Cell lines were modified to express ACE2 and TSS2, the two known SARS-CoV-2 host factors, and NRP1 to assess the contribution of NRP1 to infection. Autopsy specimens from multiple airway sites were stained with antibodies against SARS-CoV-2 proteins, ACE2, and NRP1, to visualize co-localization of proteins. *Limitations:* Upstream research and implications for treatment or prevention of infection unclear.

Figure 1



Note: Adapted from Cantuti-Castelvetri *et al*. Infectivity of SARS-CoV-2 in cultured cells that express no known host factors (first bar), the host factors ACE2 and TSS2 (middle bar) and ACE2, TSS2, and NRP1 (third bar). *p <0.05, **p <0.01. Licensed under CC-BY 4.0.

Figure 2



Note: Adapted from Cantuti-Castelvetri *et al*. Co-localization of NRP1 and Spike protein in olfactory epithelial cells in a control patient (left) and a COVID-19 patient (right). Licensed under CC-BY 4.0.

Implications for 2 studies (Daly *et al.* & Cantuti-Castelvetri *et al.*) These two articles provide evidence that NRP1 facilitates SARS-CoV-2 entry into cells that express ACE2. These studies elucidate a route by which SARS-CoV-2 infects cells that do not express high levels of the ACE2 receptor and also suggests potential therapeutic options to decrease infection by blocking SARS-CoV-2-NRP1 interactions.

Laboratory Science

PEER-REVIEWED

Neutralizing antibody responses in COVID-19 convalescent sera. Lee *et al*. Journal of Infectious Diseases (October 26, 2020).

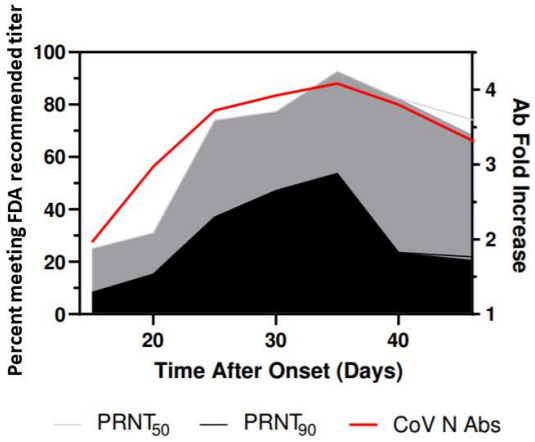
Key findings:

- Neutralizing antibody (nAb) activity increased for several weeks post-symptom onset (Figure).
  - 93% of sera had titers ≥1:160 (the initial FDA recommended level for nAb for convalescent plasma donation) at the 50% viral neutralization level, 31–35 days post-symptom onset.
  - 54% of sera had titers ≥1:160 at the 90% viral neutralization level, 31–35 days post-symptom onset.
  - 24% of sera had titers of ≥1:160 at the 90% viral neutralization level beyond day 35.
- Sera with antibody titers >1:960 generally had higher neutralizing activity, but not all contained nAbs at the initial FDA recommended levels.

Methods: Serum specimens from 3,426 COVID-19 convalescent patients were tested for SARS-CoV-2 antibodies to the receptor binding protein, spike protein, or nucleocapsid. Reactive sera were tested for ability to neutralize SARS-CoV-2 infection using plaque reduction assays. *Limitations:* Short follow-up period.

Implications: There may be a narrow window to collect convalescent plasma with maximal neutralizing activity for use as potential COVID-19 therapy. Findings also highlight the importance of characterizing serum neutralizing activity.

Figure:



Note: Adapted from Lee *et al*. Percentage of specimens that can **neutralize 50%** or **neutralize 90%** or of viral plaque formation with an antibody titer of ≥1:160 (left Y-axis) and the fold increase of **mean antibody levels** to the SARS-CoV-2 nucleocapsid (right Y-axis). Lee et al. Neutralizing antibody responses in COVID-19 convalescent sera. Journal of Infectious Diseases. DOI: https://doi.org/10.1093/infdis/jiaa673 ; Used by permission of the Infectious Diseases Society of America.

Frequency and duration of SARS-CoV-2 shedding in oral fluid samples assessed by a modified commercial rapid molecular assay. Bordi *et al.* Viruses (October 20, 2020).

Key findings:

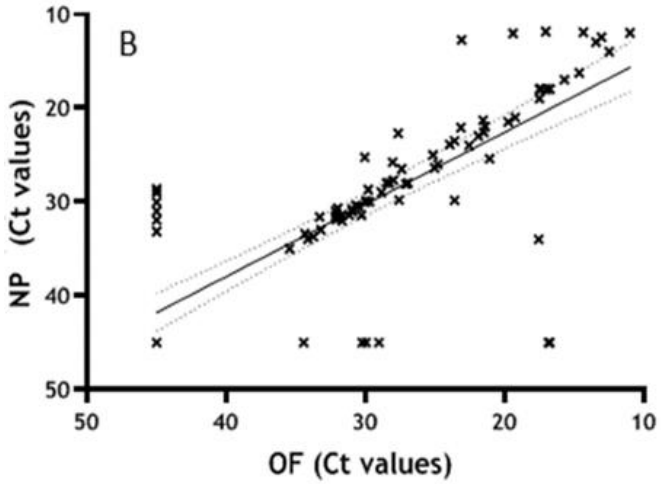
- Parallel testing for SARS-CoV-2 RNA in 337 oral fluid (OF) and nasopharyngeal (NP) specimens found 309 concordant and 28 discordant results (kappa statistic = 0.831, 95% CI 0.771-0.891).

  - Ct values for OF and NP specimens were highly correlated (correlation coefficient r = 0.921; p <0.0001) (Figure).
- SARS-CoV-2 RNA was observed in:
  - 67% of OF and 72% of NP specimens collected within 30 days of symptom onset (DSO).
  - 65% of OF and 76% of NP specimens collected between 30 and 60 DSO.
  - 32% of OF and 29% of NP specimens collected between 60 and 100 DSO.

Methods: The Simplexa™ COVID-19 Direct assay was used to test concordance in 337 paired OF and NP specimens from 164 patients hospitalized with suspected COVID-19. A sub-sample of 162 specimens was analyzed for viral RNA in OF and NP specimens, by DSO range. ***Limitations***: Did not evaluate effectiveness of OF or NP samples for specific clinical, surveillance, and epidemiologic uses.

Implications: Several assays find that OF samples are highly correlated with NP samples and may be an alternative to NP samples for diagnosis of SARS-CoV-2 infection. As noted in a recent paper in Clinical Infectious Diseases (Azzi, L. Saliva is the Key Element for SARS-CoV-2 Mass Screening), saliva can be easily and noninvasively self-collected, minimizing transmission risk to clinicians and facilitating more frequent testing of contacts, which may be critical to containing spread of SARS-CoV-2.

Figure:



Note: Adapted from Bordi *et al*. Results from samples tested for SARS-CoV-2 RNA both in NP and OF displayed in linear regression adjusted for repeated measures, sex and age (r = 0.921; p <0.0001). Licensed under CC-BY 4.0.

PREPRINT (NOT PEER-REVIEWED)

Prevalence of antibodies to SARS-CoV-2 in healthy blood donors in New York. Kamath *et al.* MedRxiv (October 21, 2020).

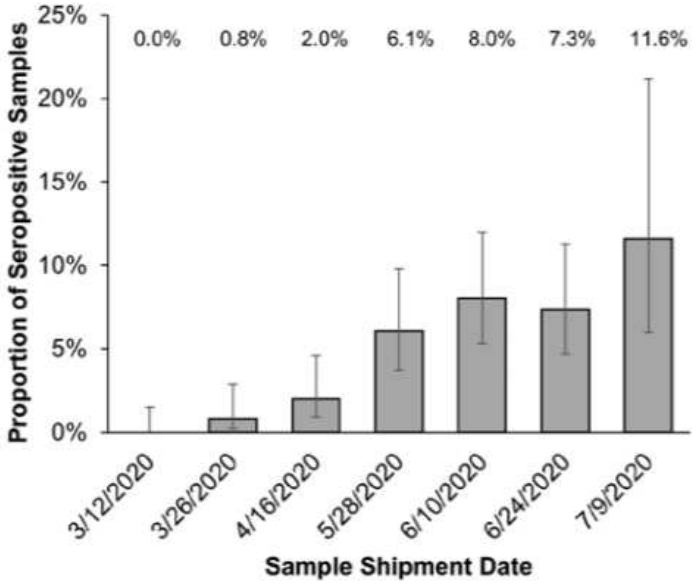
Key findings:

- 68 of 1,559 blood donor samples had IgG antibodies against SARS-CoV-2.
  - Seropositivity rate increased from 0% (95% CI 0-1.5%) in March 2020 to 11.6% (95% CI 6.0-21.2%) in July 2020.

Methods: Screen for antibodies to SARS-CoV-2 in samples from 1,559 healthy blood donors from the greater New York metropolitan area between March and July 2020. ***Limitations***: Unclear what proportion of donors were asymptomatic cases.

Implications: Although the pandemic significantly affected the greater New York metropolitan area, seropositivity for SARS-CoV-2 antibodies was low indicating that the population is far from reaching a threshold for herd immunity.

Figure:



Note: Adapted from Kamath *et al*. SARS-CoV-2 seropositivity over time in blood donors. Shipment date is when sample was sent to the laboratory for testing (within 2 weeks of sample collection). I bar represents the 95% CI. Used by permission of author.

Epidemiology

PEER-REVIEWED

COVID-19 transmission in US child care programs. Gilliam *et al.* Pediatrics (October 1, 2020).

Key findings:

- 0.7% (n = 427) of child care providers reported testing positive or being hospitalized for COVID-19.
  - No association was found between exposure to child care programs and COVID-19 (OR 0.94; 95% CI 0.73-1.21).
  - Being a home-based rather than center-based provider was associated with diagnosis of COVID-19 (OR 1.59, 95%CI 1.14-2.23) but this was independent of reported exposure.

Methods: Survey of 57,335 child care providers between May 22 and June 8, 2020, identified through two national child care organizations and 28 state child care workforce registries. Participants were surveyed on exposure to child care programs in the previous 8 weeks and whether they had tested positive for SARS-CoV-2 or had been hospitalized for COVID-19. Logistic regression was conducted to control for confounders (county COVID-19 mortality rate, hand washing and social distancing, child care facility type). *Limitations*: Child care program not defined; state policy-level variables may not have been adequately controlled.

Implications: Early in the pandemic, exposure to child care programs did not appear to place child care providers at increased risk of COVID-19. This may be partially attributable to infection mitigation efforts in child care programs and background incidence rates. Infections among child care providers will need to be re-evaluated once facilities more broadly re-open.

Social determinants of COVID-19 mortality at the county level. Fielding-Miller *et al.* PLoS One (October 14, 2020).

Key findings:

- The number of COVID-19 deaths per 100,000 was substantially higher in urban than non-urban counties, 39.1 per 100,000 (IQR: 15.0–107.3) and 5.6 (IQR: 0–19.7), respectively.
- Factors independently associated with higher numbers of deaths for the US overall included:
  - % of farmworkers (5.79 additional deaths per percentage point increase of farmworkers, p = 0.001).
  - % of residents living in poverty (4.41 additional deaths per percentage point increase, p <0.001).
  - % of residents aged >65 years (4.58 additional deaths per percentage point increase, p = 0.002).
  - Population density (0.25 additional deaths per resident per square mile, p <0.001).
- Factors independently associated with deaths per 100,000 persons varied substantially by census region.

Methods: Spatial models to determine county-level associations between COVID-19 mortality and percentage of hired farmworkers, percentage of households without a fluent, adult English-speaker, percentage of uninsured individuals under the age of 65, and percentage of individuals living at or below the federal poverty line, across all 3,024 counties as of July 12, 2020. *Limitations*: Negative associations in some regions might represent unmeasured confounding or gaps in testing or data collection for poor and uninsured individuals.

Implications: Findings indicate that the epidemic is heterogenous and is affecting geographic regions differently. The differences in geographic regions might, in part, reflect regional demographic variation or varied state and local social distancing and other public health policies.

PREPRINT (NOT PEER-REVIEWED)

What predicts adherence to COVID-19 government guidelines? Longitudinal analyses of 51,000 UK adults. Wright *et al.* MedRxiv. (October 21, 2020).

Key findings:

- Increased confidence in government to handle the pandemic was related to higher compliance with government COVID-19 guidelines.
- Mental health and wellbeing, worries about future adversities, and social isolation and loneliness were unrelated to compliance.

Methods: Data from a longitudinal study of over 51,000 adults in the UK were used to determine factors associated with compliance with government guidelines during the initial implementation of social distancing measures (April 1 to June 22, 2020). Factors studied included mental health and wellbeing, social experiences, confidence in institutions, knowledge of COVID-19, and time spent on various activities. *Limitations:* All data were self-reported.

Implications: Findings highlight the role of policy makers in shaping the impact of compliance with mitigation efforts.

Clinical Treatment & Management

PEER-REVIEWED

Registry of arterial and venous thromboembolic complications in patients with COVID-19. Piazza *et al.* Journal of the American College of Cardiology (November 3, 2020)

Key findings:

- 4.6%, 5.9%, and 8.3% of COVID-19 patients experienced a symptomatic thromboembolic event (VTE), a major arterial or venous VTE, or major adverse cardiovascular event, respectively, within 30 days of diagnosis.
    - Events occurred despite high rates of thromboprophylaxis in ICU (90%) and general medical ward (GMW) (85%) patients.
    - No events occurred in outpatients.

Methods: Retrospective study of patients diagnosed with RT-PCR-confirmed COVID-19 at one health network between March 13 and April 3, 2020. Primary outcome was the proportion of ICU patients (n = 170), GMW patients (n = 229) and outpatients (n = 715) who experienced a symptomatic VTE (e.g., deep vein thrombosis), major arterial or VTE (e.g., stroke) or major adverse cardiovascular event (e.g., heart failure) within 30 days of diagnosis. *Limitations*: Microvascular thrombosis was not assessed; unable to assess adherence to antiplatelet or antithrombotic therapy prior to COVID-19.

Implications The high frequency of arterial or venous thromboembolism in hospitalized patients with COVID-19, despite routine thromboprophylaxis, suggests the need for improved risk stratification and enhanced preventive efforts.

PREPRINTS (NOT PEER-REVIEWED)

Viral infections have been associated with several autoimmune diseases. These infections can trigger production of autoantibodies that are directed toward the host's own body potentially causing tissue damage and transient or chronic symptoms and disease.

Clinically identifiable autoreactivity is common in severe SARS-CoV-2 infection. Woodruff *et al.* MedRxiv (October 28, 2020).

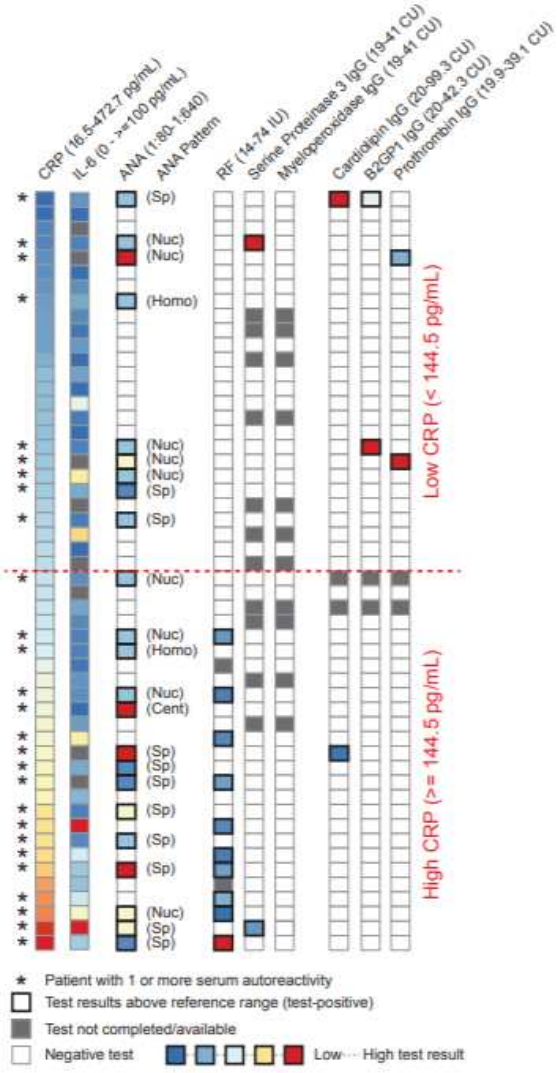
Key findings:

- 44% of patients had antinuclear antibody (ANA) ≥1:80 (the diagnostic threshold for the autoimmune disease systemic lupus erythematosus) and 81% of these positive tests had titers ≥1:160.
    - 59% of ANA-positive patients had ≥1 other positive autoreactive antibody test such as rheumatoid factor (10/52), phospholipids (3/52), prothrombin (2/52), or antineutrophil cytoplasmic antibodies (2/52) (Figure).
    - All patients with >1 positive autoreactive antibody test were positive for either ANA or rheumatoid factor.
- Autoreactivity was correlated with increasing serum levels of c-reactive protein (CRP), a protein found in the bloodstream in response to inflammation.

Methods: Study of 52 severe or critically ill patients with COVID-19 and no known history of autoimmune disease treated at two ICUs in Atlanta, Georgia, between June 1st and July 2nd, 2020. Patients were tested for a variety of autoimmune antibodies. *Limitations*: Limited follow-up.

Implications: Severe COVID-19 may cause *de novo* autoreactive antibody production against a variety of self-antigens which could argue for clinical interventions aimed at modifying the immune response.

Figure:



Note: Adapted from Woodruff *et al*. Heatmap display of clinical results organized by ascending CRP values. Values for individual tests are indicated following the test name (top of figure). **Horizontal red dotted line** indicates low or high levels of serum CRP. Used by permission of author.

Cognitive deficits in people who have recovered from COVID-19 relative to controls: An N = 84,285 online study. Hampshire *et al.* MedRxiv. (October 21, 2020).

Key findings:

- Decreased global cognitive performance was seen among the following (Figure 1):
  - In persons hospitalized and on ventilators cognitive performance was -0.57 standard deviations (SDs) below healthy controls (approximates an 8.5-point difference in IQ).
  - Persons hospitalized but not on a ventilator, -0.45 SDs.
  - Persons assisted at home for respiratory difficulty, -0.12 SDs.
  - Persons with respiratory difficulty but received no medical assistance, -0.10 SDs.

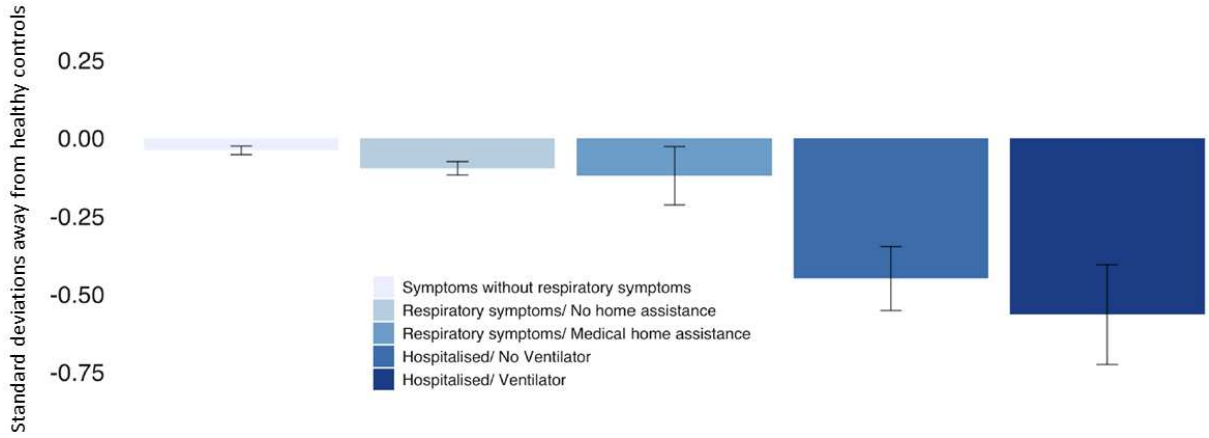
- Persons ill without respiratory difficulty, -0.04 SDs.

- The most apparent deficits were in semantic problem solving and visual selective attention which were associated with disease severity (Figure 2).

Methods: An online survey of cognition, wellbeing, and behavior of 84,285 participants who completed a questionnaire regarding impacts of the pandemic among persons with suspected (n = 12,689) and confirmed (n = 361) SARS-CoV-2 infection were analyzed to determine associations between COVID-19 and cognitive deficits. Testing addressed semantic problem solving, spatial working memory, selective attention and emotional processing. *Limitations*: Most cases unconfirmed; symptom severity was self-reported; cross-sectional design.

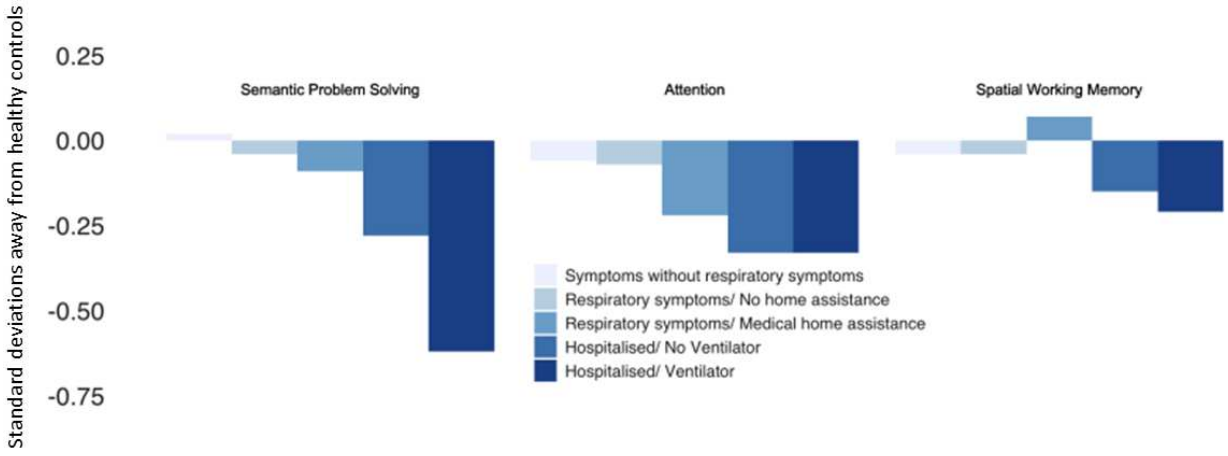
Implications: Cognitive deficits were found in persons with history of COVID-19 and there may be a need for cognitive assessment of persons recovered from COVID-19.

Figure 1



Note: Adapted from Hampshire *et a*l. Global cognitive performance by COVID-19 symptom severity. Licensed under CC-BY 4.0.

Figure 2



Note: Adapted from Hampshire *et al*. Cognitive domain performance by symptom severity. Licensed under CC-BY 4.0.

In Brief

Testing

- Rafiei & Mello. **The missing piece — SARS-CoV-2 testing and school reopening.** NEJM. Authors argue that SARS-CoV-2 testing is necessary to safely re-open schools and discuss challenges in implementing school testing programs and ways in which state and federal governments can assist.
- Rubin, R. **The challenges of expanding rapid tests to curb COVID-19.** JAMA. Authors discuss the merits of ramping up rapid SARS-CoV-2 testing and challenges including variable test accuracy, manufacturing logistics and public perceptions that testing can be used in lieu of other preventive measures such as mask wearing.

Mental health and well being

- Fong & Iarocci. **Child and family outcomes following pandemics: A systematic review and recommendations on COVID-19 policies.** Journal of Pediatric Psychology. A systematic review of mental health outcomes and needs of children and families during past pandemics.
- Ickert *et al*. **Maintaining resident social connections during COVID-19: Considerations for long-term care.** Gerentology and Geriatric Medicine. Considerations for facilitating social connections of long-term care residents and their families while restrictions on visitation are in place.

Miscellaneous

- Vignesh *et al*. **Is herd immunity against SARS-CoV-2 a silver lining?** Frontiers in Immunology. Authors discuss a variety of elements that factor into whether populations reach herd immunity thresholds and argue that the most practical way to achieve this is through vaccination.
- Blecker *et al*. **Hospitalizations for chronic disease and acute conditions in the time of COVID-19**. JAMA Internal Medicine. Study found a substantial decrease in the number of non-COVID-19 related hospitalizations between March 22 to April 11, 2020.
- Lan *et al*. **Effects of universal masking on Massachusetts healthcare workers' COVID-19 incidence.** Occupational Medicine. Study found universal masking, implemented in healthcare systems statewide, was associated with decreasing incidence trend of COVID-19 among healthcare workers while incidence rose in the surrounding community.
- Figueiredo-Campos *et al*. **Seroprevalence of anti-SARS-CoV-2 antibodies in COVID-19 patients and healthy volunteers up to six months post disease onset.** European Journal of Immunology. Study of 2,998 COVID-19 patients demonstrated that IgG antibodies to SARS-CoV-2 receptor-binding domain protein lasted up to 6 months post-symptom onset and that titers were proportional to neutralizing activity.
- Ong *et a*l. **Environmental contamination in a COVID-19 intensive care unit (ICU) – what is the risk?** Infection Control and Hospital Epidemiology. Study found that environmental contamination with SARS-CoV-2 in a hospital intensive care unit was lower than that of a general medical floor and that use of mechanical ventilation or high-flow nasal oxygen was not associated with greater surface contamination.

Declines in SARS-CoV-2 Transmission, Hospitalizations, and Mortality After Implementation of Mitigation Measures— Delaware, March–June 2020

Florence A. Kanu[1,2]; Erica E. Smith[3]; Tabatha Offutt-Powell[3]; Rick Hong[3], Delaware Case Investigation and Contact Tracing Teams[3]; Thu-Ha Dinh[2]; Eric Pevzner[2]

Mitigation measures, including stay-at-home orders and public mask wearing, together with routine public health interventions such as case investigation with contact tracing and immediate self-quarantine after exposure, are recommended to prevent and control the transmission of SARS-CoV-2, the virus that causes coronavirus disease 2019 (COVID-19) (*1*–*3*). On March 11, the first COVID-19 case in Delaware was reported to the Delaware Division of Public Health (DPH). The state responded to ongoing community transmission with investigation of all identified cases (commencing March 11), issuance of statewide stay-at-home orders (March 24–June 1), a statewide public mask mandate (from April 28), and contact tracing (starting May 12). The relationship among implementation of mitigation strategies, case investigations, and contact tracing and COVID-19 incidence and associated hospitalization and mortality was examined during March–June 2020. Incidence declined by 82%, hospitalization by 88%, and mortality by 100% from late April to June 2020, as the mask mandate and contact tracing were added to case investigations and the stay-at-home order. Among 9,762 laboratory-confirmed COVID-19 cases reported during March 11–June 25, 2020, two thirds (6,527; 67%) of patients were interviewed, and 5,823 (60%) reported completing isolation. Among 2,834 contacts reported, 882 (31%) were interviewed and among these contacts, 721 (82%) reported completing quarantine. Implementation of mitigation measures, including mandated mask use coupled with public health interventions, was followed by reductions in COVID-19 incidence and associated hospitalizations and mortality. The combination of state-mandated community mitigation efforts and routine public health interventions can reduce the occurrence of new COVID-19 cases, hospitalizations, and deaths.

Using laboratory and case investigation data, changes in COVID-19 incidence and associated hospitalization and mortality in Delaware during March 11–June 25 were assessed. Laboratory data from the Delaware Electronic Reporting and Surveillance System (DERSS) and case investigation data from Delaware DPH were obtained. DERSS data included case classification (e.g., laboratory-confirmed or probable*); case investigation data included hospitalization status and outcome, including death. Incidence was defined as the number of newly confirmed COVID-19 patients per 10,000 Delaware residents per week (*4*). Hospitalization and mortality rates were calculated similarly, as the number of patients with confirmed COVID-19 who were hospitalized or died per 10,000 persons per week. Percent change was calculated to describe the magnitude of rate change. Delaware mitigation and public health interventions included 1) case investigations (starting March 11), which involved interviewing patients with SARS-CoV-2 infection, asking each to immediately self-isolate while collecting information on demographic characteristics, potential exposure source, symptoms,† and close contacts§;

* A probable case was defined as an illness meeting clinical criteria and having an epidemiologic link with no confirmatory laboratory testing performed for COVID-19, or an illness with presumptive laboratory evidence (detection of antigen or antibody) and either meeting clinical criteria or having an epidemiologic link, or an illness in a person meeting vital records criteria with no confirmatory laboratory testing for COVID-19 performed. https://www.cdc.gov/coronavirus/2019-ncov/covid-data/faq-surveillance.html.

† The following signs and symptoms were monitored: cough, fever, fatigue, body aches, loss of taste/smell, shortness of breath, chills, and sore throat.

§ Case investigation included inquiries about close contacts in May 2020. At time of data collection, CDC guidance on contact definition was "persons less than 6 feet from a confirmed case for at least 10 minutes." CDC guidance now defines contacts as any person within 6 feet of an infected person for a cumulative total of 15 minutes or more over a 24-hour period starting from 2 days before illness onset (or, for asymptomatic patients, 2 days prior to test specimen collection). https://www.cdc.gov/coronavirus/2019-ncov/php/contact-tracing/contact-tracing-plan/appendix.html#contact.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-002228

2) statewide mandated stay-at-home order[¶] (March 24–June 1); 3) statewide mandated mask use in public[**] (instituted April 28); and 4) contact tracing (starting May 12), wherein close contacts were interviewed and asked to self-quarantine and report symptoms for 14 days following an exposure. Changes in COVID-19 incidence and associated hospitalizations and mortality from March through June were assessed.

After the initial case report and stay-at-home order, COVID-19 incidence, hospitalization, and mortality rates increased, peaking during the week of April 13 at 15.0, 2.0, and 0.8 per 10,000 persons, respectively (Figure). After the peak, incidence declined by 18%, hospitalizations by 20%, and deaths by 13%, before increasing slightly during the week of April 20. Rates declined again the same week the mask mandate went into effect (April 28) and continued to decline by 82% (incidence), 88% (hospitalization) and 100% (mortality) from late April through June, as contact tracing was added to case investigations, the stay-at-home order, and the mask mandate.

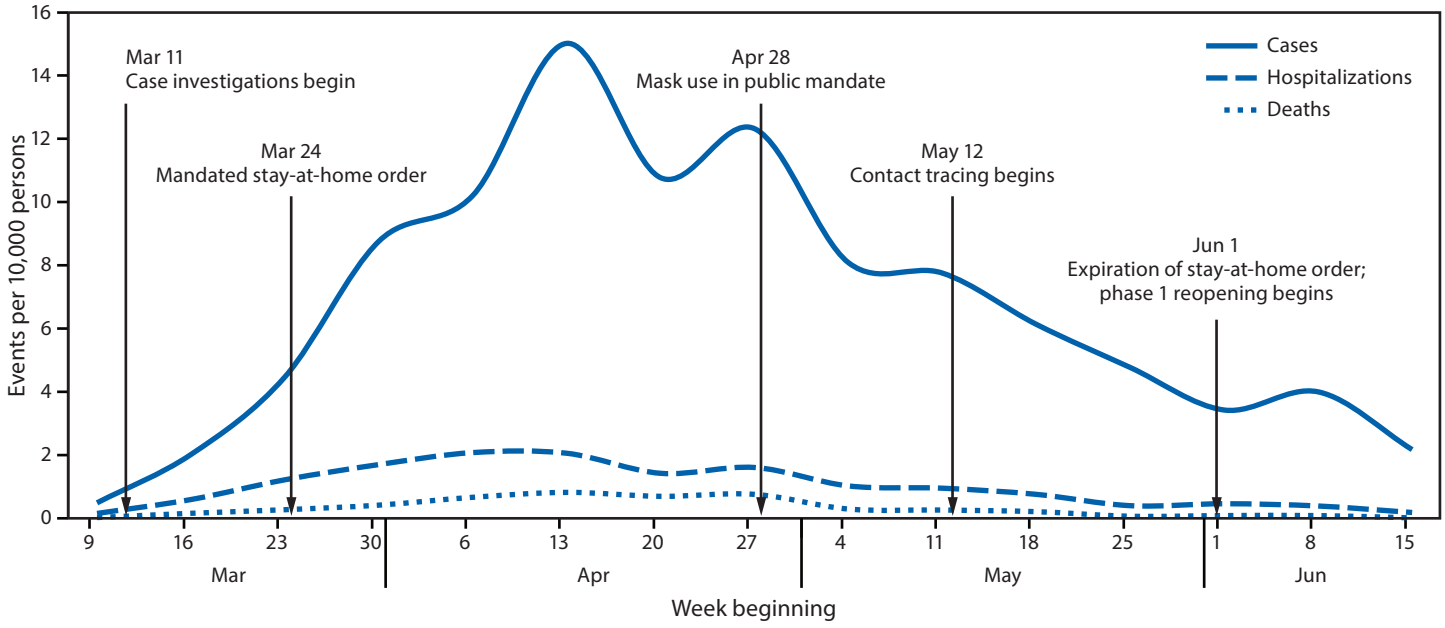
During March 11–June 25, a total of 9,762 newly confirmed COVID-19 cases were identified in DERSS; among these cases, 6,527 (67%) patients were interviewed and asked to self-isolate, among whom 5,823 (89%) had been released from isolation[††] at the time of data collection. Median patient age was 41 years (interquartile range [IQR] = 28–54 years), and 55% were female (Table). The median interval from receiving a positive test result to interview was 8 days (IQR = 6–12 days) and from DPH's receipt of case report to interview was 5 days (IQR = 2–8 days). Patients who were not interviewed were those who did not respond to call attempts (1,134, 12%), were in a hospital/long-term care facility at time of contact (788, 8%), did not have an available phone number (673, 7%), had died (433, 4%), or were not interviewed for other reasons[¶¶] (207, 2%). Among interviewed patients, 5,742 (88%) reported having any COVID-19–related symptoms before the interview date, and 55% reported close contact with someone with diagnosed COVID-19.

Among 6,527 interviewed patients with laboratory-confirmed COVID-19, 5,390 (83%) either refused to name contacts or could not recall contacts. The mean number of contacts reported per patient who reported one or more contacts was 2.5 (IQR = 1–3). Among the 2,834 contacts reported, complete contact information was obtained for 1,869 (66%), and 882 (47%) of those were interviewed and asked to self-quarantine. The median interval from patient interview to contact interview was 2 days (IQR = 1–4 days). The median age of interviewed contacts was 25 years (IQR = 14–47 years), 433 (49%) were female, 721 (82%) did not develop symptoms during quarantine, and 771 (87%) lived in the same household as someone with confirmed

[¶] https://governor.delaware.gov/health-soe/fifth-state-of-emergency/.
[**] https://governor.delaware.gov/health-soe/thirteenth-state-of-emergency/.
[††] Release from isolation was dependent on CDC guidance during this study period: initially, patients were asked to isolate for 14 days from symptom onset or test date and be symptom-free for 7 days. Later, patients were asked to isolate for 10 days from symptom onset or test date and be symptom-free for 3 days. Patients with asymptomatic cases were asked to isolate for 10 days after test date.

[¶¶] Other status was reserved for unique circumstances that could not be addressed by case investigators or contact tracers without additional information.

FIGURE. Confirmed COVID-19 cases, associated hospitalizations, and deaths reported to Delaware Division of Public Health, by week, and COVID-19 mitigation efforts — Delaware Department of Health and Social Services, March 9–June 15, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

MS-DOH-21-1816-A-002229

COVID-19. Overall, 161 (18%) of the 882 contacts who were reached experienced symptoms during quarantine and were urged to be tested for SARS-CoV-2. A manual search of DERSS data determined that among 161 symptomatic contacts, 20 (12%) were tested, four of whom (3%) received a COVID-19 diagnosis. Reasons for not interviewing contacts included that the contact did not respond to call attempts (265, 14%), had no available phone number (208, 11%), refused (88, 5%), was a non-Delaware resident (20, 1%), or other reasons (406, 22%).

TABLE. Characteristics of persons with confirmed COVID-19 (patients) and contacts interviewed during case and contact investigations — Delaware, March–June 2020

Characteristic	No. (%)	
	Interviewed patients (n = 6,527)	Interviewed contacts (n = 882)
Age, yrs, median (IQR)	41 (28–54)	25 (14–74)
Time from positive COVID-19 test to interview, days, median (IQR)	8 (6–12)	N/A
Time from report to interview, days, median (IQR)	5 (2–8)	2 (1–4)

† Household exposure defined as possible exposure to COVID-19 from a household member with confirmed COVID-19.

Discussion

A stay-at-home order and case investigations instituted weeks before the peak in COVID-19 cases (week of April 13) in Delaware likely contributed to the subsequent decline observed in COVID-19 incidence and associated hospitalization and deaths. As expected, the impact on incidence was not immediate but occurred weeks after measures were implemented, as new cases represented exposure that occurred during previous weeks. Additional steep declines in reports of new cases occurred after a public mask use mandate was issued in late April. Masks are critical for reducing SARS-CoV-2 transmission from persons with symptomatic or asymptomatic infection (*5*). Wearing masks can prevent respiratory droplets containing SARS-CoV-2 from traveling into the air and being transmitted to other persons and thus can reduce exposures and infections (*6*,*7*).

Early detection, self-isolation, and investigation of COVID-19 cases and self-quarantine of close contacts can be effective in preventing community transmission, if contacts are identified and reached soon after exposure (*8*). Because of limited resources and the growing number of cases, contact tracing in Delaware officially began in May when the Delaware National Guard was activated to assist Delaware DPH. In Delaware, contacts were monitored until symptom onset or quarantine completion. Testing was recommended for contacts reporting symptoms; however, no active follow-up was performed because of constrained resources. Case investigation was completed among contacts who received positive test results; therefore, having active follow-up and referral systems for testing contacts could expand disease prevention and containment opportunities.

Several barriers to case investigation and contact tracing were identified. First, low numbers of contacts were identified: 83% of interviewed patients either refused to disclose contacts or could not recall contacts. Second, cases were contacted a median of 8 days after receiving their positive test result and 5 days after report of this result to DPH. Earlier initiation of case investigation might increase recall and early identification of close contacts and thus prevent further disease transmission. Lastly, 22% of contacts could not be reached for reasons designated as "other," an interaction outcome in case investigations and contact tracing reserved for circumstances interviewers could not address without additional information. Daily and weekly data monitoring to provide additional information for those with "other" as an interaction outcome could increase the number of persons reached. These barriers to contact tracing might have limited effectiveness and were missed opportunities to recommend other mitigation strategies (e.g., testing, quarantine, or isolation).

MS-DOH-21-1816-A-002230

Summary

What is already known about this topic?

COVID-19 mitigation measures (e.g., stay-at-home orders and public mask mandate) and fundamental public health interventions (e.g., case investigations and contact tracing with prompt isolation or quarantine) are primary approaches to preventing and controlling SARS-CoV-2 community transmission.

What is added by this report?

State-mandated stay-at-home orders and public mask mandates coupled with case investigations with contact tracing contributed to an 82% reduction in COVID-19 incidence, 88% reduction in hospitalizations, and 100% reduction in mortality in Delaware during late April–June.

What are the implications for public health practice?

The combination of state-mandated community mitigation efforts and routine public health interventions can reduce the occurrence of new COVID-19 cases, hospitalizations, and deaths.

The findings in this report are subject to at least three limitations. First, data on adherence to the state-mandated stay-at-home order and use of masks in public were not available. Second, adherence to self-quarantine was self-reported. Finally, because of the observational design of the study, the decline in COVID-19 incidence, hospitalization, and mortality could not be attributed to the relative contribution of each mitigation measure.

A combination of mitigation measures including stay-at-home orders, mandated mask use in public, and case investigations with contact tracing, can reduce COVID-19 incidence and associated deaths (*9*). No single mitigation strategy is likely to be effective alone. These strategies are effective in limiting potential exposure to SARS-CoV-2 and reducing community transmission when implemented as part of a multicomponent strategy (*10*). In Delaware, state-mandated community mitigation efforts, such as stay-at-home orders, coupled with mask use, likely contributed to the decline in new COVID-19 cases. SARS-CoV-2 community transmission, hospitalization, and mortality can be reduced with statewide mitigation strategies implemented in tandem with the routine public health interventions of case investigation with contact tracing, and immediate self-isolation of cases and self-quarantine of contacts.

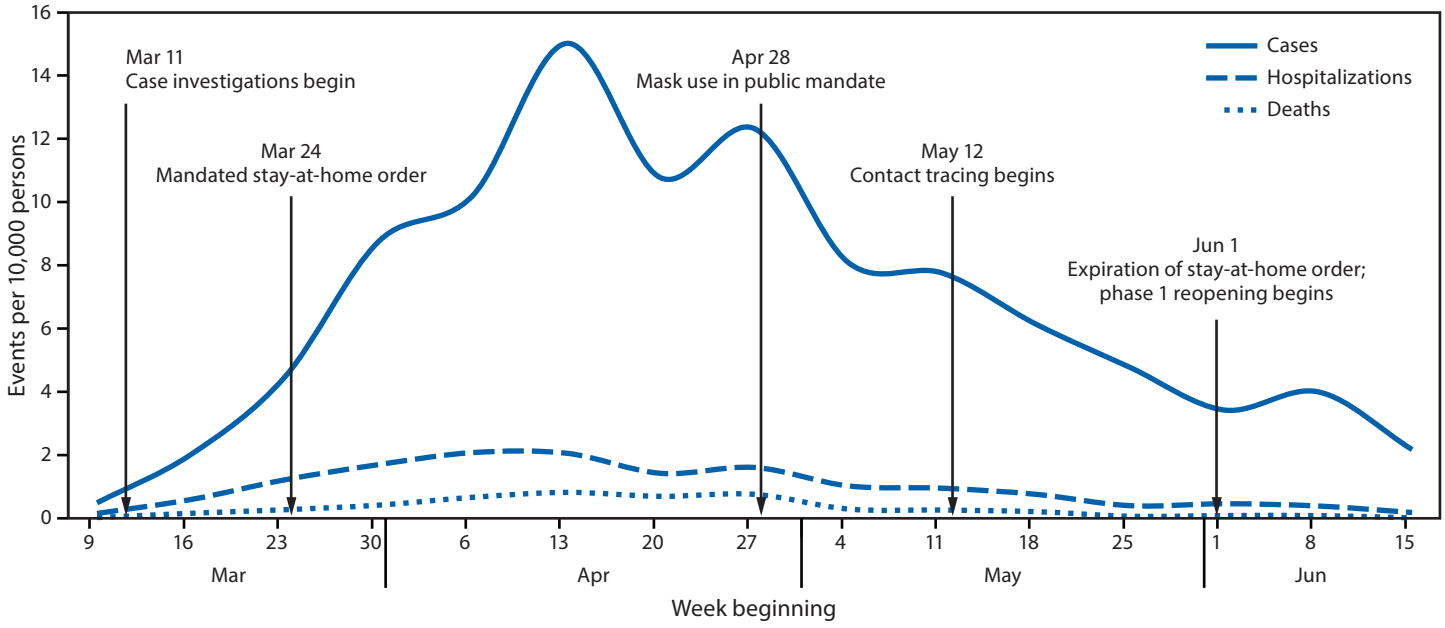
[††] Release from isolation was dependent on CDC guidance during this study period: initially, patients were asked to isolate for 14 days from symptom onset or test date and be symptom-free for 7 days. Later, patients were asked to isolate for 10 days from symptom onset or test date and be symptom-free for 3 days. Patients with asymptomatic cases were asked to isolate for 10 days after test date.

[¶¶] Other status was reserved for unique circumstances that could not be addressed by case investigators or contact tracers without additional information.

FIGURE. Confirmed COVID-19 cases, associated hospitalizations, and deaths reported to Delaware Division of Public Health, by week, and COVID-19 mitigation efforts — Delaware Department of Health and Social Services, March 9–June 15, 2020



Abbreviation: COVID-19 = coronavirus disease 2019.

MS-DOH-21-1816-A-002233

COVID-19. Overall, 161 (18%) of the 882 contacts who were reached experienced symptoms during quarantine and were urged to be tested for SARS-CoV-2. A manual search of DERSS data determined that among 161 symptomatic contacts, 20 (12%) were tested, four of whom (3%) received a COVID-19 diagnosis. Reasons for not interviewing contacts included that the contact did not respond to call attempts (265, 14%), had no available phone number (208, 11%), refused (88, 5%), was a non-Delaware resident (20, 1%), or other reasons (406, 22%).

TABLE. Characteristics of persons with confirmed COVID-19 (patients) and contacts interviewed during case and contact investigations — Delaware, March–June 2020

Characteristic	No. (%)	
	Interviewed patients (n = 6,527)	Interviewed contacts (n = 882)
Age, yrs, median (IQR)	41 (28–54)	25 (14–74)
Time from positive COVID-19 test to interview, days, median (IQR)	8 (6–12)	N/A
Time from report to interview, days, median (IQR)	5 (2–8)	2 (1–4)
Sex		
Male	2,911 (44.6)	449 (50.9)
Female	3,614 (55.4)	433 (49.1)
Missing	2 (0.03)	0 (—)
Race/Ethnicity		
White, non-Hispanic	1,769 (27.1)	202 (22.9)
Black or African American, non-Hispanic	1,949 (29.9)	155 (17.6)
Hispanic/Latino	2,237 (34.3)	350 (39.7)
Asian, non-Hispanic	128 (2.0)	6 (0.7)
Other/Multiple races, non-Hispanic	327 (5.0)	20 (2.3)
Unknown/Missing	117 (1.8)	149 (16.9)

Sources: Delaware Case Investigation and Contract Tracing Systems, Delaware Department of Health and Social Services, Division of Public Health.
Abbreviations: COVID-19 = coronavirus disease 2019; IQR = interquartile range; N/A = not applicable.
* Patients were asked if they had symptoms from 14 days before test date to date of interview; contacts were asked during monitoring period if they had symptoms.
† Household exposure defined as possible exposure to COVID-19 from a household member with confirmed COVID-19.

Discussion

A stay-at-home order and case investigations instituted weeks before the peak in COVID-19 cases (week of April 13) in Delaware likely contributed to the subsequent decline observed in COVID-19 incidence and associated hospitalization and deaths. As expected, the impact on incidence was not immediate but occurred weeks after measures were implemented, as new cases represented exposure that occurred during previous weeks. Additional steep declines in reports of new cases occurred after a public mask use mandate was issued in late April. Masks are critical for reducing SARS-CoV-2 transmission from persons with symptomatic or asymptomatic infection (*5*). Wearing masks can prevent respiratory droplets containing SARS-CoV-2 from traveling into the air and being transmitted to other persons and thus can reduce exposures and infections (*6*,*7*).

Early detection, self-isolation, and investigation of COVID-19 cases and self-quarantine of close contacts can be effective in preventing community transmission, if contacts are identified and reached soon after exposure (*8*). Because of limited resources and the growing number of cases, contact tracing in Delaware officially began in May when the Delaware National Guard was activated to assist Delaware DPH. In Delaware, contacts were monitored until symptom onset or quarantine completion. Testing was recommended for contacts reporting symptoms; however, no active follow-up was performed because of constrained resources. Case investigation was completed among contacts who received positive test results; therefore, having active follow-up and referral systems for testing contacts could expand disease prevention and containment opportunities.

Several barriers to case investigation and contact tracing were identified. First, low numbers of contacts were identified: 83% of interviewed patients either refused to disclose contacts or could not recall contacts. Second, cases were contacted a median of 8 days after receiving their positive test result and 5 days after report of this result to DPH. Earlier initiation of case investigation might increase recall and early identification of close contacts and thus prevent further disease transmission. Lastly, 22% of contacts could not be reached for reasons designated as "other," an interaction outcome in case investigations and contact tracing reserved for circumstances interviewers could not address without additional information. Daily and weekly data monitoring to provide additional information for those with "other" as an interaction outcome could increase the number of persons reached. These barriers to contact tracing might have limited effectiveness and were missed opportunities to recommend other mitigation strategies (e.g., testing, quarantine, or isolation).

MS-DOH-21-1816-A-002234

Summary

What is already known about this topic?

COVID-19 mitigation measures (e.g., stay-at-home orders and public mask mandate) and fundamental public health interventions (e.g., case investigations and contact tracing with prompt isolation or quarantine) are primary approaches to preventing and controlling SARS-CoV-2 community transmission.

What is added by this report?

State-mandated stay-at-home orders and public mask mandates coupled with case investigations with contact tracing contributed to an 82% reduction in COVID-19 incidence, 88% reduction in hospitalizations, and 100% reduction in mortality in Delaware during late April–June.

What are the implications for public health practice?

The combination of state-mandated community mitigation efforts and routine public health interventions can reduce the occurrence of new COVID-19 cases, hospitalizations, and deaths.

The findings in this report are subject to at least three limitations. First, data on adherence to the state-mandated stay-at-home order and use of masks in public were not available. Second, adherence to self-quarantine was self-reported. Finally, because of the observational design of the study, the decline in COVID-19 incidence, hospitalization, and mortality could not be attributed to the relative contribution of each mitigation measure.

A combination of mitigation measures including stay-at-home orders, mandated mask use in public, and case investigations with contact tracing, can reduce COVID-19 incidence and associated deaths (*9*). No single mitigation strategy is likely to be effective alone. These strategies are effective in limiting potential exposure to SARS-CoV-2 and reducing community transmission when implemented as part of a multicomponent strategy (*10*). In Delaware, state-mandated community mitigation efforts, such as stay-at-home orders, coupled with mask use, likely contributed to the decline in new COVID-19 cases. SARS-CoV-2 community transmission, hospitalization, and mortality can be reduced with statewide mitigation strategies implemented in tandem with the routine public health interventions of case investigation with contact tracing, and immediate self-isolation of cases and self-quarantine of contacts.

Good afternoon,

Please see below for a collection of Coronavirus Disease 2019 (COVID-19) information, gathered for your awareness:

New Information

- CDC Lab Alert: Ellume Issues Voluntary Recall of Specific Lots of Ellume COVID-19 Home Tests [Attachment, Links]
    - Please see the following message from CDC's Laboratory Outreach Communication System (LOCS):
      *"On **October 1**, the digital diagnostics company Ellume announced a voluntary recall on specific lots of the Ellume COVID-19 Home Test, the company's rapid, self-administered COVID-19 antigen test, because there is an increased chance that tests from the affected lot numbers may give a false positive result. Ellume advises consumers to visit their website to check whether their product is part of the affected lots and, if affected, to receive further instructions."*
- MMWR Early Release: "National and State Trends in Anxiety and Depression Severity Scores Among Adults During the COVID-19 Pandemic — United States, 2020–2021" [Attachment, Link]
    - From the summary: *"Nationwide, average anxiety severity scores increased 13% from August to December 2020 and then decreased 26.8% from December 2020 to June 2021. Similar increases and decreases occurred in depression severity scores."*
- FDA Authorizes Additional OTC Home Test to Increase Access to Rapid Testing for Consumers [Attachment, Link]

On **October 4**, the U.S. Food and Drug Administration (FDA) issued an emergency use authorization (EUA) for the ACON Laboratories Flowflex COVID-19 Home Test, an over-the-counter (OTC) COVID-19 antigen test, which adds to the growing list of tests that can be used at home without a prescription. This action (linked here and attached) should significantly increase the availability of rapid, at-home tests and is expected to double rapid at-home testing capacity in the U.S. over the next several weeks. By years end, the manufacturer plans to produce more than 100 million tests per month, and this number will rise to 200 million per month by February 2022.

- CDC MasK-12 Project [Attachment]
    - CDC is partnering with schools and districts in states throughout the U.S. this fall to evaluate mask adherence in K-12 schools. CDC will train school-identified observers to collect data on mask adherence across participating schools. Observers may include high school students who are interested in science or public health, and the project offers a great opportunity for real-world public health experience. Schools can also use staff or volunteers to conduct observations.
    - Results from this investigation will be used to inform decision-making around masking in K-12 school settings, report findings to evaluate messaging and education around mask use, and to identify locations on school campuses where mask adherence can be improved. Enrollment for the MasK-12 project will occur in early October. If you are interested in participating or would like to learn more, email eocevent335@cdc.gov.

Standing Updates

- CDC Partner Update – October 4 [Attachment]
    - Please see attached for the latest updates from CDC's State, Tribal, Local, and Territorial (STLT) Task Force.
- HHS COVID-19 Update – October 4 [Attachment]
    - Please see attached for the latest COVID-19 updates from the HHS Office of Intergovernmental and External Affairs. Updates typically include highlights from any recent COVID-19 Response Team briefings, as well as vaccine, testing, treatment and research updates, toolkits, and resources.
- Press Briefings: White House COVID-19 Response Team and Public Health Officials [Link]
    - The White House COVID-19 Response Team holds regular press briefings during the week, typically on **Mondays, Wednesdays,** and **Fridays** at **11:00 am EDT**. *Please note:* Briefings sometimes begin after 11:00 am. Visit www.whitehouse.gov/live for the latest schedule and broadcast links. All COVID briefings are publicly available on the White House YouTube channel; past briefings may appear in this playlist link.
- CSTE COVID-19 Response Resource Repository [Link]
    - The CSTE COVID-19 Response Resource Repository and related discussion forums are available via Basecamp to encourage jurisdictional sharing of information, resources, best practices, and challenges. To sign-up and access the Basecamp, please visit this link.
- Request Form for CSTE COVID-19 Call Topics [Link]
    - CSTE encourages members to suggest topics for future COVID-19 response-related calls with CSTE members, CDC, and/or partner organizations. To submit a request, please

CDC Resources

Community

- Recommendations for Tribal Ceremonies and Gatherings During the COVID-19 Outbreak: CDC offers the following recommendations to help tribal communities, elders, and leaders decide how best to keep their communities safe and prevent the spread of COVID-19. These considerations are meant to support—not replace—tribal laws, rules, and regulations aimed at protecting the health of tribal communities.

Science and Data

- COVID-19 Public Readiness and Emergency Preparedness (PREP) Act: HHS made a technical amendment to the current COVID-19 Public Readiness and Emergency Preparedness (PREP) Act declaration to supplement the references to the Advisory Committee on Immunization Practices (ACIP) with references to the Centers for Disease Control and Prevention (CDC). This change is being made to clarify that "ACIP recommendations" and "ACIP standard immunization schedules" are in fact recommendations and schedules made by CDC after consultation with ACIP. This clarification also applies to related guidance and opinions.
- COVID-19 Science Update Edition 107: The October 1, 2021 update includes information pertaining to detection, burden, impact, prevention, mitigation, and intervention strategies, and the social, behavioral, and communication science related to COVID-19.
- COVID-19 Vaccination for Pregnant People to Prevent Serious Illness, Deaths, and Adverse Pregnancy Outcomes from COVID-19: CDC recommends urgent action to increase Coronavirus Disease 2019 (COVID-19) vaccination among people who are pregnant, recently pregnant (including those who are lactating), who are trying to become pregnant now, or who might become pregnant in the future. CDC strongly recommends COVID-19 vaccination either before or during pregnancy because the benefits of vaccination outweigh known or potential risks.
- FAQs About Medical Consent & Pfizer-BioNTech Booster Doses for Long-term Care Residents: A resource for providers participating in the CDC COVID-19 Vaccination Program, long-term care residents and their families.
- Interim Clinical Considerations for Use of COVID-19 Vaccines Currently Approved or Authorized in the United States: CDC now recommends that people aged 65 years and older, residents in long-term care settings, and people aged 50–64 years with underlying medical conditions **should** receive a booster shot of Pfizer-BioNTech's COVID-19 Vaccine at least 6 months after completing their Pfizer-BioNTech primary series. Other groups **may** receive a booster shot based on their individual risk and benefit. Learn more.

Work and School

Updated on September 29, 2021:

- Responding to COVID-19 Cases in K-12 Schools: Resources for School Administrators
- Overview of COVID-19 Quarantine for K-12 Schools

Upcoming Meetings

- **CDC Community of Practice Call:** On October 5th, 3:00 PM ET CDC will replay the Community of Practice on *The Role of Prevention Measures, Testing Strategies, and Vaccinations to Prevent the Spread of COVID-19 at Summer Youth Camps*. To watch the replay, please use your existing link or click here to register for the call series.
- **CDC Global COVID-19-Associated Orphanhood webinar**: On October 6th, 8:30-10:00 AM ET CDC will host a webinar on how increases in mortality of parents and other caregivers in the COVID-19 pandemic are accompanied by increases in extreme vulnerability from loss of livelihoods, schooling, health recovery and usual sources of service provision and support for children. To register for the webinar, please click here.

- **CDC All-State, Tribal, Local, and Territorial (STLT) Update Call:** The next call will be on Tuesday, October 12th, 2:00-2:45 PM ET. CDC hosts a weekly national call series to provide state, tribal, local, and territorial partners with the latest information on the COVID-19 outbreak and U.S. preparedness efforts. To register for the weekly call series, please click here.

Additional Resources

- FDA Vaccines and Related Biological Products Advisory Committee (VRBPAC) meeting: On October 14th and 15th, the advisory committee will meet to discuss the use of booster doses of the Moderna COVID-19 Vaccine and the Janssen COVID-19 Vaccine.
- Find a COVID-19 vaccine near you: Vaccines.gov
  - Individuals in the U.S. can now utilize a text messaging service to locate vaccine locations, available in both English and Spanish. Individuals can text their ZIP code to 438829 (GETVAX) and 822862 (VACUNA) to find three locations nearby that have vaccines available.

FDA - Center for Devices and Radiological Health

FDA Authorizes Additional COVID-19 Over-the-Counter Home Antigen Test

Today, the U.S. Food and Drug Administration issued an emergency use authorization (EUA) for ACON Laboratories Flow*flex* COVID-19 Home Test, an over-the-counter COVID-19 antigen test.

- It can be used to test both symptomatic and asymptomatic individuals without the need for repeat testing over several days, known as serial testing.
- The authorization should significantly increase the availability of rapid, at-home tests for consumers and is expected to double rapid at-home testing capacity in the U.S. over the next several weeks. By years end, the manufacturer plans to produce more than 100 million tests per month, and this number will rise to 200 million per month by February 2022.

Learn More

Over-the-Counter and At-Home Tests Remain a High Priority

Since March 2020, the FDA has authorized over 400 COVID-19 tests and sample collection devices, including authorizations for rapid, OTC at-home tests. Today's action highlights the agency's continued commitment to increasing the availability of accurate and reliable at-home COVID-19 diagnostic tests, and to facilitating consumer access to these tests.

HHS Office of Intergovernmental and External Affairs COVID-19 Update for October 4, 2021

CASE UPDATE

New Cases (based on 7-day rolling average)

- **43,605,623** US cases
- **10.4% decrease** in new cases (7-day average), as of October 1st; (was 18.6% decrease last week)

Testing

- **582,771,630** tests completed (10/4)
- **6.5% positive** test rate as of the week of 9/24 – 9/30 (was 7.1% last week)

Hospitalizations

- **3,069,152** total COVID hospital admissions
- The 7-day average (9/25– 10/1) number of new confirmed COVID-19 admissions **decreased from 8,906 to 7,600** admissions per day

Deaths

- **700,176** total US deaths
- The 7-day average (9/25 – 10/1) number of reported deaths **decreased from 1,595 to 1,501** deaths per day

Vaccines

- **396,919,564** vaccine doses **administered** (10/4)
- **64.9%** (215.5 million people) of the population has received **1 or more doses** and **56%** (185.8 million people) of the population have been **fully vaccinated**
- **77.7%** of adults 18 and older have received **at least 1 dose** and **67.3%** have been **fully vaccinated**

STATEMENT BY PRESIDENT BIDEN (10/2) ON 700,000 AMERICAN DEATHS FROM COVID-19

Read the full statement here.

“To heal we must remember, and as our nation mourns the painful milestone of 700,000 American deaths due to COVID-19, we must not become numb to the sorrow. On this day, and every day, we remember all those we have lost to this pandemic and we pray for their loved ones left behind who are missing a piece of their soul.

As we do, the astonishing death toll is yet another reminder of just how important it is to get vaccinated. The vaccines are safe, free, and easy—and we have made extraordinary progress in our fight against COVID-19 over the last eight months because of the vaccines. More than three-quarters of all Americans age 12 and up have now received at least one vaccine dose—including nearly 94 percent of all seniors. Hundreds of thousands of families have been spared the unbearable loss that too many Americans have already endured during this pandemic.

If you haven’t already, please get vaccinated. It can save your life and the lives of those you love. It will help us beat COVID-19 and move forward, together, as one nation.”

HIGHLIGHTS FROM FRIDAY'S (10/1) WHITE HOUSE COVID-19 RESPONSE TEAM BRIEFING

Read the full briefing here.

Dr. Walensky

- **Vaccine Effectiveness:** Dr. Walensky outlined that there are still places in the country where far too many people remain unvacated, and many states where vaccination rates are less than 50 percent. Dr. Walenksy emphasized that COVID-19 vaccines are highly effective in preventing serious disease, hospitalizations, and deaths due to COVID-19. She also stated that "high vaccination coverage in your community translates into fewer cases, less of a burden on your local healthcare system, lower disease rates in your classrooms, and better health for those around you, including protecting children less than 12 years old who are not yet eligible for vaccination."
- **Vaccination in Pregnant Women:** Dr. Walensky commented that this week, CDC released ahealth alert highlighting the incredibly low rates of vaccination in pregnant people and those who may become pregnant, a group of people who are at high risk for severe complications from COVID-19. Overall, only 31 percent of pregnant people are fully vaccinated, and only 15 percent of Black pregnant people are vaccinated. Dr. Walenksy reinforced that these vaccines are safe and effective, including during pregnancy. She urged, "The benefits of vaccination far outweigh any risk to both mom and to baby."

Dr. Fauci

- **Vaccine Effectiveness:** Similar to Dr. Walensky, Dr. Fauci highlighted the effectiveness of the COVID-19 vaccines. Dr. Fauci pointed to a study in Seattle and King County which found that "p eople who are not fully vaccinated are eight times more likely to test positive, 41 times more likely to be hospitalized, and 57 times more likely to die compared to people who are vaccinated."
- **Booster Shots**: Dr. Fauci stated that booster shots provide further protection against SARS-CoV-2 infection and symptomatic COVID-19 disease for people who are at increased risk of severe COVID-19 disease. Dr. Fauci commented, "Twelve days or more after the booster dose, the rate of confirmed infection was lower in the booster group than in the non-booster group by a factor of 11.3 and the rate of severe illness lower by a factor of 19.5."
- **Vaccinating Children:** Dr. Fauci reiterated that a few days ago, Pfizer and BioNTech submitted their data to the FDA from their Phase 2/3 trials of the vaccine in children 5 to 11. He stated, "the FDA will make a regulatory determination, and the CDC with their ACIP will make a recommendation."

Jeff Zients

- **Vaccination Requirements:** Mr. Zients stated that the President's vaccination requirements will apply to about 100 million workers, which is two-thirds of all workers across the country. Mr. Zients reiterated that all employers should act now to protect their workforce and communities by enacting vaccination requirements. Mr. Zients emphasized, "When organizations implement vaccine requirements, vaccination rates soar to 90 percent or greater."
- **Booster Shots:** Mr. Zients commented that as we vaccinate the unvaccinated, the Administration is also focused on enhancing protection for vaccinated Americans through booster shots. Mr. Zients stated, "We estimate that by day's end, almost 2 million Americans will have rolled up their sleeves and gotten a booster shot — nearly 2 million booster shots in the first week. That's a very strong start."

Dr. Murthy

- **Process of Getting Children the Vaccine:** Dr. Murthy outlined the process towards vaccinating children for COVID-19. He stated that the Administration is following a guiding principle of safety, which warrants conducting separate clinical trials for children. He commented that once there is sufficient data from those clinical trials, the vaccine developers submit their data and a formal request to the FDA, which then conducts a thorough independent evaluation; if the FDA grants the vaccine an emergency use authorization, or EUA, then the vaccine can be administered. Dr. Murthy continued, "If the FDA grants the authorization, the CDC's Advisory Committee on Immunization Practices then meets to conduct their own review on specific clinical recommendations for healthcare providers."
- **Pfizer Vaccine Process for Children:** Dr. Murthy stated that the FDA has released a statement saying that, once they receive a formal request for authorization from Pfizer, they are prepared to complete a thorough independent review as quickly as possible, likely in a matter of weeks rather than months. Dr. Murthy emphasized, "The COVID-19 vaccines are FDA's top priority, and they know the urgency with which our children need a vaccine. They will be guided by science and safety as they evaluate vaccine data for children."
- **Get Vaccinated:** Dr. Murthy emphasized that up until children 5-11 years old can get vaccinated, it is important to follow masking policy, social distance outside/ in places with good ventilation, and get vaccinated. He stated, "Even though our youngest kids can't get vaccinated yet, the rest of us can. And when we are vaccinated, we act as barriers between our kids and the virus. So, if you are eligible to get vaccinated, please do so — if not for your own safety, then for the safety of unvaccinated children in your community."

VACCINE UPDATES

Mandatory COVID-19 Vaccination of DoD Civilian Employees: The Secretary of Defense directed the mandatory vaccination of Service members against the coronavirus disease 2019 (COVID-19) by signing the memorandum, "Mandatory Corona virus Disease 2019 Vaccination of Department of Defense Service Members ," on August 24, 2021. On September 9, 2021, the President of the United States directed Executive Branch agencies to implement a COVID-19 vaccination requirement for Federal employees to ensure the health and safety of the Federal workforce and members of the public with whom they interact by signing Executive Order 14043, "Requiring Coronavirus Disease 2019 Vaccination for Federal Employees." All DoD civilian employees must be fully vaccinated by November 22, 2021, subject to exemptions as required by law. Employees are considered fully vaccinated 2 weeks after completing the second dose of a two-dose COVID-19 vaccine or 2 weeks after receiving a single dose of a one-dose COVID-19 vaccine. New DoD civilian employees must be fully vaccinated by their entry on duty (start) date, or November 22, 2021, whichever is later.

FDA to Hold Advisory Committee Meetings to Discuss EUA for Booster Doses and COVID-19 Vaccines for Younger Children: On Friday, the U.S. Food and Drug Administration announced two upcoming meetings of its Vaccines and Related Biological Products Advisory Committee (VRBPAC) to discuss newly available data for the currently available COVID-19 vaccines. On October 14 and 15, the advisory committee will meet to discuss the use of booster doses of the Moderna COVID-19 Vaccine and the Janssen COVID-19 Vaccine. Both vaccines are currently authorized for emergency use to prevent COVID-19 in individuals 18 years of age and older. The committee will also hear presentations and discuss the available data on the use of a booster of a different vaccine than the one used for the primary series of an authorized or approved COVID-19 vaccine (heterologous or “mix and match” booster).

Janssen COVID-19 Vaccine: On September 29, the FDA authorized an emergency use authorization (EUA) for one additional batch of the Janssen COVID-19 vaccine manufactured at the Emergent facility. To date, a total of nine batches of Janssen COVID-19 vaccine that were manufactured at the Emergent facility have been authorized. The FDA conducted a thorough review of facility records and quality testing performed by the manufacturer. Based on this review and considering the current COVID-19 public health emergency, the FDA has concluded that these batches are suitable for use. While the FDA is not yet ready to include the Emergent BioSolutions plant in the Janssen EUA as an authorized manufacturing facility, the agency continues to work through issues on this matter with Janssen and Emergent BioSolutions management.

Janssen COVID-19 Vaccine Booster Shots: CDC updated their webpage on the Janssen COVID-19 vaccine to include information on the booster shot. At this time, people who got the J&J/Janssen vaccine are not eligible for a booster shot. More data on the effectiveness and safety of J&J/Janssen booster shots are expected soon. With those data in hand, CDC will keep the public informed with a timely plan for J&J/Janssen booster shots.

COVID-19 Booster Shots: On September 24, Janet Woodcock, M.D., Acting FDA Commissioner and Peter Marks, M.D., Ph.D, director of the FDA’s Center for Biologics Evaluation and Research, discussed the FDA’s authorization of a single booster dose of the Pfizer-BioNTech COVID-19 Vaccine for certain populations with stakeholders.

TESTING AND TREATMENT

DLA Supports White House Initiative with $2.78 Billion in Testing Supplies: The Defense Logistics Agency (DLA) awarded six contracts with a combined maximum value of just over $2.78 billion for up to 150 million at-home and 400 million point-of-care COVID-19 test kits in support of White House initiatives to defeat COVID-19. The combination of test types was requested by HHS to support the White House initiative announced Sept. 9, 2021. Kits will be sent on a recurring basis to federally qualified health centers, nursing homes, colleges and universities and other vulnerable populations over the one-year period of the respective contracts.

Contact Tracing: CDC updated their information on contact tracing , which is the key to slowing the spread of COVID-19 and helps protect you, your family, and your community. Specifically, CDC added in what to do if you come into close contact with someone diagnosed with COVID-19 (and are vaccinated, unvaccinated, or recovered from COVID), if you think you may have COVID-19 and are waiting for the test results, if you have symptoms of COVID-19, or if you are diagnosed with COVID-19.

FDA Testing Update: As of Friday, 412 tests and sample collection devices are authorized by the FDA under emergency use authorizations (EUAs) . These include 289 molecular tests and sample collection devices, 88 antibody and other immune response tests and 35 antigen tests. There are 65 molecular authorizations and one antibody authorization that can be used with home-collected samples. There is one molecular prescription at-home test, three antigen prescription at-home tests, seven antigen over-the-counter (OTC) at-home tests and two molecular OTC at-home tests. The FDA has authorized 16 antigen tests and eight molecular tests for serial screening programs. The FDA has also authorized 641 revisions to EUA authorizations.

INFORMATION FOR SPECIFIC POPULATIONS

CDC Completes Sixty-Day Assessment of Order under 42 U.S.C. 265: Following a review of the latest information regarding the status of the COVID-19 pandemic and associated public health risks, the CDC is expanding the requirement for a negative COVID-19 test to all air passengers entering the United States . After examining the current impact of the COVID-19 pandemic throughout the United States and at the U.S. borders, the ongoing risks of transmission and spread of COVID-19 in the congregate settings of facilities at the ports of entry and U.S. Border Patrol stations, the continued threat from the Delta variant, and the availability of testing, vaccination, and other mitigation measures, CDC has determined that the Order continues to be necessary at this time. CDC will continue to reassess the Order.

Medical Conditions: CDC updated their information for people who have medical conditions. Specifically, CDC added information on receiving a booster shot. People aged 18–49 years with underlying medical conditions may get a booster shot of Pfizer-BioNTech vaccine based on their individual benefits and risks. Bring your vaccination card, which you received at your first vaccination appointment, to your booster dose vaccination appointment.

Patient Tips for Healthcare Provider Appointments for Post-COVID Conditions: CDC updated their information for patients on preparing for their healthcare provider appointments for post-COVID conditions. Specifically, CDC uploaded a Healthcare Appointment Checklist for Post-COVID Conditions in Spanish to review before your next appointment.

Emergency Rental Assistance Program: Administration for Community Living (ACL) released a webinar on the Emergency Rental Assistance Program (ERAP), and tools to assist the people you serve.

RESEARCH

Multicomponent Strategies to Prevent SARS-CoV-2 Transmission: CDC released an *MMWR* on the multicomponent strategies to prevent SARS-CoV-2 transmission at nine overnight youth summer camps from June – August 2021. Previous studies have demonstrated the importance of prevention strategies to reduce SARS-CoV-2 transmission in overnight camps. During June–August 2021, a total of 7,173 campers and staff members attended nine U.S. overnight camps that implemented multiple prevention strategies including high vaccination coverage (>93% among eligible persons aged ≥12 years); prearrival and frequent screening testing (38,059 tests); and additional concomitant prevention measures. Nine laboratory-confirmed COVID-19 cases and no secondary infections were detected. Implementation of high vaccination coverage coupled with multiple prevention strategies is critical to averting COVID-19 outbreaks in congregate settings, including overnight camps. These findings highlight important guiding principles for school and youth-based COVID-19 prevention protocols.

COVID-19 Outbreaks at Youth Summer Camps: CDC released an *MMWR* on COVID-19 outbreaks at youth summer camps in Louisiana from June – July 2021. According to sequencing data reported by CDC, the highly transmissible B.1.617.2 (Delta) variant of SARS-CoV-2, the virus that causes COVID-19, has been the predominant lineage circulating in Louisiana since the week of June 20, 2021. In Louisiana, the increased spread of the Delta variant corresponded with the start of the state's fourth and largest increase in average daily COVID-19 incidence to date. This report describes COVID-19 outbreaks in Louisiana youth summer camps as the Delta variant became the predominant lineage during June–July 2021. This activity was reviewed by the Louisiana Department of Health (LDH) and was conducted consistent with applicable state law and LDH policy.

NCI Study Highlights the Pandemic's Disproportionate Impact on Black, American Indian/ Alaska Native, and Latino Adults: The National Cancer Society (NCI), part of NIH, found that the global COVID-19 pandemic has taken a disproportionate toll on Black, American Indian/Alaska Native, and Latino individuals in the United States, causing more deaths by population size, both directly and indirectly, in these groups compared with white or Asian individuals. Roughly 2.9 million people died in the United States between March 1, 2020, and December 31, 2020. Compared with the same period in 2019, there were 477,200 excess deaths, with 74% of them due to COVID-19. The scientists found that, after adjusting for age, the number of excess deaths by population size among Black, American Indian/Alaska Native, and Latino men and women were more than double those in white and Asian men and women.

Science Update: On Friday, CDC released their weekly COVID-19 Science Update. This week's research includes research on COVID-19 in the phase 3 trial of MRNA-1273 during the Delta-variant surge, the social and economic inequality in COVID-19 vaccination coverage across Illinois counties, and more.

COVID Data Tracker Weekly Review: On Friday, CDC released their weekly review from the COVID Data Tracker . Last week the U.S. Food and Drug Administration (FDA) issued an emergency use authorization (EUA) for a single booster shot of the Pfizer-BioNTech COVID-19 vaccine. Certain populations are now eligible to receive a booster shot of the Pfizer-BioNTech vaccine at least 6 months after receiving their second Pfizer-BioNTech shot. These populations include people ages 65 years and older, people ages 18 years and older who have underlying medical conditions, and people ages 18 years and older who live or work in high-risk settings.

Subject: Lab Alert: Ellume Issues Voluntary Recall of Specific Lots of Ellume COVID-19 Home Tests

Audience: Clinical Laboratory Professionals
Level: Laboratory Alert

On October 1, 2021, the digital diagnostics company Ellume announced a voluntary recall on specific lots of the Ellume COVID-19 Home Test, the company's rapid, self-administered COVID-19 antigen test, because there is an increased chance that tests from the affected lot numbers may give a false positive result.

Ellume advises consumers to visit their website to check whether their product is part of the affected lots and, if affected, to receive further instructions.

The voluntary recall is being taken after specific product lots reported false positive test result rates higher than was observed in clinical testing. Ellume has investigated the issue, identified the root cause, implemented additional controls, and is working on resolving the issue that led to this recall. Information relating to the action to be taken by distributors and retailers for the affected lots is also provided on the company's website.

Please share this message with your networks and invite them to opt in to LOCS to receive future updates.

MasK-12

Mask Adherence Surveillance in K-12 Settings Project

What is it? MasK-12 is a mask observation project to measure the proportion of students, teachers, and staff wearing masks, and wearing them correctly, in school.

How does it work?

School-based trained observers visit various areas within the school to note the proportion of students, teachers, and staff who are wearing masks correctly. School districts will identify the observers, which may include high school students, staff, or other volunteers.

How do I get involved?

School districts interested in participating should partner with their state health department to submit a project enrollment survey and letter of interest to the Centers for Disease Control and Prevention (CDC). **Both schools with and without mask mandates can participate.**

What are the benefits?

Data collected will be regularly reported to schools throughout the project to allow for regular feedback and monitoring at each school site. **High school student observers gain valuable hands-on public health experience.**

Please direct questions and comments to eocevent335@cdc.gov.

National and State Trends in Anxiety and Depression Severity Scores Among Adults During the COVID-19 Pandemic — United States, 2020–2021

Haomiao Jia, PhD[1]; Rebecca J. Guerin, PhD[2]; John P. Barile, PhD[3]; Andrea H. Okun, DrPH[2]; Lela McKnight-Eily, PhD[4]; Stephen J. Blumberg, PhD[5]; Rashid Njai, PhD[6,7]; William W. Thompson, PhD[7,8]

Recent studies indicate an increase in the percentage of adults who reported clinically relevant symptoms of anxiety and depression during the COVID-19 pandemic (*1*–*3*). For example, based on U.S. Census Bureau Household Pulse Survey (HPS) data, CDC reported significant increases in symptoms of anxiety and depressive disorders among adults aged ≥18 years during August 19, 2020–February 1, 2021, with the largest increases among adults aged 18–29 years and among those with less than a high school education (*1*). To assess more recent national trends, as well as state-specific trends, CDC used HPS data (*4*) to assess trends in reported anxiety and depression among U.S. adults in all 50 states and the District of Columbia (DC) during August 19, 2020–June 7, 2021 (*1*). Nationally, the average anxiety severity score increased 13% from August 19–31, 2020, to December 9–21, 2020 (average percent change [APC] per survey wave = 1.5%) and then decreased 26.8% from December 9–21, 2020, to May 26–June 7, 2021 (APC = –3.1%). The average depression severity score increased 14.8% from August 19–31, 2020, to December 9–21, 2020 (APC = 1.7%) and then decreased 24.8% from December 9–21, 2020, to May 26–June 7, 2021 (APC = –2.8%). State-specific trends were generally similar to national trends, with both anxiety and depression scores for most states peaking during the December 9–21, 2020, or January 6–18, 2021, survey waves. Across the entire study period, the frequency of anxiety and depression symptoms was positively correlated with the average number of daily COVID-19 cases. Mental health services and resources, including telehealth behavioral services, are critical during the COVID-19 pandemic.

Data were obtained from HPS (*4*), a biweekly, online survey. The survey, developed with assistance from CDC and other federal agencies to assess the social and economic impacts of the COVID-19 pandemic on U.S. households, began on April 23, 2020. Samples for HPS are drawn from an extract of the U.S. Census Bureau's master address file that includes email and mobile telephone numbers of approximately 117 million U.S. housing units. Survey data include sample weights to be used in analyses to generate results representative of U.S. adults aged ≥18 years based on age, sex, race/ethnicity, and educational attainment; the data from this experimental product were designed to produce estimates at state and national levels.* This analysis examined data for adults aged ≥18 years collected from the 19 biweekly surveys (waves) conducted during August 19, 2020–June 7, 2021 (waves 13–31), with breaks during December 22, 2020–January 5, 2021, because of expected decreases in survey response rates during holiday seasons, and during March 30–April 13, 2021, when HPS transitioned to a new survey cycle (Supplementary Table 1, https://stacks.cdc.gov/view/cdc/110122). The total sample size was 1,526,154 for all 19 waves, ranging from 58,729 (wave 18) to 110,019 (wave 14). Overall survey response rates ranged from 5.3% to 10.3% among the 19 waves examined.

Frequency of experiencing anxiety and depressive symptoms was assessed using the four-item Patient Health Questionnaire (PHQ-4),† which includes the two-item Generalized Anxiety Disorder (GAD-2) scale and the two-item PHQ-2, which assesses symptoms of depression (*5*). For each survey response,

* U.S. Census Bureau experimental data products are statistical products created using new data sources or previously untested methodologies.

† HPS includes a modified version of the validated PHQ-4 measure for depression and anxiety with a 1-week (versus a 2-week) recall period to reflect the weekly administration of the questions. The two anxiety questions asked about 1) feeling nervous, anxious, or on edge and 2) not being able to stop or control worrying. The two depression questions asked about 1) having little interest or pleasure in doing things and 2) feeling down, depressed, or hopeless.

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

MS-DOH-21-1816-A-002255

answers were assigned a numerical value: not at all = 0, several days = 1, more than one half of the days = 2, and nearly every day = 3. The anxiety severity score was calculated by summing the two GAD-2 responses, and the depression severity score was calculated by summing the two PHQ-2 responses. The sum of both severity scores could range from 0 to 6.

Weighted mean anxiety and depression severity scores for the United States were calculated for each wave. For state estimates, weighted age-standardized mean scores were calculated using direct standardization. State-specific trends were modeled using linear mixed models with cubic splines for sampling waves (*6*) to obtain smoothed age-adjusted estimates for each wave. The age-standardized state-level average anxiety and depression severity scores for the 50 states and DC are presented for the first two waves (August 19–September 24, 2020), the peak period in anxiety and depression severity scores nationally (December 9, 2020–January 18, 2021), and the last two waves (May 12–June 7, 2021). APCs for anxiety and depression severity scores per wave were calculated, and bootstrapping was used to obtain 95% confidence intervals (CIs) for APCs[§] (*7*). A change in the mean severity score indicates a change in the frequency of symptoms. To allow relative comparisons of HPS estimates with those from a nonpandemic period, weighted means and CIs were calculated for anxiety and depression severity scores using data from the 2019 National Health Interview Survey (NHIS), with data from 31,997 adults aged ≥18 years.[¶] Daily numbers of COVID-19 cases were obtained from the CDC COVID Data Tracker and were averaged across the same periods that the HPS anxiety and depression symptom data were collected. Average counts of daily cases were compared with the symptom data using Pearson correlations. This activity was reviewed by CDC and was conducted consistent with applicable federal law and CDC policy.[**]

Nationally, the average anxiety severity scores increased from 2.0 during August 19–31, 2020, to 2.3 during December 9–21, 2020 (APC = 1.5% per wave), reflecting a 13.0% increase in symptoms (Figure) (Supplementary Table 2, https://stacks.cdc.gov/view/cdc/110123). During this same period, the average depression severity score increased from 1.6 to 2.0, reflecting a 14.8% increase. From December 9–21, 2020, to May 26–June 7, 2021, the average anxiety severity score decreased to 1.7 (APC = –3.1% per wave), reflecting a 26.8% decrease; during this same period, the average depression severity score decreased to 1.4 (APC = –2.8% per wave), reflecting a 24.8% decrease.

Analyses of 2019 NHIS data indicate that the weighted average anxiety and depression severity scores among adults aged ≥18 years were 0.63 and 0.51, respectively. Quarterly weighted average anxiety and depression severity scores ranged from 0.61 to 0.65 and from 0.50 to 0.52, respectively; variation in these quarterly scores was substantially less than that in HPS during similar months.

In most states, the average anxiety and depression severity scores increased from August–September 2020 to December 2020–January 2021 (Table 1) (Supplementary Figure, https://stacks.cdc.gov/view/cdc/110121). By May–June 2021, anxiety and depression severity scores were similar to or lower than those during August–September 2020. During August–December 2020 and January–June 2021, state-level trends in anxiety and depression severity scores were similar to national trends, with scores for most states peaking during December 9–21, 2020, or January 6–18, 2021. States with larger increases in severity scores during August–December 2020 also tended to have larger decreases during January–June 2021 (Table 2). Mississippi, Oklahoma, and South Carolina had the largest percentage increases in anxiety scores during August–December 2020, whereas Minnesota, Mississippi, and South Carolina had the largest percentage increases in depression scores; Florida and New York had the smallest percentage increases in depression and anxiety scores, respectively. During January–June 2021, Minnesota, Rhode Island, and Utah had the largest percentage decreases in anxiety scores; Idaho, Michigan, and Wisconsin had the largest percentage decreases for depression severity scores, whereas New York had the smallest decrease in both anxiety and depression scores.

For the same periods that HPS was administered, an association was found between numbers of COVID-19 cases and the frequency of anxiety and depression symptoms. The average number of daily COVID-19 cases was highly positively correlated with anxiety (rho = 0.79) and depression (rho = 0.81) severity scores (Supplementary Table 2, https://stacks.cdc.gov/view/cdc/110123).

[§] Percent change (PC) from wave i to i+1 is defined as $PC_{t+1} = \left(\frac{\mu_{i+1} - \mu_i}{\mu_i} - 1\right) \times 100$. APC was calculated for a period of n+1 waves' data from wave i to wave i+n as $APC = \left\{exp\left[\frac{\sum_{t=i+1}^{i+n} ln(PC_t + 1)}{n}\right] - 1\right\} \times 100$.

[¶] Data for the 2019 survey year were obtained from NHIS, a survey conducted continuously throughout the year by CDC's National Center for Health Statistics. NHIS is a nationally representative cross-sectional survey of the U.S. civilian noninstitutionalized population. NHIS uses geographically clustered sampling to select each household; one adult per household is randomly selected to be interviewed. Interviews are generally conducted in respondents' homes; follow-up interviews to complete surveys might occur by telephone when necessary. Methodological details, protocols, and Ethics Review Board approvals are described elsewhere (https://www.cdc.gov/nchs/nhis/data-questionnaires-documentation.htm). Weighted means for the anxiety and depression severity scores were estimated, accounting for the complex sampling design. Means and CIs for adults aged ≥18 years were estimated using the SAS SurveyMeans procedure.

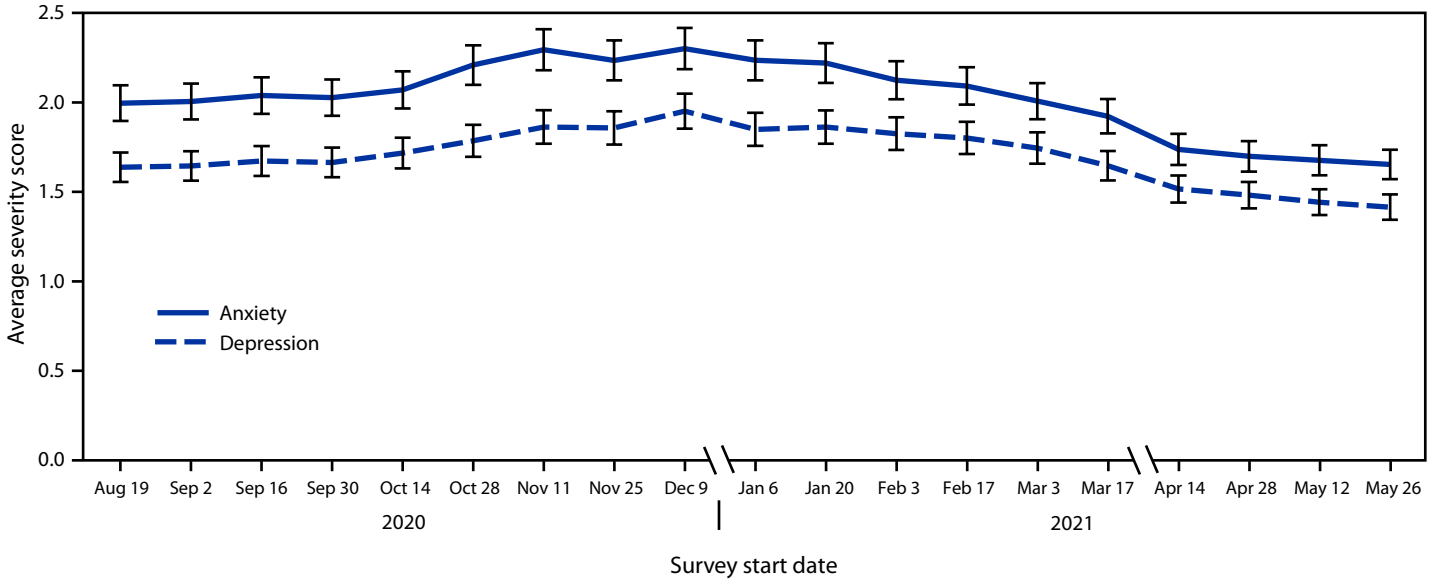
FIGURE. Trends in average anxiety and depression severity scores* among adults, by survey start date — Household Pulse Survey, United States, August 19, 2020–June 7, 2021†



* 95% confidence intervals indicated by error bars.
† Data for adults aged ≥18 years were collected from 19 biweekly surveys (waves) conducted during August 19, 2020–June 7, 2021 (waves 13–31), with breaks during December 22, 2020–January 5, 2021, and March 30–April 13, 2021.

Discussion

The frequency of anxiety and depression symptoms experienced among U.S. adults increased after August 2020 and peaked during December 2020–January 2021. The frequency of symptoms subsequently decreased but in June 2021 remained elevated compared with estimates from the 2019 NHIS. The relative increases and decreases in frequency of reported symptoms of anxiety and depression at both the national and state levels mirrored the national weekly number of new COVID-19 cases during the same period.

An international group of clinicians and mental health experts recommends that during pandemics, delivery systems for mental health care be adapted to mitigate disparities in the provision of health care (*8*). Predicting and planning for fluctuations in demand for behavioral health services is often difficult; however, real-time monitoring of mental health symptoms can provide important information for responding to surges in the demand for mental health services during national emergencies. The observed differences in severity score magnitude and peaks across states in this study indicate that these efforts are important at both the national and state levels.

The findings in this report are subject to at least six limitations. First, modified GAD-2 and PHQ-2 items were administered using a 1-week time frame rather than a 2-week time frame, which might have reduced comparability between HPS and NHIS. Second, short forms were used for GAD and PHQ; restricted ranges of scores might have decreased the likelihood of detecting differences in symptoms nationally or by state. Third, the HPS response rate was <10%, which might have introduced bias; however, trends are less likely than point estimates to be affected, and sample weights somewhat mitigate this bias (*9*). Fourth, peak periods in mental health symptoms overlapped with a break in survey data collection during the holiday season; reported symptoms during that period might have been underestimates if the peak occurred during the break. Fifth, the decrease in the frequency of symptoms observed through June 2021 occurred before the recent surge in COVID-19 cases involving the B.1.617.2 (Delta) variant; that decreasing trend might have slowed or reversed since June. Finally, these data are based on self-report and are subject to recall and social desirability biases.

The increased frequency of reported symptoms of anxiety and depression in this study indicates that mental health services and resources, including telehealth behavioral services, are critical during the COVID-19 pandemic, particularly among populations disproportionately affected by COVID-19. National COVID-19 trends demonstrate that certain populations have been disproportionately affected by high COVID-19 incidence, which also suggests that these populations might be more vulnerable to the psychological consequences of COVID-19. The mental health impact of COVID-19 also might have community-specific effects when morbidity and mortality rates are increasing as a result of COVID-19. Fluctuations in symptoms of anxiety and depression during the

Abbreviation: CI = confidence interval.

* Percent change (PC) from wave *i* to *i*+1 is defined as $PC_{t+1} = \left(\frac{\mu_{i+1} - \mu_i}{\mu_i} - 1\right) \times 100$. Average percent change (APC) was calculated for a period of *n*+1 waves' data from wave *i* to wave *i*+*n* as $APC = \left\{exp\left[\frac{\sum_{t=i+1}^{i+n} ln(PC_t + 1)}{n}\right] - 1\right\} \times 100$. https://doi.org/10.1002/sim.3733

Summary

What is already known about this topic?

U.S. Census Bureau Household Pulse Survey data indicate that the percentage of U.S. adults with symptoms of anxiety and depressive disorders increased nationwide from August 2020 to February 2021.

What is added by this report?

Nationwide, average anxiety severity scores increased 13% from August to December 2020 and then decreased 26.8% from December 2020 to June 2021. Similar increases and decreases occurred in depression severity scores.

What are the implications for public health practice?

Mental health services and resources, including telehealth behavioral services, are critical during the COVID-19 pandemic.

pandemic highlight the importance of real-time monitoring of mental health symptoms. Tracking these outcomes, including by demographic characteristics, can provide early indicators of potential increases in the demand for mental health services and for the health care providers needed to treat persons with clinically significant symptoms (*10*).
